# FPGA Libraries Reference Guide

Lattice supports some libraries used in designing FPGAs with different device architectures in a number of CAE synthesis, schematic capture, and simulation platforms. These libraries are the main front-end design libraries for Lattice FPGAs. Logic design primitives in these libraries offer flexibility and efficiency to facilitate building specific applications with Lattice devices. Many primitives can be used in multiple Lattice device architectures. With Schematic Editor, you can place the primitive symbols from the Lattice Symbol Library, `lattice.lib`, which is composed of primitives compatible with most Lattice FPGA device families. For macro-sized primitives like architectural blocks, arithmetic, or memories, use IPexpress™ to configure and generate schematic symbols and files for implementation. You can also use physical macros that you create in EPIC. See the appropriate topic in the online help system for more information.

A specific primitive can be found according to the device family and functional category. Primitives available to each of the following device families are listed according to appropriate functional categories.

- ▶ [Primitive Library - ECP5](#)
- ▶ [Primitive Library - LatticeECP/EC and LatticeXP](#)
- ▶ [Primitive Library - LatticeECP2/M](#)
- ▶ [Primitive Library - LatticeECP3](#)
- ▶ [Primitive Library - LatticeSC/M](#)
- ▶ [Primitive Library - LatticeXP2](#)
- ▶ [Primitive Library - MachXO and Platform Manager](#)
- ▶ [Primitive Library - MachXO2 and Platform Manager 2](#)
- ▶ [Primitive Library - MachXO3L](#)

The “Alphanumeric Primitives List” section contains descriptions of all available primitives in their alphanumeric order. The following information is provided for each primitive, where applicable:

**Table 1: Information Provided for Each Primitive**

Fields	Description
Name	Primitive name
Definition	Brief description of primitive
Architectures Supported	Index of FPGA families supported by the primitive

**Table 1: Information Provided for Each Primitive (Continued)**

Fields	Description
Port Interface Symbol	Graphic to represent the primitive port interface. Data, address, clock, clock enable type ports appear on the left-hand side of the block. Synchronous control ports appear on the top of the symbol, asynchronous control ports on the bottom, and output ports on the right-hand side of the block. Some of the graphic symbols are shown in bus notation for proper layout. Those primitives must be instantiated in expanded bus notation format with each individual bit.
Attributes	<p>Index of attributes compatible with the primitive. The first value is usually the default value, if it is not explicitly indicated. Attribute function, range, and port-to-attribute or attribute-to-attribute relationships for the primitive are noted.</p> <p>For descriptions of all the attributes used in primitives, see <a href="#">List of Primitive-Specific HDL Attributes</a>.</p>
Description	Detailed description of primitive function. Exceptions are identified by device family. This section sometimes includes truth table, waveform, state diagram, or other graphical methods to illustrate behavior. References to appropriate Lattice technical notes are listed.
Port Description	Index of port names, polarity, and function.
Connectivity Rules	Some primitive ports, such as DDR and DSP blocks, are connected to dedicated routing with source or loads related to other primitives. This section describes connection rules.

# Naming Conventions

The table shows the convention for naming all of the sequential primitives. Each primitive is identified using up to seven characters.

Flip-Flop/Latch Naming Conventions (name = abcdef)

**Table 2: Naming Conventions**

a=	F - Static implementation
b=	D - D type flip-flop
	J - J/K type flip-flop
	L - Cells contain a positive select front end (loadable)
	N - Cells contain a negative select front end (loadable)
	S - R-S type flip-flop
	T - Toggle type flip-flop
c=	Value - Number of clocks
d=	This parameter identifies the enable capability.
	S - No enable input
	P - Positive-level enable
	N - Negative-level enable
e=	This parameter identifies the clock capability
	1 - Positive-level sense (latch)
	2 - Negative edge-triggered (flip-flop)
	3 - Positive edge-triggered (flip-flop)
	4 - Negative-level sense (latch)
f=	A - No clear or preset inputs
	B - Positive-level asynchronous preset
	D - Positive-level asynchronous clear
	I - Positive-level synchronous clear
	J - Positive-level synchronous preset
	X - Standard primitive where GSR asynchronously clears or presets the flip-flop depending upon the function of the local clear or preset. If no local clear or preset is present (f=A), then GSR clears the register element.
	Y - Primitive is preset using GSR rather than cleared
	Z - Primitive not compatible with similar primitives available in the standard cell library

Example:

FD1P3BX is a single clock, positive edge-triggered, static, D-type flip-flop with a positive-level enable and a positive-level asynchronous preset.

**Table 3: Example: FD1P3BX**

FD1P3BX	a = F	Static cell
	b = D	D type
	c = 1	Single clock
	d = P	Positive-level enable
	e = 3	Positive edge-triggered
	f = B	Positive-level asynchronous preset

When creating designs from schematic or synthesis, please observe the following rules:

- ▶ Component, net, site, or instance names should be unique and independent of case. For example, if a net in a design is named "d0", then you cannot have an instance of AND2 named "D0".
- ▶ Component, net, site, or instance names cannot be any cell name.
- ▶ Component, net, site, or instance names cannot be GND, PWR, VSS, VDD, GSR, GSRNET, TSALL, TSALLNET, and so forth.
- ▶ Component, net, site, or instance names cannot contain preference keywords such as DIN, DOUT, SITE, COMP, and so forth.
- ▶ Component, net, site, or instance names cannot contain names starting with 0–9, /, \, +, –, and other special characters.
- ▶ Component, net, site, or instance names cannot be named using VHDL or Verilog keywords such as IN, OUT, INOUT, and so forth.

Note the following about numbering used throughout this Help:

- ▶ Least significant bits (LSBs) on a primitive are always determined by the lowest integer value (usually zero) expressed in a pin name input or output in a pin grouping just as most significant bits (MSBs) are always determined by the highest integer value.

For example, out of the pin group containing pins A0, A1, A2, and A3, A0 is the LSB and A3 is the MSB. The LSB or MSB is not affected by the order in which pins are numbered (that is, whether or not they are in ascending or descending order).

# Memory Primitives Overview

The architectures of various Lattice FPGAs provide resources for on-chip memory intensive applications. The sysMEM™ embedded block RAM (EBR) complements the distributed PFU-based memory. Single-port RAM, dual-port RAM, FIFO, and ROM memories can be constructed using the EBR. LUTs and PFU can implement distributed single-port RAM, dual-port RAM, and ROM. The Lattice Diamond software enables you to integrate the EBR- and PFU-based memories in various device families.

The EBR-based and PFU-based memory primitives are listed in this document. Designers can utilize the memory primitives in several ways via the IPexpress tool in the Diamond software. IPexpress allows you to specify the attributes of the memory application, such as required type and size. IPexpress takes the customized specification and constructs a netlist to implement the desired memory, using one or more of the memory primitives.

The available memory primitives include:

- ▶ [RAM\\_DP \(Dual Port RAM\)](#)
- ▶ [RAM\\_DP\\_BE \(Dual Port RAM with Byte Enable\)](#)
- ▶ [RAM\\_DP\\_TRUE \(True Dual Port RAM\)](#)
- ▶ [RAM\\_DP\\_TRUE\\_BE \(True Dual Port RAM with Byte Enable\)](#)
- ▶ [RAM\\_DQ \(Single Port RAM\)](#)
- ▶ [RAM\\_DQ\\_BE \(Single Port RAM with Byte Enable\)](#)
- ▶ [ROM \(Read Only Memory\)](#)
- ▶ [Distributed\\_DPRAM \(Distributed Dual Port RAM\)](#)
- ▶ [Distributed\\_ROM \(Distributed Read Only Memory\)](#)
- ▶ [Distributed\\_SPRAM \(Distributed Single Port RAM\)](#)
- ▶ [FIFO \(First In First Out Single Clock\)](#)
- ▶ [FIFO\\_DC \(First In First Out Dual Clock\)](#)
- ▶ [Shift Registers \(Distributed RAM Shift Register\)](#)

AGEB2 is a 2-bit comparator that can be cascaded together to build larger comparators. It has two 2-bit inputs and a carry-in input. The carry-in (CI) on the first stage should be tied HIGH. The compare-out (GE) output is HIGH if  $A[1:0] \geq B[1:0]$  and LOW if  $A[1:0] < B[1:0]$ . To build larger comparators, tie the GE on the lower stage to CI on the upper stage.

**Note**

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

### Description

ALEB2 is a 2-bit comparator that can be cascaded together to build larger comparators. It has two 2-bit inputs and a carry-in input. The carry-in (CI) on the first stage should be tied HIGH. The compare-out (LE) output is HIGH if  $A[1:0] \leq B[1:0]$  and LOW if  $A[1:0] > B[1:0]$ . To build larger comparators, tie the LE on the lower stage to CI on the upper stage.

\* When REG\_INPUTCFB\_CLK != NONE, then the CFB ports are being used and CFB -> CO is using these attributes. C -> Cr is unregistered and a DRC can check to make sure C0/C1\_CLK = NONE

corresponds to [53:18] of R.

\*When REG\_INPUTCFB\_CLK = NONE, then it means that the CFB ports are not used, and C -> Cr using the C0/C1\_CLK attributes.

\*When REG\_INPUTCFB\_CLK != NONE, then the CFB ports are being used and CFB -> CO is using these attributes. C -> Cr is unregistered and a DRC can check to make sure C0/C1\_CLK = NONE.

### Description

ANEB2 is a 2-bit comparator that can be cascaded together to build larger comparators. It has two 2-bit inputs and a carry-in input. The carry-in (CI) on the first stage should be tied LOW. The compare-out (NE) output is LOW if  $A[1:0] = B[1:0]$  and HIGH otherwise. To build larger comparators, tie the NE on the lower stage to CI on the upper stage.

### Description

CIDLLA removes the clock tree delay, aligning the external feedback clock to the reference clock. It has a single output coming from the fourth delay block. Its features include clock tree insertion removal,  $N \cdot T_{cyc} = 4 \cdot T_{del} + T_{inj}$ , lock achieved starting from minimum delay, and when it goes through all delay stages, the minimum frequency is  $1/(4 \cdot T_{del})$ . Its requirements include external feedback only, that you must use all delay cells, a maximum frequency of 700MHz, and a minimum frequency of 100MHz.

## CLKCNTL

### Clock Controller

Architectures Supported:

- ▶ LatticeSC/M

INPUTS: D, CE, CLK

OUTPUT: Q

ATTRIBUTES:

**CLKMODE:** "ECLK" (default), "SCLK"

### Description

The CLKCNTL is the post-amble detect circuit required for the DQS input. The DQS generation will use the DELAY, TRDLLA and the CLKCNTL primitives.

The CLKCNTL primitive's instantiation rules allow the CLK input to be fed via secondary (local) routing paths, rather than constraining the routing to be via the Edge Clock tree. The Edge Clock tree is optimized for minimum skew rather than minimum delay. Although the Edge Clock delay is not a problem at the DDR/DDR2 clock frequencies originally targeted (300 MHz), the

CLKCNTL is capable of operating at much higher frequencies (beyond 1 GHz). If the CLK input path utilizes the faster local routing resources, it is capable of properly gating an 800 MHz clock, as is required for testing of DDR3 memory devices. This requires changes to the mapper.

The CLKMODE attribute is supported for the CLKCNTL primitive. The legal values are ECLK (default) and SCLK.

INPUTS: CLKI, RST, ALIGNWD

OUTPUTS: CDIV1, CDIVX

ATTRIBUTES:

**GSR:** "DISABLED" (default), "ENABLED"

**DIV:** 2.0 (default), 3.5, 4.0

#### Description

A MachXO2/Platform Manager 2 device contains four CLKDIV with 1200 LUTs or more. The CLKDIV, or "clock divider" block, generates clock outputs one half, divided by three and a half or one quarter of the frequency of the input clock. It also generates an output clock of the same frequency as the input clock. All the outputs match input to output delay.

CLKDIV takes its inputs from the outputs of ECLK muxes. The divided outputs of the CLKDIV drive the primary clock center muxes directly and are also available on CIB ports for distribution to routing or secondary high fan out nets. The figure below represents the block diagram of CLKDIV:

The table below shows CLKDIVC IO description.

### DCCA

#### Dynamic Quadrant Clock Enable/Disable

Architectures Supported:

- ▶ ECP5
- ▶ MachXO2
- ▶ MachXO3L
- ▶ Platform Manager 2

INPUTS: CLKI, CE

OUTPUT: CLKO

#### Description

DCCA is the dynamic quadrant clock enable/disable primitive. In each quadrant, the dynamic quadrant clock enable/disable is available on the output of the center mux for the primary clocks CLK[5:0]. The dynamic quadrant clock enable/disable feature lets the internal logic control the quadrant primary clock network. When a clock network is disabled, all the logic fed by the clock network does not toggle, reducing the overall power consumption of the device. You need to instantiate a primitive (DCCA) in order to control the enable/disable function.

The DCCA IO description is shown below.

Port Name	I/O	Unused Nets	Description
CLKI	I	Tie low	Input clock
CE	I	Tie high	Clock enable
CLKO	O	Dangle	Output clock

## DCS

### Dynamic Clock Selection

Architectures Supported:

- ▶ LatticeECP/EC
- ▶ LatticeECP2/M
- ▶ LatticeECP3
- ▶ LatticeSC/M
- ▶ LatticeXP
- ▶ LatticeXP2

INPUTS: CLK0 CLK1 SEL

OUTPUT: DCSOUT

ATTRIBUTES:

**DCSMODE:** "NEG" (default), "POS", "HIGH\_LOW", "HIGH\_HIGH", "LOW\_LOW", "LOW\_HIGH", "CLK0", "CLK1"

### Note

For LatticeECP/EC, LatticeECP2/M, LatticeXP, and LatticeXP2 devices, the DCSMODE default has been changed from POS to NEG since ispLEVER 7.0 SP2. If your pre-7.0SP2 design included the DCS macro and you didn't specify the DCSMODE value, the design may behave differently in Diamond. To avoid the issue, you can manually set DCSMODE to POS in your old design.

### Description

DCS is a global clock buffer incorporating a smart multiplexer function that takes two independent input clock sources and avoids glitches or runt pulses on the output clock, regardless of where the enable signal is toggled. Located in pairs at the center of each edge, there are eight DCS primitives per device.

Function	Pins
Input Clock Select	SEL
Primary Clock Input 0	CLK0
Primary Clock Input 1	CLK1
To Primary Clock Mid-Mux	DCSOUT

For each DCS:

- ▶ Inputs are from primary clocks at PLC routing block (one branch per DCS)
- ▶ Selects are from a routing block's LUT port (A0, B0, etc.)
- ▶ Outputs are connected to the DCS output sources of the feedline muxes

The outputs of the DCS then reach primary clock distribution via the feedlines. The connections from CIB to DCS are shown in the table below. The selected CIB interfaces to a PIC and is located at the center of each bank and next to

the mid-muxes. Note that the CIB to DCS connections are merged with the existing PIC-CIB connections at that CIB. It is up to the hardware designer to select the most convenient CIB.

### CIB to DCS Connections

CLK1(jclk2)	CLK1

## DCSC

### Dynamic Clock Selection

Architectures Supported:

- ▶ ECP5

INPUTS: CLK0 CLK1, SEL1, SEL0, MODESEL

OUTPUT: DCSOUT

ATTRIBUTES:

**DCSMODE:** "NEG" (default), "POS", "HIGH\_LOW", "HIGH\_HIGH", "LOW\_LOW", "LOW\_HIGH", "CLK0", "CLK1"

### Description

DCS is a 2-to-1 clock mux. Two modes exist. The glitchless mode switches between two clock sources (CLK0 and CLK1). The other mode added allows switching between the two clock sources asynchronously, based on the Sel signals. The second mode can produce a glitch on the output clock (DCSOUT), since the Sel signals could be changed at the same time the input clocks switching.

In the first mode (glitchless mode), there is a limitation on the circuit. If one of the clock source is at a static H or L, the DCS will not make the switch. This is because the DCS has to look at the two sources to synchronize the switch in order to not produce a glitch.

:

If the select inputs change from selecting one source (i.e. [01] to select CLK0), to selecting another source (i.e. [10] to select CLK1), where CLK1 is connected to GND, the user can cycle the select input from [10] -> [00] (a few cycles) -> [01] to allow the switch from active clock (CLK0) to GND without glitching the output.

Alternatively, the user can select non-glitchless mode (MODESEL = 1), and make the switch on the inputs. This could also make the output DCSOUT to switch from active clock (CLK0) to GND, but it could create a glitch when it makes the switch.

## DDRDLA

90 degree delay for the DQS Input during a memory interface or the clock input for a generic DDR interface

Architectures Supported:

ATTRIBUTES:

**FORCE\_MAX\_DELAY**: "NO" (default), "YES"

**LOCK\_CYC:** (For simulation only)

### Description

The DDRDLL is used to generate a 90 degree delay for the DQS Input during a memory interface or the clock input for a generic DDR interface.

There are two DDRDLL modules per half the device. The DDRDLL outputs delay codes that are used in the DQSBUF elements to delay the DQS input or in the DLLDEL module to delay the input clock. DDRDLL by default will generate 90-degrees, but the user may choose to generate 77, 88, 101 or 112 degrees as well.

### DDRDLA Port Definition

Port Name	I/O	Definition
CLK	I	Reference clock input to the DDRDLL. Should run at the same frequency as the clock to the delayed.
RST	I	Reset Input to the DDRDLL
UDDCNTLN	I	Update Control to update the delay code. When low the delay code out the DDRDLL is updated. Should not be active during a read or a write cycle.
FREEZE	I	When FREEZE goes high, it glitchlessly turns off the DLL internal clock and ring oscillator output clock. When FREEZE goes low, turns it back on.
DDRDEL	O	The delay codes from the DDRDLL to be used in DQSBUF or DLLDEL
LOCK	O	Lock output to indicate the DDRDLL has valid delay output

- ▶ LatticeXP2

INPUTS: A, DEL0, DEL1, DEL2, DEL3

OUTPUT: Z

### Description

Data going to the DDR registers can be optionally delayed using the delay block. The DELAYB block receives a 4-bit delay value from the DLL. The user can also choose to implement a fixed delay value instead of using the delay generated by the DLL. The various fixed delay choices can be made in the IPexpress software tool.

The DELAYB block can also be used to delay non-DDR inputs that use the input PIO register.

**DQS\_LO\_DEL\_VAL**: integers 0~63 (PLUS), 1~64 (MINUS) (default: 0)

**DQS\_LO\_DEL\_ADJ**: "PLUS" (default), "MINUS"

### Description

DQSBUFC implements the DQS delay and the DQS transition detector logic. The primitive is composed of the DQS Delay, the DQS Transition Detect and the DQSXFER block as shown in the following figure. This block inputs the DQS and delays it by 90 degrees. It also generates the DDR Clock Polarity and the DQSXFER signal. The preamble detect (PRMBDET) signal is generated from the DQSI input using a voltage divider circuit.

DQSBUFC Function

**DQS Delay Block:** The DQS Delay block receives the digital control delay line (DQSDEL) coming from one of the two DQSDLL blocks. These control signals are used to delay the DQSI by 90 degrees. DQSO is the delayed DQS and is connected to the clock input of the first set of DDR registers.

**DQS Transition Detect:** The DQS Transition Detect block generates the DDR Clock Polarity signal based on the phase of the FPGA clock at the first DQS transition. The DDR READ control signal and FPGA CLK inputs to this coming and should be coming from the FPGA core.

**DQSXFER:** This block generates the 90-degree phase shifted clock to for the DDR Write interface. The input to this block is the XCLK. The user can choose to connect this either to the edge clock or the FPGA clocks. The DQSXFER is routed using the DQSXFER tree to all the I/Os spanned by that DQS.

**Data Valid Module:** The data valid module generates a DATAVALID signal. This signal indicates to the FPGA that valid data is transmitted out of the input DDR registers to the FPGA core.

The following table describes DQSBUFC I/O ports.

Port Name	I/O	Definition
DQSI	I	DQS strobe signal from memory.
CLK	I	System CLK.
READ	I	Read generated from the FPGA core.
DQSDEL	I	DQS delay from the DQSDLL primitive.
XCLK	I	Edge clock or system CLK.
DQSO	O	Delayed DQS strobe signal, to the input capture register block.
DQSC	O	DQS strobe signal before delay, going to the FPGA core logic.
DDRCLKPOL	O	DDR clock polarity signal.
PRMBDET	O	Preamble detect signal, going to the FPGA core logic.
DQSXFER	O	90 degree shifted clock going to the output DDR register block.
DTATVALID	O	Signal indicating transmission of valid data to the FPGA core.

### READ Pulse Generation

The READ signal to the DQSBUFC block is internally generated in the FPGA core. The READ signal goes high when the READ command to control the DDR-SDRAM is initially asserted. This precedes the DQS preamble by one cycle, yet may overlap the trailing bits of a prior read cycle. The DQS Detect circuitry of the LatticeECP2 device requires the falling edge of the READ signal to be placed within the preamble stage.

The preamble state of the DQS can be detected using the CAS latency and the round trip delay for the signals between the FPGA and the memory device. Note that the internal FPGA core generates the READ pulse. The rise of the READ pulse should coincide with the initial READ command of the Read Burst and need to go low before the Preamble goes high.

## DQSDLL

### DLL used as DDR memory DQS DLL

Architectures Supported:

- ▶ LatticeECP/EC

- ▶ LatticeXP
- ▶ LatticeXP2

INPUTS: CLK, RST, UDDCNTL

OUTPUTS: LOCK, DQSDEL

ATTRIBUTES:

**LOCK\_SENSITIVITY:** "LOW" (default), "HIGH"

### Description

DQS delay calibration DLL. The primitive generates a 90-degree phase shift required for the DQS signal and implements the on-chip DQSDLL. Only one DQSDLL should be instantiated for all the DDR implementations on one half of the device. The clock input to this DLL should be at the same frequency as the DDR interface. DLL generates the delay based on this clock frequency and the update control input to this block. The DLL updates the dynamic delay

control to the DQS delay block when this update control (UDDCNTL) input is asserted. The active low signal on UDDCNTL updates the DQS phase alignment and should be initiated at the beginning of READ cycles.

Port Name	I/O	Definition
CLK	I	System CLK should be at the frequency of the DDR interface from the FPGA core.
RST	I	Resets the DQSDLL
UDDCNTL	I	This is an active low port. It provides an update signal to the DLL that will update the dynamic delay. When held low, this signal will update the DQSDEL.
LOCK	O	Indicates when the DLL is in phase.
DQSDEL	O	The digital delay generated by the DLL, should be connected to the DQSBUF primitive.

**DQSDLL Configuration:** By default, this DLL generates a 90-degree phase shift for the DQS strobe based on the frequency of the input reference clock to the DLL. The user can control the sensitivity to jitter by using the LOCK\_SENSITIVITY attribute. This configuration bit can be programmed to be either “HIGH” or “LOW”. The DLL Lock Detect circuit has two modes of operation controlled by the LOCK\_SENSITIVITY bit, which selects more or less sensitivity to jitter. If this DLL is operated at or above 150 MHz, it is recommended that the LOCK\_SENSITIVITY bit be programmed “HIGH” (more sensitive). When running at or below 100 MHz, it is recommended that the bit be programmed “LOW” (more tolerant). For 133 MHz, the LOCK\_SENSITIVITY bit can go either way.

## ECLKSYNCB

### ECLK Stop Block

Architectures Supported:

- ▶ ECP5

INPUTS: ECLKI, STOP

OUTPUT: ECLKO

### Description

ECLKSYNCB is the optional ECLK synchronization for DDR\_MEM (DDR memory mode), DDR2\_MEM (DDR2 memory mode), and DDR3\_MEM (DDR3 memory mode). The ECP5 ECLKSYNC is similar to MachXO2 and LatticeECP3 (ECLKSYNA), however it has some added latency.

Asserting the STOP control signal (from CIB) will stop the edge clock and synchronize the signals from ECLK used in high speed DDR mode applications such as DDR memory, generic DDR and 7:1 LVDS. The STOP signal is synchronized with ECLK when asserted. When the STOP signal is released, every clock toggling from the second rising edge clock & after will be output.

The table below describes the I/O ports of the ECLKSYNCB primitive.

Port	I/O	Unused Port	Function
ECLKI	I	Tie low	Edge clock input to the stop block
STOP	I	Tie low	Control signal to stop the edge clock

DDAILAG	I	DDA lag/lead. "1": lag; "0": lead.
DDAIDEL[0:2]	I	DDA delay.
CLKOP	O	PLL output clock to clock tree (no phase shift); frequency: 20~420 MHz.

## Dynamic Delay Adjustment

The Dynamic Delay Adjustment is controlled by DDAMODE input. This feature is available in EHXPLLB primitive only. When the DDAMODE input is set to "1," the delay control is done through the inputs, DDAIZR, DDAILAG and DDAIDEL(2:0). For this mode, the attribute "DELAY\_CNTL" must be set to "DYNAMIC."

## Equations for Generating Input and Output Frequency Ranges

These values of  $f_{IN}$ ,  $f_{OUT}$ ,  $f_{VCO}$  are the absolute frequency ranges for the PLL. The values of  $f_{INMIN}$ ,  $f_{INMAX}$ ,  $f_{OUTMIN}$ , and  $f_{OUTMAX}$ , are the calculated frequency ranges based on the divider settings. These calculated frequency ranges become the limits for the specific divider settings used in the design.

$$f_{OUT} = f_{IN} * (N/M)$$

$$f_{VCO} = f_{OUT} * V = f_{IN} * (N/M) * V$$

$$f_{IN} = (f_{VCO} / (V*N)) * M$$

Where  $M = \text{CLKI DIV}$

$N = \text{CLKFB DIV}$

$V = \text{CLKOP DIV}$

$K = \text{CLKOK DIV}$

$f_{\text{INMIN}} = ((f_{\text{VCOMIN}} / (V * N)) * M)$ , if below  $33 * M$  round up to  $33 * M$

$f_{\text{INMAX}} = (f_{\text{VCOMAX}} / (V * N)) * M$ , if above 420 round down to 420

$f_{\text{OUTMIN}} = f_{\text{INMIN}} * (N / M)$ , if below  $33 * N$  round up to  $33 * N$

$f_{\text{OUTMAX}} = f_{\text{INMAX}} * (N / M)$ , if above 420 round down to 420

$f_{\text{OUTKMIN}} = f_{\text{OUTMIN}} / K$

$f_{\text{OUTKMAX}} = f_{\text{OUTMAX}} / K$

The following are descriptions of EPLLD port functions.

Port	I/O	Function
CLKI	I	Input clock.
CLKFB	I	Feedback clock.
RST	I	PLL reset (connected to the CNTRST port). High active reset.

The EPLLD primitive can be used for design migration between LatticeECP2 and LatticeXP2, which can be divided into four situations:

Design Migration From LatticeECP2 to LatticeXP2 (EPLLD Configurations):

- ▶ EPLLD Configurations without Dynamic Phase & Duty Options: The LatticeECP2 PLL configuration migrates to LatticeXP2 without any changes.
- ▶ EPLLD Configurations with Dynamic Phase & Duty Options: The LatticeECP2 PLL configuration has DPAMODE port in the top-level port list. To migrate this configuration to LatticeXP2, the user has to tie the DPAMODE port to GND.

Design Migration From LatticeECP2 to LatticeXP2 (EHXPLLD Configurations): This configuration cannot be migrated to LatticeXP2 because LatticeXP2 does not support Delay Adjust.

Design Migration From LatticeXP2 to LatticeECP2 (EPLLD Configurations):

- ▶ EPLLD Configurations without Dynamic Phase & Duty Options: The LatticeXP2 PLL configuration migrates to LatticeECP2 without any changes.
- ▶ EPLLD Configurations with Dynamic Phase & Duty Options (No Duty Trim): The LatticeXP2 PLL configuration has no DPAMODE port in the top-level port list. Two options for migration:
  - a. Regenerate the PLL configuration for LatticeECP2.
  - b. Modify the LatticeXP2 PLL configuration to bring the DPAMODE to top-level port list.

Design Migration From LatticeXP2 to LatticeECP2 (EHXPLLE Configurations): This configuration cannot be migrated to LatticeECP2 because LatticeECP2 does not support Duty Trim Options, CLKOK2 and the CLKOS Fine Delay Port (WRDEL).

REFCLKN	I	External reference clock negative input port
REFCLKO	O	Single-ended clock signal to be connected to PCS PLL inputs.

### Description

The EXTREFB module takes the differential external reference clock pins (refclkp/n) and sends out a single-ended clock signal to the SerDes TxPLL. The EXTREFB can only connect to SerDes TxPLL in the same DCUA, or to SerDes TxPLL in the complementary sharing DCUA.

## FADD2

### 2 Bit Fast Adder

Architectures Supported:

INPUTS: A1, A0, B1, B0, CI

OUTPUTS: COUT1, COUT0, S1, S0

### Description

FADD2 is a 2-bit adder. It has a carry-in input (CI) and two 2-bit input (A0, A1 and B0, B1). The FADD2 produces a 2-bit sum output (S0, S1) along with a 2-bit carry-out output (COUT1, COUT).

output	S1, S0
carry-in input	CI

Function	Pins
carry-out output (Bit-0)	COUT0
carry-out output (Bit-1)	COUT1

- ▶ Platform Manager 2

INPUTS: A0, A1, B0, B1, BCI, CON

OUTPUTS: BCO, S0, S1

#### Description

FADSU2 is a 2 bit adder/subtractor. When the control signal (CON) is high FADSU2 functions as a 2 bit adder with a carry-in input (BCI) and two 2 bit inputs (A0:A1 and B0:B1), producing a 2 bit SUM output (S0:S1) along with a carry-out output (BCO).

When the control signal (CON) is low, FADSU2 functions as a 2 bit two's complement subtractor with a borrow-in input (BCI) and two 2 bit inputs (A0:A1 and B0:B1), producing a 2 bit two's complement output of A minus B (S0:S1) along with a borrow-out output (BCO).

INPUT: GSR

#### Description

GSR is used to reset or set all register elements in your design. The GSR component can be connected to a net from an input buffer or an internally generated net. It is active LOW and when pulsed will set or reset all flip-flops, latches, registers, and counters to the same state as the local set or reset functionality.

It is not necessary to connect signals for GSR to any register elements explicitly. The function will be implicitly connected globally. The functionality of

---

the GSR for sequential cells without a local set or reset are described in the appropriate library help page.

IDDR supports two clock domains (right side only). IDDRDQSX1A is the input for DDR1/2 memory. It is used for right bank only.

See the following table for port description of the IDDRDQSX1A primitive.

Port Name	I/O	Definition
D	I	DDR input from sysIO buffer.
DQSR90	I	Shifted DQS input for read.
DDRCLKPOL	I	DQS clock polarity. This signal is used to connect to the DDRCLKPOL output of DQSBUFH.
SCLK	I	System clock.

## IDDRFXA

### DDR Generic Input with Full Clock Transfer (x1 Gearbox)

Architectures Supported:

- ▶ LatticeECP2/M
- ▶ LatticeXP2

INPUTS: D, CLK1, CLK2, RST, CE

OUTPUTS: QA, QB

#### Description

This primitive inputs DDR data at both edges of clock CLK1 and generates two streams of data aligned to clock CLK2. CLK1 is used to register the DDR registers and the first set of synchronization registers. CLK2 is used by the third stage of registers. Both CLK1 and CLK2 should be clocked by the FPGA clock. The LatticeECP2/M Family Data Sheet explains the input register block in more detail.

Note that LSR is only for second stage register/latch. For supporting DDR modes configured for bidirectional use, software will tie LSR LOW for input registers. The default for LSR is HIGH.

See the following table for port description of the IDDRFXA primitive.

Port Name	I/O	Definition
D	I	DDR data
CLK1	I	Clock connected to the FPGA clock
CLK2	I	Clock connected to the FPGA clock
CE	I	Clock enable signal
RST	I	Signal used to reset the DDR register
QA	O	Data at the positive edge of the CLK
QB	O	Data at the negative edge of the CLK

For more usage, see related technical notes or contact technical support.

## IDDRMF1A

### DDR Input and DQS to System Clock Transfer Registers with Full Clock Cycle Transfer

Architectures Supported:

- ▶ LatticeECP2/M
- ▶ LatticeXP2

INPUTS: D, ECLK, CLK1, CLK2, RST, CE, DDRCLKPOL

OUTPUTS: QA, QB

#### Description

This primitive implements a full clock cycle transfer as compared to the IDDRMX1A primitive that will only implement a half clock cycle transfer. The DDR registers are designed to use edge clock routing on the I/O side and the primary clock on the FPGA side. The ECLK input is used to connect to the DQS strobe coming from the DQS delay block (DQSBUFC primitive). The CLK1 and CLK2 inputs should be connected to the slow system (FPGA) clock. DDRCLKPOL is an input from the DQS Clock Polarity tree. This signal is generated by the DQS Transition detect circuit in the hardware.

Note that the DDRCLKPOL input to IDDRMF1A should be connected to the DDRCLKPOL output of DQSBUFC. LSR is only for second stage register/latch. For supporting DDR modes configured for bidirectional use, software will tie LSR LOW for input registers. The default for LSR is HIGH.

See the following table for port description of the IDDRMX1A primitive.

Port Name	I/O	Definition
D	I	DDR data.
ECLK	I	The phase shifted DQS should be connected to this input.
RST	I	Reset.
CLK1	I	Slow FPGA CLK.
CLK2	I	Slow FPGA CLK.
CE	I	Clock enable.
DDRCLKPOL	I	DDR clock polarity signal.
QA	O	Data at the positive edge of the CLK.
QB	O	Data at the negative edge of the CLK.

For more usage, see related technical notes or contact technical support.

Architectures Supported:

- ▶ LatticeECP2/M
- ▶ LatticeXP2

INPUTS: D, ECLK, SCLK, RST, CE, DDRCLKPOL

OUTPUTS: QA, QB

### Description

This primitive implements the input register block. The DDR registers are designed to use edge clock routing on the I/O side and the primary clock on the FPGA side. The ECLK input is used to connect to the DQS strobe coming from the DQS delay block (DQSBUFC primitive). The SCLK input should be connected to the system (FPGA) clock. DDRCLKPOL is an input from the DQS Clock Polarity tree. This signal is generated by the DQS Transition detect circuit in the hardware. The DDRCLKPOL signal is used to choose the polarity of the SCLK to the synchronization registers.

Note that the DDRCLKPOL input to IDDRMX1A should be connected to the DDRCLKPOL output of DQSBUFC. LSR is only for second stage register/latch. For supporting DDR modes configured for bidirectional use, software will tie LSR LOW for input registers. The default for LSR is HIGH.

See the following table for port description of the IDDRMX1A primitive.

Port Name	I/O	Definition
D	I	DDR data.
ECLK	I	The phase shifted DQS should be connected to this input.
RST	I	Reset.
SCLK	I	System CLK.
CE	I	Clock enable.
DDRCLKPOL	I	DDR clock polarity signal.
QA	O	Data at the positive edge of the CLK.

Architectures Supported:

- ▶ LatticeECP2/M
- ▶ LatticeXP2

INPUTS: D, ECLK, SCLK, CE, RST

OUTPUTS: QA0, QA1, QB0, QB1

### Description

This primitive is used when a gearing function is required. This primitive inputs DDR data at both edges of the edge and generates four streams of data. The DDR registers and the first set of synchronization registers are clocked by the ECLK input of the primitive, which should be connected to the fast ECLK. SCLK is used to clock the third stage of registers and should be connected to the FPGA clock. This primitive outputs four streams of data. Two of these data streams are generated using the complementary PIO registers.

Note that LSR is only for second stage register/latch. For supporting DDR modes configured for bidirectional use, software will tie LSR LOW for input registers. The default for LSR is HIGH.

See the following table for port description of the IDDRX2B primitive.

## LUT4

### 4-Input Look Up Table

Architectures Supported:

- ▶ ECP5
- ▶ LatticeECP3
- ▶ MachXO2
- ▶ MachXO3L
- ▶ Platform Manager 2

INPUTS: A, B, C, D

OUTPUT: Z

ATTRIBUTES:

**INIT:** hexadecimal value (default: 16'h0000)

### Description

LUT4 defines the programmed state of a LUT4 primitive of a Slice. While this primitive is typically targeted by logic synthesis tools, it can also be instantiated in HDL source for intimate control over LUT4 programming. The contents of the look up table are addressed by the 4 input pins to access 1 of 16 locations.

The programming of the LUT4 (that is, the 0 or 1 value of each memory location within the LUT4) is determined by the value assigned with INIT. The value is expressed in hexadecimal code. Highest memory locations are in the most significant hex digit, the lowest in the least significant digit.

For example, hex value BF80 produces these 16 memory locations and values:

1011 1111 1000 0000

Memory location 0 (D=0, C=0, B=0, A=0) contains a 0, memory location 2 (D=0, C=0, B=1, A=0) contains a 0. Memory location 15 (D=1, C=1, B=1, A=1) contains a 1, etc.

The LUT4 may encode the Boolean logic for any Boolean expression of 4 input variables. For example, if the required expression was:

$$Z = (D * C) + (B * !A)$$

then the INIT value can be derived from the truth table resulting from the expression:

```
D C B A : Z
0 0 0 0 : 0
0 0 0 1 : 0
0 0 1 0 : 1
0 0 1 1 : 0

0 1 0 0 : 0
0 1 0 1 : 0
0 1 1 0 : 1
0 1 1 1 : 0

1 0 0 0 : 0
1 0 0 1 : 0
1 0 1 0 : 1
1 0 1 1 : 0

1 1 0 0 : 1
1 1 0 1 : 1
1 1 1 0 : 1
```

:

```
1 1 1 1 : 1
```

INIT = F444 (16)

### LUT4 Usage with Verilog HDL

```
// LUT4 module instantiation
LUT4
#(.init (16'hF444))
I1 ( .A (A), .B (B), .C (C), .D (D), .Z (Q[0]) );
```

### LUT4 Usage with VHDL

```
-- LUT4 component instantiation
I1 : LUT4
  Generic Map (INIT=>b"1111_0100_0100_0100")
  Port Map ( A=>A, B=>B, C=>C, D=>D, Z=>N_1 );

### Description

LatticeECP DSP Block Multiplier. MULT18X18 is a combinational signed 18-bit by 18-bit multiplier used in the DSP block. The value represented in the 18-bit input A is multiplied by the value represented in the 18-bit input B. Output P is the 36-bit product of A and B. MULT18X18 may be represented as either unsigned or two's complement signed. The primitive consists of three types of optional pipeline registers:

- ▶ Input registers, located before the multipliers and registering the operands
- ▶ Multiplier pipeline registers, located after the multipliers and product registration

- ▶ Output registers, located before leaving the block, and registering the mode-specific output.

There are 12 register controls signals that enter the DSP block: CLK[0:3], CE0[0:3], and RST[0:3]. Each incoming signal also has the option of being tied high, tied low, or inverted. These 12 control signals are used to control the register banks in the DSP block. Dynamic control signals must match the register pipelining of the datapath. To facilitate this, the following bank control for each individual dynamic signal's input register and pipeline register (total 8 signals x 2 registers / signal = 16 registers) is as follows:

- ▶ Bypass or no-bypass of the registers.
- ▶ Clock is selected from CLK[0:3], one of four sources available to the DSP block.
- ▶ Clock enable is selected from CE0[0:3], one of four sources available to the DSP block.
- ▶ Reset is selected from RST[0:3], one of four sources available to the DSP block.

You can turn registers off or on via attribute settings. For example, setting REG\_INPUTA\_CLK= "CLK0" means the input A register is used, and the clock drive A register is coming from CLK0 of the DSP block. Setting REG\_INPUTA\_CE= "CE1" means input A register CE control is coming from CE1 of the DSP block. Setting REG\_INPUTA\_RST= "RST3" means input A register reset control is coming from RST3 of the DSP block. If REG\_INPUT\_A\_CLK="NONE", this means the input A register is bypassed, therefore, REG\_INPUT\_A\_RST or REG\_INPUT\_A\_CE becomes irrelevant.

In case you want to use the register but do not care about the clock enable (CE), then this pin needs to be tied to VCC (always enabled). In this case you could set REG\_INPUT\_A\_CE="CE3", then tie CE3 of the to VCC. If you want to use the register but do not care about the reset (RST), then this pin must to be tied to GND (always do not reset). In this case, you you could set REG\_INPUT\_A\_RST="RST2", then tie RST2 of the to GND.

SIGNEDAB is a pin which controls whether the multiplier performs the signed or unsigned operation. It applied to both operand A and B. It can be tied to VCC (signed) or GROUND (unsigned). There are also two delay registers associated with this control pin, in order to match with incoming data. Setting REG\_SIGNEDAB\_0\_CLK= "CLK0 | CLK1 | CLK2 | CLK3" will turn on the pipeline register for SIGNEDAB. Setting REG\_SIGNEDAB\_0\_CLK= "NONE" will turn off the first pipeline register for SIGNEDAB. Setting REG\_SIGNEDAB\_1\_CLK= "NONE" will turn off the second pipeline register for SIGNEDAB.

Input registers receive operand values from a serial shift chain or routing input. There is separate control for A and B operands. When in shift chain mode, multiplier operands may be bypassed using the bank bypass feature. The shift chain supports one chain of two 18-bit operands or two chains of two 9-bit operands. GSR "DISABLED" attribute disables the asynchronous global set reset input when in user mode.

### Description

LatticeECP Block Adder/Subtractor. MULT18X18ADDSUB can be configured to either add or subtract its inputs, adding or subtracting the inputs from two multiplier products. The add/subtract control is either configured as a static HIGH (Vcc), LOW (GND). In Lattice Diamond, the static settings are implemented by setting Vcc or GND in the CIB ISB.

The primitive consists of three types of optional pipeline registers:

- ▶ Input registers, located before the multipliers and registering the operands

### Description

LatticeECP DSP Block Adder/Subtractor. MULT18X18ADDSUBSUM can be configured to either add or subtract its inputs, adding or subtracting the inputs from two multiplier products. The add/subtract control is either configured as a static HIGH (Vcc), LOW (GND), or as dynamic control signals ADDNSUB1 and ADDNSUB3. In Lattice Diamond, the static settings are implemented by setting ADDNSUB1 and ADDNSUB3 signal to Vcc or GND in the CIB ISB.

The primitive consists of three types of optional pipeline registers:

- ▶ Input registers, located before the multipliers and registering the operands
- ▶ Multiplier pipeline registers, located after the multipliers and product registration
- ▶ Output registers, located before leaving the block, and registering the mode-specific output.

See the description of MULT18X18 for more information on control signals for DSP blocks and attributes.

Note:

The multipliers linked by SROA/SRIA or SROB/SRIB pin pair can only be implemented in a continuous shift chain with multipliers placed next to each other. However, the length of the shift chain is limited on each DSP row and different depending on the device selected. For example, with the LatticeECP3-35 device, each DSP row has 32 MULT18s. So for the shift chained MULT18, it can support a continuous chain of length 32 for MULT18. If a chain is more than 32 MULT18s, you have to employ SRO/A,B pin pair for connecting the 32nd and 33rd MULT18s for implementing the chain in two DSP rows. But this capability is only limited to port A on SRO side in LatticeECP3. That is to say, only SROA is allowed to connect to A,B input pin of another MULT18, but not SROB. So if a chain is linked by SROB/SRIB pin pair, the length cannot exceed 32 for the LatticeECP3-35 device.

### Description

MULT18X18MAC supports operand bit widths for 18X18 multiplication and accumulates the output up to 52 bits. The DSP block includes optional registers for the input and intermediate pipeline stage. Pipeline stages may be set using a pipeline attribute. The output registers are required for the accumulator. Signed and unsigned arithmetic are supported. The OVERFLOW bit is also provided when the accumulated results are in the overflow condition. ACCUMSLOAD determines the mode of operation for either loading the multiplier product or to accumulate.

The primitive consists of three types of optional pipeline registers:

- ▶ Input registers, located before the multipliers and registering the operands
- ▶ Multiplier pipeline registers, located after the multipliers and product registration
- ▶ Output registers, located before leaving the block, and registering the mode-specific output.

See the description of MULT18X18 for more information on control signals for DSP blocks and attributes.

OUTPUTS: P0, P1, CO

### Description

MULT2 is a 2x2 multiplier. This primitive is useful for implementing an array multiplier using a dedicated carry chain. With this unique configuration, the two separate “and” inputs can be added together to perform the add and shift operations within a single slice. MULT2 must be cascaded together when performing the multiply function. Here are descriptions of the MULT2 pins:

Function	Pins
multiplicand	A0, A1, A2, A3
multiplier	B0, B1, B2, B3
carry in	CI
carry out	CO
output	P0, P1

The equations for this primitive are shown in the table below:

### Equations

$$\text{CO\_int, P0} = \text{A0*B0} + \text{A1*B1} + \text{CI}$$

$$\text{CO, P1} = \text{A2*B2} + \text{A3*B3} + \text{CO\_int}$$

CO\_int and P0 are the carry-out and sum of a full adder with inputs (A0 AND B0), (A1 AND B1), and CI. CO and P1 are the carry-out and sum of a full adder with inputs (A2 AND B2), (A3 AND B3), and CO\_int.

### Description

LatticeECP Block Multiplier. MULT36X36 is a combinational signed 36-bit by 36-bit multiplier used in the DSP block. The value represented in the 36-bit input A is multiplied by the value represented in the 36-bit input B. Output P is the 72-bit product of A and B. MULT36X36 may be represented as either unsigned or two's complement signed. The primitive consists of three types of optional pipeline registers:

- ▶ Input registers, located before the multipliers and registering the operands
- ▶ Multiplier pipeline registers, located after the multipliers and product registration
- ▶ Output registers, located before leaving the block, and registering the mode-specific output.

See the description of MULT18X18 for more information on control signals for DSP blocks and attributes.

Input registers receive operand values from a serial shift chain or routing input. There is separate control for A and B operands. When in shift chain mode, multiplier operands may be bypassed using the bank bypass feature. The shift chain supports one chain of two 18-bit operands or two chains of two 9-bit operands. GSR "DISABLED" attribute disables the asynchronous global set reset input when in user mode.

**Description**

LatticeECP DSP Block Multiplier. MULT9X9 is a combinational signed 9-bit by 9-bit multiplier used in the DSP block. The value represented in the 9-bit input A is multiplied by the value represented in the 9-bit input B. Output P is the 18-bit product of A and B. MULT9X9 may be represented as either unsigned or two's complement signed. The primitive consists of three types of optional pipeline registers:

- ▶ Input registers, located before the multipliers and registering the operands
- ▶ Multiplier pipeline registers, located after the multipliers and product registration
- ▶ Output registers, located before leaving the block, and registering the mode-specific output.

See the description of MULT18X18 for more information on control signals for DSP blocks and attributes.

### Description

MULT9X9MAC supports operand bit widths for 9X9 multiplication and accumulates the output up to 34 bits. The DSP block includes optional registers for the input and intermediate pipeline stage. Pipeline stages may be set using a pipeline attribute. The output registers are required for the accumulator. Signed and unsigned arithmetic are supported. The

OVERFLOW bit is also provided when the accumulated results are in the overflow condition. ACCUMSLOAD determines the mode of operation for either loading the multiplier product or to accumulate.

The primitive consists of three types of optional pipeline registers:

- ▶ Input registers, located before the multipliers and registering the operands
- ▶ Multiplier pipeline registers, located after the multipliers and product registration
- ▶ Output registers, located before leaving the block, and registering the mode-specific output.

See the description of MULT18X18 for more information on control signals for DSP blocks.

- ▶ MachXO2
- ▶ Platform Manager 2

INPUTS: DQSW90, SCLK, D0, D1, RST

OUTPUT: Q

ATTRIBUTES:

**GSR:** "ENABLED" (default), "DISABLED"

### Description

ODDRDQSX1A is the output for DDR1/2 memory using the PIC hardware cell. It is used for right side only. See the below table for the port description.

Signal	I/O	Description
DQSW90	I	Shifts the DQS signal by 90 degree, from DQSBUFH
SCLK	I	Clock from the CIB
D0	I	Data A primary phase of data (first out)
D1	I	Data B secondary phase of data (second out)

## ODDRMXA

### DDR Output Registers

Architectures Supported:

- ▶ LatticeECP2/M
- ▶ LatticeXP2

INPUTS: CLK, DA, DB, RST, DQSXFER

OUTPUT: Q

### Description

The ODDRMXA primitive implements the output register for both write and tristate functions. This primitive is used to output DDR data and DQS strobe to the memory. All DDR output tristate functions are also implemented using this primitive.

The following table provides description of all I/O ports associated with the ODDRMXA primitive.

Port Name	I/O	Definition
CLK	I	System CLK or ECLK
DA	I	Data at the negative edge of the clock
DB	I	Data at the positive edge of the clock
RST	I	Reset
DQSXFER	I	90-degree phase shifted clock coming from the DQSBUFC block
Q	O	DDR data to the memory

Notes:

- ▶ RST should be held low during DDR Write operation. By default the software will implement CE High and RST low.

- ▶ DDR output and tristate registers do not have CE support. RST is available for tristate DDRX mode (while reading). LSR will default to set when used in tristate mode.
- ▶ When asserting reset during DDR writes, it is important to know that it resets only the flip-flops but not the latches.

For more usage, see related technical notes or contact technical support.

## ODDRXC

### DDR Generic Output

Architectures Supported:

- ▶ LatticeECP2/M
- ▶ LatticeXP2

INPUTS: DA, DB, CLK, RST

OUTPUT: Q

### Description

This DDR output module inputs two data streams and multiplexes them together to generate a single stream of data going to the sysIO™ buffer. CLK to this module can be connected to the edge clock or to the FPGA clock. This primitive is also used when DDR function is required for the tristate signal. See the following table for port description.

Port Name	I/O	Definition
DA	I	Data at the negative edge of the clock
DB	I	Data at the positive edge of the clock
CLK	I	Clock from CIB
RST	I	Reset signal
Q	O	DDR data to the memory

### Notes:

- ▶ LSR should be held low during DDR Write operation. By default, the software will be implemented with CE High and LSR low.
- ▶ DDR output and tristate registers do not have CE support. LSR is available for the tristate DDRX mode (while reading). The LSR will default to set when used in the tristate mode.
- ▶ CE and LSR support is available for the regular (non-DDR) output mode.
- ▶ When asserting reset during DDR writes, it is important to keep in mind that this would only reset the flip-flops but not the latches.

For more usage, see related technical notes or contact technical support.

## ORCALUT4

### 4-Input Look Up Table

Architectures Supported:

- ▶ LatticeECP/EC
- ▶ LatticeECP2/M
- ▶ LatticeXP
- ▶ LatticeXP2
- ▶ MachXO
- ▶ Platform Manager

INPUTS: A, B, C, D

OUTPUT: Z

ATTRIBUTES:

**INIT:** hexadecimal value (default: 16'h0000)

### Description

ORCALUT4 defines the programmed state of a LUT4 primitive of a Slice. While this primitive is typically targeted by logic synthesis tools, it can also be instantiated in HDL source for intimate control over LUT4 programming. The contents of the look up table are addressed by the 4 input pins to access 1 of 16 locations.

### Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

The programming of the ORCALUT4 (that is, the 0 or 1 value of each memory location within the LUT4) is determined by the value assigned with INIT. The value is expressed in hexadecimal code. Highest memory locations are in the most significant hex digit, the lowest in the least significant digit.

For example, hex value BF80 produces these 16 memory locations and values:

1011 1111 1000 0000

Memory location 0 (D=0, C=0, B=0, A=0) contains a 0, memory location 2 (D=0, C=0, B=1, A=0) contains a 0. Memory location 15 (D=1, C=1, B=1, A=1) contains a 1, etc.

The ORCALUT4 may encode the Boolean logic for any Boolean expression of 4 input variables. For example, if the required expression was:

$$Z = (D * C) + (B * !A)$$

then the INIT value can be derived from the truth table resulting from the expression:

D C B A : Z

0 0 1 0 : 1

0 1 1 0 : 1
0 1 1 1 : 0

1 0 0 0 : 0
1 0 0 1 : 0
1 0 1 0 : 1
1 0 1 1 : 0

1 1 0 0 : 1
1 1 0 1 : 1
1 1 1 0 : 1
1 1 1 1 : 1
```

INIT = F444 (16)

### Adding INIT to HDL

INIT can be used as an HDL attribute. The following examples demonstrate how to use INIT with the ORCALUT4 primitive in your Verilog or VHDL source. INIT takes binary value in HDL.

#### Verilog Example

```
// synopsys translate_off
// parameter definition
defparam I1.init = 16'hF444 ;
// synopsys translate_on

// ORCALUT4 module instantiation
ORCALUT4 I1 (.A(A), .B (B), .C(C), .D(D), .Z(Q[0]))
/* synthesis init = "16'hF444" */;
```

#### VHDL Example

```
-- component definition
component ORCALUT4
  port (
    A,B,C,D: In std_logic;
          Z: Out std_logic
  );
end component;

-- attribute definition
attribute INIT: string;
attribute INIT of I1: label is "1000000000000000";--Z=A*B*C*D
...
-- ORCALUT4 component instantiation
I1 : ORCALUT4
```

```
Port Map ( A=>A, B=>B, C=>C, D=>D, Z=>N_1 );
```

## OSCA

**Internal Oscillator**

- ▶ LatticeSC/M

OUTPUT: OSC

**ATTRIBUTES:**

**DIV:** 1 (default), 2, 4, 8, 16, 32, 64, 128

**Description**

The OSCA is the source of the internal clock for configuration. After configuration this oscillator is disabled by default. If needed, it can be enabled by instantiating the OSCA or the Sysbus (with `sys_clk_sel=OSC` option). OSCA may be used as a general-purpose clock to drive FPGA logic.

The internal clock frequency can be one of eight values: 1, 1/2, 1/4, 1/8, 1/16, 1/32, 1/64, or 1/128 of the oscillator frequency (about 128 MHz). During start-up, the clock divider is set to 1/128 (about 1 MHz). During initialization, it is set to 1/8 (about 16 MHz). After initialization, if OSCA is enabled, it is set to the user-specified value.

Port Name	I/O	Description

### Description

The OSCG element performs multiple functions on the ECP5 device. It is used for configuration, soft error detect (SED), as well as optionally in user mode. In user mode, the OSCG element has the following features:

- ▶ It permits a design to be fully self-clocked, as long as the quality of the OSCG element's silicon-based oscillator is adequate, and provides performance superior to a "roll-your-own" user-created implementation.
- ▶ If it's unused it can be turned off for power savings.
- ▶ It has a direct connection to primary clock routing through the left mid-mux.
- ▶ It can be configured for operation at a wide range of frequencies via configuration bits.
- ▶ The bandgap controller can't be shut off in ECP5 so there is no need for any caveats for BGOFF.

The one feature available to the user is the user-mode OSCG oscillator function.

The OSCG provides an internal clock source to user designs.

### OSCG Usage with VHDL

```

COMPONENT OSCG
  -- synthesis translate_off
  GENERIC (DIV: integer := 128);
  -- synthesis translate_on
  PORT (
    OSC      : OUT std_logic);
END COMPONENT;

attribute DIV : integer;

begin
  OSCInst0: OSCG
  -- synthesis translate_off

```

```

    GENERIC MAP (DIV => 128)
    -- synthesis translate_on
    PORT MAP (OSC      => OSC);

```

### OSCG Usage with Verilog

```

module OSCG(OSC);
parameter DIV = 128;

output OSC;

defparam OSCInst0.DIV = 128;
OSCG OSCInst0 (.OSC(OSC));

endmodule

```

User can disable the internal oscillator by instantiating it in the design and using the STDBY port. This port can be connected to a user signal or an I/O pin. The user must insure that the oscillator is not turned off when it is needed for operations such as WISHBONE bus operations, SPI or I2C configuration, SPI or I2C user mode operation, SPI or I2C background Flash updates or SED.

## PERREGA

### Persistent User Register

Architectures Supported:

- ▶ LatticeECP3

INPUTS: D15, D14, D13, D12, D11, D10, D9, D8, D7, D6, D5, D4, D3, D2, D1, D0

OUTPUTS: Q15, Q14, Q13, Q12, Q11, Q10, Q9, Q8, Q7, Q6, Q5, Q4, Q3, Q2, Q1, Q0

### Description

The PERREGA primitive enables you to use 16-bit registers to store information when the device goes into the configuration mode. The data on these registers will stay intact during the reconfiguration and be available for use after then. For example, you can use these registers to capture the last pattern that causes an error to reboot from the golden source when using SED.

These latches are available through the internal CIB. The below table describes the I/O ports of the PERREGA primitive.

Signal	Type	Description	Function
D[15:0]	CIB Input	Parallel Data In	Provides parallel data from the FPGA fabric for the latch.
Q[15:0]	CIB Output	Parallel Data Out	Provides parallel data to the FPGA fabric for the latch.
PROGRAMN	Control Signal	High to Low Edge on the PROGRAMN pin	Latch in the data from D[15:0].
DONE	Internal Signal	Done signal	Prohibits multiple latching due to transitional glitches on the LE CIB or PROGRAMN pin.

**PG**

**Power Guard**

Architectures Supported:

- ▶ MachXO2
- ▶ MachXO3L
- ▶ Platform Manager 2

INPUTS: D, E

OUTPUT: Q

### Description

In the power guard mode, the receiver input is disconnected from the pad and held low with a weak pull down. The pad can be toggling and no receiver power will be used. Power guard is enabled on a bank by a bank basis. Each bank has a CIB input signal to enable power guard. In addition, each PIO has individually programmable bit control to disable or enable the power guard capability.

PG is the power guard primitive for MachXO2/Platform Manager 2 devices. You can generate a primitive for a group of I/O pins and then connect it in the design. The PG primitive D port must be connected to the IO pin. You are required to connect the enable input of the primitive to the signal that is used to activate the power guard function. Only one enable signal can be used for all I/Os within an individual I/O bank using power guard. An individual I/O pin is only allowed to connect to one PG primitive module but there could be more than one PG module active in a single I/O bank. Once an I/O signal is connected to the power guard primitive, the software sets the individually programmable bit for that PIO to enable power guard. The default setting for this bit is to disable the power guard function for a PIO.

The following table describes the IO ports of the PG primitive.

Port Name	I/O	Description
D	I	This is the signal coming from an input or I/O pad. This pin cannot have any fanout—only connects between pad and PG.
E	I	This is the “ENABLE” input that is tied to BIE (Block Input Enable). When E=0, Q is connected to D. When E=1, Q is isolated from D.
Q	O	This is the output of the power guard that drives towards the core. When E=0, the output Q is driven by the input D.

## PLLREFCS

### PLL Dynamic Reference Clock Switching

Architectures Supported:

- ▶ ECP5
- ▶ MachXO2
- ▶ MachXO3L
- ▶ Platform Manager 2

INPUTS: CLK0, CLK1, SEL

OUTPUT: PLLCSOUT

#### Description

The PLLREFCS primitive is used to support the dynamic reference clock switching using the SEL signal. This primitive does not require a wrapper.

You only need to instantiate the PLLREFCS primitive if you want to select between two different reference clocks in your application. If you only use one reference clock for the PLL, the software will automatically make the correct connections.

The following table describes the I/O ports of the PLLREFCS primitive.

Port Name	I/O	Description
CLK0, CLK1	I	There are two clock input MUXES (8 inputs each) which are labeled as REFCLK1 and REFCLK2. CLK0 is the output of REFCLK1. CLK1 is the output of REFCLK2.
SEL	I	Selects which signal goes to the input clock MUX.
PLLCSOUT	O

### Power Up Set/Reset

Architectures Supported:

- ▶ ECP5
- ▶ LatticeECP/EC
- ▶ LatticeECP2/M
- ▶ LatticeECP3
- ▶ LatticeSC/M
- ▶ LatticeXP
- ▶ LatticeXP2
- ▶ MachXO
- ▶ MachXO2

INPUT: PUR

ATTRIBUTES:

**RST\_PULSE:** integer (default: 1)

### Description

PUR is used to reset or set all register elements in your design upon device configuration/startup. The PUR component can be connected to a net from an input buffer or an internally generated net. It is active LOW and when pulsed will set or reset all register bits to the same state as the local set or reset functionality.

It is not necessary to connect signals for PUR to any register elements explicitly. The function will be implicitly connected globally.

## PVTIOCTRL

### PVT Monitor Circuit Controller

Architectures Supported:

- ▶ LatticeSC/M

INPUT: UPDATE

### Description

The PVTIOCTRL primitive is used to generate a signal to control the PVT (Process, Voltage, and Temperature) monitor circuit. When UPDATE is 1, the PVT monitor circuit output will be updated. When UPDATE is 0, the last value of the PVT monitor circuit output is latched in.

# R

## RDBK

### Readback Controller

Architectures Supported:

- ▶ LatticeSC/M

INPUTS: RDCFGN, FFRDCFG, FFRDCFGCLK

OUTPUT: RDDATA

### Description

RDBK is used to read back the configuration data and optionally the state of the PFU outputs. RDBK can be done while the FPGA is in normal system operation. To use RDBK, select options in the bit stream generator within the place and route tool.

- ▶ You can choose the option to prohibit readback, allow a single readback, or allow unrestricted readback. For more information on RDBK, refer to applicable technical notes or contact technical support.

*RDCFGN*: A high-to-low transition on this input initiates a readback operation. This pin must remain low during the readback operation.

*RDDATA*: Readback data is available at this output, which in turn is connected to the same pad as that used by TDO for boundary scan.

### Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

INPUTS: GSR, CLK

### Description

SGSR is used to reset or set all register elements in your design. The SGSR component can be connected to a net from an input buffer or an internally generated net. It is active LOW and when pulsed will set or reset all flip-flops, latches, registers, and counters to the same state as the local set or reset functionality. When input GSR is HIGH, the global signal is released at the positive edge of the clock (CLK).

It is not necessary to connect signals for SGSR to any register elements explicitly. The function will be implicitly connected globally. The functionality of the SGSR for sequential cells without a local set or reset are described in the appropriate library help page.

### SPIM Primitive Distributed RAM

Architectures Supported:

- ▶ LatticeECP2/M
- ▶ LatticeECP3

INPUTS: SEL, A0, A1, A2, A3, A4, A5, A6, A7

### Description

Some devices have a built-in SPI CIB interface that is embedded into the hardware. The SPI CIB interface allows the user to control the dual-boot flash support based on the user's logic. Users can interface with this hardwired SPI controller through the use of the SPIM primitive. The SPIM primitive have 9

input ports only. The SEL line indicates which SPI Flash device to boot from and the signals [A0..A7] indicate the address from where the device will reboot during reconfiguration.

## SPR16X2

### Distributed Single Port RAM

Architectures Supported:

- ▶ LatticeSC/M

INPUTS: AD0, AD1, AD2, AD3, DI0, DI1, CK, WRE, WPE

OUTPUTS: DO0, DO1

ATTRIBUTES:

**INITVAL:** (*Verilog*) 64'hXXXXXXXXXXXXXXXX (16-bit hexadecimal value)  
 (*VHDL*) 0XXXXXXXXXXXXXXXX (16-bit hexadecimal value)  
 Default: all zeros

**GSR:** "ENABLED" (default), "DISABLED"

### Description

The SPR16X2 symbol represents a 16 word by 2 bit asynchronous single port RAM. It has two data inputs DI[1:0], a positive Write Enable (WRE), one positive Write Port Enables (WPE), and one set of address inputs.

The WRE and WPE must be HIGH for the rising clock edge if the write to the RAM is occurring on the falling edge. The data is written into the locations specified by the write address lines AD[3:0] on the next negative clock (CK) edge. The data read operation is always performed asynchronously, with the memory contents specified by the address inputs AD[3:0] output on the data output signals DO[1:0].

In other words, the read operation is asynchronous and is always active. The write operation is synchronous and only occurs when there is a falling edge of the clock and the write enables are high prior to that falling edge.

If desired, the contents of the SPR16X2 can be assigned an initial value, which is loaded into the RAM during configuration. The INITVAL=<value> attribute is used to assign the initial value. The <value> should consist of 16 hexadecimal data written into the RAM from the highest address to the lowest address. For example, if the following attribute is specified:

```
INITVAL=0x0123012301230123 (in hex)
```

it implies that the above data is loaded sequentially from location FH to 0H (where FH would contain the 0 and 0H the 3). If no INITVAL attribute is specified, the RAM is initialized with zeros on configuration.

If the INITVAL is specified as a hex string of 16 values, the values should not be greater than 3, since 3 is setting both memory locations to 1. If a value greater than 3 is used for synthesis or mapping, only the last two (least significant) bits are used for initialization by the mapper. For example,

```
INITVAL=0x00000000ffffff
```

is equivalent to

```
INITVAL=0x0000000033333333
```

for mapping purposes, since the first two bits of the "f" are ignored.

### Description

Implements the dedicated "TAG Memory" block, which is a one page FLASH non-volatile memory accessible by the hardwired Serial Peripheral Interface port or the JTAG port. This stand-alone TAG memory is ideal for scratch pad memory for mission critical data, board serialization, board revision log and programmed pattern identification.

The XP2 family of devices provides dedicated TAG memory ranging from 632 to 3384 bits depending on device density. The user can read and write to the TAG memory either through the SPI port (External Slave SPI) or the CIB interface (Internal Slave SPI) by setting the `SLAVE_SPI_PORT` attribute. The software default for access to the Tag memory is the CIB interface. The TAG memory initialization file format is similar to that of EBR.

- ▶ The TAG interface through the SPI port (External Slave SPI): When the TAG interface is set for the SPI port, four SPI pins will be reserved for the TAG access through the SPI port.
- ▶ The TAG interface through the CIB interface (Internal Slave SPI): When the TAG interface is set for the CIB interface, the user can select any four general purpose IO pins to access the TAG memory using the SPI commands. The four SPI pins on each XP2 device are considered general purpose IOs if they are not reserved using `SLAVE_SPI_PORT` attribute.

## STFA

### Store to Flash Primitive

Architectures Supported:

- ▶ LatticeXP2

INPUT: STOREN

OUTPUTS: UFMFAIL, UFMBUSYN

### Description

The LatticeXP2 store-to-flash primitive is for user flash module (UFM) operations. The main function of a UFM is to protect the user data from being lost when the system is powered OFF. The user data in the UFM will be used by the system for initialization when the power comes back. To emulate the UFM capability, the users can use the EBR (shadow flash) memory configurations and then transfer the data to UFM through Store-to-Flash operation. The store-to-flash operation is a single-command-two-operation process. When the store-to-flash operation is initiated, an erase-UFM-Flash CIB signal will be enabled to erase the Flash, followed by the transfer-to-flash operation. Once the transfer is done, the flash controller will send a transfer-done signal back to the user logic. During the Store-to-Flash operation, the EBR's are not accessible. There is no difference between regular EBR RAM configuration and shadow flash (UFM) EBR RAM configuration in Lattice Diamond GUI. The presence of a STFA primitive in the design determines EBR RAM configuration. Due to a silicon limitation, the user cannot use the Store-to-Flash operation if the SED is operating in an Always mode. Only one STFA instance in the design is allowed.

## STFA Port Description

Port Name	Corresponding Hardware Port Name	I/O	Description
STOREN	storecmdn	I	Initiates to store the EBR content to Flash
UFMFAIL	ufm_fail	O	Store to Flash operation failed
UFMBUSYN	fl_busrn	O	Tells the user whether the FLASH is in busy state or not

You can refer to LatticeXP2 technical notes on the Lattice web site for more information.

## STARTUP

### Startup Controller

Architectures Supported:

- ▶ LatticeECP/EC
- ▶ LatticeECP2/M
- ▶ LatticeSC/M

INPUT: UCLK

### Description

After configuration, the FPGA enters the start-up phase, which is the transition between the configuration and operational states. Normally, the relative timing of the following three events is triggered by the configuration clock (CCLK): DONE going high, release of the set/reset of internal FFs, and activation of user I/Os. The three events can also be triggered by a user clock, UCLK. This allows the start-up to be synchronized by a known system clock. For more detailed information refer to an available data book or contact technical support.

Another set of bitstream options for the STARTUP block allows the DONE pin to be held low and then released to be used with either CCLK or UCLK to control the release of the set/reset of internal FFs and the activation of user I/Os. This allows the synchronization of the start-up of multiple FPGAs.

:

---

*UCLK*: User defined clock to trigger DONE going high, release of set/reset of internal FFs, and activation of user I/Os.

**Note**

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

### Description

TRDLLA will generate four phases of the clock, 0, 90, 180, 270 degrees, along with the control setting used to generate these phases. This mode features registered control bit output with separate enable, addition and subtraction on the outgoing control bits, lock achieved starting from minimum delay which guarantees lock to first harmonic (fundamental frequency), and four available output phases (0, 90, 180, 270) degrees. This requires internal feedback only, a maximum frequency 700MHz, and a minimum frequency 100MHz.

## TSALL

### Global Tristate Interface

Architectures Supported:

- ▶ LatticeSC/M
- ▶ MachXO
- ▶ MachXO2
- ▶ MachXO3L
- ▶ Platform Manager
- ▶ Platform Manager 2

INPUT: TSALL (TSALLN for LatticeSC/M)

### Description

TSALL is used to tristate buffers in your design. The TSALL component is connected to a net to drive all output and bidirectional buffers into a HIGH impedance state when active LOW.

It is not necessary to connect signals to buffers explicitly. The function will be implicitly connected globally.

### Note

- ▶ The TSALL component may be driven by general FPGA logic or by the read-configuration block. In the latter case, the TSALL block must be driven by a buffer located at the RDCFGN pin. When locating the TSALL to the RDCFGN, you must do this by explicitly designating "RDCFGN" in the attribute. Check with customer support or with FAEs for more details.
- ▶ This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

## USRMCLK

### Allows User Function to Access SPI PROM

Architectures Supported:

- ▶ ECP5

INPUTS: USRMCLKI, USRMCLKTS

### Description

A primitive to allow the user function to access the SPI PROM. It has two inputs. This feature allows the user to tie a specific user clock to be used as MCLK. Without this instantiation the device will use the CFG MCLK as MCLK. This primitive can only be instantiated if the device is in MSPI mode. DRC error will be issued if this primitive be instantiated in any mode other than MSPI, The table below describes the ipnputs of the USRMCLK primitive.

Port	I/O	Function
USRMCLKI	I	User defined MCLK.
USRMCLKTS	I	User defined MCLK tri-state.

## Primitive-Specific HDL Attributes

The following is a comprehensive list of HDL attributes that are commonly set automatically during module generation and are associated with specific primitives. We list these attributes here mainly for purposes of identification.

In almost all cases, it is not recommended that any of these attributes be edited manually. They should appear in your source as a result of module generation in IPexpress only. There are many interdependencies that exist between certain related attributes and their valid values on an architecture or device basis. These interdependencies make it impractical to simply edit the source HDL. If you were to do so, its very likely an invalid value may result in a failure in your design.

### List of Primitive-Specific HDL Attributes

The below table lists all the primitive-specific attributes in alphabetic order.

Attribute	Type	Allowed Values	Default	Description
AEPOINTER	Binary	( <i>LatticeSCM</i> ) 15-bit binary value; ( <i>MachXO/Platform Manager</i> ) 14-bit binary value	All zeros	Specifies the Almost Empty Flag Pointer. AEPOINTER1 refers to the Almost Empty Flag Pointer 1.
AFPOINTER	Binary	( <i>LatticeSCM</i> ) 15-bit binary value; ( <i>MachXO/Platform Manager</i> ) 14-bit binary value	All zeros	Specifies the Almost Full Flag Pointer. AFPOINTER1 refers to the Almost Full Flag Pointer 1.
ALU_INIT_CNTVAL	Integer	( <i>LatticeECP3</i> ) 0 to 31; ( <i>Others</i> ) 0, 4, 8, 12, 16, 32, 48, 64, 72 (0 = DISABLED)	0	Specifies the minimum number of delay taps that ALU will count for. This forces the ALU to count for a minimum number of delay taps before it can find lock, and prevents the DLL finding lock at the minimum possible delay setting and then "falling off the end" of the delay chain if the input clock has jitter. Used in all clock injection cancellation modes where the lock point is not predictable.
ALU_LOCK_CNT	Integer	3 to 15	3	Specifies the Lock Count Cycles. Attached to a DLL-type primitive.
ALU_UNLOCK_CNT	Integer	3 to 15	3	Specifies the Unlock Count Cycles. Attached to a DLL-type primitive.
