Chapter 1

Help for Lattice Diamond

Lattice Diamond™ is the complete design environment for Lattice Semiconductor FPGAs. The software includes a comprehensive set of tools for all design tasks, including project management, design entry, simulation, synthesis, place and route, in-system logic analysis and more.

To start learning about Diamond, see the Lattice Diamond User Guide To quickly get some hands-on experience, try the Lattice Diamond Tutorial .

To help you experiment further, example projects are available. These examples are designed to illustrate different aspects of designing with Diamond. To see the examples, choose **File > Open > Design Example**. Then open an example folder and open the example's .ldf file. (An .ldf file defines a design project for Diamond.)

The rest of the Help system provides complete instructions for the different stages of the Diamond design flow and extensive reference material.

Getting Help

For almost all questions, the place to start is this Help. It describes the FPGA design flow using Diamond, the libraries of logic design elements, and the details of the Diamond design tools. The Help also provides easy access to many other information sources.

To make the most effective use of the Help, please review this section.

Opening the Help

The Help can be opened in several ways:

- In Windows, choose **Start > Programs > Lattice Diamond > Accessories > Diamond Help**.
- In the main window, choose **Help > Lattice Diamond Help**.
- To go directly to the Help for the tool that you're using do one of the following:
  - If the tool is attached to the main window, choose **Help >** <*Tool Name*> **Help**.
  - If the tool is detached, choose **Help >** **Help**.
- To go directly to the Help for the view of the tool that you're using, press **F1**.
- For a description of how to use a dialog box, click **Help** (if available).
- For a description of a feature in a dialog box, right-click on the feature. If a box appears saying "What's This?," click it. Or click on the feature and then press **Shift-F1**. In Windows, you can also click the question mark button in the title bar and then hover over the feature. If the cursor turns into an arrow with a question mark, click on the feature.

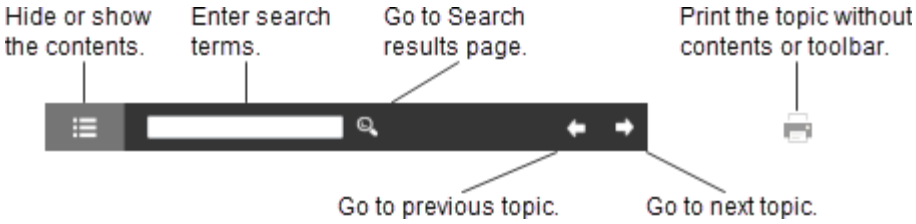
  Note: Not all dialog box features have pop-up descriptions.
- To learn more about a property in the Strategies dialog box, select the property and press **F1**.

- To get more information related to a message, right-click the message. If a menu appears with a Help command available, choose it.

JavaScript must be enabled in your default browser. If you are have trouble opening the Help, see “Troubleshooting the Help” on page 15.

Using the Help

The Help has several features to help you find information.



Contents The contents organizes the information in the Help. Look here to see what subjects are covered or to begin in-depth study of a subject.

Click the (Contents) button to hide or show the contents pane.

Search The search locates all topics that contain specific text. This can be the fastest way to find information once you are familiar with the contents of the Help.

Enter one or more words and click the (Search) button. The Search page opens with a list of topics containing all of the words (an AND function).

Some tips:

- Enter phrases between a pair of double-quote marks. For example: "block module".
- Use an asterisk * as a wildcard to also find plurals and different verb tenses, or to search on word parts. For example, search* finds search, searches, searching, and searched. Searching on *annotate finds annotate and backannotate.
- Capitalization does not matter.
- Leave out punctuation except for hyphens in hyphenated words.

Search results are ordered by the number and types of hits found. The first few topics are most likely to have substantial information on the search terms. Topics at the end of the list may have just a casual mention of the terms.

Search Navigation Tip

Your browser's forward and back buttons may not work the way you expect with the Search page. To go to the Search page, always click the (Search) button. If you're on the Search page and want to go back to the topic you were looking at, click the (Contents) button.

Glossary The "Glossary" on page 2604 has definitions of hundreds of technical terms and abbreviations. The Glossary is in the contents under "Reference Guides."

Design Tool Reference "Design Tool Reference" on page 2669 is an index of all the tools in the Diamond tool set. This can be an easy way to find information about a tool. Design Tool Reference is in the contents under "Reference Guides."

Type Conventions Used in This Document

Convention	Meaning or Use
Bold	Items in the user interface that you select or click. Text that you type into the user interface.
<*Italic*>	Variables in commands, code syntax, and path names.
Ctrl+L	Press the two keys at the same time.
`Courier`	Code examples. Messages, reports, and prompts from the software.
`...`	Omitted material in a line of code.
`.` `.` `.`	Omitted lines in code and report examples.
`[ ]`	Optional items in syntax descriptions. In bus specifications, the brackets are required.
`( )`	Grouped items in syntax descriptions.
`{ }`	Repeatable items in syntax descriptions.
`|`	A choice between items in syntax descriptions.

Troubleshooting the Help

If you are have trouble opening the Help, check for the following situations:

Active Content or Scripts Are Blocked Opening the online Help may be interrupted by one of the following messages on the Internet Explorer Information Bar:

- "To help protect your security, Internet Explorer has restricted this file from showing active content that could access your computer. Click here for options..."
- "To help protect your security, Internet Explorer has restricted this file from running scripts or ActiveX controls that could access your computer. Click here for options..."

To see the Help, click on the Information Bar and choose **Allow Blocked Content**. A dialog box with an expanded warning opens. Click **Yes**.

To avoid these warnings, either use a different browser or turn off the warning for active content in Internet Explorer.

Note

Doing either of these means that when you open any Web page that is resident on your computer—not just Diamond Help—the page will automatically run any active content that it has. While active content is common and can be very useful, malicious content can damage your files. Be sure you trust the software on your computer.

To turn off the warning:

1. In Internet Explorer, choose **Tools > Internet Options**.
2. Click the **Advanced** tab.
3. Under Security, select **Allow active content to run in files on My Computer**.
4. Click **OK**.

Back and Forward Buttons Do Not Work with the Search Page Your browser's back and forward buttons may not work the way you expect with the Search page. Instead of returning to the Search page, you go to the previous or next topic. Instead of returning from the Search page to the previous or next topic, you stay on the Search page. The Search page is not in the stack of visited pages.

To go to the Search page, always click the  (Search) button. If you're on the Search page and want to go back to the topic you were looking at, click the  (Contents) button.

Updating Diamond from the Web

You can update Diamond from the Lattice Web site with UPDATE. The UPDATE program can be set to automatically check for service patches and alert you when one is available. You can also use UPDATE to manually check for service patches. When you find a patch you can download it and install it at your convenience. Or, in Windows, you can have the patch automatically installed after downloading it.

Start by setting the UPDATE options. See “Setting Options for Updates” on page 17.

See Also

- “Getting a Service Patch” on page 18
- “Installing a Downloaded Service Patch” on page 19

Setting Options for Updates

To get service patches, you must specify the Internet settings and if you want the software to check for service patches. These options can be set in the Diamond main window or in the UPDATE program. The following instructions are for the Diamond main window. In UPDATE, start by choosing **Settings > Update Settings**.

To set update options:

1. In Diamond’s main window, choose **Tools > Options**.

   The Options dialog box opens.

2. In the hierarchy tree of the Options dialog box, choose **Environment/ Startup**.

3. If you want the software to automatically check for patches, select **Automatic check for software update when Lattice Diamond launches**, and then select the desired interval.

   Clear this option to disable automatic checking. If you disable this option, you should occasionally run a manual check as described in “Getting a Service Patch” on page 18.

4. In the hierarchy tree of the Options dialog box, choose **Environment/ Network Settings**.

   You need to set up an Internet connection to download patches regardless of whether you selected automatic checking.

5. If you use a proxy server to reach the Internet, select **Use a Proxy Server**. Then fill in the rest of the form.

Ask your system administrator for the host address, port assignment, and proxy type. You may also find the proxy information in the options or preferences of your browser. Check for Advanced or Connections options.

6. Click **OK**.

Getting a Service Patch

There are two ways to get service patches: checking manually with the UPDATE program or, more conveniently, through the Start Page of Diamond's main window. If you enabled automatic checking in the UPDATE options, Diamond notifies you whenever a new service patch becomes available.

In Windows, if a service patch is available, you have a choice between installing the patch immediately or downloading it now and installing it later, at a convenient time.

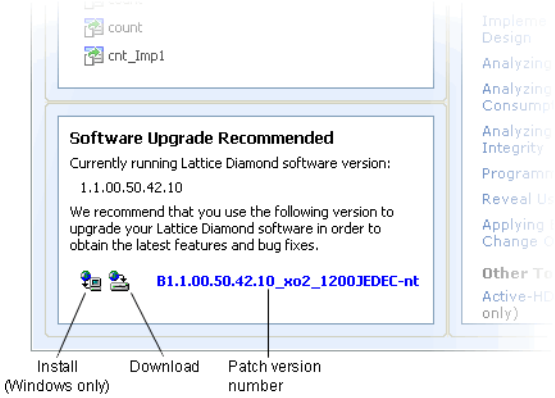
In Linux, you download the service patch and install it manually at your convenience.

Whether you are installing immediately or just downloading the service patch, getting it may take several minutes. Depending on the size of the patch, installing it may take a few more minutes.

To get a service patch from the Start Page:

1. If you do not have automatic checking enabled, choose **Help >** **Check for Updates**.
2. Check the lower-left corner of the Start Page. If there is a service patch available, the frame is titled "Software Upgrade Recommended" and shows a list of patches as shown below.

Figure 1: Part of Start Page Showing a Patch Available



3. For information about a patch, click the patch version number.

   Your default browser opens with an update notice. This notice includes information about installing the patch and links to the Lattice Web site for more information.

4. After reading the update notice, do one of the following:

   - (Windows only) Click the Install icon that is next to the version number to immediately install the service patch. Close all Diamond tools and then restart Diamond.
   - Click the Download icon that is next to the version number to save the service patch to a directory and install it later. In the Save File dialog box, navigate to the location where you want to save the file and click **Save**.

   Hover the cursor over an icon to see a label for it.

To get a service patch from UPDATE:

1. Start UPDATE:

   - In Windows: Choose **Start > Programs > Lattice Diamond > UPDATE**.
   - In Linux: On a command line, enter <*install_path*>**/bin/lin/update**.
2. If you have more than one version of Diamond installed, choose the version that you want to update in the “Installed versions” box.
3. If you do not have automatic checking enabled, click **Update**.
4. Check the “Available update versions” box. If there is a service patch available, the box shows a list of patches.
5. For information about a patch, click the patch version number.

   An update notice appears in the lower portion of the window. This notice includes information about installing the patch and links to the Lattice Web site for more information.
6. After reading the update notice, do one of the following:

   - (Windows only) Click **Install** to immediately install the service patch.
   - Click **Download** to save the service patch to a directory and install it later. In the Save File dialog box, navigate to a location where you want to save the file and click **Save**.

See Also

- “Setting Options for Updates” on page 17
- “Installing a Downloaded Service Patch” on page 19

Installing a Downloaded Service Patch

After you have downloaded a service patch, you can install it to update your Diamond software.

Installing on Windows To install the service patch:

1. Close all Diamond tools.
2. Go to the location where you saved the service patch.

3. Double-click the service patch's executable file (.exe).

   The Lattice Semiconductor Setup program opens.

4. Follow the on-screen instructions.

Installing on Linux To install a service patch, you need to be listed in the system's sudoer file. The sudo utility allows the files to be installed with you as the owner and with the proper permissions.

To install the service patch:

1. Close all Diamond tools.
2. On a command line, change to the directory holding the service patch:

   cd <*temp_tools*>

3. Run the service patch's executable file (.rpm) using the sudo and rpm utilities:

   sudo rpm -ivh <*service_patch*>**.rpm**

Chapter 2

Managing Projects

Managing design projects involves a variety of activities: creating and maintaining the project, keeping track of the stages in the design implementation process, reviewing reports detailing the results of the process, and comparing different versions (implementations) of the project. Managing projects can also include writing Tcl scripts to automate your own design and test procedures.

Creating a project in Diamond is a simple matter of specifying a location for the project files, any existing design source files, and the FPGA type. You do this with the New Project wizard (choose **File > New > Project**). Diamond creates a folder with a project file (.ldf) containing basic information about the project, the beginning of a logical preference file (.lpf), which controls how the design is implemented in the map and place-and-route stages, and a default strategy (Strategy1.sty).

A “strategy” is a collection of settings for controlling the different stages of the implementation process (synthesis, map, place & route, and so on). Strategies can control whether the design is optimized for area or speed, how long place and route takes, and many other factors. Diamond provides a default strategy, which may be a good collection to start with, and some variations that you can try. You can modify Strategy1 and create other strategies to experiment with or to use in different circumstances.

The project folder also contains an implementation folder. Implementation folders contain the source files, process reports, and other information for different implementations, or versions, of a design. Having different project implementations helps you to experiment and compare different designs. With Run Manager (choose **Tools > Run Manager**) you can process multiple implementations simultaneously and compare the results. You can check the details of each implementation in a set of process reports (choose **View > Reports**).

As you develop your design, routine tasks can be controlled through the Diamond graphical user interface or through scripts. Diamond comes with command-line and Tcl commands for many of its functions.

See Also ▶“Creating a New Project” on page 23

- “Using Strategies” on page 47
- “Working with Implementations” on page 45

▶ “Viewing Logs and Reports” on page 100

Running Lattice Diamond

The Diamond main window is the primary interface and provides an integrated environment for managing the project elements and processes, as well as accessing all Lattice Diamond tools and views.

To run the Diamond main window:

- From your Windows desktop, choose **Start > Programs > Lattice Diamond > Lattice Diamond**.

  Note

  Lattice Diamond is the default Programs folder name when you install the Lattice Diamond software. Change this name accordingly if you have chosen another folder name during installation.

- From your Linux platform shell window or C-shell window, execute:

  `<install_path>/bin/lin/diamond`

Pin Diamond to Start Menu or Taskbar

You can pin Diamond to your Windows Start menu or taskbar, so you can open it quickly and conveniently, rather than looking for Diamond in the Start menu.

To pin Diamond to the Start menu or Taskbar:

- Choose the Windows **Start** menu. Find the **Lattice Diamond** icon. Right-click the **Lattice Diamond** icon, and then click **Pin to Start Menu** or **Pin to Taskbar**.

Note

You should not pin Diamond to the Taskbar through the minimized icon on the taskbar while Diamond is running.

If you want to remove the pinned Diamond from the Start menu or the taskbar, right-click on a pinned **Lattice Diamond** icon from the Start menu or the taskbar, choose **Unpin from Start Menu** or **Unpin this program from taskbar**.

Managing Diamond Layout

The Diamond main window has many controls, views, tools, reports, outputs, and a Tcl console. They are very flexible and can be configured to store your preferred layout by using the Load Layout, Manage Layout, and Save Layout menu commands.

Refer to the Lattice Diamond User Guide, the “User Interface Operation” chapter, for more details.

Creating a New Project

A project is a collection of all files necessary to create and download your design to the selected device. The New Project wizard guides you through the steps of specifying project name and location, selecting a target device, and adding existing sources to the new project.

Note

Do not place more than one project in the same directory.

To create a new project:

1. From the Diamond main window, choose **File > New >**  **Project**.

   The New Project wizard opens.

2. Click **Next**.

3. In the Project Name dialog box, do the following:

   - Under Project, specify the name for the new project.

     File names for Diamond projects and project source files must start with a letter (A-Z, a-z) and must contain only alphanumeric characters (A-Z, a-z, 0-9) and underscores (_).

   - To specify a location for your project, click **Browse**. In the Project Location dialog box, you can specify a desired location.

   - Under Implementation, specify the name for the first version of the project. You can have more than one version, or “implementation,” of the project to experiment with. For more information on implementations, refer to “Working with Implementations” on page 45.

   - When you finish, click **Next**.

4. In the Add Source dialog box, do the following if you have an existing source file that you want to add to the project. If there are no existing source files, click **Next**.

a. Click **Add Source**. You can import HDL, schematic, EDIF netlist, LPF constraints, or Reveal Inserter project files at this time.

Tip

When you create a new project, the Diamond software always creates a default <*project*>.lpf file for the project. If you already have an .lpf file and want to use it in your new project, you will need to add this .lpf into the project. In this way this pre-existing .lpf file will be used as the active .lpf. Otherwise, you will need to add this pre-existing .lpf later, and mark the <*project*>.lpf inactive.

b. In the Import File dialog box, browse for the source file you want to add, select it, and click **Open**.

The source file is then displayed in the Source files field.

c. Repeat the above to add more files.

d. To copy the added source files to the implementation directory, select **Copy source to implementation directory**. If you prefer to reference these files, clear this option.

e. When you finish, click **Next**.

5. In the Select Device dialog box, select a device family and a specific device within that family. Then choose the options you want for that device. When you finish, click **Next**.
6. In the Select Synthesis Tool dialog box, select the synthesis tool that you want to use. This choice can be changed at any time. See "Selecting a Synthesis Tool" on page 88 for more information. When you finish, click **Next**.
7. In the Project Information dialog box, make sure the project settings are correct and then click **Finish**.

Note

If you want to change some of the settings, click **Back** to modify them in the previous dialog boxes of the New Project Wizard.

See Also

- "Tips for Saving and Naming Projects" on page 31
- "Reserved File Names" on page 31

Modifying a Project

After creating a project, you can modify the project by using the right-click menu.

To modify a project:

1. Right-click on any part of the project in the File List view.

The right-click menu varies upon the different part of the project you have chosen.

2. You can choose to edit a device in the Device Selector, add source files, implementations, or strategies as needed to the project, clone a strategy, set the current highlighted strategy as active strategy, exclude certain source files from an implementation or remove a file.
3. You can also edit properties of the project in the Project Properties dialog box. You can set the top-level unit, specify the VHDL Library name, and Verilog Include Search path in the Project Properties dialog box.

Importing ispLEVER Projects

Design projects created in ispLEVER can easily be imported into Diamond. The process is automatic except for the ispLEVER process properties, which are similar to the Diamond strategy settings, and PCS modules. All your ispLEVER project settings can be handled smoothly in Diamond. After importing a project, you need to set up a strategy for it and regenerate any PCS modules.

Note

Before converting an ispLEVER project, make a backup copy of the project. In ispLEVER, open the project and choose **File > Archive Current Project**. See the ispLEVER Help for details.

To import an ispLEVER design project:

1. In Diamond, choose **File > Open > Import ispLEVER Project**.
2. In the Select ispLEVER Project dialog box, browse to the project's **.syn** file.
3. Click **Open**.

   The Import ispLEVER Project dialog box opens showing the .syn file.
4. If desired, change the base file name or location for the Diamond project. If you change the location, the new Diamond files will go into the new location. By default, the "Copy design source to Implementation's Source directory" option is checked. The original source files will be copied to the new location.

   Note

   If you choose to copy source files when importing an ispLEVER project, the following limitations need to be noted:

   - Only source list in the project will be copied to your current project directory.
   - The files, .v, .txt, .ngo, and so on, related to an LPC file listed in the project will not be copied. You can copy them to the current project directory manually.
   - Schematic symbols will not be copied.
   - Included Verilog files (specified in the source files) will not be copied.
5. Click **OK**.

The project files are converted to Diamond format with the default strategy settings.

6. Adjust the strategy settings.

See Also ►"Adjusting PCS Modules" on page 26

Adjusting PCS Modules

PCS modules created with IPexpress have an unusual file structure and need additional adjustment when importing a project from ispLEVER. There are two ways to do this adjustment. The preferred method is to regenerate the module in Diamond. However this may upgrade the module to a more recent version. An upgrade is usually desirable but if, for some reason, you do not want to upgrade the PCS module, you can manually adjust the module by copying its .txt file into the implementation folder. If you use this method, you must remember to copy the .txt file into any future implementation folders.

To regenerate a PCS module:

1. Find the module in the Input Files folder of the File List view. The module may be represented by an .lpc, .v, or .vhd file such as pcs_1.lpc.
2. If the File List view shows the Verilog or VHDL file for the module, and you want to regenerate the module, import the module's .lpc file:
   a. In the File List view, right-click the implementation folder  and choose **Add > Existing File**.
   b. Browse for the module's .lpc file, <*module_name*>**.lpc**, and select it.
   c. Click **Add**.

      The .lpc file is added to the File List view.
   d. Right-click the module's Verilog or VHDL file and choose **Remove**.
3. In File List, double-click the module's .lpc file.

   The module's dialog box opens.
4. In the bottom of the dialog box, click **Generate**.

   The Generate Log tab is displayed. Check for errors.
5. Click **Close**.

   In File List, the .lpc file is replaced with an .ipx file. The IPexpress manifest (.ipx) file is new with Diamond. The .ipx file keeps track of the files needed for complex modules.

To manually adjust a PCS module:

1. Open a file window and browse to the new Diamond project.
2. Find the module's .txt file, <*module_name*>**.txt**.
3. Copy the .txt file into the Diamond project's implementation folder. The implementation folder's name is based on the name of the .syn file. For

example, if the ispLEVER project has a design_pcs.syn file and a PCS module named pcs_1, move pcs_1.txt into the design_pcs folder.

Note

If you choose to copy source files when importing an ispLEVER project, the following limitations need to be noted:

- Only source list in the project will be copied to your current project directory.
- The files, .v, .txt, .ngo, and so on, related to an LPC file listed in the project will not be copied. You can copy them to the current project directory manually.
- Schematic symbols will not be copied.
- Included Verilog files (specified in the source files) will not be copied.

See Also "Importing ispLEVER Projects" on page 25

Targeting a Device

Lattice Diamond lets you retarget a design to a different device any time during the design process.

To target a device:

1. In the File List view, double-click the device name.

   The Device Selector dialog box opens. It contains all available devices and their options.

2. Under Select Device, select a device family and a specific device within that family. Then choose the options you want for that device.

   You can also click **Online Data Sheet for Device** to view the data sheet for any specific device.

   Note

   If you could not find the device you want in the device list, select **Show Obsolete Devices**. Then the device list will also include obsolete devices.

3. When you finish, click **OK**.

   The specified target device appears in the File List view.

Note

If you have an .ipx file whose device is not the same as the project device, double-click the .ipx file in the File List view. You will get a Mismatch Device message asking you to run IPexpress to regenerate the .ipx file. Click **Yes** if you want to regenerate the .ipx file.

Viewing Project Properties

After creating a project, you can view the project-related information in the Project Properties dialog box.

To view project properties:

1. Right-click on any part of the project in the File List view, and choose **Properties**.

   The Project Properties dialog box opens.

2. In the dialog box, you can see the file name, category, and location of the selected file. You can even enter values for some of the selected sections of the project in the Value field.

Saving Project Files

You can save changes to source files and to project properties. You can also save copies of individual files and whole design projects.

Saving Changes

As you are making changes to source files or to the project properties you should frequently save the files. Diamond offers three save commands for this:

- **File > Save**: Saves the currently active item.
- **File > Save All**: Saves all the content changes in the Power Calculator files (.pcf), Reveal Project files (.rvl), schematic files (.sch), Verilog files (.v, .veri, .ver, .vo, .h), VHDL files (.vhd, .vhdl, .hdl, .vho), EDIF netlist files (.edf, .edif, .edi, .edn, .edj), preference files (.lpf, .prf, .tpf), text files (.txt), synthesis constraint files (.ldc, .sdc), timing preference files (.tpf), waveform files (.wdl), memory files (.mem), Reveal Analyzer files (.rva), symbol library files (.lib), symbol files (.sym), and manifest files (.ipx).
- **File > Save Project**: Saves project properties such as the target device, implementation file lists, and strategy setting.
- **File > Save Project As**: Opens the Save Project As dialog to save the active project.

Also, if there are any unsaved changes when you close a project, a dialog box will open offering a chance to specify which files you want to save.

Copying a Source File

You can create copies of source files using Diamond.

If you make a copy of a source file in the same project folder as the original file, remember that they must have different names and that modules in different files must have different names.

To copy a source file:

1. Open the source file with a Diamond tool.
2. Choose **File > Save** <*filename*> **As**.

   The “Save as” dialog box opens.
3. Browse to where you want to save the file.
4. Enter a new file name.

   Note

   In the Linux version of Diamond, when you save or export a file, the dialog box does not automatically append an extension to the file name you specify. That is the standard way Linux handles the **Save As** dialog box. You need to manually add the relevant file extension.
5. Choose the file type from the “Save as type” menu. Be careful to choose the right type or your copy will have the wrong extension and tools will not recognize it.
6. Click **Save**.

Copying a Project

You can make a copy of a design project to use as the beginning of another project. (If you want the copy to backup or move the project, see “Archiving a Project” on page 30 instead.) This process saves all source and other project files that are within the project folder to another folder. Referenced files are not included.

To copy a design project:

1. Choose **File > Save Project As**.

   The Save Project As dialog box opens.
2. In the dialog box, browse to where you want to save the copy.
3. Click the Create New Folder  button to create a new project folder.
4. Type a new name for the folder and press **Enter**.
5. Double-click the new folder to open it.
6. If desired, give the project a new name in the “File name” box.
7. If you want the copy to include files generated by the implementation processes, select **Copy generated files**.
8. Click **Save**.

   If there are open files, the Save Modified Files dialog box may open. Select files to be saved before copying and click **OK**.

The current design project closes and the new one opens.

Check references to files outside of the project folder. These may need adjustment.

See Also ►"Tips for Saving and Naming Projects" on page 31

Archiving a Project

Diamond offers you an easy way to archive the current project. A project archive is a single compressed file (.zip) containing the information for the entire project. After archiving a project, you can reload it in the main window at any time.

When you archive a project that contains source files stored outside the project folder, the remote files are compressed under the remote_files subdirectory in the archive.

To archive the current project:

1. In the main window, make sure the project you want to archive is open.
2. Choose **File > Archive Project**.
3. In the Archive Project dialog box, specify the file name and location.
4. If you want to include all files in the project directory, not just source files, select **Archive all files under the Project directory**.

   Clearing this option may make a much smaller archive by leaving out nonessential files such as temporary files or documentation. Without this option Diamond archives only those files it recognizes as part of the project. *With* this option Diamond archives *all* files in the project directory of all kinds.
5. Click **Save**.

   The archive file is created and stored in the specified location.

To reload the archived project:

1. In the Diamond main window, choose **File > Open > Archived Project**.
2. In the Select Archived Project File dialog box, browse to the archive file.
3. Click **Open**.
4. In the Open Archived Project dialog box, check the destination directory. If this is not where you want to place the project files, click the Browse (**...**) button.
5. In the Browse for Folder dialog box, browse to where you want to place the project files.
6. Click **OK**.
7. In the Open Archived Project dialog box, click **OK**.

The project files are extracted to the specified folder and the project is opened in Diamond.

See Also ▶"Copying a Project" on page 29

Tips for Defining Projects

Use the following guidelines when defining your projects:

- Avoid using VHDL, Verilog HDL, or EDIF reserved words for module and signal names in any of your source files.
- Each source file must have a unique name in the project. You cannot have two different source files with the same name. You can use the same source file many times in a design by instantiating the source file. Two different source files with the same name can cause problems with the hierarchy. For example, do not use a Verilog file called "compare" and a schematic file also called "compare."
- Do not include the same module name in different sources within one project.

Tips for Saving and Naming Projects

Use the following guidelines when saving and naming source files and your projects:

- Do not save more than one project in the same directory.
- File names for Lattice Diamond projects and project source files must start with a letter (A-Z, a-z) and must contain only alphanumeric characters (A-Z, a-z, 0-9) and underscores (_).
- Try to shorten the length of the path name and levels of the directory. Problems might occur when the path of a project is too long.

Reserved File Names

Lattice Diamond reserves some filename extensions for its own use. You should avoid using the following extensions when naming your own files:

File Extension	File Use
_sc	Schematic Editor log file
_sy	Symbol Editor log file
_wt	Waveform Editor Viewer log file
_wv	Waveform Viewer log file
.asc	ASCII schematic file

File Extension	File Use
.asy	ASCII symbol file
.ed*	EDIF netlist
.err	Error output file
.fp0, .fp1	ORCAstra configuration file
.fpm	ORCAstra macro file
.his	Waveform Viewer history file
.ipx	Manifest file. This file is loaded into IPexpress so that modifications can be made to the module.
.lci	Constraint file
.lco	Constraint output from the Fitter (such as the post-fit pinouts)
.lct	Temporary working copy of the constraint file
.ldc	Lattice synthesis constraint file
.ldf	Lattice Diamond project file
.lpc	Lattice parameter configuration file created with IPexpress in ispLEVER
.lpf	Logical preference file
.nam	Binary waveform name file
.pcf	Power Calculator project file
.pin	Netlist file for generic netlist by pin
.rva	Reveal Analyzer file
.rvl, .rvs	Reveal Inserter project file
.sch	Schematic Editor files
.sty	Lattice Diamond strategy file
.sym	Symbol Editor file
.syn	ispLEVER project file (reserved only when importing an ispLEVER project into Lattice Diamond)
.spf	Lattice Diamond Simulation Wizard file
.tpf	Lattice Diamond Simulation timing preference file
.vis	ORCAstra custom Visual Window definition
.wav	Waveform Viewer waveforms and trigger information
.wdl	Waveform Editor display file
.wet	Waveform Editor database

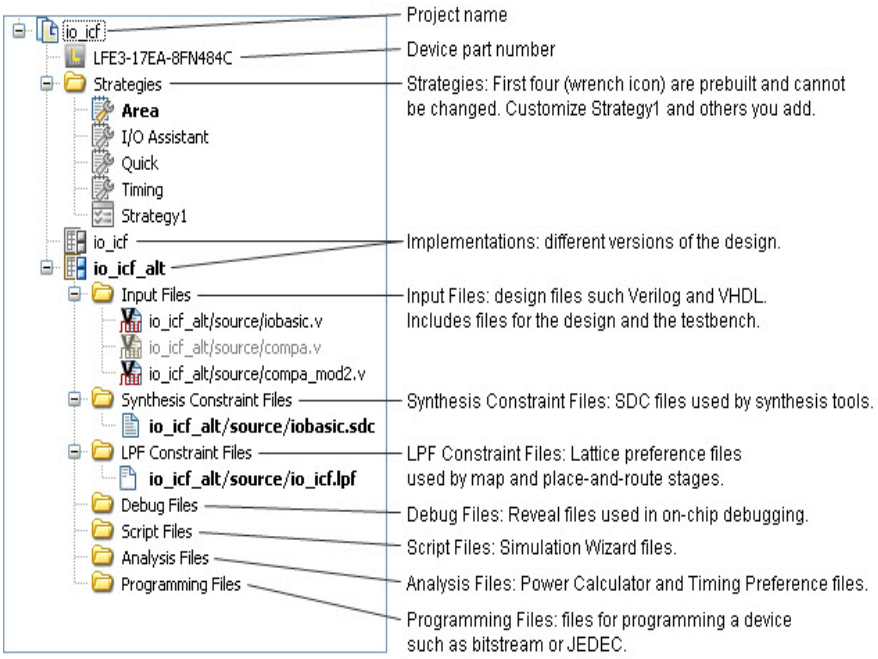
Managing Project Sources

The Diamond software combines design sources into different categories and list them in the File List view. You can see folders in the File List view. The source files are classified and listed under these folders. There are Strategies, Input Files, Synthesis Constraint Files, LPF Constraint Files, Debug Files, Script Files, Analysis Files, and Programming Files.

The HDL, schematic, edif netlist, and IP Module files can be found in the Input Files folder. The logic preference files are in the LPF Constraint Files folder. The Reveal project files can be found in the Debug Files folder. The Power Calculator, and timing preference files are in the Analysis Files folder.

You can also see implementations listed in the File List view. For details about implementations, see "Working with Implementations" on page 45.

File List View The File List view of the Diamond main window lists all the design sources. The sources are categorized by different types and are identified with different icons. Bold items are active and will be used when processing the design project. Grayed out items will not be used.



Files Listed in the File List View

File Type	Icon	File Extension
Project Title		None
Target Device		None
Predefined Strategy (Area, I/O Assistant, Quick, and Timing)		.sty

File Type	Icon	File Extension
Strategy1 (that can be customized)		.sty
Implementation		None
Verilog Files		.v, .veri, .ver, .vo, .h
SystemVerilog		.sv
VHDL Files		.vhd, .vhdl, .hdl, .vho
Schematic Files		.sch
EDIF Netlist Files		.edf, .edif, .edi, .edn, .edj
IP Module Config Files		.ipx
Undefined or incorrect		Any source reference
Synthesis Constraint Files		.sdc, .fdc, .ldc
Preference Files		.lpf
Reveal Project File		.rvl
Simulation Project File		.spf
Reveal Analyzer Files		.rva
Timing Preference File		.tpf
Power Calculator Files		.pcf

Note for Linux

In the Linux version of Diamond, when you save or export a file, the dialog box does not automatically append an extension to the file name you specify. That is the standard way Linux handles the Save As dialog box. You need to manually add the relevant file extension.

SystemVerilog Limitations The following tools do not support SystemVerilog files:

- Lattice Synthesis Engine (LSE)—Use Synplify Pro for Lattice or another synthesis tool that supports SystemVerilog.
- Hierarchy
- Simulation Wizard
- Reveal Inserter and Reveal Analyzer

See Also ▶"Running Processes" on page 69

Creating a New Source File

You can create a new source from within Diamond or external to Diamond.

To create a new source file:

1. In the Lattice Diamond main window, choose **File > New > File**.

   The New File dialog box opens.

2. In the dialog box, select the type of file you want to create. Fill in the file name, browse to choose a location for the file, check the **Add to project** option, choose the Implementation you want the file to be part of, and then click **New**.

   Diamond starts an editor that you can use to enter the information for your new source file. For language-based sources, the Source Editor is started. For schematic sources, the Schematic Editor is started. For module sources, IPexpress is started.

3. In the editor, create a source file.

   Some of the files can be directly added to the input files or constraint files folder of the File List view in Diamond, while some can be called by certain modules when running certain processes.

   Note

   - File names for Diamond projects and project source files must start with a letter (A-Z, a-z) and must contain only alphanumeric characters (A-Z, a-z, 0-9) and underscores (_).
   - In the Linux version of Diamond, when you save or export a file, the dialog box does not automatically append an extension to the file name you specify. That is the standard way Linux handles the Save As dialog box. You need to manually add the relevant file extension.

See Also ▶"Analyzing a Design" on page 53

Importing an Existing Source File into a Project

You can easily import existing source files into your project. Source files for a project can be stored in different locations.

The files added to the project appear in the Input Files folder. You can adjust the file order by drag-and-drop. If several modules are detected as being uninstantiated, the last one will be automatically treated as the top-level module. You can also set the top-level module from the implementation property dialog box.

To import an existing source file:

1. Choose **File > Add > Existing File** from Lattice Diamond. Or, with a project opened in Lattice Diamond, right-click the current implementation and choose **Add > Existing File**.

   The Add Existing File dialog box opens.

2. Browse for the source file you want to import.
3. Select the file and click **Add**.

   The selected file is added to the Input Files folder of the File List view. If the source file is stored outside the project folder, the path of the file is displayed.

   Double-click the imported file. The file can be opened in the associated editor (this is a Windows-only feature).

   Tip

   - If you want a source file that is outside the project folder to be copied to the project directory, select the **Copy file to Implementation's Source directory when adding existing file** option from the Options dialog box, in the **Environment > General** section.
   - Diamond project creation supports mixed language source files, allowing you to freely mix Verilog HDL, VHDL, and schematic design. The Diamond software will figure out the hierarchy structure that is associated with the module names. You need to pay special attention to the module names and the case, as Verilog is case-sensitive and VHDL is case-insensitive.

See Also "Analyzing a Design" on page 53

"Setting the Top-Level Unit for Your Project" on page 42

Importing an IPexpress Module

After generating module source files using IPexpress, you can import the IPexpress manifest file (.ipx) into Lattice Diamond. If the module was originally customized with ispLEVER, you may see an .lpc file but no .ipx file. The .ipx file is new with Diamond. However, Diamond also supports .lpc files for backward compatibility. The ispLEVER .lpc file can be converted to a Diamond .ipx file by re-generating the IPexpress module. When you regenerate a module from Diamond, the .lpc file is replaced with an .ipx file. For details on how to import ispLEVER modules, refer to "Adjusting PCS Modules" on page 26.

To import a module source (.ipx) file:

1. In the Lattice Diamond main window, choose **File > Add > Existing File**.

   The Add Existing File dialog box opens.

2. Browse for the .ipx file you generated and select it.
3. Click **Open**.

The selected .ipx file is added and listed in the File List view.

Note

When you import an existing ispLEVER project with an existing .lpc file, you need to re-open IPexpress using the .lpc file, regenerate the module, then add the .ipx file to the Lattice Diamond project.

For information on how to create a module source file, refer to "Designing with Modules" on page 189.

See Also ▶"Modifying a Source File in IPexpress" on page 44

Importing an IPexpress IP Core

After generating LatticeCORE IP source files using IPexpress, you can import the IPexpress manifest file (.ipx) into the Lattice Diamond main window. If the module was originally customized with ispLEVER, you may see an .lpc file but no .ipx file. The .ipx file is new with Diamond. However, Diamond also supports .lpc files for backward compatibility. When you regenerate an IP core from Diamond, the .lpc file is replaced with an .ipx file. For details on how to import ispLEVER modules, refer to the "Adjusting PCS Modules" on page 26.

To import an IP source (.ipx) file:

1. In the Lattice Diamond main window, choose **File > Add > Existing File**.

   The Add Existing File dialog box opens.

2. Browse for the .ipx file you generated and select it.
3. Click **Open**.

   The selected .ipx file is listed in the File List view.

Note

Some IP cores require factory assistance to generate custom configurations. See the Intellectual Property section of the Lattice Web site for more details on which IP cores are user-configurable versus factory-configurable.

For information on how to create an IP core, refer to "Designing with Modules" on page 189.

See Also ▶"Modifying a Source File in IPexpress" on page 44

Adding Reveal Debug Information

Reveal Inserter manages the addition of Reveal debug information into the Lattice Diamond source file. By default the Reveal Inserter project file (.rvl) will be automatically added to the File List view once Reveal Inserter has successfully merged trigger and trace signal features into your design. The procedure below describes how to manually import an .rvl file.

To import a Reveal project file (.rvl):

1. In the Lattice Diamond main window, choose **File > Add > Existing File**.

   The Add Existing File dialog box opens.

2. Browse for the .rvl file you generated and select it.
3. Click **Add**.

   The selected .rvl file is listed in the File List view.

   You can have multiple Reveal project files for your project. However, you can only set only one .rvl file active at one time.

For more information, refer to "Testing and Debugging On-Chip" on page 1039.

Adding a LatticeMico Platform

LatticeMico platforms are modeled with a behavioral Verilog HDL file (<*platform_name*>.v) and in some cases a combination of IP core peripherals generated by IPexpress, and custom peripherals written in VHDL. The Mico System Builder (MSB) creates a design file list of the entire platform to ease importing into the Lattice Diamond main window.

To import a platform design file list output by MSB:

1. In the Diamond main window, choose **Tools > Options**.
2. In the Options dialog box, expand the Environment list and select **General**.
3. Make sure that the **Copy file to Implementation's Source directory when adding existing file** option is cleared, and click **OK**.
4. In the File List pane of Diamond, create a new implementation, or select the implementation that you want to use for the platform files.
5. Choose **File > Add Existing File**.
6. In the dialog box, browse to the MSB platform file list <*platform_name*>soc location, select the source files to be added, and click **Add**.
7. In the Choose Top Module dialog box, select the top-level source file from the drop-down menu and click **OK**.

For complete information on creating a microprocessor platform, refer to the Lattice Mico System Builder section of the LatticeMico System online Help.

Importing Test Stimulus Files Using Simulation Wizard

If your design needs Verilog test fixture (.v) or VHDL test bench (.vhd), use the **Simulation Wizard**.

If multiple hierarchical test stimulus files are to be used, you should first import the top-level test file, and then add lower-level test stimulus as dependency files. Lattice Diamond will run all these test files in a hierarchical order during the simulation process.

To import a test stimulus file:

1. In Lattice Diamond, choose **Tools >** **Simulation Wizard**.

   The Preparing the Simulator Interface dialog box opens.

2. Click **Next**.
3. In the Simulator Project Name dialog box, enter a name for your simulation project in the Project name field. Browse to find a desired location for your project. Then choose either Active-HDL or ModelSim as the Simulator.
4. In the Process Stage dialog box, all the available process stages of the FPGA implementation strategy are automatically displayed. Choose the stage you want to run simulation.
5. Click **Next**.
6. In the Add Source dialog box, browse for your desired Verilog test fixture (.v) or VHDL test bench (.vhd) and select it. Check the **Copy Source to Simulation Directory** option if you need.
7. Click **Next**.
8. In the Summary dialog box, all your simulation project information is listed, including simulator name, project name, project location, simulation stage, simulation files, and simulation libraries.

   Check the “Run simulator” option if you want to run the simulation right away.

9. Click **Finish** to exit the Simulator Wizard. Your simulation project (.spf) is added to the Script Files folder of the File List view.

Note

The simulation flow in Diamond 1.3 or later has been enhanced to support source files that can be set in the File List view to be used for the following purposes:

- Simulation & Synthesis (default)
- Simulation only
- Synthesis only.

This allows the use of test benches, including multiple file test benches. Additionally, multiple representations of the same module can be supported, such as one for simulation only and one for synthesis only.

Refer to “Simulating the Design” on page 307 for more details on how to use the Simulation Wizard.

Managing Constraint Files

There are different types of constraint files in Diamond.

- Synthesis constraint file: SDC, FDC, LDC
- LPF constraint file: LPF

About Synthesis Constraint Files Depending on the synthesis tool you chose, you can add .fdc files for Synplify Pro, .sdc files for Precision, or .ldc files for Lattice Synthesis Engine (LSE). The files are listed in the Synthesis Constraint Files folder in the File List view.

Adding, Activating, Editing, and Removing Synthesis Constraint Files You can add, activate, edit, or remove synthesis constraint files of your project.

To add a synthesis constraint file:

1. Right-click the **Synthesis Constraint Files** folder in the File List view, and choose **Add**.
2. Choose **New File** if you want to add a new synthesis constraint file. Choose **Existing File** if you want to add an existing synthesis constraint file.

   The selected file is added to your project.

To activate a synthesis constraint file:

- Right-click the synthesis constraint file in the File List view of Diamond, and choose **Set as Active**.

  The selected synthesis constraint file is activated.

Note

- You can make zero or one .ldc constraint file active in your project.
- You can make multiple .sdc and .fdc constraint files active in your project.

To edit a synthesis constraint file:

- Double-click the synthesis constraint file you want to edit from the File List view of Diamond. Or, right-click the synthesis constraint file you want to edit from the File List view of Diamond.

  The selected synthesis constraint file is opened in the Source Editor. You can edit the selected file in the editor. See “Using Templates” on page 170 for more information.

To remove a synthesis constraint file:

- Right-click the synthesis constraint file in the File List view of Diamond, and choose **Remove**.

  The selected file is removed from your project.

About LPF Constraint Files You can add one or multiple logic preference files (.lpf) to your project. They are listed in the LPF Constraint File folder of the File List view.

Note

You can set only one .lpf file active in your project at one time.

Adding, Activating, Editing, and Removing LPF Constraint Files You can add, activate, edit, or remove LPF constraint files (.lpf) of your project.

To add an LPF constraint file:

1. Right-click the LPF Constraint Files folder in the File List view of Diamond, and choose **Add**.
2. Choose **New File** if you want to add a new LPF constraint file. Choose **Existing File** if you want to add an existing LPF constraint file.

   The selected file is added to your project.

To activate an LPF constraint file:

- Right-click the LPF constraint file in the File List view of Diamond, and choose **Set as Active**.

  The selected file is activated.

Note

You can set only one .lpf file active in your project at one time.

To edit an LPF constraint file:

- Double-click the LPF constraint file you want to edit from the File List view of Diamond. Or, right-click the LPF constraint file you want to edit from the File List view of Diamond.

  The selected LPF constraint file is opened in Source Editor. You can edit the selected file in the editor. See "Using Templates" on page 170 for more information.

To remove an LPF constraint file:

- Right-click the LPF constraint file in the File List view of Diamond, and choose **Remove**.

  The selected file is removed from your project.

See "Applying Design Constraints" on page 358 for more information.

Setting the Top-Level Unit for Your Project

It is a good practice to specify the top-level unit (or module) of the design. If you don't, Diamond will try to determine the top-level unit. While usually accurate, there is no guarantee that Diamond will get the correct unit.

You may also want to change the top-level unit when experimenting with different designs or switching between simulation and synthesis.

Notes for EDIF Modules

- In a mixed language design, you cannot set an EDIF module as the top-level unit. This is also true when a project with EDIF modules is mixed with .ipx files, which represent modules and IP generated with IPexpress.
- In a pure EDIF design, do not use the following procedure. Instead, in the File List view, arrange the input files so that the top-level unit is in the last file in the list.

To set the top-level unit for your project:

1. In the File List view, right-click the active implementation folder  .
2. From the drop-down menu, choose **Properties**.

   The Project Properties dialog box opens.
3. Click in the Value cell for **Top-Level Unit**.
4. Type the name of the top-level unit.

   At its right end, the Value cell also shows an arrow for a drop-down menu. Usually the menu shows one name or just "<Edit>." But if Diamond found multiple possible top-level units, the menu will show those names. If the correct top-level unit is in the menu, you can choose it.
5. Click **OK**.

   If the hierarchy is up to date, the source file that contains the top-level unit is displayed in bold.

Modifying a Source File

You can edit any of the source files that make up your project by double-clicking on them to open the corresponding editor.

Note

In order for Windows file associations to work properly with Diamond, in the main window choose **Tools > Options**. Then in the Options dialog box, find the **Environment > File Associations** section.

Modifying a Source File in Schematic Editor Use the Lattice Diamond Schematic Editor to edit a schematic file (.sch). You can open the Schematic Editor in the following ways:

- Double-click the schematic file name from the File List view of Lattice Diamond.
- In the File List view, right-click the schematic file and choose **Open** or **Open with** from the pop-up menu.

The Symbol Editor works in conjunction with the Schematic Editor. You can open the Symbol Editor by creating a new a symbol file in Lattice Diamond. For details on how to create a symbol, see "Creating Schematic Symbols" on page 267 in the Schematic Design Entry Help for more details.

Modifying a Source File in Source Editor You can use the Source Editor to enter or edit VHDL (.vhd), Verilog HDL (.v), or Preference (.lpf) files.

You can open the Source Editor in these ways:

- Double-click the text file name in the File List view of Lattice Diamond.
- In the File List view, right-click the text file and choose **Open** or **Open with** from the pop-up menu.

Modifying a Source File in Your Favorite Text Editor Similarly, you can use any text editor to edit the above-mentioned files, and then import them into your project using **File > Add > Existing File** from the Lattice Diamond main window.

Note

A preference file (.lpf) can also be created or edited in the Spreadsheet View.

You can open any text editor in this way:

- In the File List view, right-click the text file and choose **Open with** from the pop-up menu. In the Open with dialog box, click **Add** if you want to add your favorite text editor; or, click **Edit**, if you want to edit your favorite text editor. In the Add or Edit dialog box, specify command arguments for the external editor. The mapping between the argument substitution values and the value which replaces them are:

  %F = File Name; %L = Line Number

  For example, to configure the gVim text editor, use the following command line: <*path*>/gvim +%L %F
- In the Options dialog box, choose **Options > Environment > File Associations**. From the File Associations table, you can see the file extension and the default associated program. You can choose the file type you want to open/edit with your favorite text editor. Click the **Add** button from the **External programs for ... file extension** field to add your favorite text editor. Use the **Edit** or **Remove** button to manage your file and associated editor list.

After adding or editing the external text editor, you can save it as your default text editor in the Open with dialog by clicking **Save As Default**.

Note

If you change a source file in a third-party text editor, you need to choose **Design > Refresh Design** so that Lattice Diamond can refresh the process list to reflect the current process status and update views such as Hierarchy.

Modifying a Source File in IPexpress You can use IPexpress to edit the module or IP core source (.ipx) file.

To modify a module or IP core source:

1. In the File List view, double-click the .ipx file.

   IPexpress opens.

2. Make modifications as you want, and then exit IPexpress.

The .ipx file in the File List view is updated. You may need to rerun the design to reflect the changes you made.

For information on how to use IPexpress, refer to "Designing with Modules" on page 189.

See Also ▶"Importing an IPexpress Module" on page 36

▶ "Importing an IPexpress IP Core" on page 37

Excluding a Source File

Sometimes you may want to exclude specific source files from logic synthesis and simulation. The excluded source files remain in your design project, but they will not be synthesized or simulated by the software.

To exclude a source file:

1. In the File List view, right-click the target source file and choose **Exclude from Implementation**.

   The selected file is excluded from the implementation. The target file is grayed out.

Note

To include the source file again, right-click the target source file and choose **Include in Implementation**.

Removing a Source File

You can remove a source from a project by using the Lattice Diamond **Remove** command, or the Windows' **Delete** command.

Removed source files are no longer part of your project. If you just want to exclude a file from logic synthesis and simulation, see "Excluding a Source File" on page 44.

To remove a source file from a project:

1. In the File List view, select the file that you want to remove.
2. Right-click the filename and choose **Remove**, or press the Delete key on your keyboard.

   The Lattice Diamond software removes the source from the project.

Working with Implementations

Implementations define the design structural elements for a project. An implementation contains the structure of a design and can be thought of as the source and constraints to create the design. For example, one implementation may use inferred memory and another implementation may use instantiated memory. There can be multiple implementations in a project, but only one implementation can be active at a time and there must be at least one implementation.

An implementation is automatically created whenever you create a new project. You can create new implementations using the source files of an existing implementation. You can also clone (copy) an existing implementation including all the related files and settings.

Implementations consist of:

- Input files
- Constraint files
- Debug files
- Script files
- Analysis files

Creating New Implementations

To create a new implementation:

1. With the project opened in Lattice Diamond, choose **File > New > Implementation**.
2. In the New Implementation dialog box, enter a name for the new implementation.

This name also becomes the default name for the folder of the implementation.

3. Change the name of the implementation's folder in the Directory text box if desired.
4. Change the location of the implementation's folder if desired.
5. Choose the synthesis tool from the drop-down menu.
6. Choose the default strategy from the drop-down menu.
7. Add sources files by clicking **Add Source** and choosing either:
   - **Browser** to select individual files.
   - **From Existing Implementation >** <*implementation name*> to use the source files of an implementation that already exists in this design project.

   Remove unwanted files by selecting the files and clicking **Remove Source**.
8. If you want to copy all of the source files into the new implementation folder, giving you the freedom to change the files without affecting other implementations, select the **Copy source to implementation directory** option.
9. To view or set properties of the source files, select a file and click **Properties**. The Properties dialog box opens. To change a property, click in its **Value** cell. Enter or choose the new setting. Then click **OK**.
10. Click **OK**.

Cloning Implementations

To clone an implementation:

1. In File List view, right-click on the name of the implementation that you want to copy and choose **Clone Implementation**.

   The Clone Implementation dialog box opens.
2. In the dialog box, enter a name for the new implementation. This name also becomes the default name for the folder of the implementation.
3. Change the name of the implementation's folder in the Directory text box if desired.
4. Decide how you want to handle files that are outside of the original implementation directory. Select one of the options:
   - **Continue to use the existing references**

     The same files will be used by both implementations.
   - **Copy files into new implementation source directory**

     The new implementation will have its own copies that can be changed without effecting the original implementation.
5. Click **OK**.

6. In File List view, right-click on the name of the default strategy and choose Edit.

   The Strategies dialog box opens.

7. In the Process column, choose **Translate Design**.
8. Check the search paths. If they point to the folder of the original implementation, change them to use the folder of the new implementation
9. Click **OK**.

Customizing Files in an Implementation After creating an implementation, you can choose to include or exclude source files for the implementation. You can customize files that are under the Constraint Files, Debug Files, Script Files, and Analysis Files folders.

Customizing Input Files You can choose to:

- Add a new source file or add an existing file.
- Include the file for Synthesis, Simulation, or Synthesis and Simulation.
- Exclude the file from the current implementation.
- Remove the file from the project.

Activate Files You can have multiple files under each of the Constraint Files, Debug Files, Script Files, and Analysis Files folders in the File List view. But only one file can be active in each of those folders. To change a file's status, right-click the file and choose **active** or **inactive**.

Saving an Implementation If you want to save an implementation to the project, choose **File > Save Project** from the Diamond main window.

See Also ▶"Using Strategies" on page 47

Using Strategies

A **strategy** provides a unified view of all settings related to the optimization controls of implementation tools, such as logic synthesis, mapping, and place and route. Any number of strategies can be applied to your project to find the best solution to meet your design objectives. For example, you might have one strategy with a very fast placement and routing attempt to get a quick look at the design, and another one with a higher effort level that's more thorough and takes longer to try to meet timing constraints. Although you can create an unlimited number of strategies, only one can be active at a time for each implementation, and each implementation must have an active strategy.

Strategy settings are listed in the Strategies dialog box. You can open the dialog box by double-clicking a strategy name in the File List view. Each strategy is stored as an .sty file.

There are two different kinds of strategies: predefined strategy and customized strategy.

Predefined Strategy Several strategies are predefined and supplied by Lattice: Area, I/O Assistant, Quick, and Timing. They are designed to solve particular types of designs.

- **Area**

  The Area strategy will try to minimize area by enabling the tight packing option available in map. Use this strategy to achieve area requirements. It is commonly used for low density devices such as MachXO and MachXO2.

  The benefit is that if it works, you will get results in area reduction. However, applying this strategy to large and dense designs may cause some difficulties in the place-and-route process with longer run time or not completing routing.

- **I/O Assistant**

  This I/O Assistant strategy will try to place I/O efficiently for your design at an early stage. It helps to check if you set a legal I/O location that affects board-level pin-outs.

  The benefit is that if it works, you will get results in I/O placement information at first without long runtime after finishing place and route. However, applying this strategy to your design may take extra runtime on the design, because it only executes logic synthesis, translation, map, and I/O placement processes.

  Note

  If you choose the I/O Assistant strategy for your project, the generated NCD file is incomplete. Running the Export Files > Bitstream File or Export Files > JEDEC File process (in the Process view) may fail.

  If you want to implement a complete design, you need to choose another strategy to rerun all the processes again.

- **Timing**

  The Timing strategy tries to achieve timing closure. The Timing strategy uses a very high effort level in place and route. Use this strategy if you are trying to reach the maximum frequency on your design. If you cannot meet timing requirement with this strategy, try to customize a strategy with individual settings.

  The benefit is that if it works, you will get results in good timing performance. However, this strategy may increase your runtime on place and route compared to the Quick and Area strategies.

- **Quick**

  The Quick strategy uses a very low effort level in place and route to get results with minimum processing time. If your design is small and your target frequencies are low, this is a good strategy. Even if your design is large, you might want to start with this strategy to get a first look at place-and-route results and to tune your preference file with minimum processing time.

The benefit is that if it works, you will get results in the least possible time. The quality of these results in terms of achieved frequency should be expected to be low, and large or dense designs may not complete routing.

The settings of predefined strategies cannot be modified in the Strategies dialog box. You can view their settings by:

- Double-clicking the predefined strategy name in the Files List view and opening the Strategies dialog box.
- Right-clicking on the predefined strategy name in the File List view and choosing **View** to open the Strategies dialog box.

Customized Strategy Excluding the predefined strategies, all other strategies can be customized in the Strategies dialog box. The settings of the strategy can be edited in the Strategy dialog box. You can edit its settings by:

- Double-clicking the strategy name in the File List view and open the Strategies dialog box.
- Right-clicking the strategy in the File List view and choosing **Edit** to open the Strategies dialog box.

- "Removing a Strategy" on page 52
- "Strategy Reference Guide" on page 1113

Creating a Strategy

You can create a new strategy for your design.

To create a new strategy in Lattice Diamond:

1. Choose **File > New > Strategy**.

   The New Strategy dialog box opens.

2. In the New Strategy dialog box, enter a name for the new strategy. Specify a file name for the new strategy and choose a directory to save the strategy file (.sty).

The new strategy is with all the default settings of the current design. You can modify its settings in the Strategies dialog box.

If you want to save the strategy changes to your current project, choose **File > Save Project** from the Diamond main window.

Cloning a Strategy

You can clone any strategy you created or any of the Lattice predefined strategies from the File List view. The new cloned file will contain all settings of the strategy being cloned. You can then modify the settings for the cloned strategy from within the Strategies dialog box.

To clone a strategy:

1. In the File List view, right-click on the strategy you want to clone and choose **Clone** <*name*> **Strategy**.
2. In the Clone Strategy dialog box, enter a name for the new strategy in the Strategy ID field. Specify a file name for the new strategy and choose a directory to save the strategy file (.sty). By default, when you enter the strategy ID, the file name is automatically specified the same.

The strategy you cloned is with all the settings of the base strategy. You can modify the settings for the cloned strategy in the Strategies dialog box.

If you want to save the strategy changes to your current project, choose **File > Save Project** from the Diamond main window.

Adding an Existing Strategy

You can add existing strategy to your design.

Note

A strategy copied from another design project may include inappropriate settings, such as path names, that could cause problems. If you copy a strategy from another project, review its settings carefully and adjust them as needed.

To add existing strategy to your design:

1. In Lattice Diamond, choose **File > Add > Existing Strategy**.
2. In the Select Existing Strategy dialog box, browse to the desired strategy file (.sty) and click **Open**.
3. In the Add Existing Strategy dialog box, enter the name for the added strategy as you want to see it appear in the File List view.
4. If the selected strategy file is not in the current project directory, you may want to select the **Copy strategy file to project directory** option.
5. Click **OK**.

   The new strategy appears in the File List view.
6. Double-click the new strategy to open the Strategies dialog box.
7. Carefully review the settings to make sure that they are appropriate for your current project. Be sure to check the following items:
   - Under Synthesize Design > LSE, check:

Macro Search Path

Memory Initial Value File Search Path

- Under Translate Design:

  Macro Search Path

  Memory Initial Value File Search Path

- Under Bitstream:

  Search Path

Note

If you did not select the “Copy strategy file to project directory” option when adding the strategy, remember that you are working with the original file, which might also be used by another project.

8. When your review is done, click **OK**.

If you want to save the strategy changes to your current project, choose **File > Save Project** from the Diamond main window.

Specifying Strategy Options

You can use the Strategy dialog box to specify settings for a specific design strategy.

To specify strategy settings:

1. In the File List view, double-click the active strategy.

   The Strategies dialog box opens.

2. In the left-hand pane, select a process for which you want to specify settings. The left-hand pane shows a process list. Each of the processes has its own settings.
3. In the right pane, double-click the Value column for the setting to be changed to activate the pulldown menu with choices of settings or to be able to enter filenames or directory paths into the field.
4. Select the value from the drop-down list, or type in the text value, and click **Apply**.
5. Repeat steps 2-4 to specify more settings.
6. When you finish, click **OK** to close the dialog box.

   All your changes to the strategy are updated in the system memory in your Diamond session. Be aware that these changes are not automatically written to your current project. If you want to save the

strategy changes to your current project, choose **File > Save Project** from the Diamond main window.

Tip

When a setting is highlighted, its brief definition will be displayed at the bottom of the dialog box. You can also press **F1** to view additional information for the highlighted option.

See Also ▶"Strategy Reference Guide" on page 1113

Saving a Strategy

If you want to save a new strategy, a cloned strategy, or any change of a strategy setting to your project, click **File > Save Project** from the Diamond main window.

Setting Active Strategy

If you have more than one strategies in the project, you can choose to set an active strategy.

To set an active strategy:

- Right-click the target strategy and choose **Set as Active Strategy**.

If you want to view the settings of the active Strategy, choose **Project > Active Strategy**. From the submenu, choose the settings you want to view. The Strategies dialog box opens with the settings you have chosen. You can view or edit the values of the settings.

Removing a Strategy

You can remove a strategy from the design by right-clicking on the target strategy and choosing **Remove**.

Getting Help on Strategies

To find the online Help description of strategy settings, do one of the following:

- Open the "Strategy Reference Guide" on page 1113 in the Contents pane of the Lattice Diamond Online Help. The Contents pane displays all process options in the order they appear in the Strategies dialog box. Choose the desired process option. You will see the strategies associated with this process. Use the scroll bar to select a setting and view its description.

- In the Lattice Diamond File List view, double-click a strategy name to open the Strategies dialog box. You can then highlight a setting to display its brief definition at the bottom of the dialog box, or press **F1** to view additional information for the highlighted option.

- "Setting Active Strategy" on page 52
- "Removing a Strategy" on page 52

Analyzing a Design

There are a few ways to analyze your design while it is being implemented.

Before synthesis, the Hierarchy view provides a nested list of all modules plus commands to access the source code for individual modules, to set up test benches, and more. See "Hierarchy View" on page 53.

After synthesis, the Hierarchy view also provides information on how the modules are using device resources.

After synthesis, schematic views are also available. These views depend on which synthesis tool you are using. If you are using Lattice Synthesis Engine (LSE), you can use Diamond's Netlist Analyzer to see and analyze the design. If you are using Synplify Pro, you can use its HDL Analyst. See *Synplify Pro for Lattice User Guide.*

After mapping, the Hierarchy view provides updated information on how the modules are using device resources. Also, if you are using LSE, Netlist Analyzer shows how the design is mapped to the device's architecture.

Hierarchy View

The Hierarchy view shows the design hierarchy as a nested list of modules. The Hierarchy view opens automatically when you open a project. If the Hierarchy view is not open, choose **View > Show Views > Hierarchy** from the Diamond main window.

The Hierarchy view also shows the full path name of the files that define each module and, once synthesis has been run, the amount of device resources that each module would consume.

Commands in the Hierarchy View

Right-click in the Hierarchy view to get several useful commands described below.

Goto Source Definition This command opens the source editor with the source code that contains the definition for that object, and automatically scrolls the view to the position in the code where the object is defined. For objects that include multi-line definitions, the entire definition is highlighted.

Goto Source Instantiation This command brings you directly to the source file where the module is instantiated, making it easy to see and fix errors.

Goto RTL Definition After synthesis has been run with LSE, this command opens Netlist Analyzer with a schematic view of the design element.

Verilog Test Fixture Declarations This command creates the Verilog test fixture declarations include file (.tfi) based on the Verilog unit selected from the Hierarchy view. This include file should be referenced by your test fixture using: ‘include “<*file_name*>.tfi”. By including the.tfi file in your simulation test fixtures, you ensure that the design and the test fixtures stay synchronized.

Verilog Test Fixture Template This command creates a Verilog test fixture template file (.tft) based on the Verilog unit selected from the Hierarchy view. The template file includes a Verilog design unit with a module declaration. Use the procedure below to create a Verilog test fixture from the .tft file.

To create a Verilog test fixture from a Verilog Test Fixture Template (.tft) file:

1. Open the .tft file from the project directory and save it with a .v file extension.
2. Import the new .v file into the project as a Verilog test fixture. Then add codes to the user defined section to complete the stimulus for your design.

VHDL Test Bench Template This command creates a VHDL template file (.vht) based on the VHDL unit selected from the Hierarchy view. The template file includes a VHDL design unit with a component declaration and an instantiation based on the entity interface of the first VHDL design unit encountered.

Note

Avoid using user-defined record type array in your design. Try to use standard data type such as std_logic_vector. Using your own defined record type array may cause the signal width to be incorrect in the VHDL test bench template file generated.

Generate Schematic Symbol This command creates a schematic symbol (.sym) based on the design unit selected from the Hierarchy view. This process runs an independent utility to convert the NAF file that is associated with the selected design unit to a SYM file.

Note

Avoid using user-defined record type array in your design. Try to use standard data type such as std_logic_vector. Using your own defined record type array may cause the signal width to be incorrect in the schematic symbol file generated.

Set as Top-Level Unit You can directly set the selected module as the top-level unit by using this command.

Device Resources

Device resources that would be consumed are shown to the right of each module. The first number in each column is the number of that resource that would be used by that module and all of its submodules. The second number, in parentheses, is the number of that resource that would be used by just that module, not including any of its submodules. The numbers are updated after the synthesis and map stages of the implementation process. For definitions of the resource types, see Table 1 on page 55.

Note

If your source files for the design include one or more EDIF files, the resources shown may not represent the whole design. After synthesis but before the translate or map stages, results are only for the files that went through the synthesis tool. EDIF files, being the result of synthesis, are not included. After the translate or map stages, the results represent the whole design including any EDIF files.

The Hierarchy view only shows the design. It does not include any Reveal modules. However, when the top module of the design shows device resources, it does include the resources of any Reveal module. So, if you have included a Reveal module, the top module shows more resources than the submodules add up to.

Table 1: Resource Definitions

Hierarchy View Term	Synthesis Report Term	Definition
LUT4	OrcaLut, Lut	Four-input look-up tables that can implement Boolean functions with up to four variables
Registers	FD	Sequential elements with clock, enable, and synchronous or asynchronous set and reset
IO Registers	IF, OF	Sequential elements (registers) within input/output blocks

Table 1: Resource Definitions

Hierarchy View Term	Synthesis Report Term	Definition
DSP MULT	MULT	Configurable multipliers for high speed operations
DSP ALU	ALU	Configurable adders for high speed addition, subtraction, and logic functions like AND/OR
EBR	SP, DP, PDP	Embedded Block RAM to store large sets of data; configurable for word size and depth
Distributed RAM	SPR, DPR	RAM distributed with every logic element to store small sets of data such as register files
ROM	ROM	EBR configured as read-only memories
PFUMux	PFU	Dedicated multiplexers that implement 5-input functions using two LUT4 that directly drive the mux inputs
L6Mux	L6M	Dedicated multiplexers that implement 6-input functions using four LUT4 and two PFUMux that drive the L6Mux inputs
Carry cells	CCU	Dedicated logic cells to implement fast carry generation and propagation in adders
SLICE		Elements with two LUT4 that feed two registers and associated logic that can perform functions such as LUT8
Instantiated		Anything not covered by the other terms

Changing the Display

You can adjust the display by re-arranging the columns and sorting the rows. You can also choose which ones you want to see.

To change which columns are displayed:

1. Right-click in any column heading.
2. In the drop-down menu, the resource that you want to show or hide.

   Note: Resources that are not being used by the design at all are automatically hidden in Hierarchy view regardless of the option settings.

To re-arrange columns:

- Click on the heading of the column that you want to move and drag it to where you want it.

To sort the modules:

1. Click in the heading of the desired column.

   The rows are sorted according to the contents of that column.

2. To reverse the order of the rows, click in the same column again.

To change the width of columns:

- Click on the right-hand border of a column and drag to make that column narrower or wider.

Saving the Data You can save resource counts for the top-level module as either an ASCII (.txt) file or a comma-separated values (.csv) file that can be opened with a spreadsheet tool such as Excel.

To save the data:

1. Right-click on any module row and choose either:
   - **Export Resource to ASCII file**
   - **Export Resource to CSV file**
2. In the dialog box, browse to where you want to save the data.
3. Enter the file name.
4. Click **Save**.

See Also "Commands in the Hierarchy View" on page 54

About Netlist Analyzer

Netlist Analyzer works with Lattice Synthesis Engine (LSE) to produce schematic views of your design while it is being implemented. (Synplify Pro also provides schematic views.) Use the schematic views to better understand the hierarchy of the design and how the design is being implemented.

To start Netlist Analyzer:

1. Synthesize the design with LSE.
2. Choose **Tools > Netlist Analyzer**.

   The Netlist Analyzer window opens with the RTL netlist showing.
3. In the window's tool bar, click one of the following buttons:

   RTL View to see the design's logic (gates and registers) after LSE has optimized it

   Technology View to see the design after synthesis and translated into Lattice primitive modules

   Post-Mapping View (available only after mapping) to see how the design is mapped to the device's architecture

   Open External File to browse to a desired netlist database (.vdb) file

   A new tab opens and is filled as described below.

About Netlist Analyzer Views The Netlist Analyzer window has four parts:

- Tool bar provides buttons for various functions.
- Netlist browser provides nested lists of module instances, ports, nets, and clocks.
- Schematic view shows a schematic of the design. Depending on the size of the design, the schematic may be made of multiple sheets.
- Mini-map, which is a miniature view of the sheet, helps you pan and zoom in the schematic view.

Netlist Analyzer can have multiple schematics open. The open schematics are shown on tabs along the bottom of the window.

Bold lines are buses. Green lines are clock signals.

There are several ways to adjust the view of a schematic and to navigate through the hierarchy.

Setting Netlist Analyzer Options

With Netlist Analyzer you can specify labels in the schematics, how the hierarchy gets expanded, the highlight color, and the size of the sheets.

To change tool options:

1. Choose **Tools > Options**.

   The Options dialog box opens.
2. In the left-hand list, find and expand **Netlist Analyzer**.
3. See the following instructions for specific options.
4. When finished, click **OK**.

To specify labels:

1. Under Netlist Analyzer, select **Text**.
2. Select the labels that you want to see in the schematics.

To create a schematic bookmark:

1. Under Netlist Analyzer, select **Bookmarks**
2. In the Add Bookmark dialog box, add a name for the bookmark. All bookmarks are associated with a specific .vdb file with a time stamp. This feature allows you to save a schematic graph after a series of operations, such as filter and expand, for future reference. This features also allows you to save and restore different critical paths of the design.

To control how the hierarchy gets expanded:

1. Under Netlist Analyzer, select **Schematic**.

2. Adjust the values of the following items:
   - Hierarchy Depth: The number of levels to show when using the Dissolve Instances command. The default, 0, means to show all levels.
   - Levels of Logic to expand: The number of additional levels to show with the Expand To/From command.
   - Search depth to expand: The number of additional levels to show with the Expand to FF/IO and Expand to Primitive commands. The default, 0, means to show all levels.

To change the colors:

1. Under Netlist Analyzer, select **Schematic**.
2. Click on the **Select Color** or **Highlight Color** block. The select color is used to outline objects that you select in the schematic view. The highlight color is used to outline objects that you want to keep highlighted after selecting them.

   The Select Color dialog box opens.
3. Select a color by doing one of the following:
   - Click one of the basic colors on the left.
   - Click in the color pallet on the right.
   - Enter values in the boxes at the bottom right. Work in one column or the other as they are two separate methods of coding color.

   The rectangle in the lower-middle changes to show the selected color. You can change the darkness with the vertical slider at the upper-left.
4. Click **OK**.

   In the Options dialog box, the color block changes to match.
5. If you want to see the effect of your change in the views, drag the Options dialog box aside and click Apply.

To change the sheet size:

1. Under Netlist Analyzer, select **Sheet**.
2. Change the width and height as desired.

Adjusting the Schematic View

Netlist Analyzer schematics are usually displayed on many sheets, depending on the size of the design. You may also have a few different schematic views open at the same time.

There are a few ways to change the sheet being displayed and the arrangement of the views. If you are dissatisfied by the layout of a sheet, you can try regenerating it.

To change the sheet being displayed:

- Do one of the following:
  - Click the Next Sheet button.
  - Click the Previous Sheet button.
  - Click the arrow in the Goto Sheet button. In the drop-down menu, choose a sheet number.
  - Click the name at the end of a net on the left or right side of a schematic (but not a port). This takes you to the continuation of the net on another sheet.

To arrange views within the Netlist Analyzer window:

Anytime you open a schematic view it, along with its netlist browser, fills the Netlist Analyzer window. There is a tab for each view along the bottom of the window.

- To change the arrangement, do one of the following:
  - Click the Tile button to change the views into smaller windows that are arranged so that you can see them all at the same time.
  - Click the Cascade button to change the views into smaller windows that are arranged in a cascading, overlapping fashion.

The tabs remain in all modes. Click a tab to bring its window to the top.

In the tile and cascade modes, the schematic windows can be resized and dragged within the Netlist Analyzer window. Maximizing a window restores the tab mode.

To change the layout in a sheet:

- Right-click in the schematic and choose **Regenerate**.

  The schematic might change to a clearer layout. However, there will often be no change as the layout is already the best that Netlist Analyzer can do.

Zooming and Panning

You can zoom and pan within the Netlist Analyzer schematics using a variety of methods. These include toolbar commands, dragging with the schematic, and Netlist Analyzer's mini-map.

Toolbar Commands The following commands are available on the Diamond toolbar.

Zoom In – enlarges the view of the entire layout.

Zoom Out – reduces the view of the entire layout.

Zoom Fit – reduces or enlarges the entire layout so that it fits inside the window.

Zoom To – enlarges the size of one or more selected objects on the layout and fills the window with the selection.

Pan – enables you to use the mouse pointer to drag the layout in any direction. This command is useful for viewing a hidden area on the layout after zooming in.

Zooming with Function Key Shortcuts The following key combinations enable you to instantly zoom in or out from your keyboard.

- Zoom In – Ctrl++
- Zoom Out – Ctrl+-

Zooming with the Mouse Wheel The mouse wheel gives you finer zoom control, enabling you to zoom in or out in small increments.

- While pressing the **Ctrl** key, move the mouse wheel forward to zoom in and backward to zoom out.

Zooming by Dragging You can zoom by holding the right mouse button and dragging:

- To zoom to fit the window, drag up and to the left. The image adjusts to fill the window.
- To zoom out, drag up and to the right. The distance you drag determines the amount of zoom. 1 means half as big, 2 means ¼ as big, and so on. The image is reduced and centered in the window.
- To zoom in, drag down and to the right. The distance you drag determines the amount of zoom. 1 means twice as big, 2 means four times as big, and so on. The image is enlarged and centered in the window.
- To zoom in on a specific area, start at the upper-right corner of the area that you want to see better and drag to the lower-left corner of the area. The area that you drag across is adjusted to fill the window.

Zooming and Panning with Mini-Map The mini-map is a small display of a schematic at the lower-left of the Netlist Analyzer window. The mini-map shows the entire sheet with a purple rectangle marking the area that is actually showing in the schematic view.

If the mini-map is not showing, click the Mini-map button at the lower-right corner of the schematic view.

To enlarge the mini-map, click on one of the control tabs on the edge of the mini-map and drag.

To zoom, click on one of the control tabs of the purple rectangle and drag. As the rectangle changes size, the schematic view zooms in or out.

To pan, click in the purple rectangle and drag it so that it covers the area that you want to see. As you drag, the schematic view shifts.

Or, you can click on the spot that you want to see. The schematic view will jump to be centered on that spot.

Saving Schematics

You can save a schematic as either a PDF or SVG file. As a PDF file, the whole schematic is a single file with each sheet an 8.5-inch by 11-inch page. As an SVG file, only the currently displayed sheet is saved.

To save a schematic:

1. If saving as an SVG file, select the desired sheet.
2. Choose **File >** **Export**.

   The Export Schematic dialog box opens.
3. Browse to where you want to save the file.
4. Enter a file name.
5. Click the **Save as type** drop-down menu and choose the format.
6. Click **Save**.

Printing Schematics

Use the print functions of Diamond to print the schematics.

To print a schematic:

1. Choose **File >** **Print Preview**.

   The Print Preview window opens.
2. Expand the Print Preview window until you are comfortable with the display of the page.
3. To maximize the printout, click for landscape mode.
4. Click the Page setup button and adjust the paper size and margins if necessary.
5. Click the Print button.
6. Adjust the printer settings if necessary and click **Print**.

Navigating the Design with Netlist Analyzer

There are several ways to explore a design. Most start with selecting one or more objects. Then right-click in the schematic view and choose a command from the drop-down menu.

These commands help you to:

- Focus on one part of the design
- Flatten the layers of hierarchy
- Trace the paths between objects
- Expand selected parts of the schematic

Most commands can be reversed by clicking the Backward button. They can be repeated by clicking the Forward button. To jump back to the original view after several commands, right-click in the schematic view and choose **Restore Current Schematic**.

While exploring a design, you may see a need to set a synthesis constraint. If so, you can get a quick start by dragging the port, net, or register to the relevant tab of LDC Editor. See "Applying Lattice Synthesis Engine Constraints" on page 364.

To select objects:

- Click the Select button and do one of the following:
  - Click on the object in the schematic view. Ctrl-click to select more objects.
  - Click on the object in the netlist browser. Ctrl-click to select more objects.
  - Click and drag to draw a selection rectangle around one or more modules in the schematic view. This method only selects modules, not ports or nets.
  - Right-click in the schematic view and choose **Select All Schematic > Instances**. This command selects all module instances showing in all sheets of the schematic.
  - Right-click in the schematic view and choose **Select All Schematic > Ports**. This command selects all ports showing in all sheets of the schematic.
  - Right-click in the schematic view and choose **Select All Sheet > Instances**. This command selects all module instances showing in the current sheet of the schematic.
  - Right-click in the schematic view and choose **Select All Sheet > Ports**. This command selects all ports showing in the current sheet of the schematic.

You can keep an object highlighted, but not actively selected, by right-clicking in the schematic view and choosing **Highlight**. This outlines the selected objects in the highlight color, making them easy to spot, while you continue to explore the design. Highlighted objects are not "selected" for commands. Highlighting can be erased if you use the Backward button enough to hide the highlighted object.

To erase highlighting and return an object to normal display, select the object. Then right-click and choose **Unhighlight**.

Focusing on Part of the Design

Often you want to focus on just one part of the design. You can filter the schematic, reducing it to selected modules, trim away objects that are in the way, or ask for more details of a single module.

To filter the schematic:

1. In either the netlist browser or schematic view, select one or more modules of interest.
2. Click the Filter Schematic button.

   The schematic is replaced with just the selected modules. Only nets connecting the selected modules are included. Use other commands to expand the schematic.

To filter with signal paths:

1. Select one or more modules of interest.
2. Right-click anywhere in the schematic view and choose **Isolate Path**.

   The schematic is replaced with just the selected modules *and* modules connected to the selected modules. Only nets connecting the modules are included.

To trim the schematic:

1. Select one or more objects that you do *not* want to see.
2. Right-click anywhere in the schematic view and choose **Less**.

   The selected objects disappear. If the objects include a branch of a net, the remaining branches become dotted lines to show that part of the net is hidden.

To see the structure inside a module:

1. Click the Push down/Pop up button.
2. Drag the cursor to the module.

   If there is further hierarchy to see (that is, the module is not already a primitive), the cursor changes to a blue down-pointing arrow .
3. Click in the module with the down-pointing arrow.

   The schematic changes to show just the structure of the module at the next lower level of hierarchy. To go further down the hierarchy, click in one of these modules with the down-pointing arrow.

After you've started pushing down, the cursor shows a green up-pointing arrow when it is not over a module. To go back up the hierarchy, click when this up-pointing arrow is showing.

Remember that if you want to perform other commands in the schematic, you first need to click the Select button.

To quickly push down or pop up:

There is an easy way to push down into a module while staying in select mode:

- Right-click the module and drag straight down until the words “push down” appear. Then release the mouse button.
- To go back up the hierarchy, right-click anywhere in the schematic view and drag straight up until the words “pop up” appear. Then release the mouse button.

To work on just one module:

1. Go to the Hierarchy view. If it is not showing, choose **View > Show Views > Hierarchy**.
2. Right-click on the desired module and choose **Goto RTL Definition**.

   Netlist Analyzer opens with the RTL view of the module. The rest of the design is not available in this schematic.

Flattening the Design

Going back and forth through multiple layers of hierarchy can be confusing. An alternative is to flatten the design, displaying all the layers together. This makes for a much bigger, much more detailed schematic. But you do not have to keep track of where you are in the hierarchy. You can flatten the entire schematic or just selected modules.

To flatten the entire schematic:

- Right-click anywhere in the schematic view and choose **Flatten Schematic**.

  The entire design is shown in terms of primitives.

To return to the original schematic, right-click and choose **Unflatten Schematic**.

To flatten a module:

1. Select the module.
2. Right-click and choose **Dissolve Instances**.

   The schematic expands to include the selected module’s primitives. Boundaries, ports, and labels of the module and any submodules are included. So you can still identify and select the modules and their ports.

Tracing Paths between Objects

In a complicated schematic it can be difficult to trace a signal but Netlist Analyzer can do it for you.

To trace a signal path:

1. Select two or more objects. They can be on different sheets.
2. Right-click and choose **Expand > Expand Paths**.

   Nets and modules between the selected objects are highlighted. Modules along the paths are expanded to show primitives.

Expanding from a Module

After focusing a schematic to one or a few modules, you may want to see what the modules are connected to.

To see all the nets attached to a module:

1. Select the module.
2. Right-click and choose one of the following:
   - **Show Connectivity**

     Highlights all nets attached to the selected module, expanding the schematic as necessary.
   - **Expand > Expand To/From**

     Highlights all nets attached to the selected module and all primitives attached to those nets, expanding the schematic as necessary.

To see the next higher level of the hierarchy:

1. Select a module, right-click and choose **Show Context**.
2. If nothing happens, click the Push down/Pop up button. Move the cursor to the schematic view. If you see the green up-pointing arrow, click it.

Depending on the situation, one the above shows the schematic of the next higher level of the hierarchy.

Expanding from a Port

Instead of expanding all the nets from a module, you can expand the net from a single port. If the module is not a primitive, you have the choice of expanding outward or inward to a lower level of the module's hierarchy. Make this choice by selecting the port pointing out or the port pointing in.

To see what a single port is attached to:

1. Double-click the port.

   The schematic expands to show the port's net and one more object that is on the net.
2. If the net shows as a dashed line, you are seeing only part of the net. Double-click the port again to see another branch of the net.

If the net shows as solid line, you are seeing the full net.

If the full net is already visible, nothing happens.

To see a fuller signal path from a single port:

1. Select the port. If the port is on a module, take care whether it is pointing out or in.
2. Right-click and choose **Expand.**

   A sub-menu drops down.
3. Choose one of the following from the sub-menu:

   - **Expand to FF/IO**

     Highlights the net until it finds a flip-flop or an I/O pin, expanding the schematic as necessary. Modules along the path are expanded to show primitives.
   - **Current Level > Expand to FF/IO**

     Same as above except that modules are *not* expanded.
   - **Expand to Primitive**

     Highlights the net and all attached primitives, expanding the schematic as necessary.
   - **Current Level > Expand to Primitive**

     Same as above except that modules are *not* expanded.

Expanding from a Net

You can expand a net to show all connected primitives and ports or to show just the primitive or port driving it.

To see all modules on a net:

1. Select the net.
2. Right-click and choose **Go to Connected Instances**.

   Highlights the selected net and all connected primitives and ports, expanding the schematic as necessary.

To see just the driver of a net:

1. Select the net.
2. Right-click and choose **Go to Driver**.

   Highlights the selected net and the driving primitive or port, expanding the schematic as necessary.

Searching in Netlist Analyzer

With large designs, finding objects may be easier with a text search. The Find function in Netlist Analyzer allows you to search for objects in the schematic using instance, symbol, port, and net names. Found objects can be selected in the netlist browser and schematic view.

To search the design in Netlist Analyzer:

1. Choose **Edit >** **Find**.

   The Find dialog box opens.

2. Select the type of object that you want to find by clicking one of the tabs at the top of the dialog box.

3. Select the part of the design that want to search by selecting a level in the Search box.

4. At the bottom-left of the dialog box is the Un-Highlight Search box. Click in this box and type in your search term. You can use the following wildcards:

   - ***** for any number of characters
   - **?** for a single character

   Or, click the arrow at the end of the box and choose from previously used search terms.

5. Click either **Find 200** or **Find All**.

   The found objects are listed in the UnHighlight box.

6. If you clicked Find 200 and want to see more, click either **Next 200** or **Find All** until satisfied.

7. To highlight found objects in the schematic view, do one of the following:

   - For just some of the objects, select the desired objects in the UnHighlight box and then click the -> (right arrow) button.
   - For all of the found objects, click the **All** -> button.

   The selected objects move to the Highlight box and are highlighted in the netlist browser and schematic view. But the schematic view does not expand to show objects in other layers or on other pages.

8. To reduce the number of objects in the Highlight box, select unwanted objects and then click the <- (left arrow) button. You can find objects in the Highlight list using the Highlight Search box. Anything entered in the Highlight Search box is automatically searched for and selected.

9. When you have the Highlight list the way you want, click **Close**.

   Highlighted objects in the schematic view stay highlighted after the Find dialog box closes.

Getting More Information about an Object

You can get more information about an object in the schematic view such as names, number of fanouts, and the pins that nets connect to. You can also get the source code for the object.

To get more information about an object:

1. Select one or more objects.
2. In the schematic view, right-click the object of interest and choose **Properties**.

   The Properties dialog box opens showing a list of various properties of the object.

   If the object is a module, the dialog box also has a drop-down menu listing all the ports of the module. Choosing a port shows the properties for that port.

   If the object is a bus, the dialog box has a drop-down menu listing all the nets that make up the bus. Choosing a net shows the properties for that net.
3. When finished, click **Close**.

To get just the hierarchy name of an object:

1. Select one or more objects.
2. In the schematic view, right-click and choose  **Copy**.
3. Paste into any text editor.

   The format of the name will be similar to this example:

   ```
   {i:UART_INST/u_txmitt/add_24}
   ```

   The first letter is i for instance, n for net, or p for port.

To get the source code for an object:

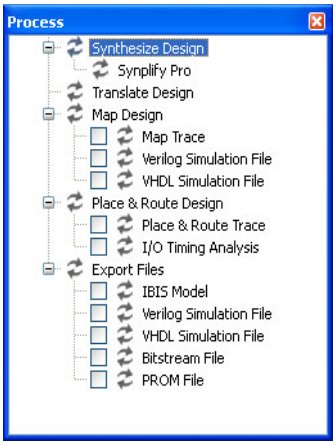
1. Select one or more objects.
2. In the schematic view, right-click the object of interest and choose **Jump to > Jump to HDL File**.

   Source Editor opens with the code highlighted.

Running Processes

A process is a specific task in the overall processing of a source or project. Typical processing tasks include synthesizing, mapping, placing, and routing. You can view the available processes for a design in the Process view. Some of the processes are device-dependent, such as JEDEC File and Bitstream File.

Process View



Processes are grouped into categories according to their functions.

- **Synthesize Design**

  By default, this process runs the Synplify Pro Synthesis tool in batch mode to synthesize the associated HDL design. For details, see "Synthesizing the Design" on page 576.

  If you are using Lattice Synthesis Engine (LSE) as the synthesis tool (**Project > Synthesis Tool**, see "Selecting a Synthesis Tool" on page 88 for details), This process will be changed to **Lattice Synthesis Engine**. Click on this process and Lattice Synthesis Engine (LSE) runs in batch mode to synthesize the design.

- **Translate Design**

  This process allows you to convert the EDIF file from the synthesis program to a Lattice internal database. If the design utilizes Lattice modules (such as Dual-Port RAM, Multiplier, ROM, Shift-Registers, and Adder/Subtractor), the modules will be expanded in this process. For details, see "Translating the Design Database" on page 586.

  Note for LSE

  If you have chosen LSE as the synthesis tool, the Translate Design process cannot be seen in the Process view. The translate design process is included in the Synthesize Design process.

- **Map Design**

  This process maps a design to an FPGA. Map Design is the process of converting a design represented as a network of device-independent components (such as gates and flip-flops) into a network of device-specific components (for example, configurable logic blocks). For details, see the Implementing the Design > Mapping section in the online Help.

  - **Map Trace**

    Trace can be used to run timing analysis in the post-mapping stage in the FPGA design flow. You can run this process after having mapped a design. Trace will create a timing report file (.twr) that will help a designer to determine where timing constraints will not be met. In

post-map timing analysis, Trace will determine component delay values and substitute zero values for missing routing delays. If path delay constraints that are unmet at this stage will be included in the report and may have to be relaxed.

- **Verilog Simulation File**

  This process backannotates the mapped design without timing information so that you may run a simulation of your design. The backannotated design is a Verilog netlist.

- **VHDL Simulation File**

  This process backannotates the mapped design without timing information so that you may run a simulation of your design. The backannotated design is a VHDL netlist.

- **Place & Route Design**

  After a design has undergone the necessary translation to bring it into the Native Circuit Description (.ncd) format, you can run the Place & Route Design process. This process takes a mapped physical design .ncd file, and places and routes the design, and outputs a file that can then be processed by the design implementation tools. For details, see "Place and Route" on page 600.

  - **Place & Route Trace**

    Trace can be used to run timing analysis in the post-routing stage in the FPGA design flow. You can run this process after having routed a design. Trace will create a timing report (.twr) that will allow a designer to verify timing. In post-route timing analysis, Trace analyzes your path delays and will report where these occur in the design.

  - **I/O Timing Analysis**

    This process runs I/O timing analysis and generates an I/O Timing Report. For each input data port in the design, this process generates the setup and hold time requirements and min/max clock-to-out delay for every output port. The computation is performed over all performance grades available for the device and at the voltage and temperature specified in the preference file. I/O timing analysis also automatically determines the clocks and their associated data ports.

  - **Thermal Analysis**

    (MachXO3L/LF 9400C/E devices only). This process must be run for MachXO3L/LF 9400C/E devices before running Bitstream File and JEDEC File processes. The Thermal Analysis process calculates the maximum safe ambient temperature for the user design implemented in MachXO3-9400C and mounted on three standard boards: JEDEC, Small, and Medium boards. This is to assist designers to determine if their design, implemented in MachXO3L/LF 9400C/E device, could safely be used in their application environment.

    The thermal analysis software uses the clock specified in the TWR file. If the clock frequency is not set in the TWR file, the thermal analysis process errors out. The designer can either set the clock frequency in the strategy section or in the timing constraint file which will be reported in the TWR file after running Timing Analysis.

The Thermal Analysis report will include Device Operation Conditions, Operating Clock frequency, Percentage of LUT utilization; Percentage of I/O Utilization, and Activity Factor information.

The report contains Thermal Impedance and Maximum Ambient temperature based on three different Board Mounts, No Heat Sink, and No Air Flow.

By default, the Thermal Analysis process is checked. Uncheck this box if you do not wish to run this process.

- **Export Files**

  You can check the desired file you want to export and run this process.

  - **IBIS Model**

    This process generates a design-specific IBIS model file (<*project_name*>.ibs).

    IBIS stands for I/O Buffer Information Specification. IBIS models provide a standardized way of representing the electrical characteristics of a digital IC's pins (input, output, and I/O buffers). For details, refer to "Lattice Semiconductor IBIS Models" on page 795.

  - **Verilog Simulation File**

    This process backannotates the routed design with timing information so that you may run a simulation of your design. The backannotated design is a Verilog netlist.

  - **VHDL Simulation File**

    This process backannotates the routed design with timing information so that you may run a simulation of your design. The backannotated design is a VHDL netlist.

  - **JEDEC File**

    This process produces a JEDEC file for programming the device. The JEDEC Standard is the industry standard for PLD formats. In the Diamond software, JEDEC refers to the fuse map of your design for the selected device. For details, refer to "Bit Generation" on page 637.

  - **Bitstream File**

    This process takes a fully routed physical design or Native Circuit Description (.ncd) file as input and produces a configuration bitstream (bit images). The bitstream file contains all of the configuration information from the physical design defining the internal logic and interconnections of the FPGA, as well as device-specific information from other files associated with the target device. For details, refer to "Bit Generation" on page 637.

  - **PROM File**

    This process takes a bitstream (.bit) file as input and generates output files in one of several PROM file formats. The output files are used to program PROMs. For details, refer to "PROM Generation" on page 646.

See Also "Managing Project Sources" on page 33

Process State

The Process view always shows the state of the processes in the active implementation. Each state is identified with different icons as shown in the table below.

Process State	Icon	Description
Initial		The process has never been run or an input dependency time stamp has changed since it was last run.
Completed		The process has been run successfully.
Warning		The process or report has been run successfully, but warning messages were issued.
Error		The process did not complete successfully.

Conditions that Re-initialize Process State A process or report is re-initialized under the following conditions:

- A process state earlier in the sequence has changed.
- An input file of the process or report has changed since the last run. For example, changing the .lpf file will cause the map process to be rerun.

  Note

  Input file changes are only detected if touched by the Lattice Diamond Source Editor or a process or report triggered by the Lattice Diamond main window. Changes applied by third-party text editors will NOT be detected.

- Process settings have changed.
- Target device has changed. All processes listed in the Process view in the sequence later than Translate Design will be re-initialized.
- The Process > Rerun All function is run.

See Also "Running Processes" on page 69

- "Starting a Process" on page 74
- "Forcing a Process to Run" on page 74

- "Stopping a Process" on page 75
- "Refreshing Process State" on page 75
- "Cleaning Up Processes" on page 75

Starting a Process

You can start a process on a single source file or on the entire project.

To start a process, do one of the following:

- Select the process in the Process view. Choose **Process >**  **Run**.
- Right-click the process and choose **Run**.
- Double-click the process.

See Also

- "Running Processes" on page 69
- "Process State" on page 73
- "Forcing a Process to Run" on page 74
- "Stopping a Process" on page 75
- "Refreshing Process State" on page 75
- "Cleaning Up Processes" on page 75

Forcing a Process to Run

If the process is up-to-date (indicated by a check mark to the left of the process), it will not run again. However, you can force a process to run by doing the following:

- Choose **Process >**  **Rerun** to start the selected process and run all the intermediate steps, even if the process is up-to-date. Using Rerun will force the selected tool to do a clean run overwriting any previous results.
- Right-click the highlighted process and choose **Rerun**.

You can use **Process >**  **Rerun All** to force all the processes before the one you selected to rerun. Using Rerun All will also force all tools to do a clean run overwriting any previous results.

- "Process State" on page 73
- "Starting a Process" on page 74
- "Stopping a Process" on page 75
- "Refreshing Process State" on page 75
- "Cleaning Up Processes" on page 75

Stopping a Process

If you want to stop running certain process, choose **Process >**  **Stop**.

See Also ▶"Running Processes" on page 69

- "Process State" on page 73
- "Starting a Process" on page 74
- "Forcing a Process to Run" on page 74
- "Refreshing Process State" on page 75
- "Cleaning Up Processes" on page 75

Refreshing Process State

You can choose **Design > Refresh Design** to refresh the process state. For example, after running a certain process, you have made changes to a source file using a source editor outside Lattice Diamond. Then you can use Refresh Process to check the most recent state of the processes. This will also update the Hierarchy view and Reveal Inserter with any design changes.

- "Starting a Process" on page 74
- "Forcing a Process to Run" on page 74
- "Stopping a Process" on page 75
- "Cleaning Up Processes" on page 75

Cleaning Up Processes

You can use the **Process > Clean Up Process** command to reset all the processes as shown in the Process view. This command returns the status of all of the processes back to their initial  state.

Setting Security Options

Some FPGA device families contain a hard-wired Advanced Encryption Standard (AES) engine that enables you to download an encrypted bitstream into the device. The ECP5, LatticeECP2S, LatticeECP2MS, LatticeECP3, and LatticeXP2 devices are equipped with this AES technology for downloading encrypted bitstream. MachXO3D devices have AES technology and ECDSA Authentication capability.

The Lattice Diamond software provides the Security Setting Tool that enables you to set up both the configuration security and an encryption key for those devices.

IMPORTANT!

To turn on this security feature, you need to install the Control_Pack_Encryption_Security.

Unencrypted JEDEC (.jed) and Bitstreams (.bit) can also be encrypted using Deployment Tool. Refer to:

- "Encrypting a JEDEC with Deployment Tool" on page 999
- "Encrypting a Bitstream with Deployment Tool" on page 1000

See Also "Security Setting Dialog Boxes and Security Files" on page 76

- "Setting Security and Encryption for MachXO3D Devices with Security Setting Tool" on page 79
- TN1212 - LatticeXP2 Advanced Security Programming Usage Guide
- TN1215 - Advanced Security Encryption Key Programming Guide for ECP5, LatticeECP3, and LatticeECP2/MS Devices

Security Setting Dialog Boxes and Security Files

The security setting tool consists of several successive dialog boxes, with which you can specify security settings for your target device and set a password to encrypt your security settings.

The Security Settings dialog box enables you to specify a flash protect key for LatticeXP2, and an encryption key for all other devices.

Once you have specified all the security settings, an encrypted .bek file will be generated in the project folder to hold the security settings. The .bek file contains readable header information that identifies the project, software version, device used, and creation date. The header is not encrypted so that you can identify the encrypted file.

If you have specified the flash protect key for LatticeXP2, a .key file will also be created in the project folder. The .key file holds the flash protection key.

The Enter Password dialog box and Change Password dialog box allow you to set a password to further encrypt your security settings. This password will

be used by Lattice Diamond to encrypt the .bek file and Programmer to decrypt the .bek file.

IMPORTANT!

You must track and remember all the keys and passwords you have specified. They will not be stored in any of the design files.

- TN1215 - Advanced Security Encryption Key Programming Guide for ECP5, LatticeECP3, and LatticeECP2/MS Devices

Setting Security and Encryption for FPGA Devices with Security Setting Tool

To run the Security Setting tool and set security settings:

1. In Lattice Diamond, choose **Tools > Security Setting**.

   The Enter Password dialog box opens. Because the project does not yet contain a .bek file, the dialog box shows LATTICESEMI as the default password.

2. To change the password, click **Change** to open the Change Password dialog box.
3. In the Enter Password field, type in a password of at least eight but no more than sixteen characters.
4. Type the password again in the Verify Password field and click **OK**.

   The Security Settings dialog box opens.

5. To set up keys, check the **Advanced Security Settings** option in the Security Settings dialog box.

   For LatticeXP2 devices, you have the option to set Flash Protect Key only or both Encryption Key and Flash Protect Key.

   For all other devices, you can only set the Encryption Key.

6. Select a key format from the Key Format drop-down list, and then type a key in the text boxes as follows, depending on the format selected:

- For the default ASCII format, type alphanumeric values using up to 16 characters.
- For hex format, type values of 0 through F, using up to 32 characters.
- For binary format, type 0 and 1 values, using up to 128 characters.

7. Click **OK** to apply the settings.

   A Security Setting message informs you that the encrypted files have been produced.

8. Click **OK** to close the Security Setting dialog box.

Note

The .bek and .key files are stored in the root project directory, instead of the implementation directory. In case you have more than one implementation, the .bek and .key files are generated for the active implementation.

See Also "Setting Security Options" on page 75

- "Security Setting Dialog Boxes and Security Files" on page 76
- "Encrypting a JEDEC with Deployment Tool" on page 999
- "Encrypting a Bitstream with Deployment Tool" on page 1000

- TN1215 - Advanced Security Encryption Key Programming Guide for ECP5, LatticeECP3, and LatticeECP2/MS Devices

Setting Security Password for MachXO2/MachXO3L/LF Devices with Security Setting Tool

To run the Security Setting tool and set security settings:

1. In Lattice Diamond, choose **Tools > Security Setting**.

   The Enter Password dialog box opens. Because the project does not yet contain a .key file, the dialog box shows LATTICESEMI as the default password.

2. To change the password, click **Change** to open the Change Password dialog box.
3. In the Enter Password field, type in a password of at least eight but no more than sixteen characters.
4. Type the password again in the Verify Password field and click **OK**.

   The Security Settings dialog box opens.

5. Click **OK** to apply the settings.

6. Click **OK** to close the Security Setting dialog box.

Note

The .key files are stored in the root project directory, instead of the implementation directory. In case you have more than one implementation, the .key files are generated for the active implementation.

See Also ▶"Setting Security Options" on page 75

- "Security Setting Dialog Boxes and Security Files" on page 76

Setting Security and Encryption for MachXO3D Devices with Security Setting Tool

The Security Setting Tool (Security GUI) allows you to generate and/or verify keys used for bitstream obfuscation. Additionally, ECDSA Authentication Signature provides the capability to generate and/or verify a signature for any data.

IMPORTANT

To turn on this security feature, you need to install the Control_Pack_Encryption_Security.

See Also ▶"Security Settings with Security Setting Tool" on page 79

- "Signature Authentication with Security Setting Tool" on page 84

Security Settings with Security Setting Tool

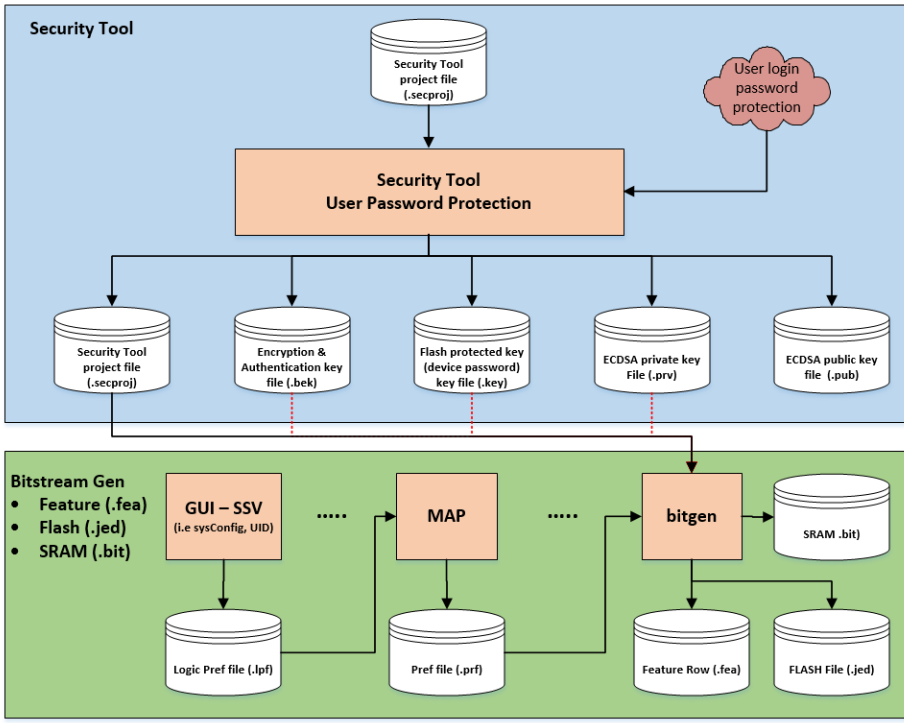
Security Settings provides the user entry for Flash protection (128-bit device password), AES-256 Encryption, and ECDSA Authentication.

User login password protection is required in Security GUI. You can either define a new password or use the preset default LATICESEMI password.

Security GUI generates various output key files that are user login password protected:

- Security Tool project file (.secproj), which is encrypted by user login password.
- Flash Protect Key file (.key) contains 128-bit device password.
- Encryption Key file (.bek) contains 256-bit AES key, which is encrypted by user login password.

- Authentication (ECDSA) Private Key file (.prv) contains either the 256-bit Private Key or 256-bit Signature.
- Authentication (ECDSA) 512-bit Public Key file (.pub)



The level of bitstream obfuscation depends on the options selected in Security GUI.

Flash Protection (Device Password) Flash protection generates a 128-bit device password key.

To run the Security Setting tool and set security settings:

1. In Lattice Diamond, choose **Tools > Security Setting**.

   The Enter Password dialog box opens. Because the project does not yet contain a .key file, the dialog box shows LATTICESEMI as the default password.

2. To change the password, click **Change Password** to open the Change Password dialog box.
3. In the Enter Password field, type in a password of at least eight but no more than sixteen characters.
4. Type the password again in the Verify Password field and click **OK**.

   The Security Settings dialog box opens.

5. To set up device password, check the **Flash Protection (Device Password)** option in the Security Settings dialog box.

6. Select a key format from the Key Format drop-down list, Load from file, or Default Key.
   - Select a key from the Key Format drop-down list, and then type a key in the text boxes as follows, depending on the format selected:
     - For the default ASCII format, type alphanumeric values using up to 16 characters.
     - For hex format, type values of 0 through F, using up to 32 characters.
     - For binary format, type 0 and 1 values, using up to 128 characters.
   - Select a key from Load from File.
     - The Load Key from File dialog box opens, select the key file and click Open.
   - Select a key by clicking on Default Key button.
     - The tool generates LATTICESEMICONDU key.
7. Click **OK** to apply the settings.
8. Click **OK** to close the Security Setting dialog box.

AES Encryption The AES-256 encryption can be used without any authentication. Since AES is a symmetric-key algorithm, the same key is used for both encrypting and decrypting the bitstream.

To run the Security Setting tool and set security settings:

1. In Lattice Diamond, choose **Tools > Security Setting**.

   The Enter Password dialog box opens. Because the project does not yet contain a .key file, the dialog box shows LATTICESEMI as the default password.
2. To change the password, click **Change Password** to open the Change Password dialog box.
3. In the Enter Password field, type in a password of at least eight but no more than sixteen characters.
4. Type the password again in the Verify Password field and click **OK**.

   The Security Settings dialog box opens.
5. To set up AES key, check the **AES Encryption** option in the Security Settings dialog box.
6. Select a key format from the Key Format drop-down list, Load from file, or Auto Generated Key.
   - Select a key from the Key Format drop-down list, and then type a key in the text boxes as follows, depending on the format selected:
     - For the default ASCII format, type alphanumeric values using up to 32 characters.
     - For hex format, type values of 0 through F, using up to 64 characters.

- For binary format, type 0 and 1 values, using up to 256 characters.

- Select a key from Load from File.
  - The Load Key from File dialog box opens, select the key file and click Open.
- Select a key by clicking on Auto Generated Key button.
  - The tool generates a random 256-bit AES key in hex format.

7. Click **OK** to apply the settings.

   A Security Setting message informs you that the encrypted files have been produced.

8. Click **OK** to close the Security Setting dialog box.

ECDSA Authentication The Elliptical Curve Digital Signature Algorithm (ECDSA) offers a variant of the Digital Signature Algorithm (DSA), which uses the elliptical curve cryptography. The Authentication Private key (or Signature) and Public key are used to encrypt/decrypt the bitstream with ECDSA. The Public key size is 512-bits, the Private key size is 256 bits.

The ECDSA Authentication key pair (Private key and Public key) are verified. Alternatively, the Signature with the Public key can be verified given that you provide SHA-256 Signature and Public key pair. The Signature size is 64 Bytes.

An optional feature allows to verify the SHA-256 Signature against the SHA-256 Digest.

IMPORTANT

The SHA-256 digest is used to verify Signature and Public key and is **not** saved to Security project file.

To run the Security Setting tool and set security settings:

1. In Lattice Diamond, choose **Tools > Security Setting**.

   The Enter Password dialog box opens. Because the project does not yet contain a .key file, the dialog box shows LATTICESEMI as the default password.

2. To change the password, click **Change Password** to open the Change Password dialog box.
3. In the Enter Password field, type in a password of at least eight but no more than sixteen characters.
4. Type the password again in the Verify Password field and click **OK**.

   The Security Settings dialog box opens.

5. To set up the key pair, check the **ECDSA Authentication** option in the Security Settings dialog box.

   a. Check the **Public key and private key** option. Public key and Private key dialog boxes are enabled. Select a key format from the Key Format drop-down list, Load from file, or Auto Generated Key Pair.

- Select keys from the Key Format drop-down list, and then type a key in the text boxes as follows, depending on the format selected:
  - For the default ASCII format, type alphanumeric values using up to 32 characters for Private Key and 64 characters for Public Key.
  - For hex format, type values of 0 through F, using up to 64 characters for Private Key and 128 characters for Public Key.
  - For binary format, type 0 and 1 values, using up to 256 characters for Private Key and 512 characters for Public Key.
- Select Public key and Private key from Load from File.
  - The Load Key from File dialog box opens, select the Public key file and click Open.
  - The Load Key from File dialog box opens, select the Private key file and click Open.
- Select Public key and Private key by clicking on Auto Generated Key Pair button.
  - The tool generates random 512-bit Public and 256-bit Private key pair in hex format.

b. Check the **Public key and SHA-256 signature** option. Public key and SHA-256 signature dialog boxes are enabled. Both, Public key and Signature, has size of 512 bits. Select a key format from the Key Format drop-down list or Load from file.

- Select key and signature from the Key Format drop-down list, and then type a key in the text boxes as follows, depending on the format selected:
  - For the default ASCII format, type alphanumeric values using up to 64 characters for Public Key and Signature.
  - For hex format, type values of 0 through F, using up to 128 characters for Public Key and Signature.
  - For binary format, type 0 and 1 values, using up to 512 characters for Public Key and Signature.
- Select Public key and signature from Load from File.
  - The Load Key from File dialog box opens, select the Public key file and click Open.
  - The Load Key from File dialog box opens, select the Private key file and click Open.
- (Optional) Type in the SHA-256 digest. The digest size is 256 bits. Check **Verify** to verify the SHA256 signature against the SHA-256 digest; otherwise, Public key and Signature will be saved, but **not** verified as a valid pair.

6. Click **OK** to apply the settings.

   A Security Setting message informs you that either the encrypted files have been produced or public key and private key don't match. If the key pair cannot be verified, the output encrypted files are not generated.

7. Click **OK** to close the Security Setting dialog box.

ECDSA Authentication with AES encryption A merge of AES encryption/decryption with ECDSA authentication allows for additional level of bitstream obfuscation. First, the private/public key pair is used to encrypt/decrypt the bitstream with ECDSA. Second, the bitstream is encrypted/decrypted with the AES-256 key.

To generate/verify appropriate keys, follow sections "AES Encryption" on page 81 and "ECDSA Authentication" on page 82.

Signature Authentication with Security Setting Tool

Signature Authentication allows you to generate or verify a signature for any data file. To generate signature, you must provide the public-private key pair along the data file the signature is intended for. To verify signature, it is compared against a known public key.

Signature Authentication generates these output files:

- Signature file (.sig) contains 256-bit Signature.
- Digest file (.digest) contains 256-bit Digest.

Signature Generation Signature Generation tool generates Signature and Digest for any data file. Once generated, Signature is visible in the GUI's Signature window. Generated files are saved in the same directory as the data file.'

To run the Signature Generation:

1. In Lattice Diamond, choose **Tools > Security Setting**.

   The Enter Password dialog box opens. Enter your password or use the default password LATTICESEMI. Click **OK**.

   The Security Setting dialog box opens.

2. In the **Signature Authentication** tab, select **Signature Generation**. Provide the Data File, Public, and Private Key.
3. Select both keys.
   - Select Public and Private Keys from Load from File.
     - The Load Key from File dialog box opens, select the key file and click **Open**.
   - Generate Public and Private Keys by clicking on Auto Generated Key Pair button.
     - The tool generates a random 256-bit Private Key and 512-bit Public Key in hex format.
   - If desired, change the key format from the Format drop-down list:
     - For the default ASCII format, type alphanumeric values using up to 32 characters for Private Key and 64 characters for Public Key.

- For hex format, type values of 0 through F, using up to 64 characters for Private Key and 128 characters for Public Key.
- For binary format, type 0 and 1 values, using up to 256 characters for Private Key and 512 characters for Public Key..

- Select Data File from Load from File.
  - The Select Data File to generate or verify signature dialog box opens, select any data file and click **Open**.

4. Click **Generate** to generate a signature for the provided data file.

Signature Authentication message window appears stating the Signature and Digest were successfully created and saved.

Signature Verification Signature Verification allows you to confirm the validity of the data file's signature. The tool compares provided Signature against the provided Public Key. If the verification fails, an error message occurs in the Signature Authentication message box window.

To run the Signature Verification:

1. In Lattice Diamond, choose **Tools > Security Setting**.

   The Enter Password dialog box opens. Enter your password or use the default password LATTICESEMI. Click **OK**.

   The Security Setting dialog box opens.

2. In the **Signature Authentication** tab, select **Signature Verification**. Select Public Key from Load from File.
   - The Load Key from File dialog box opens, select the key file and click **Open**.
   - If desired, change the key format from the Format drop-down list:
     - For the default ASCII format, type alphanumeric values using up to 64 characters.
     - For hex format, type values of 0 through F, using up to 128 characters.
     - For binary format, type 0 and 1 values, using up to 512 characters.
3. Select Data File from Load from File.
   - The Select Data File to generate or verify signature dialog box opens, select any data file and click **Open**.
4. Select Signature from Load from File.
   - The Load Signature from File dialog box opens, select .sig file and click **Open**.
5. Click **Verify**.

Signature Authentication message window appears with pass or fail message.

Setting Options for Synthesis and Simulation

Diamond is integrated with the Lattice Synthesis Engine (LSE), Synplify Pro synthesis tool, and the Active-HDL simulation tool. Besides the OEM tools, you can also let Diamond use LSE, your full-featured versions of Synplify Pro or Precision as the synthesis tool, and full-featured versions of ModelSim or Active-HDL as the simulation tool.

This section covers steps on selecting synthesis and simulation tools, defining file order for synthesis and simulation, customizing synthesis tool processes, specifying VHDL library name, and specifying the search path for Verilog include files. Also, how to perform interactive synthesis is discussed in this section.

About Lattice Synthesis Engine

For most devices, you have the option of using Lattice Synthesis Engine (LSE) as your synthesis tool instead of Synplify Pro for Lattice or another third-party synthesis tool.

LSE is a synthesis tool custom-built for Lattice products and fully integrated with Diamond. Depending on the design, LSE may lead to a more compact or faster placement of the design than another synthesis tool would do. LSE can be run from the Diamond main window or through the command line, similar to the other integrated synthesis tools.

Also, LSE offers the following advantages:

- Enhanced RAM and ROM inference and mapping, including:
  - multiple reads
  - dual-port RAM in write-through, normal, and read-before-write modes mapped to EBR
  - clock enable and read enable packing
  - mapping for the minimal number of EBR blocks
  - EBR mapping for minimal power
  - better support for wide-mode mapping
- Comprehensive GSR inference for area and timing
- Simpler flow to get an .ngd file: no ngdbuild command or Translate Design process required
- Post-synthesis Verilog netlist suitable for simulation

When considering LSE, note the following limitations:

- Not available with LatticeEC, LatticeECP, LatticeSC/M, or LatticeXP.
- IP must be generated with a synthesis tool other than LSE. So the synthesis of IP won't be affected by a change to LSE.
- Design code may need to be modified. Modifications may involve some VHDL requirements and inferring RAM, ROM, and I/O.

- SystemVerilog features are not supported.
- Does not include interclock domain paths in timing analysis.

- Lattice Synthesis Engine Tutorial

Switching to Lattice Synthesis Engine

When changing to Lattice Synthesis Engine (LSE) from another synthesis tool, there are a few things to do:

- Consider creating a new design implementation. You can experiment with different settings without losing your previous work. See "Working with Implementations" on page 45.
- Modify the Synopsys Design Constraint (.sdc) file into an .ldc or create a new .ldc file. See "Lattice Synthesis Engine (LSE) Constraints" on page 1338 and "Applying Lattice Synthesis Engine Constraints" on page 364.
- Adjust the LSE strategy settings. See "LSE Options" on page 1130 and "Optimizing LSE for Area and Speed" on page 579.
- Review the LSE coding tips and consider applying them to your design. See "Coding Tips for Lattice Synthesis Engine (LSE)" on page 172.
- Review the instructions for integrated synthesis. There are some differences with LSE. See "Integrated Synthesis" on page 581.

See Also

-

Bus Naming in LSE Output

In the output files from Lattice Synthesis Engine (LSE), bus names are converted to individual signal names (sometimes known as "bit blasting"). LSE adds "_c_" to the individual signal names. For example, the bus name sum[0:3] becomes:

sum_c_0
sum_c_1
sum_c_2
sum_c_3

See Also

- "Consistent Bus Name Conversion" on page 1139

Selecting a Synthesis Tool

Diamond supports Verilog HDL and VHDL designs using Lattice Synthesis Engine (LSE), Synplify Pro, or Precision RTL as the synthesis tool.

- Diamond is fully integrated with LSE and Synplify Pro. “Fully integrated” means that you can set options and run synthesis entirely from within Diamond.
- Diamond also supports Mentor Graphics Precision RTL Synthesis but does not include the tool itself. If you want to use Precision RTL Synthesis, you need to get the software on your own.
- If you prefer, you can use other synthesis tools by running them independently of Diamond.

You can specify one of them as the synthesis tool for the currently active implementation of your project. Different implementations can have different synthesis tools specified.

To select a synthesis tool:

1. Make sure you have successfully installed LSE, Synplify Pro, or Precision.
2. From the Diamond main window, choose **Project > Active Implementation > Select Synthesis Tool**.

   The Project Properties dialog box appears with the active implementation selected.
3. In the Project Properties dialog box, double-click the synthesis tool in the Value column.
4. From the drop-down menu, select a tool.
5. Click **OK**.

If you have chosen **Synplify Pro**, you can either use Synplify Pro for Lattice or your own full-featured Synplify Pro. By default, Diamond will use the Lattice version. If you want to use Synplify Pro for Lattice, you can use the main window to start running processes. If you want to use your own full-featured Synplify Pro, you need to specify the directory in the Options dialog:

1. Choose **Tools > Options**.

   The Options dialog box opens.
2. In the **Environment > Directories** tab, clear the **use OEM** option.
3. Specify the installation path for Synplify Pro in the Synplify Pro field.
4. Click **OK** to save your settings.

If you have chosen **Precision** as the synthesis tool, you need to specify the directory in the Options dialog:

1. Choose **Tools > Options**. The Options dialog box opens.
2. In the **Environment > Directories** tab, specify the installation path for Precision in the Precision field.
3. Click **OK** to save your settings.

See Also ▶"Customizing Synthesis" on page 92

▶

Specifying VHDL Library Name

The Lattice Diamond software supports VHDL design synthesis using LSE, Synplify Pro, or Precision Synthesis. You can specify the library name for synthesizing individual VHDL sources and modules. By default, all project-related design sources are compiled into the "work" library.

The VHDL library name can also be specified in the Synplify Pro or Precision Synthesis tool. See Synplify Pro or Precision Synthesis Help for details.

To specify the VHDL library target in the main window:

1. In the File List view, right-click the VHDL source for which you want to specify a library name and choose **Properties**.
2. In the Project Properties dialog box, type in the library name you want in the Value field and click **OK**.

   The LSE, Synplify Pro, or Precision Synthesis tool will then use the specified library name to synthesize the selected VHDL source file or module.

Specifying Search Path for Verilog Include Files

The Lattice Diamond software supports Verilog design synthesis using LSE, Synplify Pro, or Precision Synthesis. If a Verilog file is added to your design and additional files are referenced via the include directive, you can specify the search path in Lattice Diamond for searching include files.

Note

If the include file in your Verilog file changed after you opened the relevant project in Diamond, you need to use the **Rerun All** or **Rerun** command to force the process to rerun so that Diamond can reflect the changes of the include file.

You can also specify a Verilog include file search path directly in LSE, Synplify Pro, or Precision. See "Running SYNTHESIS from the Command Line" on page 2448, and the Synplify Pro or Precision Synthesis Help for details.

Synplify Pro and LSE Search Path If you select Synplify Pro or LSE as the synthesis tool, you can only specify the search path for the entire project. Synplify Pro or LSE searches for the include file in the following order, and stops at the first occurrence of the include file it finds.

1. The directory of the file that specifies the 'include' directive

2. The directories that are specified in the “Search Path” option for the entire project

Precision Synthesis Search Path If you use Precision, you can specify the search path for the project and for each Verilog source file. Precision searches for the include file in the following order, and stops at the first occurrence of the include file it finds.

1. The directory of the file that specifies the 'include' directive
2. The directories that are specified in the “Search Path” option for the Verilog source
3. The directories that are specified in the “Search Path” option for the entire project

Specifying Search Path in Lattice Diamond

To specify the search path in Lattice Diamond:

1. In the File List view, do either of the following:
   - Right-click the implementation name if you want to specify the search path for the entire project.
   - (*For Precision Synthesis only*) Right-click the Verilog source for which you want to specify the search path.
2. Choose **Properties** from the right-click menu.

   The Project Properties dialog box opens.
3. In the dialog box, select **Verilog Include Search Path**, and do either of the following:
   - If you want to add only one search path, click the Value field to enter a path.
   - If you want to add multiple paths, click the **...** button from the Value field to get the Verilog Include Search Path dialog box. In this dialog box, click the  icon to browse for a new path and click **OK**. The new path is displayed in the Verilog Include Search Path dialog box. Repeat to add more paths. You can use the  and  button to arrange the order of the paths, or use the  button to delete a path. Click **OK** when you finish.
4. Click **OK** to exit the Project Properties dialog box.

   The search paths you added are applied. The Synplify Pro or Precision Synthesis tool will use the specified search paths to search for the include files referenced in your design other than the directory of the file that specifies the include directive.

Specifying Verilog and VHDL Parameters

You can add Verilog compiler directives and parameters or VHDL generics for the whole design in the properties of each design implementation. You may find this method an easier way to experiment with these settings.

To add Verilog compiler directives and parameters or VHDL generics:

1. In the File List view, right-click the implementation's name and choose **Properties**.

   The Project Properties dialog box opens showing the implementation's properties.

2. In the HDL Parameters row, click under **Value**.
3. Type the statements as a single text line with different statements separated by semi-colons (;).
4. When done, click **OK**.

Selecting a Simulation Tool

Diamond supports functional and timing simulation for Lattice FPGA devices using ModelSim or Active-HDL. You can specify either ModelSim or Active-HDL as the simulation tool for your project in the Simulation Wizard (**Tools > Simulation Wizard** from main window). For more details on how to use Simulation Wizard, see "Simulating the Design" on page 307.

Specifying Input Files for Simulation

Your design probably includes one or more test bench files that you want to use during simulation but do not want synthesized. You can specify this in the properties for each input file. New files are automatically marked for both synthesis and simulation.

To change the synthesis/simulation property of a file:

1. In the File List view, right-click the filename.
2. In the drop-down menu, choose **Include for** and then the desired property:
   - Synthesis and Simulation
   - Synthesis
   - Simulation

You can also set the synthesis/simulation property in the Project Properties dialog box. You can open the dialog box by choosing **Project > Property Pages**.

Defining File Order for Synthesis and Simulation

The File List view lists design input files in a specific order. The synthesis or simulation tool uses that order to sequentially synthesize or simulate each input file. You can adjust the file order by the “drag and drop” operations. The file list can include a combination of VHDL, Verilog, and schematic files. If you have not manually set a top-level module (in the Project Properties dialog box of the main window), usually the last file on the file list is treated as the top-level module.

File order is especially important for VHDL files. Package files must be first on the list because they are compiled before they are used. If design blocks are spread over many files, you should specify the following file order: the file containing the entity must be first, followed by the architecture file, and finally the file with the configuration. Verilog file order is typically important when ‘define statements are dedicated to a single file. This file should be compiled prior to any files that refer to the variables.

To define the file order for logic synthesis and simulation:

- In the Input Files section of the File List view, change the file order as you like by dragging the file name and dropping it to the required location.

  The new file order takes effect immediately. The order will be saved when you save the design project.

Customizing Synthesis

Lattice Diamond supports Verilog and VHDL synthesizing using Lattice Synthesis Engine (LSE), Synplify Pro, and Precision.

You can adjust synthesis tool options and perform the logic synthesis process for your Verilog or VHDL design within Lattice Diamond.

To adjust synthesis tool options and perform the synthesis process:

1. Choose **Project > Active Strategy >** <*synthesis tool*> **Settings**.
2. In the Strategies dialog box, by default, the option settings of the selected process, LSE, Synplify Pro, or Precision, are listed. You can use the **Display catalog** to filter the options you need to customize.
3. Double-click the Value field of the option. You can specify the option using the drop-down menu of the Value field.
4. Click **OK** to accept the new synthesis tool options and exit the Strategies dialog box.
5. In the Process view, double-click the Synthesize Design process to execute the selected synthesis tool.

If you prefer leveraging all the interactive features available in the synthesis tool while maintaining HDL source in the main window, see "Synthesizing the Design" on page 576 for more details.

Working with Run Manager

Large designs can quickly get complicated, and the best approach is not always obvious or definite. There may be many ways to get optimal performance out of your design—the key is to find one option that works.

In Diamond, each project can contain multiple source files, strategies, and implementations. Implementations are comprised of selected source files and only one strategy. You can create multiple implementations to bind different strategies.

After creating implementations, use Run Manager to run multiple synthesis and place and route passes, compare the results of multiple implementations for further analysis to get best solutions. Run Manager helps you to manage running the design implementation process with multiple project implementations (versions) and to compare the results. You can monitor progress, view reports, and quickly identify the best implementation.

See Also ▶"Using Strategies" on page 47

▶ "Working with Implementations" on page 45

Setting Up Run Manager

Before using Run Manager, consider if you want to do multiple place-and-route runs on individual implementations to get different timing and area results.

If you have a lot of implementations and don't want to run them all, you may want to hide some of them in Run Manager.

Also, consider your system's ability to run multiple processes. If you have several implementations running simultaneously in Run Manager, you may see performance problems because of RAM resource conflicts.

Setting Up Multiple Runs on an Implementation You can get multiple place-and-route runs, using different seed values, on a single implementation. The different values can produce significantly different timing and area results.

To set up multiple place-and-route runs on an implementation:

1. In the File List view, right-click on the strategy of the implementation and choose **Edit**. Strategies are listed in the Strategies folder. If you are not sure which strategy is being used, you can check the Implementation column in Run Manager. It includes the strategy name for each implementation.

The Strategies dialog box opens.

2. In the Process box, on the left, choose **Place & Route Design**.
3. Find Placement Iterations and double-click the Value box. Enter the number of place-and-route runs you want to make. (For more on this option, see "Placement Iterations" on page 1149.)
4. Find Placement Save Best Run and double-click the Value box. Enter the number of place-and-route runs you want to see. Run Manager will show you this many of the best results. (For more on this option, see "Placement Save Best Run" on page 1149.)
5. Click **OK**.

Hiding Implementations Run Manager normally shows all the implementations of the project. But you can choose to hide any of the implementations from Run Manager except for the active implementation.

To change which implementations are showing:

1. Choose **Tools > Run Manager**.

   Run Manager opens with a table listing the implementations available. The row in bold font indicates the active implementation.
2. If you want to hide the active implementation, right-click an implementation that you will continue to show and choose **Set As Active**.

   This implementation becomes the active one for the project. The row changes to bold type and, in File List view, the implementation is expanded. The previously active implementation becomes inactive and can be hidden.
3. In Run Manager's tool bar, click the Show/Hide Implementation button.

   The Show/Hide Implementation dialog box opens.
4. In one of the columns, select one or more implementations that you want to move to the other column.
5. Click the arrow button pointing to the other column.
6. When you have the Hidden and Show lists as you want them, click **OK**.

Improving System Performance You can improve your system's performance while running Run Manager by limiting the number of processes sharing the memory. Allowing fewer processes means your computer spends less time swapping data in and out of the hard drive. But fewer processes than the number of available processors could mean processors sitting idle. You will need to find a balance based on your computer and the way you tend to use Run Manager.

To improve performance:

1. Choose **Tools > Options**.
2. In the Options dialog box, choose **Environment > General**.

3. Find the **Maximum number of implementation processes in run manager** option and change the number. The best value is the number of processors in your computer or fewer.
4. Find the **Maximum number of multi-par processes in run manager** option and change the number. The best value is the number of processors in your computer or fewer.
5. Click **OK**.

Running Run Manager

After setting up Run Manager (see "Setting Up Run Manager" on page 93), you are ready to run your implementations.

To process multiple implementations using Run Manager:

1. Choose **Tools > Run Manager**.

   Run Manager opens with a table listing the implementations available. The row in bold font indicates the active implementation.
2. Select the implementations that you want to run by setting the check boxes. Select them all by clicking the check box in the heading row.
3. In Run Manager's tool bar, click the Run button. You can force implementations that have already been run (the Status column says Completed) by clicking the Rerun button.

   While running, you can pause or stop the runs. Select a running item by clicking anywhere in its row. Then click either the Pause or Stop button. Run Manager may take a few moments to respond.

   To continue a paused run, select it and click the Run button.

   Note

   The Process menu commands also control Run Manager, but they only affect the active implementation. This is true whether you choose the command from the Process menu in the menu bar or the right-click menu in the Process view.
4. When the runs are complete, compare the statistics that appear. These statistics provide a quick comparison of the quality of results. See "Reading the Run Manager Results" on page 96.

   If you set up an implementation to do multiple place-and-route runs, click the plus sign to show the individual results. The top scoring result for each implementation is shown in italics and will be used in any further processing with that implementation.
5. If you want to save the results, go to Run Manager's tool bar and click the Export button. In the Export Run Manager File dialog box, browse to where you want to save the results and enter a file name. Then click **Save**.

All the data showing in Run Manager are saved in a comma-separated values (.csv) file that can be opened with a spreadsheet tool such as Excel.

6. For more details, go to the Reports view. The Reports view shows a tab with a set of reports for each implementation. To jump to a specific report, in Run Manager, right-click the row for the implementation and choose **Show Report >** <*report*>. See "Viewing Logs and Reports" on page 100.

   Also, examine the Output view, including checking for any warning or error messages.

7. After studying the results, you can select one of the implementations and one of its runs for further development. See "Selecting an Implementation and Run" on page 98.

Reading the Run Manager Results

Run Manager displays results with a table. Every implementation in the project gets a row. If an implementation did multiple place-and-route runs, each run has a row under its implementation. If you don't see the separate place-and-route runs, expand the hierarchy tree under the implementation row.

Bold text shows the active implementation. Italic text shows the active run out of multiple place-and-route runs. This is the run that will be used in further processing of that implementation.

There are several columns showing the results for the implementations and the place-and-route runs. The columns are described below. Compare the results across rows to see which run worked best.

For the active implementation, you can see the status of the different processes by looking at the Process view. To see the status of another implementation, right-click the implementation in Run Manager and choose **Set As Active**.

For more details, check the Reports view. The Reports view shows a tab with a set of reports for each implementation run. See "Viewing Logs and Reports" on page 100.

Changing the Display You can adjust the display by re-arranging the columns and sorting the runs. By default, many of the columns are hidden but you can choose which ones you want to see.

To change which columns are displayed:

- Right-click in any column heading and choose the column that you want to hide or show. Columns that are showing have a check mark. The Implementation<Strategy> column cannot be hidden.

To re-arrange columns:

- Click on the heading of the column that you want to move and drag it to where you want it.

To change the width of columns:

- Do one of the following:
  - Right-click in any column heading and choose Adjust Column Width to Contents.

    All columns are adjusted based on their contents.
  - Click on the right-hand border of a column and drag to make that column narrower or wider.

To sort the runs:

1. Click in the heading of the desired column.

   The rows are sorted according to the contents of that column.
2. To reverse the order of the rows, click in the same column again.

Column Descriptions There are many columns of data available. Most of these apply only to the implementation rows, not the individual place-and-route runs.

- Implementation<Strategy>: The name of the implementation followed by the strategy (in angle brackets) that implementation is using. Use the check boxes to select which implementations to run. This column cannot be hidden.
- Current Step: The implementation process, such as Synthesis and Map, that is currently running.
- Status: The status of the implementation, such as Running, Pause, and Completed.
- Next Step: The next implementation process that will run after the current process finishes.
- Worst Slack: The worst timing slack for all timing constraints. Negative values indicate timing violations.
- Timing Score: The time, in picoseconds, by which the design is failing to meet the timing constraints. Zero means the run fully met the timing constraints.

  If an implementation has multiple place-and-route runs, the implementation row shows the value of the active place-and-route run.
- Worst Slack (Hold): The worst timing slack for all timing constraints based on hold time. Negative values indicate timing violations.
- Timing Score (Hold): The time, in picoseconds, by which the design is failing to meet the timing constraints based on hold time. Zero means the run fully met the timing constraints.
- Slice: The number of slices used versus the total number available.

- Unrouted Nets: The number of unrouted nets. Anything larger than zero means that place-and-route did not finish.

  If an implementation has multiple place-and-route runs, the implementation row shows the value of the active place-and-route run.

- Run Time: The total run time for the synthesis, map, and place-and-route processes, including multiple place-and-route runs. Times for translate, trace, and exporting files are not included. The format is <*hours*>:<*minutes*>:<*seconds*>.

- Level/Cost: The first number is the Placement Effort Level specified in the Place & Route Design section of the strategy, not necessarily the effort used. See "Placement Effort Level" on page 1149.

  The second number is the number of placement iterations that were run to get a solution. If an implementation has multiple place-and-route runs, the second number is cumulative of preceding runs. That is, if the design only needs one iteration, the list of place-and-route runs shows 1, 2, 3, ...

  The implementation row shows the value of the active place-and-route run.

- Location: The full pathname for the implementation.

- Start: When synthesis started. Not applicable for EDIF projects.

- Level/Cost: The first number is the Placement Effort Level specified in the Place & Route Design section of the strategy, not necessarily the effort used. See "Placement Effort Level" on page 1149.

  The second number is the number of placement iterations that were run to get a solution. If an implementation has multiple place-and-route runs, the second number is cumulative of preceding runs. That is, if the design only needs one iteration, the list of place-and-route runs shows 1, 2, 3, ...

  The implementation row shows the value of the active place-and-route run.

- Description: An editable text box. Initially it just has the implementation name but you can change it.

  To change the description of an implementation, double-click the Description cell. Then enter any text you want.

- GSR: The number of GSR used versus the total number available.

- PIO: The number of PIO used versus the total number available.

- EBR: The number of EBR used versus the total number available.

- PCS: The number of PCS used versus the total number available.

- Number Of Signals: The number of signals in the design.

- Number Of Connections: The number of connections in the design.

Selecting an Implementation and Run

After studying the results, you can select one of the implementations and one of its runs for further development.

To select an implementation and run:

1. Right-click on the implementation's row and choose **Set As Active**.

   This implementation becomes the active one for the project. The row changes to bold type and, in File List view, the implementation is expanded. The previously active implementation becomes inactive.

2. If the implementation has multiple runs, right-click the preferred run and choose **Set As Active**.

   The results of this run will be used in further development such as exporting files. The row changes to italic type.

Finding Results

After you load a design in Diamond, you can find the information you need via the following ways.

- In the active Reports view, choose **Edit > Find**. You can type the desired text into the Find field at the bottom-left of the Reports view window. The first occurrence of the desired text will be found and highlighted in the right side of the window for you. Click **Next** or **Previous** to find more. And check the **Case Sensitive** option if needed for the search. While typing in the text, the Find field will be automatically colored if no occurrence of the text is found.
- In the active Source Editor, after choosing **Edit > Find**, you will get the Find and Replace dialog box. You can enter the text you want to search in the Find What field and start a search. Use the **Find Next** command to find more. If you want to replace the current find, you can use the Replace tab of the dialog box. Check **Match Case**, **Match Whole Word**, **Search Up**, **Regular Expression** options as needed. Use the **Replace** or **Replace All** command to replace the text found.
- If you want to find information without loading the files, you can choose **Edit > Find in Files** from Diamond main window. In the pop-up Find In Files dialog box, type the text you want to find, specify the search path and search filters, and check the desired options: **Search subdir**, **Include hidden files**, **Match case**, **Match whole word**, and **Regular expressions**. Press **Find**. The results will be displayed in the Find Results frame. Double-click any of the findings from the Find Results frame to open the associated source file in the associated editor. For example, if the finding is in a log file, the log file will be opened in the Reports view with the first finding appears on the first line.
- You can search the Output log by clicking in the Output view (in the text, not on the tab) and then pressing **Ctrl**-**F**. This opens a basic text search dialog box at the top of the Output view. You can type the text in the Find text field and start a search.

Find Results View The Find Results view may not be displayed automatically in your Diamond main window. To turn on the Find Results view, select **View > Show Views > Find Results**. A check mark indicates the frame is displayed.

The Find Results view can be detached from the main window by clicking the detaching icon on the upper-right corner of the view. After detaching, you can double-click on the title bar of the view to get it back to the main window.

See Also ▶"Viewing Logs and Reports" on page 100

- "Navigating Errors and Warnings" on page 102
- "Finding Text in Logs and Reports" on page 102

Viewing Logs and Reports

Lattice Diamond generates log files for all project activities. The log files contain processing information, as well as error and warning messages. If you run processes, reports are generated.

Viewing Logs A log file is displayed in the Output frame as a process is running. A scroll bar can be used to scroll up and down in the information.

Errors are displayed in red. Warnings are displayed in orange. There are also information messages. These messages are also displayed in the Warning, Error, and Info views. These views may not automatically be visible in your Diamond main window. To turn on the views, choose **View > Show Views >** <*view*>. A check mark indicates the view is displayed.

Viewing Reports The Reports view displays reports for the major processes.

There are two panes in the Reports view. The left pane lists the Design Summary information including the report types. The reports in detail are displayed in the right pane.

Type of Report	Description
Project Summary	Lists the summary information of the project including module name, synthesis tool chosen, implementation name, strategy name, target device, device family, device type, package type, performance grade, operating conditions, logic preference file, software product version, project file name, and location.
Process Reports	Lists the synthesis, map, place and route, signal/pad, and bitstream reports in HTML format.
Analysis Reports	Lists the trace and timing reports.
Tool Reports	Lists the I/O SSO analysis, hierarchy parsing, PIO DRC, and ECO Editor reports. Also has a log of Tcl commands used in recent sessions.
Messages	Lists the implementation messages and user defined filters for the messages.

In the Design Summary pane, there is the report icon . If a report has been generated, the icon appears as  . If the report is not the most recent version,

the icon appears as  . To view the contents of the entire report, click on the report to be viewed. The entire report is then displayed in the right pane of the Reports view. Use the scroll bar to navigate through the report. Some of the reports are divided into sections (for example, Map, Place & Route, and Signal/Pad). Expand the report listing to display the sections in a list. Choose the desired section. The whole report will be displayed with the selected section displayed at the top of the right pane of the Reports view.

You can navigate the reports quickly by using the Find function (right-click in the right pane of the Reports view and choose **Find in Text**).

Other Reports The Synthesize Design stage produces reports that do not appear in the Reports view. You can find these reports in the implementation folder. In the File List view, right-click the implementation name and choose **Open Containing Folder**. A window will open showing the contents of the folder. All of these reports can be read with a text editor.

One of the reports is a detailed description of the device resources that will be used by the design. This report is much more detailed than the synthesis report in the Reports view. The report includes the resources used by each module of the design. Similar information can also be found in the Hierarchy view. For Synplify Pro, look for <*top_module*>.areasrr; for Lattice Synthesis Engine, look for <*top_module*>.arearep.

See Also ▶"Finding Results" on page 99

Cross-Probing from Reports to Schematics

While studying one of the timing or trace reports you might want to see where a module or port is in the design. You can cross-probe, or jump, from the Lattice Synthesis Engine (LSE) timing report and from the place & route trace report to a schematic view of the design.

To cross-probe from the LSE timing report to a schematic view:

1. After running synthesis with LSE, open the Reports view.
2. In the Design Summary column, click **LSE Timing Report**. It's under Analysis Reports.
3. Select text that has the name of one or more module instances or ports of interest.
4. Right-click and choose **Filter in Netlist Analyzer**.

   Netlist Analyzer opens with the technology netlist view of the selected objects. For more information, see "About Netlist Analyzer" on page 57 and "Navigating the Design with Netlist Analyzer" on page 62.

To cross-probe from the place & route trace report to a schematic view:

1. After running place & route of the design, choose **Tools > Synplify Pro for Lattice**.

2. In Synplify Pro, click the **Implementation Directory** tab.
3. Find the **.twr** file and double-click it.

   A text editor opens in Synplify Pro with the report.
4. Find the name of an instance or port of interest and select it.
5. Right-click in the selected name and choose one of the following:
   - **Filter in Analyst** to see the item by itself
   - **Select in Analyst** to find the item in the full schematic
6. If a suitable Analyst view is not open, a dialog box asks if you want to open one. Click **Yes**.
7. Go to the Analyst schematic view to see the item.

Navigating Errors and Warnings

If an error or a warning results from the specific line in an HDL source file, you can easily go to that line to edit the source file.

To navigate errors and warnings:

- In the Reports, Output, Error, or Warning view, double-click the line describing the error or warning.
- In the Reports, Output, Error, or Warning view, right-click the message and choose **Locate in > Text Editor**. If the command is dimmed, there is no link to a source file.

Your default text editor opens with the appropriate HDL source file at the line number specified in the error or warning message. You can then modify the file to debug your design.

See Also "Finding Results" on page 99

Finding Text in Logs and Reports

You can search for text in the Output, Error, Warning, Info, and Reports views.

To search for text in the Output, Error, Warning, and Info views:

1. Right-click in the Output, Error, Warning, or Info view of the Diamond main window and choose **Find in Text**.

   The Find toolbar appears.
2. In the **Find** text box, enter the text that you want to search for. Check the **Case Sensitive** option if you want the text to match exactly as it was entered into the text box. Or, check the **Whole Words** option as desired. As you type each character, the focus in the window changes to where a match is found.

3. Use the **Next** and **Previous** buttons in the Find toolbar to find other occurrences of the text.

To search for text in the Reports view:

1. Right-click in the right pane of the Reports view, and choose **Find in Text**.

   The Find toolbar appears.

2. In the Find text box, enter the text that you want to search for. Check the **Case Sensitive** option if you want the text to match exactly as it was entered into the text box.
3. Use the **Next** and **Previous** buttons in the Find toolbar to find other occurrences of the text.

See Also ▶"Finding Results" on page 99

Filtering Messages

The number of messages produced by the design implementation process can be very large. There are several ways to filter these messages to find the ones of most interest. Messages can be filtered by:

- Implementation process (synthesis, translate, map, place & route, export, or other tool)
- Severity (information, warning, and error)
- ID number
- Text

Filter settings can be saved for use later or to apply to the Output view. Saved settings are available in the Reports view under Messages > User Defined Filters.

Messages are automatically sorted by severity: Error, Warning, and Info. Look for these tabs in the message area of the main window alongside the Output view. If the one you want is not showing, choose **View > Show Views** and select the one you want.

To set filter options:

The message list changes as you set filter options.

1. After running part or all of the implementation process, go to the Reports view. This view opens automatically. If it is not showing, choose **View > Reports**.
2. At the bottom of the Design Summary column, under the Messages folder, select either **All Messages** or one of the user defined filters.

   Messages appear to the right in a spreadsheet display.

3. If filter options are not visible above the spreadsheet, click the Show Filter Selection button. It's the arrow at the top-right of the Reports view.

Several check boxes and buttons appear at the top of the view.

4. Select the processes and severity levels you want to hide.
5. Specify any message ID that you want to hide by right-clicking a message that has that ID and choosing **Filter Messages with This ID**.
6. To hide a specific message, right-click on an example of the message and choose **Filter Messages Exactly Like This**. This hides all messages with the same process, severity, ID, and text. The text must be completely the same. Messages of the same type but using a different signal or module name will show.

   To see messages hidden by this option, click **Filter Details** in the Filter Selection area or right-click in the Message area and choose **Filter Details List**. The Detailed Filter List dialog box opens showing just this set of hidden messages.
7. To stop hiding messages hidden by the Filter Messages with This ID and the Filter Messages Exactly Like This options, open the Detailed Filter List dialog box (above). Clear the **Filter Enable** check box of the desired messages and click **Apply**.

Note

You can also select options by right-clicking a message of the type that you want to hide and choosing one of the Filter Messages commands. These commands hide all messages with the same process, severity, or ID as the selected message.

To undo all filter settings:

1. Click **Reset**.

   A dialog box opens.
2. Do one of the following:
   - If there have been changes, you are offered the option of saving the settings. If you choose to save, see the following procedure.
   - If there have been no changes, click **OK** in the dialog box.

To save filter settings:

1. If the filter options are not visible above the spreadsheet, click the Show Filter Selection button. It's the arrow at the top-right of the Reports view.
2. Click **Save Filter**.

   The Save Filter dialog box opens.
3. Enter a name for the filter.
4. Click **OK**.

   The new filter's name appears in the Design Summary column under Messages > User Defined Filters.

To apply user defined filters to the Output view:

Filter settings must be saved before they can be applied to the Output view.

1. Before running part or all of the implementation process, go to the Reports view. If it is not showing, choose **View > Reports**.
2. At the bottom of the Design Summary column, under the Messages folder, expand **User Defined Filters**.
3. Right-click the desired filter and choose **Apply "***<filter>***" to Output View**.

   A filter icon is placed by the filter's name.
4. Run the desired implementation processes.

   The Output view is loaded as usual except that the specified messages are missing. To see the missing messages, look in the Error, Warning, or Info tabs or select All Messages in the Reports view.
5. To stop using the filter on the Output view, right-click the filter name and choose **Apply "***<filter>***" to Output View** again.

   The Output view does not change, but will display all messages from future processing.

Changing Warnings to Errors

There may be warning messages that you consider to be serious problems and want to stand out more. You can change these warnings to show the error severity level in your design project. You can also save these "promotions" to use in other design projects.

Promotions only show for messages from future actions. Promotions do not affect the display of messages from past actions.

To change a warning to an error in the Reports view:

1. In the Reports view, go to the Messages section.
2. Right-click on the message that you want to promote and choose **Promote Messages with This ID**.

   Not all warning messages can be promoted so this command may be dimmed.

To change a warning to an error without the Reports view:

1. Choose **Project > Message Promotion**.

   The Message Promotion dialog box opens.
2. In the IDs box, type the ID number of the messages that you want to promote. Separate multiple ID numbers with semi-colons (**;**).
3. Click **Promote**.

   Not all warning messages can be promoted so some ID numbers may be rejected.
4. When you are finished in the Message Promotion dialog box, click **Close**.

To restore a message ID to the warning level:

1. Choose **Project > Message Promotion**.

   The Message Promotion dialog box opens.

2. Select the message that you want to restore to the warning level.
3. Click **Remove**.
4. When you are finished in the Message Promotion dialog box, click **Close**.

To save the list of promoted messages for another project:

1. Choose **Project > Message Promotion**.

   The Message Promotion dialog box opens.

2. Click **Export**.
3. In the Export Promotion dialog box, browse to where you want to save the list.
4. Enter a file name.
5. Click **Save**.

   The list is saved to a file with a ".pmt" extension.

6. When you are finished in the Message Promotion dialog box, click **Close**.

To use an existing list of promoted messages:

1. Choose **Project > Message Promotion**.

   The Message Promotion dialog box opens.

2. Click **Import**.
3. In the Import Promotion dialog box, browse to the list.
4. Click **Open**.

   The list of messages appears in the Message Promotion dialog box.

5. When you are finished in the Message Promotion dialog box, click **Close**.

Getting Help for Messages

Some messages have a link to more information in the online Help. This information may help to understand what the message is about or how to fix the problem.

To check for help on a message:

1. Right-click on the message in the Reports, Error, Warning, or Info view.

   A menu appears. The last item in the menu is Help. If it is dimmed, there is no link.

2. If the Help command is available, choose it.

   The Help opens with the appropriate topic.

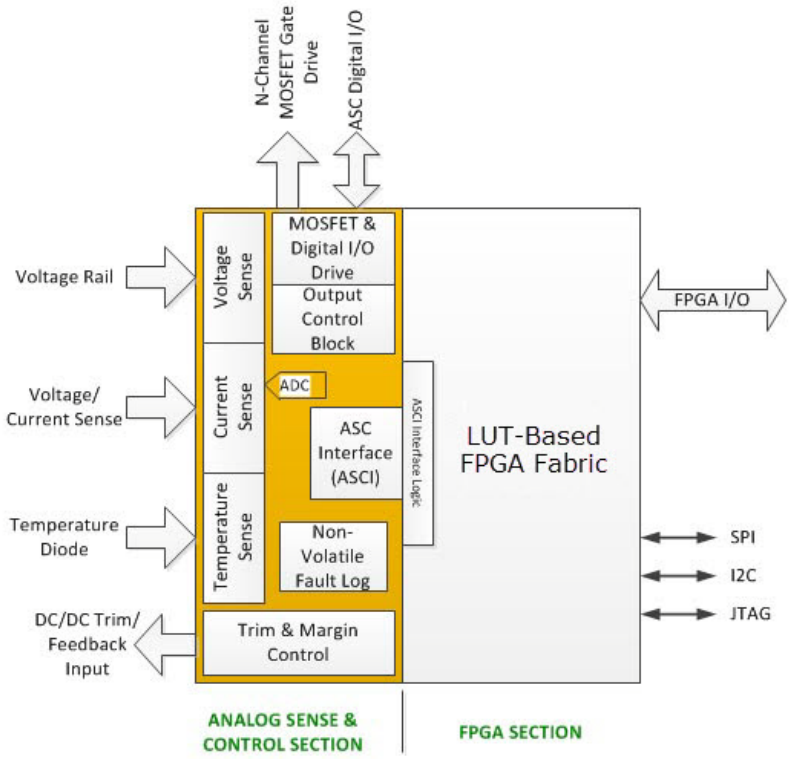
Designing with Lattice Diamond Platform Designer

Included with the Lattice Diamond software is the Platform Designer tool which enables you to build and control a complete hardware management system. With Platform Designer, you can build and control:

- Platform Manager 2
- Platform Manager 2 in a two-device (LPTM21 and LPTM21L) configuration
- Certain devices in the MachXO2HC/HE family with external Analog Sense and Control (ASC) devices
- Certain devices in the MachXO3LF family with external ASC devices
- Certain devices in the ECP5U/UM family with external ASC devices.

The larger LPTM21 device can configure both ASC and/or LPTM21L as slave devices.

Figure 2: Platform Manager 2 Block Diagram



As shown in the previous figure, the Platform Manager 2 device is made up of an ASC block and an FPGA block. These two blocks provide the necessary programmable building blocks to enable integration of various combinations of hardware management functions into a single chip. The hardware management algorithm is implemented within the FPGA block of the Platform Manager 2. The monitoring and control resources can be scaled up, to meet application requirements, by adding an external ASC to the Platform Manager 2. Each of the ASCs provides additional monitor and control of up to ten voltage rails, two temperature sensors and two current sensors. The overall platform management algorithm that uses the inputs from the external ASC device(s) is located within the FPGA block of the Platform Manager 2. The following diagram shows how an ASC device can be connected to a Platform Manager 2 device to implement a hardware management circuit that monitors the board voltage rails (V), supply currents (I), and board temperatures (T).

Figure 3: ASC Device Connected to a Platform Manager 2 Device

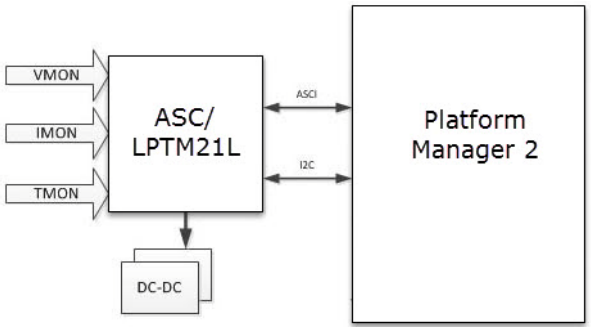


Figure 4: Connecting Multiple ASCs to Lattice Device

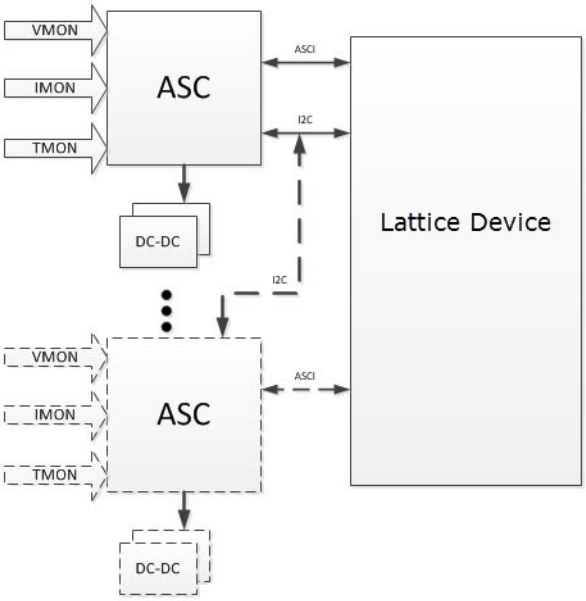

Multiple ASC devices can also be connected to imilar to the Platform Manager 2, to offer wider flexibility and control when implementing a complete hardware management system. Devices include:

- Certain devices in the MachXO2HC/HEHC/HE family
- Certain devices in the MachXO3LF family with external ASC devices
- Certain devices in the ECP5U/UM family with external ASC devices

Unique to Platform Manager 2 is the smaller package LPTM21L device can be also configured as a slave device combining with ASC. Table 2 lists Platform Manager 2, MachXO2HC/HEHC/HE, and MachXO3LF and ECP5U/

UM devices that support ASCs, and also lists the maximum number of ASCs that can be used for each device.

Table 2: External ASCs/LPTM21 supported by Platform Manager 2, MachXO2HC/HEHC/HE, MachXO3LF, ECP5U/UM

Family	Device	Maximum Number of External ASCs
Platform Manager 2	LPTM21	3 ASC and/or LPTM21L
Platform Manager 2	LPTM21L	3 ASC and/or LPTM21L
MachXO2HC/HEHC/HE	640HC	2
	1200HC	4
	2000HC	6
	4000HC	8
	7000HC	8
	2000HE	6
	4000HE	8
	7000HE	8
MachXO3LF	640E	2
	1300E/C	4
	2100E/C	6
	4300E/C	8
	6900E/C	8
ECP5U/UM	LFE5U-12F	8
	LFE5U-25F	8
	LFE5U-45F	8
	LFE5UM-25F	8
	LFE5UM-45F	8

▶ "Platform Designer Flow" on page 113

About Platform Designer

Platform Designer provides an integrated design environment that enables you to configure the device, implement the hardware management algorithm, simulate, assign pins, and finally generate the JEDEC files required to program and configure the device on the circuit board. It also allows you to import other HDL files to integrate other desired functions.

See Also ▶"Launching Platform Designer" on page 115

- "Platform Designer User Interface" on page 111
- "Platform Designer Flow" on page 113

Platform Designer User Interface

Platform Designer contains separate editors for configuring global settings; current, temperature, and voltage monitors; fan controller and fault logger components; ports, nodes, and logic controls. It also provides a view for checking design rules and resources and building the design. Each editor and view is accessed from the Platform Designer menu pane on the left, which is divided into five main sections: Global, Analog, Components, Control, and Build.

Global The Global Configuration view provides global configuration options, including options for each ASC device. The global ASC Options provide access to configuration settings like the I^2C address and other default settings. The Device Options enable you to select the programming interface, clock source, and boot mode.

Components The Components section enables you to configure the fan, fault logging, hot swap, and PMBus Adapter. It includes the following views:

- Fan Controller – The Fan Controller allows you to add a fan, specify the fan interconnections, and configure the control parameters. The fan controller can be configured to work with 2-wire, 3-wire, or 4-wire fans, and up to sixteen fans can be controlled. The fan controller generates a pulse width modulated (PWM) signal to set fan speeds.
- Fault Logger – The Fault Logger enables you to specify and configure fault conditions that are logged to non-volatile memory. You have the option of using standard fault logging that is based on voltage, current, and temperature status; or using the full-featured fault logging.
- Hot Swap – **(Platform Manager 2, MachXO2HC/HEHC/HE, and MachXO3LF only.)** The Hot Swap component enables you to configure the ASC for a hysteretic closed-loop to limit the in-rush current in an application where power is rapidly applied. Such an application can include such a line card, blade, or a PCB that is plugged into a "hot" backplane.
- PMBus Adapter – **(Platform Manager 2, MachXO2HC/HE, and MachXO3LF only.)** The PMBus Adapter component allows you to configure the adapter for connecting analog Point of Load (POL) DC-DC converters to PMBus using the ASC and FPGA.

Analog The Analog section enables you to configure the settings for current, temperature, and voltage monitors. It includes the following editors:

- Current – The Current editor enables you to configure the low-voltage and high-voltage current monitors for each ASC device. Platform Designer automatically populates the current trip points available based on the sense resistor selection. You can configure the trip points and other current monitor settings here.
- Temperature – The Temperature editor enables you to configure the temperature monitors (TMON) for each ASC device. Multiple monitor levels can be selected for each TMON, with temperature values displayed in ^{O}C.
- Voltage – The Voltage editor allows you to configure voltage monitoring, trimming, margining, and voltage identification (VID) settings for each ASC device in your system. You can edit multiple settings by using the Voltage Monitor & Control dialog box. To open the dialog box, double-click an active cell in the ASC column or the Pins Monitor/Trim column on any of the three spreadsheets, or right-click the cell and choose **Edit**. You can also edit settings individually on the Voltage spreadsheet or the VID spreadsheet by single-clicking an editable cell.

Control The Control section enables you to configure signals and set the control logic. It includes the following editors:

- Ports & Nodes – The Ports & Nodes editor provides spreadsheets for viewing the internal nodes and configuring external signals (ports) of the chip set. The Ports sheet shows all physical FPGA-based PIOs that are available for use as external connections to the design and allows you to assign labels to logical ports, specify the I/O and register type, and group ports of a common type to form a bus. The Nodes sheet shows internal signals already generated to connect the implemented features of the design. The nodes sheet allows you to create additional signals for connecting different features on-chip. The GPIO sheet allows you to configure and label the ASC-based general purpose I/Os. The HV Outputs sheet allows you to label and configure the high-voltage output ports.
- Logic – The Logic editor enables you to create sequences, exception logic, supervisory equations, and timers for one or more state machines. It also allows you to import modules into your design from HDL code. The Sequence page of the Logic editor allows you to add state machines and gives you access to the Multiple State Machines dialog box for managing the state machine library.

Build The Build view enables you to check the design status, examine the amount of hardware resources consumed, run DRC check, compile the design, and generate the merged JEDEC file. The Build view includes a summary table of enabled components and programming options, and it shows the amount of hardware resources of the device that have been consumed by the current design configuration. The Build view enables you to generate a test bench, including stimulus, for simulating your design. It also allows you to export a detailed configuration report.

See Also "Working with Platform Designer Editors" on page 118

Platform Designer Input Files

The input files for Platform Designer include the Platform Designer project file (.ptm) and HDL source files (.v, .vhd).

The .ptm file holds all of the Analog Sense and Control settings, as well as the logic and port information, for the active Platform Designer project. A .ptm file is generated automatically for a new project. You can also add a new or existing .ptm file, which allows you to choose from multiple project files in a single implementation.

HDL source files are not required, but you can add them to the Diamond project. Once the HDL files are added to the Diamond project, you can use Platform Designer's Logic Editor to import an HDL module into the Platform Designer project.

See Also
- ▶See "Working with Platform Designer Project (.ptm) Files" on page 117
- "Importing HDL Modules" on page 156.
- "Creating a New Platform Designer Project" on page 115

Platform Designer Output Files

Platform Designer automatically generates the background HDL files when you compile the design. The "Generate Jedec" process produces a merged JEDEC of the FPGA and ASC JEDEC files for programming. ECP5U/UM output file is .bit.

See Also ▶"Building the Design" on page 156

Platform Designer Flow

The number of tasks involved in the Platform Designer flow will vary, depending on the selected Platform Manager 2, or MachXO2HC/HE, or MachXO3LF, or ECP5U/UM, the number of external ASC/LPTM21L (for LPTM21/LPTM21L as masters, LPTM21L and/or ASC can be slaves) devices selected, and the types of configuration needed to complete the design. The following outline shows a typical flow of required and optional tasks.

1. Create a project in Lattice Diamond. Select the base device and package; Platform Manager 2, or MachXO2HC/HE, or MachXO3LF, or ECP5U/ECP5UM. Then add the number of external ASC devices needed. For Platform Manager 2 devices LPTM21 / LPTM21L selected as master devices, LPTM21L and/or ASCs can be combined as slave devices.
2. Specify global settings:
   - ASC options, including reset type, and default options for voltage, current, and temperature

- device options, including programming interface, clock source, and boot mode

3. Configure the ports and nodes:
   - ports and port groups
   - internal nodes
   - general-purpose I/Os
   - high-voltage outputs
4. Configure the analog settings:
   - Configure the voltage monitors (VMONs):
     - schematic net names and parameters
     - trim/margin parameters
     - voltage identification (VID) tables
   - Configure the current monitors (IMONs).
   - Configure the temperature monitors (TMONs).
   - Configure one or more fans:
     - fan type and pulse width modulation
     - fan interconnections
   - Configure PMBus Adapter.
   - Enable and configure fault logging.
5. Define the platform management logic, including sequencing and monitoring:
   - timers
   - sequencer instructions and exceptions for one or more state machines
   - supervisory logic equations
   - modules that are imported from HDL
6. Build the design.
   - Examine the resources consumed.
   - Run design rule check.
   - Compile the design to generate the HDL code and synthesize the logic.
   - Assign Pins in Spreadsheet View.
   - Generate the JEDEC to process the design and generate the merged JEDEC file.
7. Simulate the design.

See Also ▶"Platform Designer User Interface" on page 111

- "Creating a New Platform Designer Project" on page 115
- "Working with Platform Designer Project (.ptm) Files" on page 117

Launching Platform Designer

You can launch Platform Designer by creating a new project in Diamond that targets a Platform Manager 2 LPTM21/LPTM21L device with external ASCs and/or LPTM21L devices, or a MachXO2HC/HE with external ASCs, or MachXO3LF with external ASCs, or an ECP5U/UM with external ASCs. You can also launch Platform Designer by opening an existing Platform Designer project file (.ptm).

Platform Designer is also available from the Diamond Tools menu when you open an existing project that targets a Platform Manager 2 LPTM21/LPTM21L device with external ASCs and/or LPTM21L devices, or a MachXO2HC/HE with external ASCs, or a MachXO3LF with external ASCs, or an ECP5U/UM with external ASCs.

- "Opening an Existing Platform Designer Project" on page 117
- "Working with Platform Designer Project (.ptm) Files" on page 117
- "Working with Platform Designer Editors" on page 118

Creating a New Platform Designer Project

When you create a new project that targets the Platform Manager 2, or a MachXO2HC/HE with external ASCs, or a MachXO3LF with external ASCs, or an ECP5U/UM with external ASCs, Diamond generates a new Platform Designer project file (.ptm) and opens the Platform Designer user interface.

To create a new Platform Designer project in Diamond:

1. In Diamond, choose **File > New Project** to open the Create a Lattice Diamond Project wizard.
2. Click **Next**.
3. In the Project section, type a name for the project and use the Browse button to navigate to a location.
4. Click **Next**.
5. The Add Source section is an optional step that allows you to add HDL source files to the project or an existing Platform Designer project (.ptm) file. If you add an existing .ptm file, the default .ptm file will not be added to the project.

   To skip the Add Source step, click **Next**.

   To add source files to the project, click the **Add Source** button to navigate to the files and select them, and then click **Next**.
6. In the Select Device dialog box, do one of the following:
   - Select **Platform Manager 2** in the Family section, and then select the desired LPTM device from the Device section.

Platform Manager 2 devices contain one embedded Analog Sense and Control (ASC) device. There are 2 devices in the Platform Manager 2 family, LPTM21 and LPTM21L in a smaller package configuration. The LPTM21/LPTM21L device allows you to add up to three external ASC and/or LPTM21L devices. The LPTM20 device allows you to add one external ASC device. To add an external ASC and/or LPTM21L device, select **LPTM21/LPTM21L**. The “Select ASC Device” section will then appear near the bottom of the dialog box. You will note a 3 device radial button selection for mixing and matching selection of ASC and LPTM21L as slave devices.

- Select **MachXO2HC/HE** in the Family section, and then select the desired LCMXO2 HC device—640HC or larger—from the Device section.

  The “Select ASC Device” section appears near the bottom of the dialog box. Up to eight ASC devices can be added, depending upon the size of MachXO2HC/HE device.

- Select **MachXO3LF** in the Family section, and then select the desired from the Device section.

  The “Select ASC Device” section appears near the bottom of the dialog box. Up to eight ASC devices can be added, depending upon the size of MachXO3LF device.

- Select **ECP5U/UM** in the Family section, and then select the desired LFE5UM device—25F or 45F—from the Device section.

  The “Select ASC Device” section appears near the bottom of the dialog box. Up to eight ASC devices can be added.

7. In the “Select ASC Device” section, select the number of ASC devices you would like to include.

   The package type, performance grade, operating conditions, and part name are all tied to the device selection.

8. Click **Next**.

   In the Select Synthesis Tool dialog box, select the synthesis tool that you want to use. The choices are **Lattice LSE** and **Synplify Pro** and can be changed at any time.

9. Click **Next**.

   In the Project Information dialog box, the option “Create Platform Designer file” is selected by default. This will create a .ptm file using the project name shown in the File name box and cause Platform Designer to open. If desired, you can assign a different name for the .ptm file and select a different directory location.

   Note

   If you added an existing .ptm file to the project in Step 4, the “Create Platform Designer file” option will not be available.

10. Click **Finish**.

    Platform Designer opens within Diamond and loads the .ptm file.

See Also ▶"Opening an Existing Platform Designer Project" on page 117

▶ "Working with Platform Designer Project (.ptm) Files" on page 117

Opening an Existing Platform Designer Project

After you have created a project in Diamond that targets a Platform Manager 2, or a MachXO2HC/HE with external ASCs, or MachXO3LF with external ASCs, or an ECP5U/UM with external ASCs, you can open the Platform Designer project file (.ptm) for the active implementation.

To open an existing Platform Designer project in Diamond:

1. In Diamond, choose **File > Open > Project**, and navigate to the Lattice Diamond file (.ldf) for the Platform Designer project.

   Diamond loads the file and shows the .ptm file in the File List view.

2. Do one of the following:

   - Click the Platform Designer button  on the toolbar or from the Tools menu.

     Platform Designer opens and loads the active .ptm file

   - In the File List view, expand the Input Files folder and double-click the .ptm file that you want to open.

     Platform Designer opens and loads the .ptm file.

See Also ▶"Working with Platform Designer Project (.ptm) Files" on page 117

Working with Platform Designer Project (.ptm) Files

The Platform Designer project file (.ptm) holds all of the Analog Sense and Control settings, as well as the logic and port information, for the active implementation. When you create a new Platform Designer project, the .ptm file is generated automatically by Diamond. You can also add a new or existing .ptm file to your project. The project's .ptm files are maintained in the Platform Design Files folder in the File List view for the active implementation, and the active .ptm file in this folder is displayed in bold. Only one .ptm file can be active for an implementation.

To add a new .ptm file to a Platform Designer project:

1. In the File List view of Diamond, right-click the name of the active implementation, and choose **Add > New File**.
2. In the dialog box, select **Source Files** from the Category list, and then select **Platform Designer File**.

3. Type a name for the new .ptm file. If desired, select a different location for the file by clicking the Browse button.
4. Click **New**.

   Diamond loads the new .ptm file and sets it as the active Platform Designer file for the current implementation.

To add an existing .ptm file to a Platform Designer project:

1. In the File List view of Diamond, right-click the name of the active implementation, and choose **Add > Existing File**.
2. In the “Files of type” list, select **Platform Designer Files** from the drop-down menu.
3. Browse to the location of the desired .ptm file, select it, and click **Add**.

   Diamond loads the .ptm file and sets it as the active Platform Designer file for the current implementation.

To change the active/inactive status of a .ptm file:

1. If the .ptm file that you want to make active or inactive is still open in Platform Designer, close it.
2. Right-click the .ptm file and choose the appropriate command: **Set as Inactive** or **Set as Active**.

Opening an Inactive .ptm File Platform Designer allows you to open an inactive .ptm file to examine the configurations. The inactive file will open in read-only mode, which will enable you to examine each view but not allow any changes. Platform Designer will close the active .ptm file, if it is open, before opening the inactive one. It will also prompt you to save any changes. You will not be able to execute any of the operations in the Build view (such as Compile, Generate JEDEC) when viewing an inactive .ptm.

Saving a .ptm File When you save an active .ptm File, Platform Designer takes all of the configuration changes that are in memory and saves them to the .ptm file. When you use the “Save as” command to save the.ptm file with a different name or to a new location, Platform Designer includes all of the collateral files for the implementation, as well as any changes in memory. You can also use the “Save as” command for an opened inactive .ptm file.

▶ “Platform Designer Flow” on page 113

Working with Platform Designer Editors

The Current, Temperature, Voltage, and Ports & Nodes editors in Platform Designer use a format that is very similar to a spreadsheet. The columns for these editors are arranged in the order of the most commonly used settings. For example, in the Voltage editor, the four most commonly used columns—ASC Device, Pins Monitor/Trim, VMON Schematic Net Name, and Nominal

Profile 0—are positioned first and are locked from horizontal scrolling so that they are always visible for association with other columns and for easy access. The cells of columns that are locked from horizontal scrolling are colored with a light gray background. Columns for less frequently used settings, such as Window Mode, are positioned further to the right and are not locked from horizontal scrolling. The cells of these columns have a white background.

Platform Designer editors differ in a couple of ways from standard spreadsheet formats. In Platform Designer spreadsheets, when you click a cell to enter a value, you click only once and then choose a selection from the drop-down menu or type a value, depending on the type of cell selected. Because of this, navigating from cell to cell by keyboard is slightly different, and copying or cutting and pasting from multiple cells is not supported. The following sub-topics explain how to use the features of Platform Designer editors.

Sort by Columns You can sort the row order by a single column by clicking the column heading. An up arrow in the heading indicates that the rows are sorted in ascending order. Click the heading again to sort the list in descending order.

In the Voltage, Current, and Temperature editors, you can also sort the rows by multiple columns.

To sort by multiple columns:

1. Choose **View** > **Sort t**o open the Sort by Column(s) dialog box.
2. Select the first column to sort by from the “Sort by” drop-down menu. Click Ascending or Descending to control the order of the sorted rows.
3. Use the “Then by” boxes to select additional columns, as well as the Ascending/Descending option for each column. Click **More** to add more “Then by” menus if needed.

   The rows will be sorted first by the column specified in the “Sort by” box and then by the additional columns in the “Then by” boxes in sequence.
4. Click **OK**.

To return to the default layout:

- Right-click any column heading and choose **Default Layout** option. This returns the sorted order to the original view.

Adjust Column Width You can adjust column widths manually or choose the right-click command to fit the column to the text.

To adjust the column width manually:

- Drag the vertical border on the right of a column heading.

To fit the column width to the text, do one of the following:

- Double-click the vertical border on the right of a column heading.

- Right-click the desired column heading and choose **Fit Column**.
- Choose **View > Column > Fit All Columns** to fit all column widths to the text.

Hide and Re-display Columns You can hide a single column in the Voltage, Current, or Temperature editor or select several columns that you want displayed or hidden.

To hide a single column:

- Right-click the desired column heading and choose **Hide Column**.

To hide several columns:

1. Choose **View > Column > Visible Columns** or press Shift+F5 to open the Visible/Hide Columns dialog box.
2. Do one of the following:
   - In the “Show these Columns list,” select the columns that you want to hide, and then click the single-arrow button to move them to the “Hide these Columns” list.
   - Click the double-arrow button to move all columns to the “Hide these Columns” list, and then select those you want displayed by selecting them and moving them to the “Show these Columns” list.
3. Click **OK**.

To re-display some of the hidden columns:

- Press **Shift+F5**, and move the hidden columns back to the “Show these column(s) list.”

To re-display all columns:

- Press **Shift+F5**, and click the double-arrow button to move all hidden columns to the “Show these column(s)” list.

Edit Cell Values The editable cell values in each editor are color-coded blue or black. Blue indicates a default value, and black indicates an edited value. Values that appear in gray are values that cannot be edited, including tool calculated settings or settings that are implied by other areas of the editor.

To edit a single cell value, click once inside the editable cell and enter or select a new value. In the Voltage editor, you can use the Voltage Monitor and Control dialog box to edit the properties for an entire row. See “Setting Multiple VMON/Trim Properties” on page 126.

You can copy or cut a text entry of a single editable cell and paste it into another cell of the same type. You can do this by using the right-click menus or the standard Ctrl+C, Ctrl+X, and Ctrl+V keyboard shortcuts. Copying and pasting multiple cells is not supported.

Right-click a Text-entry Cell to Open the Complete Menu The right-click menu will sometimes vary for text-entry cells, depending on whether you have single-clicked a cell for editing or have highlighted the entire cell. For example, on the Ports sheet, when you single click a Logical Name cell, the text in the cell is highlighted so that you can type a new label. But if you right-click while only the text is highlighted, the menu will display editing commands such as cut, copy, paste, or delete, but it will not include the Add Group or Show In commands.

To access the complete right-click menu for a text-entry cell:

- Right-click a cell without clicking it to highlight the entire cell.
- If you have already single-clicked the cell, press the Enter key to highlight the entire cell.

Navigate from Cell to Cell Because of the convenient one-click access to parameters in the Current, Temperature, Voltage, and Ports & Nodes editors, navigating by keyboard from cell to cell involves an additional small step.

To enable the navigation capability, do one of the following:

- Select a cell in the ASC Device column or the Pin column by single-clicking it.
- If you have already opened an editable cell by clicking it, press **Enter** to highlight the entire cell. If the cell contains a drop-down menu, you might need to press Enter a second time to enable navigation.

Note

If you have single-clicked an editable cell in one of the columns that are locked from horizontal scrolling, you will only be able to navigate among the cells of the locked columns after you press Enter. To enable full navigation afterward, click a cell in the ASC Device column or Pin column, or click an editable cell in a column that is not locked from horizontal scrolling and press Enter.

You can then use the arrow keys to move up and down the cells of a column or across the cells in a row. You can also use the Tab key and the Shift+Tab combination to move forward and back across a row. When you have reached a targeted cell for editing, single-click the cell. To continue navigating afterward, press the Enter key.

Setting Global Options

For a new Platform Designer project, you would normally begin by using the Global Configuration view to configure those features that affect the entire design. This includes device options for operation mode and externally connected components such as dual-boot SPI flash. It includes ASC global options as well as options for each individual ASC of the target chip set.

See Also ▶"Setting ASC Options" on page 122

- "Setting Device Options" on page 123

- "Configuring a SPI Flash Model" on page 124

Setting ASC Options

The ASC options are divided into global ASC options, which affect the entire project, and specific ASC options that affect only a given ASC. Use the left portion of the ASC Options to set the values for each individual ASC, and use the Global ASC Options on the right to set global ASC values.

Options for Each ASC The following options are available for individual ASCs:

- ASC Name – labels the ASC with a unique name that will identify it globally.
- CLT Rate – sets the closed loop trim update rate, in µs or ms.
- I^2C Base Address (ASC0 only) – sets the 4 MSB in the 7-bit I^2C address of ASC0. This base 4 MSB is common for all ASCs in the system. This setting is not available for ECP5U/UM based designs. The I^2C base address is locked to the default value.
- I^2C External Resistor – displays the resistor values that are used by the ASC to set the three LSB of the I^2C address. See the ASC data sheet for more details.
- I^2C Address – displays the full address of each ASC, using the configured base address and the 3 LSB that are set by the external resistor.
- UES Bits – sets a 32-bit user electronic signature for storing unique data inside the ASC. This setting is not available for ECP5U/UM based designs.
- Reset Type – configures the reset type as mandatory or optional. For ASC0, the reset type is fixed to mandatory. Mandatory ASCs have their reset signals tied together on the board. If one of these ASCs needs to be reset, the whole system is reset. Optional ASCs are handled individually and have a dedicated reset signal.
- Reset Source – displays the port defined in the reset source for an optional reset type.

Global ASC Options The following global options affect all ASCs:

- EIA Resistor Standard – limits the resistor selection to the EIA standard selected or, if Exact is selected, calculates the exact resistor values. This value is used by the TRIM calculator in the voltage editor. It determines which resistor values will be recommended by the calculator.
- Open Resistor Threshold – sets the maximum resistor value above which the resistor is treated as an open circuit. This setting is used by the TRIM calculator.
- DC-DC Options
  - DC-DC Library Directory – sets the location for the DC-DC Library. The default directory location is inside the Diamond installation sub-directories.

- Build DC-DC Library – opens the DC-DC Library Builder Wizard, which enables you to add or edit a DC-DC Converter model.

- VID Options
  - VID Tables Directory – sets the location for the voltage ID tables. The default directory location is inside the Diamond installation sub-directories.
  - Build VID Tables – opens the VID Table dialog box, which enables you to add or edit a VID table.
- Voltage, Current, and Temperature Options

  The Voltage, Current and Temperature monitors are populated with default trip points each time a new project is started. The ASC Global Options Default Trip Point Selections allow you to change the default trip points for each of the monitor types at the start of a new project.

See Also "Configuring Voltage Identification (VID) Tables" on page 130

"Defining DC-DC Converter Models" on page 129

Setting Device Options

Select the Device Options tab of the Global Configuration View to configure the operation mode and the external connected components.

Operation Mode Options The Operation Mode section includes the following options:

- Programming Interface:
  - Platform Manager 2 and MachXO2HC/HE, and MachXO3LF: JTAG or I^2C
  - ECP5U/UM: JTAG only.
- Background Programming:
  - Platform Manager 2 and MachXO2HC/HE, and MachXO3LF: None, I2C, or JTAG.
  - ECP5U/UM – JTAG or SPI (Background Programming Interface to SPI Flash).
- 8MHz Clock Source for Device Operation – ASC0 or Global_Clock

External Connected Components The External Connected Components section includes the following options:

- SPI Models Directory – Select a location for the SPI models directory.
- Build SPI Models – Configure a new SPI model and add it to the SPI Models Directory, or edit or delete an existing SPI model.
- Boot Mode – Normal or Dual Boot. When Dual-Boot is selected, the SPI model option will appear. Dual-boot requires that a SPI flash be specified. ECP5 only supports Normal mode - ECP5 dual boot is configured through Diamond Deployment Tool.

- ASC I^2C Write Feature – This feature allows you to configure the I^2C write access to the ASC. This feature is locked to Enabled in the ECP5 solution.
  - When “Disabled” is selected, it prevents writing to the ASC on-chip registers over the I^2C bus.
  - When “Enabled” is selected, it allows writing to the ASC on-chip registers over the I^2C bus.
  - When “Controlled by ASCx_GPIO1” is selected, the ASCx_GPIO1 input is used to control whether I^2C write access is enabled.
  - FPGA Port (External Connection) – This option appears when “Controlled by ASCx_GPIO1” has been selected. You will need to select the FPGA port that will connect to the GPIO1 on all ASCs. Afterwards, the GPIO1 will be changed to “IN” type for each ASC.

See Also “Defining DC-DC Converter Models” on page 129

“Configuring a SPI Flash Model” on page 124

Configuring a SPI Flash Model

You can use the Global Configuration View to add and configure a new SPI flash model or edit a current one. The SPI flash models are saved in the SPI Models directory. The default directory location is inside the current project sub-directories.

To configure a SPI flash model:

1. In the Global Configuration View, select the Device Options tab.
2. In the External Connected Components section on the right, do one of the following:
   - Click **Add/Edit SPI Model** in the Value column of SPI Options.
   - If you are using Dual Boot mode, select **Add/Edit SPI Model** from the Dual-Boot SPI Flash pop-up menu in the Value column.

   The SPI Models Configuration dialog box opens and displays the library of currently available SPI models.
3. Do one of the following:
   - To edit an existing SPI model, select it from the list on the left.
   - To add a new SPI flash model, click **New**, and then select the newly created model from the list.
4. Optionally, give the selected model a unique name, by single-clicking the name and typing a new one.
5. Select the desired values for the Flash Configurations and Flash Opcodes by double-clicking the value cell and choosing from the menu, and then press enter. Click **Apply** to save one or more selected values or to save all the values for a selected model.

6. If desired, select a different SPI flash model from the list, and repeat Steps 4 and 5.
7. When all options have been set for all the models you are configuring, click **OK**.

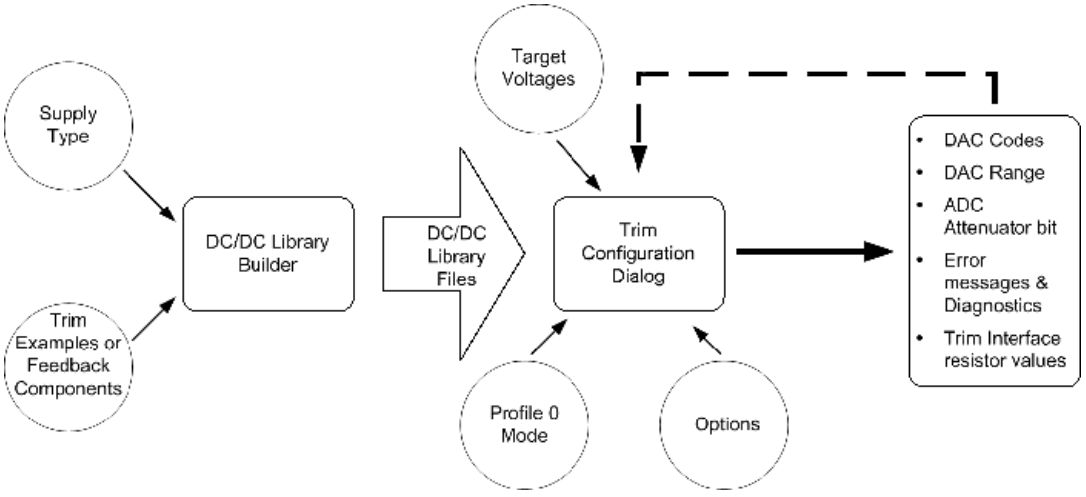
See Also ▶"Setting ASC Options" on page 122

▶ "Setting Device Options" on page 123

Configuring Voltage Sense (VMON) and Control (TRIM)

The Voltage editor enables you to manage voltages and settings related to voltage monitors (VMONs) and trim channels in the Platform Manager 2 or external ASC devices. You can edit a voltage property by clicking the desired cell on the Voltage spreadsheet, or you can use the Voltage Monitor and Control dialog box to edit multiple properties. Double-clicking a VMON/Trim cell in the Pins Monitor/Trim column opens the Voltage Monitor and Control dialog box. From the Voltage Monitor and Control dialog box, you can access the DC-DC Converter Library and the VID Table library.

Setting up the trim and margin capabilities involves the DC-DC Library Builder, which is used to define the voltage adjustment characteristics of the power supply or supplies that you wish to use. The Trim/Margin portion of the Voltage Monitor and Control dialog box is then used to configure each trim channel for the desired power supplies and output voltages. The following diagram illustrates this flow:



Modifications to existing DC/DC library files must be made from within the DC/DC Library Builder Wizard. The DC-DC Converter selection, as well as changes in the desired target voltages, can be made in the Trim/Margin section of the Voltage Monitor and Control dialog box. It is strongly advised that library files not be modified while trim cells are being configured, because

this can create confusion and make it difficult to detect errors in your work. If a “discrete” supply is to be used at several different voltages, a separate library entry for each unique output voltage should be created.

The Trim/Margin dialog enables you to recalculate the trim with a minimum amount of parameter re-entry. Target voltages need to be re-entered only if the desired supply type is changed.

See Also ▶“Defining DC-DC Converter Models” on page 129

▶ “Setting VMON Properties” on page 126

Setting Multiple VMON/Trim Properties

The easiest way to set multiple properties for a selected voltage monitor (VMON) or high-voltage monitor (HVMON) is to use the Voltage Monitor & Control Properties dialog box. The edited settings will then be displayed in the Voltage editor.

To access the Voltage Monitor & Control Properties dialog box:

1. Select the tab in the Voltage editor for those settings that you want to configure.
2. In the Pins Monitor/Trim column, double-click the VMON that you want to configure. Alternatively, right-click and choose **Edit** from the pop-up menu.

   The Voltage Monitor & Control Properties dialog box opens and displays the Voltage, Trim/Margin, or VID section, depending on the tab you selected in the Voltage editor.

The number of tabs available in the Voltage Monitor & Control Properties will depend on whether the selected VMON supports an associated TRIM pin. Most of these properties can also be defined individually on the Voltage spreadsheet.

See Also ▶“Setting VMON Properties” on page 126

▶ “Setting Trim and Margin Properties” on page 127

▶ “Configuring Voltage Sense (VMON) and Control (TRIM)” on page 125

Setting VMON Properties

The Voltage section of the Voltage Monitor & Control Properties dialog box allows you to specify the nominal voltage and the logical names and trip points for each comparator.

- Schematic Net Name – This can consist of any combination of alphanumeric characters.
- Nominal Voltage – This defines both the nominal voltage and the closed loop trim target value for voltage profile 0. If the value is 5.7V or more and the monitor is not an HVMON, the voltage will be used to calculate an

external resistor divider and select an associated trip point. A negative voltage will calculate a divider reference as well as the resistor divider. Acceptable values are from -100 volts to 100 volts.

- Logical Name – The logical names, for comparators A and B, are used in the logic builder to control the sequence and equations based on the VMON status.
- Trip Point Selection – A specific VMON trip point, for comparator A and comparator B, is associated with each logical name.
- 64 µs Glitch Filter – When selected, this option configures the comparator so that supply glitches narrower than 64 microseconds are ignored. The output will transition only if the changed status remains active for a period longer than 64 microseconds. If this option is not selected, the comparator output will toggle within 16 microseconds from the time the voltage transitions through the appropriate trip point.
- Window Mode – To use the window mode, the Comparator B threshold should be lower than the threshold setting of comparator A. The window mode output will replace the comparator A output. The window output is logical high if the Comparator B output is high and the Comparator A output is low (i.e., the voltage monitor reading is between Comparator A and Comparator B).
- External Resistor Divider – This section is used for monitoring a voltage whose highest trip point exceeds 5.70V or is a negative voltage. These values are calculated automatically when the nominal voltage specified is negative or exceeds 5.70V. You can overwrite these values to work with your preferred components.
  - Rsupply – Valid value range is 10 ohms to 10 M ohms
  - Rground – Valid value range is 10 ohms to 15 K ohms. The Rground maximum value is restricted to maintain the accuracy of the voltage monitors.
  - Divider Reference – Valid value range is 2.5 V to 6 V. The divider reference is used when monitoring voltages below ground. The external divider is connected between the negative supply being monitored and a positive reference supply.

See Also ▶"Configuring Voltage Sense (VMON) and Control (TRIM)" on page 125

Setting Trim and Margin Properties

The Trim/Margin section of the Voltage Monitor and Control dialog boxenables you to configure the trim cell operating mode and desired output voltages measured at a voltage monitor (VMON).

- Trim Schematic Net Name – This can consist of any combination of alphanumeric characters.
- Trim Configuration Mode – The Trim Calculator, which is selected by default, calculates resistor interface and DAC values from the target voltages and DC-DC converter.

Manual trim configuration mode allows you to select the CLT loop polarity and to manually enter the DAC code for each voltage profile.

- DC-DC Converter – Select a DC-DC converter model from the drop-down menu. The menu includes all of the models that are in the DC-DC Library. To add a new model, scroll down and select **Add/Edit DC-DC** to open the DC-DC Library Builder Wizard.
- CLT Loop Polarity – If you selected Manual for the trim configuration model, select the polarity for closed loop trim.
- Voltage profile – Enter a desired output voltage for each profile. These profiles are used, along with the nominal voltage profile (profile 0), as the targets for the trim calculator.
- DAC Output Range (BPZ Voltage) – If you are using the Trim Calculator, the bipolar zero output voltage range will be calculated automatically. If you are using manual trim configuration mode, select the value from the drop-down menu.

If you have selected Trim Calculator for the trim configuration mode, click the **Calculate** button after you have made your selections. The dialog box will then provide the following information:

- the resistor values needed to interface the DAC to the TRIM pin in the DC-DC converter
- the voltage that will be achieved with each of the voltage profiles
- the DAC code needed to produce each of the desired output voltages

If a profile target voltage is outside an achievable range, it will be tagged with *Error. To resolve errors, click the **Error Details** button and follow the instructions for obtaining a possible solution.

Setting Trim Configuration Options Use the Trim Configuration Options dialog boxto adjust settings and to help resolve a target voltage error.

Click the **Options** button in the Trim/Margin Properties dialog box to set the following options:

- Maximum DAC Code Range – This setting and the Max Supply Adjustment Range work together to define the sensitivity of the trim system. The value entered defines the DAC value required to trim the supply voltage by the amount specified in the Max Supply Adjustment Range box.
- Max Supply Adjustment Range – This value defines how much the power supply output voltage will change when the DAC code is at the value in the Maximum DAC Code Range box.
- Attenuation Crossover Voltage – If the voltage in Voltage Profile 0 is greater than the voltage in the Attenuation Crossover Voltage text box, the DAC input attenuator will be enabled. The attenuation crossover voltage should be selected so that the attenuation bit is turned on if any portion of the trim range is over 2.048 volts. The default value of 1.9 volts is appropriate in most cases.

- Vbpz Selection – When Auto is selected, the bi-polar zero output voltage is calculated automatically to reach all the target voltages. Selecting one of the other voltages (0.6V, 0.8V, 1V, or 1.25V) can sometimes reduce the number of resistors.

See Also ▶"Configuring Voltage Sense (VMON) and Control (TRIM)" on page 125

Defining DC-DC Converter Models

The DC-DC Library Builder Wizard enables you to define the voltage adjustment characteristics of DC-DC converters and voltage regulators. This information is stored in a library so that any given model of DC-DC converter can be used in multiple trim cells or Platform Designer projects without having to re-enter the information each time.

You can add new DC-DC converter models to the library, delete models, or edit the parameters of a model at any time by launching the wizard. Any converter model in the library can be selected in the Trim/Margin portion of the Voltage Monitor and Control dialog box.

You can launch the DC-DC Library Builder Wizard from the Global Configuration view or from the Voltage Monitor and Control dialog box.

To launch the DC-DC Library Builder Wizard from the Global Configuration View:

1. In the Global Configuration view, select the ASC Options tab.
2. In the DC-DC Options section of Global ASC Options, click **Add/Edit DC-DC**.

To launch the DC-DC Library Builder Wizard from the Voltage Monitor and Control dialog box:

1. In the Voltage view, select the Trim/Margin tab.
2. Double-click a cell in the DC-DC Converter column or a VMON/Trim cell in the Pins Monitor/Trim column.
3. In the Voltage Monitor and Control dialog box, click the DC-DC Converter drop-down menu.
4. Scroll down and choose **Add/Edit DC-DC**.

The DC-DC Library Builder Wizard provides the option of creating a new entry in the library (using the New button) or modifying an existing entry. The flow for both operations is similar, the only exception being that when an existing entry is being edited, the previously saved parameters appear in the different dialog box sections of the Wizard.

To define a DC-DC converter model:

1. In the DC-DC Converter Model Selection, select a model from the list, or click **New** to add a new model.

The Library Builder classifies all DC-DC converters and regulators into four different families:

- Supplies that can be adjusted up or down a few percent about a nominal voltage by connecting a resistor between the supply's TRIM pin and its output or ground.
- Supplies that can be adjusted over a wide range by connecting a resistor between the supply's TRIM pin and ground.
- Supplies that can be adjusted over a wide range by connecting a resistor between the supply's TRIM pin and Vout.
- Supplies that use an external feedback network. The Library Builder calls this a "discrete" implementation.

2. Click **Next** to open the Select the type of DC-DC Converter section.
3. Select the type of DC-DC Converter and click **Next**.

   The wizard opens the configuration section of the dialog box, which enables you to set the parameters for the type of converter you selected.

   For the Trim-up Trim-down supply type and the Programmable supply type, the dialog box asks for several trimming examples to be entered, and the supply's adjustment characteristics are determined from the data. Many power supply data sheets provide tables of resistor values needed to achieve various different outputs. These examples can be entered directly into the dialog box.

   For discrete implementation types, the dialog box requests the values of the feedback network components and the internal reference voltage. From the data, the supply's adjustment characteristics are determined. When a specific model of voltage regulator will be used several times to produce different voltages, separate library entries will be needed for each unique set of feedback network components.
4. After setting the configuration parameters, click **Finish**.

See Also "Setting Multiple VMON/Trim Properties" on page 126

"Setting VMON Properties" on page 126

"Setting Trim and Margin Properties" on page 127

Configuring Voltage Identification (VID) Tables

Voltage identification tables define the target voltage outputs of a DC-DC converter based on inputs of a selected bus. The VID section of the Voltage Monitor and Control dialog box enables you to select and configure a VID table for the selected voltage monitor. If your design does not yet contain VID tables, you can build them and add them to the VID Table Library.

Building VID Tables The Voltage – VID Table Library interface enables you to build a library of voltage identification tables. By default, Platform Designer stores the VID tables inside the Diamond installation sub-directories. You can specify a different location in the Global ASC Options section of the Global Configuration View.

To create a new VID table:

1. In the Voltage editor, open the VID Table library dialog box by using one of the following methods:
   - Open the Voltage Monitor & Control Properties dialog box by double-clicking the VMON/TRIM cell. Select the VID tab, and choose **Add / Edit a table** from the VID Lookup Table drop-down menu.
   - In the Global Configuration View, select the ASC Options tab. In the VID Options section on the right, click **Add / Edit a table**.
2. In the VID Table Library dialog box, click **New** to open the Create New VID Table dialog box.
3. Type a name for the VID table in the text box, and then select the table size from the drop-down menu.
4. In the Auto fill section, specify a voltage starting value and step size.

   Alternatively, you can manually enter each value in the table by double-clicking each Voltage (V) cell and typing a value. If you choose manual entry, skip Step 5.
5. Select either the Top Down or Bottom Up option, and then click **Fill**.

   Platform Designer fills in the voltage for each VID value, based on the step size and starting value. You can edit any of these values as desired.
6. Click **OK**.

   The new VID table is added to the VID Library and will be listed in the VID Table menu in the Voltage editor and in the Voltage Monitor & Control Properties dialog box.

Selecting and Configuring the VID Table The VID page of the Voltage editor enables you to select the VID lookup table from the VID Table Library and select the bus, strobe port or node, and VID strobe edge. You can also select and configure the VID table from the Voltage Monitor & Control dialog box.

Editing a VID Table To edit a VID Table, open the VID Table library dialog box by using any of the methods described in Step 1. Select a VID table and click **Edit**. In the Edit the VID Table dialog box, change the settings as desired and click **OK**.

See Also "Configuring Voltage Sense (VMON) and Control (TRIM)" on page 125

Configuring Current Sense (IMON)

The Current editor allows you to set parameters for the current monitor (IMON) and high-voltage current monitor (HIMON) for each Analog Sense and Control device. Each monitor includes settings for two precision comparators (A and B) and one fast (F) comparator.

- Schematic Net Name – Each IMON or HIMON must be identified by a unique name. The name can consist of any combination of alphanumeric characters.
- Logical Name – The monitor's comparator outputs A, B, and F must each be identified by a unique name. The name can consist of any combination of alphanumeric characters.
- Sense Resistor (Ohm) – The sense resistor value will be the same for all comparators within the monitor and can range from .0001 to 1000000.0 ohms.
- Trip Point Selection (Amps) – The selected trip point, for comparators A, B, and F, will be associated with each logical name. The trip points available are determined by the Sense Resistor value.
- Hysteresis – Hysteresis can be enabled or disabled for comparators A and B. This automatically updates the available trip point selections.
- Glitch Filter (µ) – The glitch filter can be enabled or bypassed for comparators A and B. When Yes is selected, this option configures the comparators so that supply glitches narrower than 64 microseconds are ignored.
- Window Mode – Window mode can be used for comparators A and B. To use the window mode, the Comparator B threshold should be lower than the threshold setting of comparator A. The window mode output will replace the comparator A output. The window output is logical high if the Comparator B output is high and the Comparator A output is Low.
- Low Side Sense – When Yes is selected, this sets the low voltage side sense for comparators A, B, and F. It is not available for high-voltage sense monitors.

The Programmable Gain Amplifier (PGA) Gain setting is displayed by the tool based on the selected trip points. This information is used when performing A/D measurements of the current over I^2C.

The V-Drop (V) and Peak Power (W) are calculated based on the values entered for trip point and sense resistor.

See Also "Configuring Voltage Sense (VMON) and Control (TRIM)" on page 125

Configuring Temperature Sense (TMON)

The Temperature editor allows you to set parameters for the external temperature sensor interfaces (TMON1, TMON2, etc) and the internal temperature sensor (TMON_Int). The temperature monitor function includes

an A/D converter measurement with averaging support, as well as an alarm monitor function with programmable hysteresis and filtering. Each TMON channel includes two separate programmable comparison points. The temperature sensor hardware also supports a configurable offset and ideality factor. The parameters for each temperature monitor comparator can be set in Platform Designer's Temperature editor, as follows:

- Schematic Net Name – The schematic net name must be unique and can consist of any combination of alphanumeric characters.
- Logical Name – This must be a unique name that will identify each TMON pin and comparator output. It can consist of any combination of alphanumeric characters.
- Monitoring Type – Over temperature (OT) or under temperature (UT) monitoring can be selected.
- Trip Point Selection – This sets the trip point for the comparator in degrees Celsius.
- Hysteresis – This defines the hysteresis for updating the trip point output for the comparator.
- Monitor Alarm Filter (Depth) – This sets the number of consecutive alarms that must be detected before setting the comparator output high.
- Measurement Averaging (Filter Coefficient) – This sets the coefficient on the averaging filter implemented on the temperature sensing of the TMON.
- Offset – This calibration value is used to correct the temperature reading, in degrees Celsius for the TMON.
- Short Fault Measurement Reading – This defines the measurement reading under a short fault condition. It implies the Open fault measurement reading as well. See the Platform Manager 2, MachXO2HC/HE, or MachXO3LF data sheet for more details.
- Ideality Factor – This calibration value is used to correct the diode imperfection for the TMON.
- Sensor Configuration – The external temperature monitors can be configured to interface with several different transistor circuits.

See Also ▶"Configuring Fan Control" on page 133

- "Configuring Voltage Sense (VMON) and Control (TRIM)" on page 125

Configuring Fan Control

Platform Designer's Fan Controller provides fan control for 2-wire, 3-wire, or 4-wire fans. The fan controller supports multiple fan speeds, under-speed alarm detection, and a configurable startup pulse. It enables you to set three levels of speed control through the pulse width modulated (PWM) signal. Up to 18 separate fans can be controlled.

To configure fan control:

1. Select **Fan Controller** from the menu pane, and then select a fan in the "Fan in System" list or add a new fan by clicking the add button  on the lower left.
2. In the Type Setting section on the Parameters page, select the fan type from the drop-down menu.
3. If you selected 3 Wire (Low Side Drive), 3 Wire (High Side Drive), or 4 Wire, also specify the **Sense Type** for alarm detection, as follows:
   - If the fan supports a locked signal as fan feedback to indicate that the fan is locked or stuck, select **Alarm (Active High)** or **Alarm (Active Low)**.
   - If the fan includes a tachometer feedback signal, select **Tach** (2 Pulses/Rev), and then do the following:
     - In the Alarm Interval box, type a value for the number of ms that will be allowed between pulses before an under-speed violation is registered.
     - Select a value between 1 and 10 from the Alarm Filter Count. This is the number of times the alarm interval must be detected before the Alarm signal will be asserted.

     With tachometer feedback, a +/- 10% hysteresis will be applied to the corresponding assertion/de-assertion of the failure count to prevent a false alarm.
4. In the PWM Setting section, use the sliders to select a duty cycle percentage for Speed3, Speed2, and Speed1.

   Each can be set in 5% increments, ranging from 5% to 95%. The fastest speed must be assigned to Speed3, with the middle speed assigned to Speed2, and the slowest speed assigned to Speed1.
5. Use the slider to specify the PWM frequency. The frequency can be set in increments of 0.8 kHz, up to 80.0 kHz.
6. Select the polarity for the PWM signal, based on the nature of the MOSFET switch and on-board buffers.

   Refer to the fan data sheet and the board requirements for information about the correct setting of PWM polarity.
7. Optionally, enable the Startup Control and select the pulse duration, in increments of .25s for the startup period.

   When startup control is enabled, the fan controller will send a kickstart pulse of the chosen duration to the fan before switching to the selected PWM setting.
8. Select the InterConnections tab.

   The InterConnections page allows you to specify the signals that the Platform Designer will use as fan controller ports. Each fan has an independent set of interconnections.

   The PWM Out and Tach/Alarm Sense are the external connections to the fan. The other signals (Speed Sel 1 ... Alarm Out) are logical connections that set the operation of the fan controller during runtime.

9. Assign the PWM Out and Tach/Alarm Sense to external ports by dragging the desired ports from the Signal Pool.
10. Drag the desired signals from the Signal Pool to set the logical connections for Speed Sel, Run Off, Run Full, and Alarm Out.

See Also ▶"Configuring Temperature Sense (TMON)" on page 132

▶ "Configuring Voltage Sense (VMON) and Control (TRIM)" on page 125

Setting Fault Logging Options

The Fault Logger, available from the Components section of the menu pane, enables you to specify and configure fault conditions that are logged to non-volatile memory. You have the option of using standard fault logging that is based on voltage, current, and temperature status; or using the full-featured fault logging. By default, fault logging is disabled.

Each ASC device contains a block of EEPROM memory that can be used for either the V, I, T Fault Log or for User Tag Operation. The User Tag Memory is enabled automatically when fault logging is disabled or when full-featured fault logging is selected. It is disabled when V, I, T fault logging is selected.

V, I, T Fault Logging When you select this option, the Analog Sense and Control device will log the voltage (V), current (I), and temperature (T) status when a fault is detected. The V, I, T fault log supports the logging of 8 signals per Analog Sense and Control device, in addition to the V, I, T signals. These can be digital I/O or other signals.

To configure V, I, T fault logging:

1. In the Fault Logger, select **Enable V, I, T Fault Log** from the options shown at the top left.
2. Select a signal name from the Fault Logging Trigger Signal Name drop-down menu. This signal can be an output from the user logic, an external digital I/O, or a specific monitor alarm signal.
3. In the "Basic Configuration" section, select the type of memory to log to: EEPROM or SRAM. The EEPROM is non-volatile, but a log takes longer to execute. The SRAM memory is volatile but is executed more quickly.
4. The V, I, T fault log supports the logging of 8 signals per Analog Sense and Control device in addition to the V, I, T signals. These can be digital I/O or other signals. For each signal that you want to log, drag it from the "User Signals to Log" list over to a D cell of the desired ASC.

Full-Featured Fault Logging The full-featured fault logging uses either the UFM Flash memory within the device or an external SPI flash memory. Full-featured fault logging is available for Platform Manager 2 LPTM21 devices and for MachXO2HC/HE devices of 1200 and above, and MachXO3LF devices. ECP5U/UM device support full-featured fault logging with external SPI flash memory only - UFM is not available in ECP5U/UM.

To configure full-featured fault logging (Platform Manager 2, MachXO2HC/HE, and MachXO3LF only):

1. In the Fault Logger, select **Enable Full-Featured Fault Log** from the options shown at the top left.
2. Select a signal name from the Fault Logging Trigger Signal Name drop-down menu. This signal can be an output from the user logic, an external digital I/O, or a specific monitor alarm signal.
3. n the “Basic Configuration” section, do the following:
    a. From the drop-down menu, select the contiguous ASCs that you want logged.
    b. Select **Include Timestamp** if you want Platform Designer to include a 32-bit timestamp timer.
    c. Select a signal to be used as the busy signal name from the “Busy” Signal Name menu. This signal is an output from the fault logger and can be used to inform the user logic that a fault log recording is in progress.
    d. Select a “Log to” option: the on-chip UFM memory or external SPI flash.
    e. If you selected External SPI Flash as the “Log to” option, use the Model drop-down menu to select the external flash model to be used for fault logging.
4. In the User Log Fields menu, located above the user log table on the right, select the number of additional bits to record in the fault log.
5. For each additional signal that you want to log, drag it from the “User Signals to Log” list over to a D cell of the desired user log column.

To configure full-featured fault logging (ECP5U/UM only):

1. In the Fault Logger, select **Enable Full-Featured Fault Log** from the options shown at the top left.
2. Select a signal name from the Fault Logging Trigger Signal Name drop-down menu. This signal can be an output from the user logic, an external digital I/O, or a specific monitor alarm signal.

    Select a signal to be used as the busy signal name from the “Busy” Signal Name menu. This signal is an output from the fault logger and can be used to inform the user logic that a fault log recording is in progress.
3. In the “Basic Configuration” section, do the following:
    a. From the drop-down menu, select the contiguous ASCs that you want logged.
    b. Select either Disable Time Stamp, Internally Generated Time Stamp, or Externally Assigned Time Stamp. The internally generated timestamp option includes the 1s per bit, 32-bit timestamp. The externally assigned timestamp option will automatically update the Nodes view to include a 32-bit node group, called FL_Timestamp, which can be assigned by the user based on an external, highly accurate timestamp.

c. In SPI Memory Configuration, select Log to Configuration SPI Memory or Log to Alternate SPI Memory.

d. Use the Model drop-down menu to select the external flash model to be used for fault logging.

4. In the User Log Fields menu, located above the user log table on the right, select the number of additional bits to record in the fault log.

5. For each additional signal that you want to log, drag it from the “User Signals to Log” list over to a D cell of the desired user log column.

6. In the “Fault Log Memory Space” section, do the following:

a. Enter the Start Address. This is a Hex input used by the IP to determine the starting address available to the fault logger. This setting allows the user to share the SPI memory with multiple boot images or other information. The default address is 0x030000.

b. Enter the size in K Bytes.

c. The End Address is automatically calculated and displayed by Platform Designer. The displayed value confirms for the user that it is safe to share the SPI memory with multiple boot images or other information.

7. The full-featured fault logger automatically adds a 16-bit node group called FL_Record_Counter to the nodes view. This nodes group can be connected to user logic to provide the number of Fault Records currently stored in memory.

See Also ▶“Configuring a SPI Flash Model” on page 124

Configuring Hot Swap

(Platform Manager 2. MachXO2HC/HE, and MachXO3LF only.) Platform Designer's Hot Swap utility enables you to configure a hot swap component that will control the in-rush current in applications where power is rapidly applied, such as a circuit board that is plugged into a backplane. The Hot Swap utility contains a separate page for each of the following three tasks:

- Hot Swap – Specify the settings of a hot swap component.
- Interface – Connect the hot swap component to the Platform Manager 2 resources.
- InterConnections – Connect the hot swap component to the hardware management logic.

To specify the settings of a hot swap component:

1. Select **Hot Swap** from the Components section of the menu pane.
2. On the Hot Swap page, select a hot swap component from the list or create a new hot swap component by clicking the add button  on the lower left.
3. Specify the desired options and settings:

- Input Supply
  - V_{IN} – Input voltage. This is the supply voltage input, which is used to charge C_{LOAD}. Together with I_{MAX}, C_{LOAD} and the MOSFET SOA (Safe Operating Area) information will be used to calculate the hot swap parameters, including the number of phases, voltage and current trip points.
  - I_{MAX} – Maximum current available from the input supply.
- MOSFET Parameters
  - Load/Supply – Allows you to place the MOSFET at either the Supply or the Load. Select the setting that matches your application.
  - MOSFET Name – Used, for informational purposes only, to track the part number of the MOSFET in your application.
  - V1/A1 – Voltage/Current data point pair from the MOSFET SOA curve found in the MOSFET datasheet.
  - V2/A2 – Voltage/Current data point pair from the MOSFET SOA curve. V1 must be greater than V2, and A1 must be less than A2.
- Current Sensing Configuration
  - R_S – Sense Resistor used in the application. Platform Designer uses this sense resistor value to calculate available current sensing trip points.
  - Current Sense Amp choices – Determines the current sense amp circuit used in the application.

    The choice among “External and VMON,” “External and IMON,” and “IMON (Internal)” will determine whether additional current sensing circuit information is required. The choice also determines which monitor circuits are available for assignment in the Interface tab. Certain configurations of V_{IN} and Current Sense Amp are prohibited, such as using IMON (Internal) with V_{IN} voltages above 13.2V.
  - Low Side option – Determines whether the IMON is used in a near ground hot swap application (such as -48V). Selecting this option enables the Low-Side Sense feature in the IMON circuit.
- Hot Swap Settings
  - C_{LOAD} – The load capacitor charged up during the hot swap operation. This value is used to calculate the hot swap parameters, including the number of phases and the voltage and current trip points.
  - Fast Shutdown Limit – Sets the current limit for fast shutdown during hot swap. The menu is automatically populated with available current limit trip points related to the Sense Resistor and Current Sense Amp settings. If the current exceeds the selected limit during hot swap, the hot swap will be aborted and the over current error signal will be asserted. This feature can be disabled by selecting “None.”

- Cooldown Period – The period used by the hot swap algorithm to ensure that the MOSFET does not overheat. Each time the hot swap algorithm detects a timeout, remaining in a phase longer than 10 ms, the cooldown period will be used as a wait time prior to resuming the hot swap operation.
- Hot Swap Name – A user-defined name for the hot swap setup.

4. After all the parameters have been selected, click the **Calculate** button.

   The V_{LOAD} and I_D graphs are updated with the estimated Voltage and current profiles based on the calculated Hot Swap algorithm and settings. The Results/Comments area is updated with information, including the number of hot swap phases and the number of VMON and IMON channels required to support the hot swap implementation.

   The hot swap calculation might not be able to provide a solution for all circuit configurations. In this case, error information is displayed in the Diamond message console.

5. If the results are not satisfactory, adjust the settings and calculate again.

To connect the hot swap component to Platform Manager 2 resources:

1. After you are satisfied with the hot swap calculation results, select the **Interface** tab.

   The Interface page consists of several menus that are used to assign VMONs, IMONs, HVOUT, GPIO and PIO channels to the different hot swap functions. When you assign VMON, IMON, and HVOUT channels in the Interface tab, their settings, such as trip point thresholds, will be updated automatically.

2. Select the desired setting from each of the drop-down menus in the gold-colored boxes, as follows:

   - V_{IN} Monitor – Associates a VMON channel with the input voltage monitoring function of a given hot swap. This VMON channel can be re-used across multiple hot swap components, if they use the same input voltage. The V_{IN} Monitor can be from any ASC in the Platform Manager 2 system.

     Selecting a V_{IN} Monitor is mandatory.

   - ASC – Specifies the ASC device to be used. The ASC menu is automatically populated with the ASCs used in the system. All channels from the drop-down menus inside the pink rectangle will be selected from the chosen ASC.
   - MOSFET/Charge Pump Driver – Associates an HVOUT or GPIO with the controlled output signal used in the hot swap algorithm.

     Selecting an HVOUT or GPIO is mandatory.

   - Current Sensing Monitor – Specifies the IMON or VMON channel for current sensing. The channels available are those that support the configurations that were set on the Hot Swap page.

     Selecting a current sensing monitor is mandatory.

- Fast Current Sense Monitor – Specifies an IMON or VMON channel for fast current sense. This menu is used only when a fast shutdown limit is selected on the Hot Swap page. It is used in conjunction with the fast current sense output, fast path input, and fast shutdown signal.
- Fast Current Sense Output – Specifies an HVOUT or GPIO as a fast output signal. This menu is populated with the output signals available on the ASC.
- Fast Path Input – Specifies a signal for fast path input. This menu is populated with the PIO signals from the FPGA I/O used in the Platform Manager 2 system. The signal should be externally connected to the fast current sense output signal in the application.
- Fast Shut Down Output – Specifies a signal for fast shutdown output. This menu is populated with the PIO signals from the FPGA I/O used in the Platform Manager 2 system. The signal is controlled by the hot swap IP and will perform a fast shutdown of the MOSFET when necessary.
- Load Voltage Monitor(s) – Specifies the load VMON or HVMON. This menu is populated with the voltage monitor channels from all ASCs in the Platform Manager 2 system. The number of drop-down menus available is determined by the number of phases required by the hot swap algorithm. These menus can be filled with voltage monitor channels from any ASC in the system.

  Selecting a load voltage monitor from each available menu is mandatory.

To connect the hot swap component to the hardware management logic:

1. Select the **Interconnections** tab.

   The Interconnections page includes a set of control signals that are used to connect the hot swap component to the hardware management logic. Each of these signals is typically assigned to a node.

2. Drag the desired signal from the Signal Pool over to the appropriate box, as follows:

   - Hot Swap Enable – Input signal to the hot swap component. Asserting this signal high will start the hot swap operation.
   - Over-Current Clear – Input signal to the hot swap component. This signal needs to be asserted to clear any existing Over-Current Error status.
   - Hot Swap Done – Output signal from the hot swap component. This signal is asserted by the hot swap component to inform the hardware management logic that the hot swap operation was successfully completed. This signal is cleared when the hot swap enable signal is asserted again.
   - Hot Swap Error – Output signal from the hot swap component. This signal is asserted by the hot swap component to inform the hardware management logic that an error occurred during the hot swap

operation. This signal is cleared when the hot swap enable signal is asserted again.

- Over-Current Error – Output signal from the hot swap component. This signal is asserted by the hot swap component to inform the hardware management logic that an overcurrent error occurred during the hot swap operation. This is in addition to the fast path shutdown behavior. This signal will be cleared when the over-current clear signal is asserted.

Configuring PMBus Adapter

(Platform Manager 2, MachXO2HC/HE, and MachXO3LF only.) PMBus is a serial communication bus that allows a microcontroller to configure and monitor Digital Point of Load (DPOL) DC-DC Converters. The PMBus Adapter allows the connection of analog POLs to the PMBus controller using the FPGA and ASC. Multiple POLs may be mapped to different pages configured in the PMBUS adapter. Dedicated pages for voltage, current, and temperature monitoring are provided.

The PMBus adapter supports Packet Error Checking and SMBAlert options. The PMBus adapter supports a pre-defined subset of PMBus commands.

To configure PMBus Adapter:

- In the PMBus Adapter tab, select **Enable PMBus Adapter** at the top left.

  The PMBus tab contains controls and the ASC Page Mapping table control. When **Enable PMBus Adapter** is checked, controls and the related PMBus Nodes tab are enabled. To view PMBus ports and nodes, refer to “Viewing PMBus Ports and Nodes (Platform Manager 2, MachXO2HC/HE, and MachXO3LF Only)” on page 143.

The following options are available to configure PMBus Adapter:

Enable packet Error Checking (PEC) Enables/disables the packet error checking option.

Enable SMBAlert Enables/disables the SMBAlert output pin..

PMBus Bus Speed Specifies PMBus bus speed. The two available values are 100KHz and 400KHz.

PMBus Slave Address Specifies PMBus slave address. Only legal slave addresses are selectable from the drop-down list.

ASC Page Mapping Specifies the PMBus page mapping of voltage monitors (VMONs), Current Monitors (IMONs) and Temperature Monitors (TMONs) of the ASC devices in the design. The resource list view on the left contains the VMON , IMONs, and TMON signals that are part of the current design. The user can drag and drop the VMON. IMON, and TMON signals from the resource list view and assign them to PMBus pages on the right.

VMON, IMON, and TMON signals can be assigned to page numbers as follows:

- VMON - 0x00-0x2F
- IMON - 0x30-0x3F
- TMON - 0x40-0x5F

The default values on the ASC page mapping table views is None. When the user drags the VMON, IMON, or TMON signals from the resource list on the left and drops it in the table view, a dynamic design rule check (DRC) is performed in the background to verify whether the assigned page is valid or conflicts with already assigned pages.

Implementing the Platform Management Algorithm

Implementing the platform management algorithm involves labeling and configuring ports and nodes, and then building logic instructions based on these configurations. In Platform Designer, it involves the use of the Ports & Nodes editor and the Logic editor.

See Also ▶"Designing Control Sequences" on page 148

Configuring and Viewing Ports and Nodes

Use the Ports & Nodes editor to view internal nodes and configure external signals (ports) of the Platform Manager 2, MachXO2HC/HE, MachXO3LF, ECP5U/UM device; configure and label the ASC-based general-purpose I/Os; view PMBus Ports and Nodes; and label and configure the high-voltage output ports. You can build control logic based on the labels you apply.

See Also ▶"Designing Control Sequences" on page 148

Configuring Ports

The Ports section of the Ports & Nodes editor shows all physical FPGA-based PIOs that are available for use as external connections to the design.

You can assign a user label to a logical port. A port requires a type: IN, OUT, INOUT or GRESET. The port also includes attributes for group, register type and reset level.

For register type, in addition to Registered or Combinatorial, you have the option of using "Registered Sync with ASC." The MachXO2HC/HE, MachXO3LF, ECP5U/UM device output is much faster than the ASC output because of the 3-wire interface propagation delay. So when you select the "Registered Sync with ASC" option, Platform Designer will add a delay for

MachXO2HC/HE outputs to make sure that they are triggered in the same step.

After the design is compiled, you can cross-probe from the Ports sheet to Diamond's Spreadsheet View or Netlist View to make pin assignments. Right-click a cell and choose **Show In > Spreadsheet View** or **Show In > Netlist View**.

Viewing PMBus Ports and Nodes (Platform Manager 2, MachXO2HC/HE, and MachXO3LF Only)

The PMBus tab is enabled only if the PMBus Adapter is enabled. For information on enabling PMBus Adapter, refer to "Configuring PMBus Adapter" on page 141.

The PMbus tab lists all of the available PMBus ports/nodes that can be connected to the Logic Controls, including Sequence, Supervisory equation, and HDL Import. These nodes are managed in the user logic in order to complete the configurable PMBUS support.

The PMBus ports/nodes table view includes three read-only columns:

Logical Name/Function The node names listed in this column are the nodes that are added to the user signal pool and which connect the logic to the PMBus Adapter for support of PMBus commands..

Grouped By This column lists the PMBus status word or byte name with the correct bit index. Nodes that are not used are set to zero.

Logic Connection This column shows the node direction with respect to the user logic; In goes into the user logic and Out is driven from the user logic.

See Also ▶"Creating a Port Group" on page 143

- "Designing Control Sequences" on page 148
- "Working with Platform Designer Editors" on page 118

Creating a Port Group

The group feature allows you to combine ports of a common type, using vector notation, to form a bus. The selected ports cannot be shared among multiple groups.

To create a port group:

1. On the Ports sheet or the Nodes sheet, right-click any cell of a port or node that is not already part of a group and choose **Add Group** from the pop-up menu.
2. In the New Group dialog box, type a name for the group in the Group Name text box.

3. From the Available Ports list, select the ports that you want to include in the group, and then click the > button to place the ports in the Selected Ports list.
4. Click **Add**.

To modify a port group:

1. Right-click a cell in the Group By column that references the port group you want to edit and choose **Modify Group** from the pop-up menu.
2. In the Modify Group dialog box, use the appropriate buttons to add ports to the Selected Ports list or remove them from the list.
3. Click **Update**.

To remove a port group:

- Right-click any cell and choose **Remove Group**. From the sub-menu, select the group you want to remove.

See Also "Designing Control Sequences" on page 148

- "Working with Platform Designer Editors" on page 118

Configuring Nodes

The Nodes sheet enables you to add and configure internal nodes in your design. You can assign user labels to new and existing nodes and select the register type and reset level attributes.

To add a node:

1. Press the Insert key, or right click an existing node and choose **ADD NODE**.
2. Assign a unique name to the node and select the Register Type and Reset Level.

To delete one or more nodes:

- Highlight the rows you want to delete by selecting the row numbers in the first column, and then press the Delete key. Alternatively, right-click and choose **REMOVE NODE(s)**.

Nodes can also be grouped, following the same process as described in "Creating a Port Group" on page 143.

Some nodes are automatically allocated to the component logic or other features such as fault log enable and timers.

See Also "Designing Control Sequences" on page 148

- "Working with Platform Designer Editors" on page 118

Configuring General-Purpose I/Os

The GPIO sheet allows you to enable and assign a user label to an ASC-based general purpose I/O.

For each GPIO pin, you can specify the following:

- A unique name to identify the pin.
- The type: IN or OUT
- Reset Level: Set High or Set Low

For pins GPIO2 and GPIO3 of each ASC, you can also select the following:

- Source
- Polarity: True or Inverted

See Also "Designing Control Sequences" on page 148

Configuring High-Voltage Outputs

The HV Outputs sheet allows you to enable and assign a user label to a high-voltage output port.

For each HVOUT pin, you can specify the following:

- A unique logical name to identify the HVOUT pin.
- The output setting: Charge Pump or Open Drain
- The target voltage for the output (Charge Pump mode only)
- The source current in micro-amps for the output (Charge Pump mode only)
- The sink current in micro-amps for the output (Charge Pump mode only)
- The output mode: Static or Switched
- The selected frequency for the ouput in kHz (Switched mode only)
- The duty cycle for the output (Switched output mode only)
- The output source
- The output polarity: True or Inverted
- A high or low reset level

Designing with the Logic Editor

Included with the Lattice Diamond Platform Designer is the LogiBuilder™ Logic editor, which enables you to define a power supply sequence controller and monitor or other control circuits for implementing the platform management algorithm. The tools include a set of instructions for building the sequence based on conditional events and timer delays.

See Also

- “Designing Control Sequences” on page 148
- “Sequence Controller Instruction Set” on page 147

About the Logic Editor

The Logic editor simplifies the design process by allowing you to select from menus instead of writing complex code. It enables you to add and configure timers and import HDL modules. It also supports vector notation for bus structures.

After entering the set of instructions, you can compile the design and simulate the sequence or control events. When the design is compiled, synthesizable HDL code is generated based on the sequencer and supervisory logic.

- “Designing Control Sequences” on page 148
- “Sequence Controller Instruction Set” on page 147

Logic Editor User Interface

The LogiBuilder Logic editor includes separate views for building the logic instructions and exceptions, entering supervisory equations, and defining timers. An additional view is provided that allows you to import HDL modules into your design.

- Sequence – The Sequence view enables you to define the step-by-step instructions for controlling outputs for a selected state machine. When compiled, sequencer instructions implement a digital logic state machine within the PLD core.
  - Exceptions – The Exceptions section allows you to define equations that will trigger sequence controller exceptions to modify outputs and jump out to an alternative sequence step. Exceptions can be selectively applied to any sequencer step. When compiled, exception instructions are merged with the digital logic state machine of the PLD core.
  - State Machine – A tab for each state machine is shown at the bottom of the Sequence view, which allows you to select the active state machine for editing. You can also add a new state machine by clicking the **+** tab. Right-click a state machine tab to open the Multiple State Machine dialog box, which enables you to add and delete state machines.
- Supervisory – The Supervisory view enables you to define combinatorial and registered logic independent of the sequencer control logic. When compiled, supervisory equations are concurrent to the digital logic state machine of the PLD core.
- Timers – The Timers view enables you to define timers for control sequences. To add a new timer, press the Insert key or click the **Add** button.

- Imported HDL – The Imported HDL view enables you to add HDL modules from HDL source that is included in the design project.

See Also "Designing Control Sequences" on page 148

- "Managing Multiple Control Sequences" on page 149.
- "Entering Supervisory Equations" on page 154
- "Defining Timers" on page 150
- "Sequence Controller Instruction Set" on page 147

Sequence Controller Instruction Set

The LogiBuilder Logic editor of Platform Designer provides the following instructions for designing control sequences:

BEGIN STARTUP SEQUENCE The BEGIN STARTUP SEQUENCE instruction signals to LogiBuilder that any instructions past this point may be interrupted by jumps specified in exceptions. This instruction may be deleted from a sequence, but not inserted.

OUTPUT The OUTPUT instruction is used to turn on or turn off the output signals. A single OUTPUT instruction can be used to simultaneously change the status of any number of output signals.

WAIT FOR <Boolean Expression> The WAIT FOR <Boolean expression> instruction suspends execution of the sequence until the specified expression becomes TRUE. Outputs can be assigned in this instruction. These outputs are asserted as soon as the sequencer enters the instruction.

WAIT FOR <Boolean Expression> with Timeout The WAIT FOR <Boolean expression> with Timeout instruction suspends execution of the sequence until the specified expression becomes TRUE or the selected timer expires. The timer is started when the sequence enters the instruction.

WAIT FOR <timeout> The WAIT FOR <timeout> instruction is used to specify a fixed delay in the execution sequence. The value of <timeout> is determined by which timer is specified. (The timer must first be configured on the Timers page).

IF <Boolean Expression> THEN GOTO <step x> ELSE GOTO <step y> The If/Then/Else instruction provides the ability to modify sequence flow depending on the state of inputs. If <Boolean expression> is TRUE, the next step in the sequence will be <step x>, otherwise the next step will be <step y>.

IF <timeout> THEN GOTO <step x> ELSE If <Boolean Expression> GOTO <step y> ELSE GOTO <step z> This instruction provides the ability to modify sequence flow depending on the state of inputs with an additional timeout feature. If Timer <n> has expired, the next step in the sequence will be <step x>; otherwise, if <Boolean expression> is TRUE, the next step will be <step y>. If <Boolean expression> is FALSE and Timer <n> has not

expired, then the next step will be <step z>. This instruction only checks the values of <Boolean expression> and Timer <n>; it does not start or reset the timer.

GOTO <step x> The GOTO instruction forces the sequence to jump to <step x>.

Start Timer This instruction starts the selected timer. The status of the timer must be checked using another instruction or combinational logic.

Stop Timer This instruction stops and resets the selected timer.

NOP The NOP instruction does not affect any of the outputs or the sequence of execution. It is effectively a single-cycle delay.

HALT The HALT instruction stops execution of the sequence.

BEGIN SHUTDOWN SEQUENCE The BEGIN SHUTDOWN SEQUENCE instruction signals to LogiBuilder that any instructions past this point will not be interrupted by jumps specified in exceptions. This feature allows code used for handling exceptions not to be interfered with by other exceptions that may occur. This instruction may be deleted from a sequence, but not inserted.

General Information on Instructions

All instructions are able to assign outputs, except for NOP, BEGIN STARTUP SEQUENCE, and BEGIN SHUTDOWN SEQUENCE. The outputs are assigned immediately when the sequencer enters the instruction.

The GOTO and If/Then/Else instructions cannot jump to the Wait for (timeout value), Wait for (Boolean) with Timeout, or Start Timer instruction.

See Also

- "Designing Control Sequences" on page 148
- "Managing Multiple Control Sequences" on page 149
- "Editing Sequence Instructions" on page 151
- "Entering Supervisory Equations" on page 154

Designing Control Sequences

The sequencer instructions define the steps for controlling selected outputs. The exceptions define the equations that will trigger sequence controller exceptions to modify outputs and jump out to an alternative sequence step. Exceptions can be selectively applied to any sequencer step. When compiled, the control sequence instructions implement a digital logic state machine within the PLD core.

To design a control sequence:

1. In the LogiBuilder Logic editor, select the **Sequence** tab. If your design uses multiple state machines, select the one that you want to use for the sequencer instructions.
2. In the sequence (upper) portion of the editor, click **Step 1 Begin Shutdown Sequence** to highlight it.
3. Double-click Step 1 or press the **Insert** key on your keyboard to open the Insert Step Dialog box.
4. In the dialog box, choose an instruction type, and click **OK**. Repeat as necessary to add sequence steps.
5. Double-click each instruction step to open the appropriate Edit Properties dialog box.
6. Select the desired instruction properties in the Edit dialog box, and click **OK**.
7. To add exceptions, do the following:
   a. Double-click ***<end-of-exception-table>*** in the exceptions (lower) portion of the editor, or highlight it and press the **Insert** key.
   b. Repeat as necessary to add additional exceptions.
   c. Double-click each exception placeholder, to open the Exception Properties dialog box. Alternatively, right-click the placeholder and choose **Properties**.
   d. Click the **Edit** button at the top right of the dialog box to open the Boolean Expression Editor. Set the expression that will trigger the exception and click **OK**.
   e. In the Exception Properties dialog box, select the desired exception properties, and click **OK**.

See Also ▶"Sequence Controller Instruction Set" on page 147

- "Editing Sequence Instructions" on page 151
- "Editing Exceptions" on page 153
- "Managing Multiple Control Sequences" on page 149

Managing Multiple Control Sequences

The LogiBuilder Logic editor supports multiple state machines for power-up sequence and control. The state machines are defined separately but can interact through nodes or common logic functions. Each state machine is built up in a separate tab in the Sequence section of the Logic editor.

To manage multiple control sequences:

1. In the LogiBuilder Logic editor, select the Sequence tab.

   The name of each currently defined state machine is displayed in a separate tab at the bottom. You can add a new state machine by clicking

the tab that contains the **+** sign. To delete a state machine, you must use the Multiple State Machines dialog box.

2. Right-click a tab for a state machine and choose **Multiple State Machine** from the pop-up menu. Alternatively, use the **Ctrl+M** keyboard shortcut.
3. In the Multiple State Machines dialog box, do one or all of the following:
   - Select a state machine and type a unique name for it in the State Machine Name text box.
   - Delete a state machine by selecting it and clicking **Delete SM**.
   - Click **Add SM** to add a new state machine.
4. Click **OK**.

See Also "Sequence Controller Instruction Set" on page 147

"Designing Control Sequences" on page 148

Defining Timers

Use the LogiBuilder Logic editor to set up timers for control sequences. After you have defined timers, they will be displayed in the properties dialog boxes for sequences that include timeouts. This will allow you to select the timeout value from the list.

To define a timer:

1. In the Logic editor, select the Timers tab.
2. Click the **Add** button at the bottom or press the **Insert** key to create a new timer.

   The timer is added to the list and given a default name.
3. If desired, click the default name in the Timer Name column and type a unique name.
4. Click the Clock Source cell and select a source from the drop-down menu. ECP5U/UM only support the 62.5 kHz logic sequence clock as a timer source clock.
5. Click the Period Cell. Select a time unit from the drop-down menu, and then specify the value.

   Note

   Timer delay settings must be longer than 160 µs.

   The number of LUT resources required to generate the timer is automatically recalculated.

See Also "Sequence Controller Instruction Set" on page 147

Editing Sequence Instructions

The dialog boxes provided by the Logic editor enable you to set up and edit sequence instruction properties, Boolean expressions, and exceptions. The appropriate dialog box automatically opens when you double-click an inserted step or exception for editing.

See Also ▶"Sequence Controller Instruction Set" on page 147

Editing Boolean Instruction Properties

When you double-click a Boolean step for editing, the appropriate properties dialog box opens. Each Boolean instruction's properties dialog box allows you to define output control properties, specify whether the instruction is interruptible by an exception, edit the Boolean expression, and enter descriptive comments. Boolean expressions such as conditional branches, also allow you to specify "timeout" and "goto" properties.

Edit "Wait for Bool" Properties This dialog box allows you to define a "wait for" Bool statement and specify output signal values.

Edit "Wait for Bool With Timeout" Properties This dialog box allows you to set up a "wait for" Boolean statement with an auto timeout. If the Boolean condition is met before the selected timer expires, the sequencer will continue to the next step. If the condition is not met and the timer expires, the sequencer will go to the specified step. The timer is started when the sequence enters this instruction step. The "with output" option specifies output signals that occur after the timer expires and transitions to the "Then Goto" step.

Conditional Branch (IfThenElse) This dialog box enables you to set up a conditional statement that checks a Boolean condition and then branches to an instruction step.

- The sequence will jump to the selected "Then Goto" step if the condition is true. The "With Output" option specifies output signal values that occur after the "Then Goto" transition.
- The sequence will jump to the selected "Else Goto" step if the expression is false. The "With Output" option specifies output signal values that occur after the "Else Goto" transition.

Edit "IfThenElse with Timeout" Properties This dialog box allows you to set up a conditional statement that checks a Boolean condition and the status of a timer.

- If the timer has expired, the sequencer will go to the "On Timeout Goto Sequencer step." The "with Output" option specifies output signal values that occur after the step transition.
- If the Boolean condition is met before the selected timer expires, the sequencer will go to the selected "Goto Sequencer step if no timeout and the Boolean expression is satisfied" step. The "With Output" option specifies output signal values that occur after the step transition.

- If neither the Boolean condition is met nor the selected timer has expired, the sequencer will go to the “Else Goto Sequencer step.”

Note

This instruction checks the selected timer but does not start it. The timer must be started using a “Start Timer” instruction or supervisory logic.

See Also “Sequence Controller Instruction Set” on page 147

Editing Boolean Expressions

The Boolean Expression Editor allows you to set up a Boolean expression using logic operators and a list of available inputs. You can enter the expression manually in the Expression text box at the top or select from the Logic Signal Pool and operators.

To edit a Boolean expression:

1. On the Sequence page, double-click the Boolean instruction that you want to edit.
2. In the Edit properties dialog box, click **Edit Boolean Expression**.

   You can enter the Boolean expression manually, if desired, by typing it into the Expression text box at the top and clicking OK. Otherwise, proceed with Steps 3-5.
3. Double-click a signal or bus from the Logic Signal Pool to add it to the expression.

   You can use the Filter input box below the signal pool to reduce the number of signals available. The signal pool only displays signals with the character string contained in the filter box.
4. Click the desired operator to add it to the expression.

   The following special vector operator is available for comparisons between buses and single-bit signals:

   - BITEXTEND (#) – Extends single bit to <wide> type vector. The BITEXTEND operator is only valid for single-bit signals.
5. Click **OK**.

   The Boolean Expression Editor checks the expression for correctness and will issue a message if an error is encountered.

See Also “Sequence Controller Instruction Set” on page 147

Editing Timeout Properties

The properties dialog boxes for “Wait for Timeout,” “Start Timer,” and “Stop Timer” enable you to select a defined timer, specify outputs, and specify whether the step can be interrupted by an exception.

All properties dialog boxes for sequence instructions that include timeouts—for example, the “Wait for Bool with Timeout”—allow you to select from a “Timeout” list of timers that have been defined. The properties dialog boxes for these instructions do not allow you to change the clock source and period for a selected timer. To do this, you must use the Timers sheet.

See Also ▶“Defining Timers” on page 150.

Editing Goto, NOP, and Halt Properties

The Edit “Goto” instruction properties dialog box allows you to specify the destination step for a GOTO (or branch) type of instruction, set the output signal values, enter a comment, and specify whether the instruction is interruptible by an exception.

The Edit NOP Properties dialog box allows you to enter a comment and specify that the NOP instruction is interruptible by an exception. A NOP step is essentially a single-cycle delay; it does not affect any of the outputs or the sequence of execution.

The Edit Halt Properties dialog box allows you to specify output values, enter a comment, and specify that the instruction is interruptible by an exception. A Halt step stops the execution of the sequence.

See Also ▶“Sequence Controller Instruction Set” on page 147

Editing Outputs

The Edit Output Properties dialog box enables you to select the outputs for a sequence instruction. It is immediately available when you double-click an Outputs instruction. For other instructions, it is accessible through the “Output Control” button or “With Output” button of the properties dialog box for the selected sequence.

Any single signal can be set to “Do not Modify,” which preserves the signal value; or it can be set to a binary, hexadecimal, or decimal literal value.

Port groups can also be set to Increment, Decrement, Increment with Saturation, or Decrement with Saturation. These operations support counter implementations in the logic. The “with Saturation” instructions will saturate at all 0s (decrement) or all 1s (increment). The decrement and increment operations will roll over.

See Also ▶“Creating a Port Group” on page 143

Editing Exceptions

You can add an exception for use in a control sequence by double-clicking the <end-of-exception-table> line in the Exceptions section of the Sequence page or selecting it and pressing the Insert key. Afterwards, double-click the inserted exception placeholder to set the properties.

In the Exception Properties dialog box, you can type the expression that will trigger the exception in the Expression text box at the top. Alternatively, click the **Edit** button to open the Boolean Expression Editor and select the signals and operators for the expression.

Select the step that the sequence will go to when the exception is encountered.

Then, in the Logic Signal Pool, you can select output signals or groups that will be modified when the exception occurs.

Note

Any output signals that are controlled by the exception expression are active at all times. These outputs will be modified, even if the sequence is currently in a non-interruptible step.

See Also ▶"Designing Control Sequences" on page 148

- "Editing Boolean Expressions" on page 152
- "Sequence Controller Instruction Set" on page 147

Entering Supervisory Equations

The supervisory equations define combinatorial and registered logic independent of the sequencer control logic. The supervisory equations are always active and execute in parallel to the sequencer logic.

To enter supervisory equations:

1. In the LogiBuilder Logic editor, select the **Supervisory** tab.
2. Insert an equation placeholder by double-clicking the **<end-of-supervisory-logic-table>** marker. Alternatively, highlight the marker and press the Insert key on your keyboard.
3. Double-click the equation placeholder to open the Supervisory Logic Equation Entry dialog box.
4. Select the output signal of the Supervisory equation. The output signal is chosen from the available pool, which can be reduced using the filter input. Output signal groups can also be assigned.
5. Choose the assignment type. A signal can be assigned combinatorially, as D flip-flop, or as asynchronous set or reset. Only signals that are already assigned in the sequence, or assigned as D flip-flop in other equations, can be assigned as asynchronous set or reset.
6. Edit the expression either directly in the expression or click Edit to use the Boolean Expression editor.

7. Click **OK** to complete the equation definition.

Note

The sequencing, exceptions, and supervisory equations are combined together during the compilation process. Outputs that are already assigned in the sequence cannot be assigned as D type in the logic equations. They can only be accessed by asynchronous reset or preset equations.

See Also ▶"Editing Boolean Expressions" on page 152

Copying and Pasting Sequences and Equations

The LogiBuilder Logic editor allows you to copy, cut, and paste control sequences, exceptions, and supervisory equations. If you are copying multiple instructions, they must be contiguous.

To copy or cut and paste in the Logic editor:

1. Select the sequences, exceptions, or equations that you want to copy or cut.

   Note

   The Begin Startup Sequence, Halt (end of program), <end of exceptions table>, and <end of supervisory table> cannot be included in your selection. If you include them, you will receive an error message.

2. Choose **Edit > Copy** or **Edit > Cut** or use the Ctrl+C or Ctrl+X keyboard shortcut.
3. Select the step, exception ID, or equation, where you wish to insert the copied items.
4. Choose **Edit > Paste** or use the Ctrl+V keyboard shortcut.

   The copied items are pasted before the selected step, exception, or equation. Branch targets will not be pasted along with the instruction or equation. These need to be re-entered manually.

   If you need to undo the action, chose **Edit > Undo** or use the Ctrl+Z keyboard shortcut.

See Also ▶"Sequence Controller Instruction Set" on page 147

Importing HDL Modules

The LogiBuilder Logic editor enables you to add an HDL module to a Platform Designer project. You must first add the source file to your Diamond project. Only one module can be imported into a Platform Designer project. To include multiple modules, you must structure a top-level module that you will pass to Platform Designer.

To import an HDL Module:

1. In Diamond's main window, choose **File > Add > Existing File**.
2. Navigate to the directory that contains the Verilog or VHDL source file, select the file and click **Add**.

   Diamond adds the file to the project and displays it in the Input Files folder of the File List view.
3. In Platform Designer, open the Logic editor and select the **Imported HDL** tab.
4. Select the **Enable Imported HDL** option. This will parse the input files for modules available to import.
5. Select the module from the Module Name menu.

   Platform Designer populates the File Location of the chosen module automatically. It also populates the Instance Name text box with the name of the module and adds the "Inst" extension. The left portion of the screen will be populated with any parameters available for definition in the imported HDL, as well as port information from the module.
6. If desired, rename the module instance by typing a new name in the Instance Name text box.
7. Assign values to the available HDL parameters.
8. For each port of the imported module, drag the desired signal from the Logic Signal Pool over to the Signal Name cell. The Logic editor's DRC checking will inform you if the signal you are trying to map is not compatible.

Building the Design

The Build view enables you to do a final design rule check, examine resource utilization, compile the design, assign pins, implement the design, and generate the merged JEDEC file. This view enables you to generate a test bench, including stimulus, for simulating your design. It also enables you to export a detailed configuration report.

Checking Design Rules

Design rules are checked automatically each time you issue a save command or run synthesis. Automatic design rule checking also prohibits you from entering or pasting invalid data into cells that have pre-defined ranges or numeric data types.

You can also use the Build view to run manual design rule check at any time.

To run manual design rule check:

- Click the **DRC** button at the top of the Build view.

  The results are displayed in the Output view of Diamond's main window.

Examining Resource Utilization

The Build view of Platform Designer displays a summary of the hardware resources that are being used by the current design configuration. It provides estimates of the consumption of device resource logic, major blocks, and I/Os of the current design. The Look Up Tables, Embedded Block RAM, and Programmable IOs area of the resource summary are updated after you run the Generate JEDEC step.

The Component Summary table at the top of the Build view indicates the status of the design components and programming options. The lower portion of the view provides a list of resources used in the design and the percentage of each resource consumed. At the bottom left corner, a green check mark or red X indicates the status of the implementation. When any options have been changed that affect the build output, the status will be marked "Not Current." You will then need to click the Compile button, to update the output, and complete the Pin Assignment and Generate JEDEC steps. If the implementation is successful, with no errors, the status will change to Current.

Compiling the Design

When you compile the design, Platform Designer generates the HDL code and synthesizes the logic design.

To compile the design:

- In the Build view of Platform Designer, click the **Compile** button.

  If you have unsaved changes in your design, the Save Modified Files dialog box will open. Select the .ptm file in the Modified File list and any others that you want to save and click **OK**.

  Platform Designer compiles the design and takes it through the synthesis and translation processes.

See Also "Examining Resource Utilization" on page 157

- "Exporting a Detailed Configuration Report" on page 158

Assigning Pins

After compiling the design in Platform Designer, you can open Diamond's Spreadsheet View to assign pins.

To assign pins:

1. In the Build view, click **Pin Assignments**.

   Spreadsheet View opens to the Port Assignments sheet.
2. Select the pin cells in the Pin column for the signals you want to assign.
3. Right-click the selected cells and choose **Assign Pins**.
4. Make your selections in the Assign Pins dialog box, and click **Assign Pins**.

See Also ▶"Assigning Signals in Spreadsheet View" on page 464 in Diamond online help.

Generating the JEDEC

The Build view enables you to generate a merged JEDEC file after pin assignment. This process merges the JEDEC of the FPGA with the ASC JEDECs.

To generate the merged JEDEC file:

- In the Build view, click **Generate Jedec**.

  When the process is completed, the Summary Status at the bottom of the Build view will be set to Current.

Exporting a Detailed Configuration Report

After the design has been successfully compiled and implemented, the Build view shows a green check mark, indicating that the status is current. This allows you to export a detailed report of the design's configuration.

To export a detailed configuration report:

- Select the Build view and click the **Export Configuration Report** button.

  Platform Designer automatically exports the report, named <project_name>_report.txt, to your project directory. You can view the report by following the link displayed after the report is exported.

  The report lists the components utilized in the design, along with the component settings for each feature. The report also includes full configuration information for the analog portion of the design.

Simulating the Design

After the design has been compiled successfully, you can perform functional simulation using Platform Designer and the Diamond Simulation Wizard. Platform Designer enables you to create a test bench file, based on the ASC configurations and specified connections, and it generates a stimulus file based on clock and non-clock data signals that you specify.

Generating a Stimulus and Test Bench File

After the design has been compiled successfully, you can specify the connections and signals for functional simulation. Platform Designer uses this information, plus the port-related information from the FPGA top-level HDL and the ASC configuration files, to generate a stimulus file and a test bench file.

To generate a stimulus file and a test bench file:

1. In the Build view of Platform Designer, click the **Generate Stimulus** button.

   The dialog box opens to the “Connections between FPGA and ASCs” page. The “From” and “To” sections, at the top, list all the FPGA ports and ASC signals that you can use to establish new board-level connections. The “Connection” section, at the bottom, displays the default hardware connections between the FPGA and all ASC devices in the design. These cannot be edited or removed.

2. Click the “**add connection**” button  on the bottom left.

   A new row is added at the bottom of the Connection section.

3. Scroll down to the newly added row, and then do the following:

   a. Select the desired signal in the “From” column in the top section and drag it to the “From Signal” cell in the newly created row at the bottom.

   b. Likewise, select the desired signal in the “To” column in the top section and drag it to the “To Signal” cell in the newly created row at the bottom.

   c. Type a name for the new net in the Net Name cell of the newly created row.

   Only a connection’s Net Name can be edited after you have selected the signals. To change the signals of a connection, you must remove the connection and replace it. To remove a connection, click any cell in the connection, and then click the X button.

4. Repeat Step 3 for each new connection you want to add.

5. Select the **Stimulus** tab, and then do the following:

   a. Select the **Clock** tab on the left to edit the stimulus of clock signals.

- Click the "**add clock stimulus**" button on the bottom left to add a clock. The system clock signal, ASC0_CLK, will be shown when this tab is opened, and it cannot be edited.
- Select the desired clock signal from the Signal Name drop-down menu, and then select an initial value, 1 or 0, from the Initial Value menu.
- In the Frequency or Period cell, type a value, select the measurement unit, and press **Enter**. The period is calculated automatically when you enter the frequency and vice versa.

b. Select the **Data** tab on the left to add stimulus for non-clock signals.

- Click the "**add data stimulus**" button on the bottom left to add a new row.
- Click inside the Signal Name column and choose a signal from the drop-down menu.
- The column following the Signal Name specifies the initial value. Click inside the cell and select the numerical type—Bin, Hex, or Dec—and then enter a value. Enter a value in each subsequent cell where the signal changes.

  You do not need to enter a value for each signal in each cell. Enter a value in a cell only when the value changes. The input value will be held at the last entered value if no entry is made in a cell.

  You can also select a bus and enter the values. The values can be entered as Binary, Decimal, or Hexadecimal for bus signals.
- Repeat the above steps to add stimulus for more non-clock signals.
- Add time entries for the additional columns in the top row of the display. You can select the time base to use as you enter each time value. The time entries are absolute time references rather than relative to each other. Therefore, the time values must be increasing from left to right.

  When you add a time entry in the last column on the right, a new column gets added on the right, allowing you to enter an additional time value if desired.

  To add or remove a column, right-click the time entry top row where you want to insert or remove a column and choose Insert Before, Insert After, or Remove. Make sure that the time entry cell is not open for editing before you right-click. If it is open for editing, press the Enter key, and then right-click to access the pop-up menu.

6. Click **OK**.

Simulating the Design

When you generate the stimulus for the design, the following four files are automatically created:

<project_name>_design.v This file serves as a wrapper of the MachXO2HC/HE, MachXO3LF, ECP5U/UM and ASC for functional simulation

<project-name>_test.v This file serves as the top-level file for functional simulation

<project-name>_design_post.v This file serves as a wrapper of the MachXO2HC/HE, MachXO3LF, and ASC for timing simulation.

<project-name>_test_post.v This file serves as the top-level file for timing simulation

You can use Diamond's Simulation Wizard to create the simulation project for the Platform Manager 2 or MachXO2HC/HE, MachXO3LF, ECP5U/UM design and export the simulation project into Aldec Active-HDL or ModelSim. After opening the Simulation Wizard, follow the on-screen prompts to create the simulation script.

When you create the simulation project in the Diamond Simulation Wizard and click **Finish**, the Aldec Active-HDL software will start automatically. If "Run Simulation" (the default value) was selected in the Simulation Wizard, the project will be loaded into the simulator. The project files will be compiled, and the simulation waveform window will open with all the top-level signal names. You can add signal names from within the design to the waveform window if you wish to see other signals from your design. See the Aldec Active-HDL Help for more information about adding signal names to the waveform window.

The simulation will run for a period of 1 µs after it is loaded and compiled. You can run it for additional time by using the Run command in the Active-HDL console view. To run the simulation for 100 µs, type the command `<run 100 us>` and press the Enter key. The length of time to run your simulation will depend upon the design and the stimulus file you created.

For each ASC configuration, the Simulation Wizard will copy the following files to the simulation folder:

- cfg_eeprom.hex
- flut_eeprom.hex
- i2caddress.hex
- trim_eeprom.hex

The Simulation Wizard will also copy the memory file (.mem) for the "VID table" and the MICO "scratchpad" and "prom" files.

The Simulation Wizard will not copy any memory or data file from an imported HDL module. If you have imported an HDL module into your Platform Designer project, you will need to copy it manually into the simulation folder.

See Also ▶"Simulation in Diamond" on page 307 in Diamond online help.

Working with Power Calculator

When using Platform Designer with Power Calculator, the most accurate power calculation is accomplished when using Power Calculator in integrated mode within your projects.

When calculating power for Platform Manager 2 and MachXO2HC/HE, MachXO3LF, ECP5U/UM designs using an ASC device, the Diamond integrated Power Calculator tool imports a data file generated by the Platform Designer software. This data file is generated in the current implementation directory and should not be edited by the user.

Platform Designer calculates the power mode for each ASC used and generates a data file containing each ASC, the power used by that ASC, and the power supply used (if relevant). Refer to the description of the “ASC” on page 764 page in Diamond Power Calculator online help. The data file contains both external ASC devices used and the ASC internal component in the Platform Manager 2 device.

The power consumed by an ASC device is determined by the number of HVOUTs used in the design. The data file, which is generated from Platform Designer and which has an .apw suffix, includes the number of HVOUTs used and the power model equation. The data file lists all ASCs and the power used by each and is located in the design implementation directory. This file is read by Power Calculator and then the additional power from the ASC devices is added to the total power displayed. This data is displayed in the Power Calculator Power Summary tab, Power by Block (W) section and the ASC page.

Power calculation for ASCs is different than for other Lattice devices. To calculate power consumption for ASCs, the following equations are used:

$$Current = I_O + I_{HVOUT} \times \#HVOUT$$

$$Power = V_{CC} \times Current$$

$$Power = V_{CC} \times (I_O + I_{HVOUT} \times \#HVOUT)$$

There are four variables:

$V_{CC} = 3.6V$

$I_O = 23mA$

$I_{HVOUT} = 2mA$

$\#HVOUT =$ Number of HV Outputs used

The above calculations are only used when Power Calculator is used in the integrated mode or used with a PCF file generated in this mode. To understand the different methods power is calculated refer to the list below.

Power Calculator Integrated mode

- Calculates power from multiple ASC devices for Platform Manager 2, or MachXO2HC/HE with external ASCs, MachXO3LF with external ASCs, or ECP5U/UM with external ASCs.

Power Calculator standalone mode

- Calculates power only from the internal ASC in the Platform Manager 2 device. ASC power is estimated as a fixed value, not a variable amount based on the number of HVOUTs used.
- Can correctly calculate ASC power based on HVOUTs used only if opened with a PCF file generated by Power Calculator in integrated mode instead of loading NGD database.

Power Estimator standalone mode

- Calculates power only from the internal ASC in the Platform Manager 2 device. ASC power is estimated as a fixed value, not a variable amount based on the number of HVOUTs used.
- Can correctly calculate ASC power based on HVOUTs used only if opened with a PCF file generated by Power Calculator in integrated mode.

See Also ▶"Analyzing Power Consumption" on page 753 in Diamond online help.

Chapter 4

Entering the Design

You can enter your design in several different ways and you can use the ways in almost any combination. Lattice Diamond accepts, and helps create, Verilog, VHDL, schematic, and EDIF files. Design files can be created within Diamond or outside using third-party tools. Diamond also helps you use a variety of pre-made modules, ranging from simple functions to whole processors.

Here, “entering the design” refers to describing the logic of the design. Setting specifications to control synthesis or simulation or to control how the design is implemented in hardware are treated as a separate topic. (See “Applying Design Constraints” on page 358.) You will almost always want to at least start entering your design before setting constraints.

Verilog and VHDL The hardware design languages (HDL) Verilog and VHDL are the usual ways to describe complex logic designs. You can create HDL files using you preferred HDL editor and then add them to your Diamond design project, or you can create or edit them within Diamond. See “HDL Design Entry” on page 166.

Modules Modules are functional bits of design that can be re-used wherever that function is needed. To help your design along, Lattice Semiconductor provides a variety of modules for common functions. They are optimized for Lattice device architectures and can be customized. Use these modules to speed your design work and to get the most effective results. See “Designing with Modules” on page 189.

LatticeMico Platforms A special kind of module is the LatticeMico platform. LatticeMico platforms are full-featured 32-bit processors and 8-bit controllers plus peripheral components created with LatticeMico System, an option add-on to Diamond. LatticeMico System provides the processor, the controller, and a variety of peripheral components. With it, you can customize the platform and debug C and C++ code. See “Designing with LatticeMico Platforms” on page 238.

Schematic Design An alternative to HDL is schematic design, in which you graphically lay out modules and other components and wire them together. Schematic is a very visual method but lacks the abstraction possible in an HDL. Schematic design may be better suited for smaller designs or smaller portions of a design. It’s also a good way to lay out the top level of a design. The detailed workings of lower levels could then be done in an HDL. See “Schematic Design Entry” on page 240.

EDIF Actually, EDIF (Electronic Design Interchange Format) is not a way to enter a design but is instead a way to exchange design data between different EDA systems. But EDIF files can be added to a Diamond design project like input files such as Verilog and VHDL. You may want to add EDIF files because you prefer to use another synthesizer or because you have EDIF files of modules that you want to re-use from another project. Diamond supports EDIF 2 0 0. See “Importing an Existing Source File into a Project” on page 35.

HDL Design Entry

Diamond supports HDL design including pure VHDL design, pure Verilog design, and mixed VHDL and Verilog HDL design. You can use the integrated Source Editor to create and edit your HDL source files and any text-based files.

Source Editor is a text entry tool of Lattice Diamond. You can use this tool to create and edit text-based files, such as HDL files, preference files, script files, test files, and project documentation files. Like many other advanced editing tools, it supports multiple file editing, wheel mouse scrolling, as well as popup menus for cut, copy, and paste operations. If a data source changes since the view was initialized, the view will detect this condition and provide you an option to refresh it.

Designed particularly for HDL file editing, Source Editor highlights the std_logic keywords and displays different HDL syntax elements with different colors. The color scheme can be customized in the Options dialog (**Tools > Options** from the main window) of the Diamond main window, the **Source Editor > Colors** section. Also, Source Editor enables you to check correct pairing of parenthesis constructs and offers rich template features.

Note

To avoid errors, observe the following file naming rules:

- Do not leave blank spaces in file names when you save source files in Source Editor, otherwise the files could fail to generate the database.
- Begin file names with an alpha character (letter) rather than a numeric character (number).
- Use underscores (_) rather than leave blanks in file names.
- Unicode characters are not supported.
- Keep file names, and paths to files, short as possible.
- Linux operating system is case-sensitive. Use lower-case letters in file names to avoid issues with case-sensitive operating systems.

If you are going to use Lattice Synthesis Engine (LSE) to synthesize the design, there are helpful Verilog and VHDL coding tips in “Coding Tips for Lattice Synthesis Engine (LSE)” on page 172.

See Also ▶“Running Source Editor” on page 166

- “Viewing Logs and Reports” on page 100

Running Source Editor

You can run Source Editor in several ways.

To run Source Editor, do one of the following:

- From the File List view, double-click a language file—for example, filename.vhd
- From the Diamond main window, choose **File > New > File**. In the New File dialog, choose a text-based source, for example Verilog Files. Fill in the File name and Location, click **New**.

Creating HDL Source Files in Source Editor

You can create an HDL source file in Source Editor.

To create an HDL source in Source Editor:

1. From the Diamond main window, choose **File > New > File**. In the New File dialog, choose Verilog Files or VHDL Files from the Source Files list.
2. In the pop up New File dialog, fill in the File name and Location, choose the file extension in the Ext field.
3. Check the **Add to project** option if you want to add this source to the current project.
4. click **New**.
5. In the pop up Source Editor, you can enter the text. When finished editing, click **File > Save** from the Diamond main window.

Tip

You can detach Source Editor from the Diamond main window by clicking the Detach Tool icon on the upper right corner of Source Editor. If you want to attach Source Editor back to the main window, click the Attach Window icon on the upper right corner of Source Editor window, or choose **Window > Attach Window** from Source Editor.

Editing Text Files

This section describes the editing functions in Source Editor.

Editing a Column of Text

You can cut, copy, and paste a column of selected text in Source Editor. You can also use the Tab key to increase the left indention of the selected column.

To cut, copy, and paste a column of text:

1. Hold down **Alt**, and then click and hold the left mouse button down to form a rectangle that you want to edit.

   IMPORTANT!

   This feature does not work on a Linux platform, because the **Alt** key is occupied by the Linux system.

2. Use the right-click commands or the commands on the Edit menu to cut, copy, and paste the selected text.

To indent a column of text:

1. Place the cursor in front of the text you want to indent.
2. Choose **Edit > Advanced > Indent**. Or, press **Tab**.

   Source Editor increases the indent of the selected text column by one tab size. By "Matching Braces, Parenthesis, and Brackets" on page 168, you can change the position of the indent.

To uppercase a selection:

1. Highlight the text you want to change to uppercase.
2. Choose **Edit > Advanced > Uppercase Selection**. You will see the highlighted text become uppercase.

To lowercase a selection:

1. Highlight the text you want to change to lowercase.
2. Choose **Edit > Advanced > Lowercase Selection**. You will see the highlighted text become lowercase.

To comment text:

1. Highlight the text you want to add comment, or place the cursor in front of the text.
2. Choose **Edit > Advanced > Comment/Uncomment**. You will see "--" put ahead of the text (VHDL file only). You can add comment after "--" (VHDL file only).

Matching Braces, Parenthesis, and Brackets

Source Editor monitors brace ({}), parenthesis (()), and bracket ([]) constructs. You can match an opening brace (or bracket or parenthesis) with a closing one, and vice versa.

To jump to the matching brace, parenthesis, or bracket:

1. In Source Editor, place the editing cursor adjacent to an opening or closing parenthesis (or bracket or brace).
2. Choose **Edit > Advanced > Match Brace**.

The cursor will move to the corresponding opening or closing parenthesis (or bracket or brace). This allows you the check for the balanced braces around functions and statements.

You can use the **Edit > Advanced > Select to Brace** command to force the matching brace, parenthesis, or brackets to be highlighted along with the text in between the two braces, parenthesis, or brackets,

Using Bookmarks

You can insert bookmarks into the source file to mark places where you need to enter variables. Afterwards, each time you load the file, you can use the **Edit > Bookmarks** command to jump to those marks and enter or edit variables.

To insert bookmarks in a file:

1. In Source Editor, open the file where you want to insert bookmarks.
2. Click the place you want to insert a mark.
3. Choose **Edit > Bookmarks > Toggle Bookmark**.

   A mark is inserted at the beginning of the line where the cursor points.
4. Repeat step 2 and 3 to add more marks if so desired.

To find marks in a file:

1. In Source Editor, open the file where you want to find marks.
2. Choose **Edit > Bookmarks > Previous Bookmark**, or **Edit > Bookmarks > Next Bookmark**.

   The cursor jumps to one mark or the other. You can start typing from the desired marked place to enter or edit the variable.
3. Repeat step 2 to find, enter, or edit more marks if so desired.

Using AutoComplete

When you type a keyword into Source Editor, choose **Edit > Advanced > AutoComplete**. A list of the matching values will be presented. You can then:

- Choose the first matching value by pressing **Enter** directly.
- Choose an alternate matching value by using the up/down arrow keys and then press **Enter**.
- Continue typing the rest of the value. If no matching value is found, nothing will be entered.

Using Templates

Source Editor provides templates for creating VHDL, Verilog, and constraint files. Templates increase the speed and accuracy of design entry. You can also create your own templates. Remember to replace dummy variables in the template with your own logic.

You can use Source Editor's **View > Template Editor** menu to locate and access template files. After clicking this menu, you can see the Template Editor pane located in the upper left of Source Editor. Templates are available for:

- Verilog
- VHDL
- SDC (Synopsys Design Constraints. Can also be used for FDC files.)
- LDC (Constraints for LSE.)

Each category has folders for System Templates and User Templates. System Templates holds the standard templates that come with Diamond. For Verilog and VHDL, these include commands for instantiating PMI modules and common elements of the language. For SDC and LDC, System Templates holds templates for the supported constraint statements. User Templates allows you to create your own templates for future use.

See Also ▶"Lattice Module Reference Guide" on page 1399

- "Lattice Synthesis Engine (LSE) Constraints" on page 1338

Inserting a Template into Your Source File

You can insert templates into a source file you are editing with Source Editor.

To insert a template into your source file:

1. Open the source file in Source Editor. See "Running Source Editor" on page 166.
2. Choose **View > Template Editor**.

   Two additional panes open in Source Editor. The upper pane shows the list of template folders. The lower pane is blank.
3. Place the cursor where you want to insert a template. This should be in a blank line.
4. Select the template you want to use in the template list.

   The code of the template appears in the lower pane.
5. Right-click the template name and choose **Insert to text**.

   The selected template is inserted into the file after the cursor.
6. Be sure to replace all placeholders with real values. Placeholders are terms between angle brackets such as "<event_expression>."

7. If you inserted a PMI template, also add parameter values and I/O signal names. For information about allowed parameter values, see the section on the module in the “Lattice Module Reference Guide” on page 1399.
8. If needed, make further changes such as adding code to execute within a case statement.

See Also ▶“Instantiating a PMI Module” on page 200

Creating a New Template

You can create new templates for your own use and save them into the User Templates folders. The new templates will be available for all implementations in the design project.

You can also create sub-folders to organize the templates that you create. If you plan on creating many templates, think about the organization before you start. There is no easy way to move templates once they have been created.

To create a new template:

1. Open a source file in Source Editor. This can be a file that you will use the new template in or a blank file that you will delete after creating the template. See “Running Source Editor” on page 166.
2. Choose **View > Template Editor**.

   Two additional panes open in Source Editor. The upper pane shows the list of template folders. The lower pane is blank.
3. In Template Editor, expand the appropriate folder so that its User Templates folder is showing. Every top level folder has a User Templates folder. If the User Templates folder already has contents, expand it so you can see the contents.
4. If you want to create a sub-folder, right-click **User Templates** or one of its sub-folders and choose **New Folder**. Then right-click the new folder and choose **Rename**. Type the desired folder name and press **Enter**.
5. Right-click **User Templates** or one of its sub-folders and choose **New Template**.

   A new template icon appears under the folder.
6. Right-click the new template icon and choose **Rename**. Type in the desired template name and press **Enter**.
7. Type the code for your template in the lower pane of Template Editor.

   The new template is automatically saved.

Deleting a User Template

You can only delete templates from a **User Templates** folder.

There is no undo command. Be sure you have the right template and want to permanently remove it.

To delete a template:

1. Open a source file in Source Editor. This can be a file that you are using or a blank file that you will delete after creating the template. See “Running Source Editor” on page 166.
2. Choose **View > Template Editor**.

   Two additional panes open in Source Editor. The upper pane shows the list of template folders. The lower pane is blank.
3. In Template Editor, expand the folders so that the desired folder or template is showing.

   Caution

   Deleting a folder also deletes all templates under the folder.
4. Right-click that template or folder and choose **Delete**.

Coding Tips for Lattice Synthesis Engine (LSE)

If you are going to use LSE to synthesize the design, the following coding tips may help. Mostly the tips are about writing code so that blocks of memory are “inferred”: that is, automatically implemented using programmable function units (PFU) or embedded block RAM (EBR) instead of registers. There are also tips about inferring types of I/O ports and avoiding conflicts between VHDL packages.

About VHDL Coding

LSE tends to apply the VHDL specification strictly, sometimes more strictly than other synthesis tools. Following are some coding practices that can cause problems with LSE:

ieee.std_logic_signed or unsigned When preparing VHDL code for LSE, you can include either:

USE ieee.std_logic_signed.ALL;

or:

USE ieee.std_logic_unsigned.ALL;

DO NOT include both statements. Code with both signed and unsigned packages could fail to synthesize because operators would have multiple definitions. Some synthesis tools may allow this but LSE does not.

Strict Variable Typing LSE is stricter about variable type requirements than some other synthesis tools. A std_logic_vector signal cannot be assigned to a std_logic signal and an unsigned type cannot be assigned to a std_logic_vector signal. For example:

```
din : in  unsigned (data_width - 1 downto 0);
dout : out std_logic_vector (data_width - 1 downto 0));
...
dout <= din; -- Illegal, mismatched assignment.
```

Such mismatched assignments generate errors that stop synthesis.

About Inferring Memory

There are two ways to produce RAM and ROM in a design. You can write code for the design so that the synthesis tool infers the memory or you can instantiate predefined IPexpress or PMI memory modules.

Inferring memory means that LSE, based on aspects of the code, implements a block of memory using programmable function units (PFU) or embedded block RAM (EBR)—PFU for small memories, EBR for large—instead of registers. LSE can infer synchronous RAM that is:

- single-port, pseudo dual-port, or true dual-port
- with or without asynchronous reset of the output
- with or without write enables
- with or without clock enables

LSE can also infer synchronous ROM.

One of the advantages of inferring memory is that the design is portable to almost any FPGA architecture. PMI modules, on the other hand, are optimized for Lattice FPGAs and IPexpress modules are optimized for just one FPGA family. Also, because the inferred memory is not a black box, there's full access for tools and to timing and area data.

However, there may be less efficient use of the FPGA architecture. Also, not all kinds of memory can be inferred. In these situations you may prefer to use IPexpress or PMI modules. With these modules you can also use Memory Generator to easily create memory initialization files. See "Designing with Modules" on page 189.

The following sections describe how to write code to infer different kinds of memory with LSE.

See Also

- "Inferring RAM" on page 173
- "Inferring ROM" on page 183

Inferring RAM

The basic inferred RAM is synchronous. It can have synchronous or asynchronous reads and can be either single- or dual-port. You can also set initial values. Other features, such as resets and clock enables, can be added

as desired. The following text lists the rules for coding inferred RAM. Following that, Figure 5 on page 174 (Verilog) and Figure 6 on page 175 (VHDL) show the code for a simple, single-port RAM with asynchronous read.

To code RAM to be inferred, do the following:

- Define the RAM as an indexed array of registers.
- To control how the RAM is implemented (with distributed or block RAM), consider adding the syn_ramstyle attribute. See "syn_ramstyle" on page 1380.
- Control the RAM with a clock edge and a write enable signal.
- For synchronous reads, see "Inferring RAM with Synchronous Read" on page 176.
- For single-port RAM, use the same address bus for reading and writing.
- For dual-port RAM, pseudo and true, see "Inferring Dual-Port RAM" on page 178.
- If desired, assign initial values to the RAM as described in "Initializing Inferred RAM" on page 182.

Figure 5: Simple, Single-Port RAM in Verilog

```
module ram (din, addr, write_en, clk, dout);
  parameter addr_width = 8;
  parameter data_width = 8;
  input [addr_width-1:0] addr;
  input [data_width-1:0] din;
  input write_en, clk;
  reg [data_width-1:0] mem [(1<<addr_width)-1:0];
    // Define RAM as an indexed memory array.

  always @(posedge clk) // Control with a clock edge.
  begin
    if (write_en) // And control with a write enable.
      mem[(addr)] <= din;
  end
  assign dout = mem[addr];
endmodule
```

- "About Verilog Blocking Assignments" on page 184

Figure 6: Simple, Single-Port RAM in VHDL

```
library IEEE;
use IEEE.std_logic_1164.all;
use IEEE.std_logic_unsigned.all;

entity ram is
generic (
  addr_width : natural := 8;
  data_width : natural := 8);
port (
  addr : in  std_logic_vector (addr_width - 1 downto 0);
  write_en : in  std_logic;
  clk : in  std_logic;
  din : in  std_logic_vector (data_width - 1 downto 0);
  dout : out std_logic_vector (data_width - 1 downto 0));
end ram;

architecture rtl of ram is
  type mem_type is array ((2** addr_width) - 1 downto 0) of
    std_logic_vector(data_width - 1 downto 0);
  signal mem : mem_type;
    -- Define RAM as an indexed memory array.
begin
  process (clk)
  begin
    if (clk'event and clk = '1') then --Control with clock edge
      if (write_en = '1') then -- Control with a write enable.
        mem(conv_integer(addr)) <= din;
      end if;
    end if;
  end process;
  dout <= mem(conv_integer(addr));
end rtl;
```

Inferring RAM with Synchronous Read

For synchronous reads, add a register for the read address or for the data output. Load the register inside the procedure or process that is controlled by the clock. See the following examples. They show the simple RAM of Figure 5 on page 174 (for Verilog) and Figure 6 on page 175 (for VHDL) modified for synchronous reads. Changes are in bold text.

Verilog Examples

Figure 7: RAM with Registered Output in Verilog

```
module ram (din, addr, write_en, clk, dout);
  parameter addr_width = 8;
  parameter data_width = 8;
  input [addr_width-1:0] addr;
  input [data_width-1:0] din;
  input write_en, clk;
  output [data_width-1:0] dout;
  reg [data_width-1:0] dout; // Register for output.
  reg [data_width-1:0] mem [(1<<addr_width)-1:0];

  always @(posedge clk)
  begin
    if (write_en)
      mem[(addr)] <= din;
    dout = mem[addr]; // Output register controlled by clock.
  end
endmodule
```

Figure 8: RAM with Registered Read Address in Verilog

```
module ram (din, addr, write_en, clk, dout);
  parameter addr_width = 8;
  parameter data_width = 8;
  input [addr_width-1:0] addr;
  input [data_width-1:0] din;
  input write_en, clk;
  output [data_width-1:0] dout;
  reg [data_width-1:0] raddr; // Register for read address.
  reg [data_width-1:0] mem [(1<<addr_width)-1:0];

  always @(posedge clk)
  begin
    if (write_en)
    begin
      mem[(addr)] <= din;
    end
    raddr <= addr; // Read addr. register controlled by clock.
  end
  assign dout = mem[raddr];
endmodule
```

VHDL Examples

Figure 9: RAM with Registered Output in VHDL

```
library IEEE;
use IEEE.std_logic_1164.all;
use IEEE.std_logic_unsigned.all;

entity ram is
generic (
  addr_width : natural := 8;
  data_width : natural := 8);
port (
  addr : in  std_logic_vector (addr_width - 1 downto 0);
  write_en : in  std_logic;
  clk : in  std_logic;
  din : in  std_logic_vector (data_width - 1 downto 0);
  dout : out std_logic_vector (data_width - 1 downto 0));
end ram;

architecture rtl of ram is
  type mem_type is array ((2** addr_width) - 1 downto 0) of
    std_logic_vector(data_width - 1 downto 0);
  signal mem : mem_type;
begin
  process (clk)
  begin
    if (clk'event and clk = '1') then
      if (write_en = '1') then
        mem(conv_integer(addr)) <= din;
      end if;
    end if;
    dout <= mem(conv_integer(addr));
      -- Output register controlled by clock.
  end process;
end rtl;
```

Figure 10: RAM with Registered Read Address in VHDL

```
library IEEE;
use IEEE.std_logic_1164.all;
use IEEE.std_logic_unsigned.all;

entity ram is
generic (
  addr_width : natural := 8;
  data_width : natural := 8);
port (
  addr : in  std_logic_vector (addr_width - 1 downto 0);
  write_en : in  std_logic;
  clk : in  std_logic;
  din : in  std_logic_vector (data_width - 1 downto 0);
  dout : out std_logic_vector (data_width - 1 downto 0));
end ram;

architecture rtl of ram is
  type mem_type is array ((2** addr_width) - 1 downto 0) of
    std_logic_vector(data_width - 1 downto 0);
  signal mem : mem_type;
begin
  process (clk)
  begin
    if (clk'event and clk = '1') then
      if (write_en = '1') then
        mem(conv_integer(addr)) <= din;
      end if;
      raddr <= addr;
        -- Read address register controlled by clock.
    end if;
  end process;
  dout <= mem(conv_integer(raddr));
end rtl;
```

Inferring Dual-Port RAM

For dual-port RAM, pseudo or true:

- Use two address buses.
- If the design does not simultaneously read and write the same address, add the syn_ramstyle attribute with the no_rw_check value to minimize overhead logic.
- If writing in Verilog, use non-blocking assignments as described in “About Verilog Blocking Assignments” on page 184.

The following examples are based on the simple RAM of Figure 5 on page 174 (for Verilog) and Figure 6 on page 175 (for VHDL).

Verilog Examples

Figure 11: Pseudo Dual-Port RAM in Verilog

```
module ram (din, write_en, waddr, wclk, raddr, rclk, dout);
  parameter addr_width = 8;
  parameter data_width = 8;
  input [addr_width-1:0] waddr, raddr;
  input [data_width-1:0] din;
  input write_en, wclk, rclk;
  output [data_width-1:0] dout;
  reg [data_width-1:0] dout;
  reg [data_width-1:0] mem [(1<<addr_width)-1:0]
    /* synthesis syn_ramstyle = "no_rw_check" */ ;

  always @(posedge wclk) // Write memory.
  begin
    if (write_en)
      mem[waddr] <= din; // Using write address bus.
  end
  always @(posedge rclk) // Read memory.
  begin
    dout <= mem[raddr]; // Using read address bus.
  end
endmodule
```

Figure 12: True Dual-Port RAM in Verilog

```
module ram (dina, write_ena, addra, clka, douta,
  dinb, write_enb, addrb, clkb, doutb);
  parameter addr_width = 8;
  parameter data_width = 8;
  input [addr_width-1:0] addra, addrb;
  input [data_width-1:0] dina, dinb;
  input write_ena, clka, write_enb, clkb;
  output [data_width-1:0] douta, doutb;
  reg [data_width-1:0] douta, doutb;
  reg [data_width-1:0] mem [(1<<addr_width)-1:0]
    /* synthesis syn_ramstyle = "no_rw_check" */ ;

  always @(posedge clka) // Using port a.
  begin
    if (write_ena)
      mem[addra] <= dina; // Using address bus a.
    douta <= mem[addra];
  end
  always @(posedge clkb) // Using port b.
  begin
    if (write_enb)
      mem[addrb] <= dinb; // Using address bus b.
    doutb <= mem[addrb];
  end
endmodule
```

VHDL Examples

Figure 13: Pseudo Dual-Port RAM in VHDL

```
library IEEE;
use IEEE.std_logic_1164.all;
use IEEE.std_logic_unsigned.all;

entity ram is
generic (
  addr_width : natural := 8;
  data_width : natural := 8);
port (
  write_en : in  std_logic;
  waddr : in  std_logic_vector (addr_width - 1 downto 0);
  wclk : in  std_logic;
  raddr : in  std_logic_vector (addr_width - 1 downto 0);
  rclk : in  std_logic;
  din : in  std_logic_vector (data_width - 1 downto 0);
  dout : out std_logic_vector (data_width - 1 downto 0));
end ram;

architecture rtl of ram is
  type mem_type is array ((2** addr_width) - 1 downto 0) of
    std_logic_vector(data_width - 1 downto 0);
  signal mem : mem_type;
  attribute syn_ramstyle: string;
  attribute syn_ramstyle of mem: signal is "no_rw_check";
begin
  process (wclk) -- Write memory.
  begin
    if (wclk'event and wclk = '1') then
      if (write_en = '1') then
        mem(conv_integer(waddr)) <= din;
          -- Using write address bus.
      end if;
    end if;
  end process;
  process (rclk) -- Read memory.
  begin
    if (rclk'event and rclk = '1') then
      dout <= mem(conv_integer(raddr));
        -- Using read address bus.
    end if;
  end process;
end rtl;
```

Figure 14: True Dual-Port RAM in VHDL

```
library IEEE;
use IEEE.std_logic_1164.all;
use IEEE.std_logic_unsigned.all;

entity ram is
generic (
  addr_width : natural := 8;
  data_width : natural := 8);
port (
  addra : in  std_logic_vector (addr_width - 1 downto 0);
  write_ena : in  std_logic;
  clka : in  std_logic;
  dina : in  std_logic_vector (data_width - 1 downto 0);
  douta : out std_logic_vector (data_width - 1 downto 0);
  addrb : in  std_logic_vector (addr_width - 1 downto 0);
  write_enb : in  std_logic;
  clkb : in  std_logic;
  dinb : in  std_logic_vector (data_width - 1 downto 0);
  doutb : out std_logic_vector (data_width - 1 downto 0));
end ram;

architecture rtl of ram is
  type mem_type is array ((2** addr_width) - 1 downto 0) of
    std_logic_vector(data_width - 1 downto 0);
  signal mem : mem_type;
  attribute syn_ramstyle: string;
  attribute syn_ramstyle of mem: signal is "no_rw_check";
begin
  process (clka) -- Using port a.
  begin
    if (clka'event and clka = '1') then
      if (write_ena = '1') then
        mem(conv_integer(addra)) <= dina;
          -- Using address bus a.
      end if;
      douta <= mem(conv_integer(addra));
    end if;
  end process;
  process (clkb) -- Using port b.
  begin
    if (clkb'event and clkb = '1') then
      if (write_enb = '1') then
        mem(conv_integer(addrb)) <= dinb;
          -- Using address bus b.
      end if;
      doutb <= mem(conv_integer(addrb));
    end if;
  end process;
end rtl;
```

Initializing Inferred RAM

Create initial values for inferred RAM in the usual ways for initializing memory.

Verilog In Verilog, initialize RAM with the standard $readmemb or $readmemh tasks in an initial block. Create a separate file with the initial values in either binary or hexadecimal form. For example, to initialize a RAM block named “ram”:

```
reg [7:0] ram [0:255];
initial
begin
  $readmemh ("ram.ini", ram);
end
```

The data file has one word of data on each line. The data needs to be in the same order in which the array was defined. That is, for “ram [0:255]” the data starts with address 0; for “ram [255:0]” the data starts with address 255. The ram.ini file might start like this:

```
0A /* Address 0 */
23
5C
...
```

VHDL In VHDL, initialize RAM with either signal declarations or variable declarations. Define an entity with the same ports and architecture as the memory. Use this entity in either a signal or variable statement with the initial values as shown below.

For example, to initialize a RAM block named “ram,” define an entity such as:

```
entity ram_init is
port (
  clk : in std_logic;
  addr : in std_logic_vector(7 downto 0);
  din : in std_logic_vector(7 downto 0);
  we : in std_logic;
  dout : out std_logic_vector(7 downto 0));
end;
architecture arch of ram_init is
  type ram_init_arch is array(0 to 255)
  of std_logic_vector (7 downto 0);
```

Then use the entity in a signal statement:

```
signal ram : ram_init_arch := (
"00001010",
"00100011",
"01011100",
...
others => (others => '0'));
```

Or use the entity in a variable statement:

```
variable ram : ram_init_arch := (
```

```
1 => "00001010",
...
others => (1=>'1', others => '0'));
```

- “Inferring RAM” on page 173

Inferring ROM

To code ROM to be inferred, do the following:

- Define the ROM with a case statement or equivalent if statements.
- Assign constant values, all of the same width.
- Assign values for at least 16 addresses or half of the address space, whichever is greater. For example, if the address has 6 bits, the address space is 64 words, and at least 32 of them must be assigned values.
- To control how the ROM is implemented (with distributed or block ROM), consider adding the syn_romstyle attribute. See “syn_romstyle” on page 1384.

Figure 15: ROM Inferred with Case Statement in Verilog

```
module rom(data, addr);
  output [3:0] data;
  input [4:0] addr;
  always @(addr) begin
    case (addr)
       0 : data = 'h4;
       1 : data = 'h9;
       2 : data = 'h1;
       ...
      15 : data = 'h8;
      16 : data = 'h1;
      17 : data = 'h0;
      default : data = 'h0;
    endcase
  end
endmodule
```

Figure 16: ROM Inferred with If Statement in VHDL

```
entity rom is
port (addr : in std_logic_vector(4 downto 0);
  data : out std_logic_vector(3 downto 0) );
end rom;

architecture behave of rom is
begin
  process(addr)
  begin
    if    addr =  0 then data <= "0100";
    elsif addr =  1 then data <= "1001";
    elsif addr =  2 then data <= "0001";
    ...
    elsif addr = 15 then data <= "1000";
    elsif addr = 16 then data <= "0001";
    elsif addr = 17 then data <= "0000";
    else                 data <= "0000";
    end if;
  end process;
end behave;
```

About Verilog Blocking Assignments

LSE support for Verilog blocking assignments to inferred RAM and ROM, such as “ram[(addr)] = data;,” is limited to a single such assignment. Multiple blocking assignments, such as you might use for true dual-port RAM (see Figure 17 on page 184), or a mix of blocking and non-blocking assignments are not supported. Instead, use non-blocking assignments (<=). See Figure 18 on page 185.

Figure 17: Example of RAM with Multiple Blocking Assignments (Wrong)

```
always @(posedge clka)
begin
  if (write_ena)
    ram[addra] = dina; // Blocking assignment A
  douta = ram[addra];
end
always @(posedge clkb)
begin
  if (write_enb)
    ram[addrb] = dinb; // Blocking assignment B
  doutb = ram[addrb];
end
```

Figure 18: Example Rewritten with Non-blocking Assignments (Right)

```
always @(posedge clka)
begin
  if (write_ena)
    ram[addra] <= dina;
  douta <= ram[addra];
end
always @(posedge clkb)
begin
  if (write_enb)
    ram[addrb] <= dinb;
  doutb <= ram[addrb];
end
```

About Verilog Generate Blocks

If a module has multiple generate blocks, LSE requires that they each block have a different name. Assign names with begin statements. See Figure 19 on page 185.

Figure 19: Generate Blocks with Assigned Names

```
generate
begin: R1_gen // Name first generate block.
  genvar i1;
  for (i1=0; i1<=15; i1=i1+1)
    regset R1 (.clk(clk[i1]),.q(q[i1]),.d(d[i1]));
end
endgenerate

generate
begin: IR0_gen // Name second generate block.
  genvar i;
  for (i=0; i<=7; i=i+1)
    ioreg IR0 (.clk(clk[0]),.reset(rst[i]),.q(q[i]),.d(d[i]));
end
endgenerate
```

Inferring I/O

To specify types of I/O ports, follow these models.

Verilog

Open Drain:

```
output <port>;
wire <output_enable>;
assign <port> = <output_enable> ? 1'b0 : 1'bz;
```

Bidirectional:

```
inout <port>;
wire <output_enable>;
```

```
wire <output_driver>;
wire <input_signal>;
assign <port> = <output_enable> ? <output_driver> : 1'bz;
assign <input_signal> = <port>;
```

VHDL

Tristate:

```
library ieee;
use ieee.std_logic_1164.all;
entity <tbuf> is
port (
  <enable> : std_logic;
  <input_sig> : in std_logic_vector (1 downto 0);
  <output_sig> : out std_logic_vector (1 downto 0));
end tbuf2;
architecture <port> of <tbuf> is
begin
  <output_sig> <= <input_sig> when <enable> = '1' else "ZZ";
end;
```

Open Drain:

```
library ieee;
use ieee.std_logic_1164.all;
entity <od> is
port (
  <enable> : std_logic;
  <output_sig> : out std_logic_vector (1 downto 0));
end od2;
architecture <port> of <od> is
begin
  <output_sig> <= "00" when <enable> = '1' else "ZZ";
end;
```

Bidirectional:

```
library ieee;
use ieee.std_logic_1164.all;
entity <bidir> is
port (
  <direction> : std_logic;
  <input_sig> : in std_logic_vector (1 downto 0);
  <output_sig> : out std_logic_vector (1 downto 0);
  <bidir_sig> : inout std_logic_vector (1 downto 0));
end bidir2;
architecture <port> of <bidir> is
begin
  <bidir_sig> <= <input_sig> when <direction> = '0' else "ZZ";
  <output_sig> <= <bidir_sig>;
end;
```

Customizing Source Editor

You can set file and window modes, set encoding, and configure line number showing, text wrapping, and printing options in Source Editor.

Setting File and Window Modes

Source Editor offers you the flexibility to configure file and window modes, such as line number showing, text wrapping, and printing options. The configuration can be applied to the current file, the specified types of files, or any new files created in Source Editor.

To set file modes:

1. In Source Editor, choose **View > Language**. You will see list of menu items beside, cpp, hypertext, perl, python, tcl, verilog, vhdl, preference, and edif.
2. Choose the desired file mode from the list. Source Editor will become that specific language sensitive.

To set window modes:

1. In Source Editor, choose **Window > Attach Window**. The Source Editor window is attached to the Diamond main window.
2. If want to detach Source Editor from the Diamond main window, click the Detach Tool icon on the upper-right corner of Source Editor.

Customizing Source Editor from the Diamond Main Window

To customize Source Editor settings in the Diamond main window:

1. In the Diamond main window, choose **Tools > Options**.
2. In the Options dialog, find the Source Editor section.

   You can set settings in the each related section.

   General

   Show Line Number: Displays line numbers of the files (on the left side of the Editor).

   Show Indicator Margin: Displays the side bar where you can click to select the whole row.

   Show Folder Margin: Displays the side bar (on the left side of the Editor) that is used to fold/unfold the syntax.

   Tab Size: Specifies how many spaces are entered when a tab character is pressed.

   Set Default Brings back to the default setting.

   Fonts

   Lists the current fonts used in Source Editor. If you want to change the current fonts, click the font box. From the pop-up Select Font dialog, you can select the desired font. Click **OK** to quit the dialog. The selected font name, font type, and font size will be displayed.

Set Default	Brings back to the default font setting.

Colors

Lists the syntax elements and the current color settings for them. Click the color box to choose a different color.

Set Default	Brings back to the default font setting.

If you want to change to use your own text editor other than Source Editor, you can customize to add your own text editor and associate files to your own text editor program in the Options dialog (**Tools > Options** from the Diamond main window), the **Environment > File Associations** section.

References

This section includes the following references.

Verilog HDL Language Reference

If you have installed Synplify Pro for Lattice, refer to the *Synplify and Synplify Pro for Lattice Reference Manual* in the Synplify Pro installation directory.

VHDL Language Reference

If you have installed Synplify Pro for Lattice, refer to the *Synplify and Synplify Pro for Lattice Reference Manual* in the Synplify Pro installation directory.

Designing with Modules

Modules are functional bits of design that can be re-used wherever that function is needed. Creating such modules with hardware design languages is common practice. To help your design along, Lattice Semiconductor provides a variety of modules for common functions. They are optimized for Lattice device architectures and can be customized. Use these modules to speed your design work and to get the most effective results.

Lattice Semiconductor's modules come in a variety of forms:

- IPexpress provides a variety of functions ranging from the most basic, such as arithmetic and memory, to much more complex functions. With IPexpress these modules can be extensively customized. They can be created as part of a specific project or as a library for multiple projects. See "Creating IPexpress Modules and IP" on page 190.

  However, many of these modules can also be used with PMI (see next item). To decide which method to use, see "Use PMI or IPexpress?" on page 190.

- PMI (Parameterized Module Instantiation) is an alternate way to use some of the modules that come with IPexpress. With PMI, instead of using IPexpress, you directly instantiate a module into your HDL and customize it by setting parameters in the HDL. You may find this easier than using IPexpress if your design requires many variations of the same module. To decide which method to use, see "Use PMI or IPexpress?" on page 190.

- Clarity Designer provides modules similar to those from IPexpress but for ECP5. As with IPexpress, with Clarity Designer you can customize these modules. Clarity Designer also helps you connect these modules to each other and place the PCS and DDR modules in the device's architecture. See "Creating Clarity Designer Modules" on page 210.

- LatticeMico32 microprocessors and LatticeMico8 microcontrollers are exceptions in that they are not customized with IPexpress. LatticeMico32 and LatticeMico8 have their own development environment. To design with LatticeMico System, see "Designing with LatticeMico Platforms" on page 238.

- Reference designs provide you with a starting point on creating your own modules. Lattice Reference Designs are available in Verilog and VHDL, and can be downloaded from the Lattice Web site: www.latticesemi.com/ip.

- Lattice library primitives are very basic functions, such as logic gates and flip-flops. They can be directly instantiated as HDL into designs. But this is an advanced technique and should usually be avoided. For more information, see "Designing with Lattice Library Primitives" on page 208.

Of course you can also create your own modules and that is fully supported too. In fact, Diamond supports creating your own black-box modules. See "Creating Your Own Black Box Modules" on page 205.

Use PMI or IPexpress?

Many IPexpress modules are also available as PMI modules. Why would use one instead of the other?

PMI is a convenient way to use modules of the same type but that vary from instance to instance. This eliminates the need to create a separate module for each instance using IPexpress.

For example, a design might require dozens of FIFOs that are functionally the same but require different address depths. With PMI, you could insert the same FIFO instantiation command wherever it's needed in the HDL and just change the address depth parameter as you go. The alternative would be to use IPexpress to generate different modules for each variation and then insert the instantiation template for each of them. In such a situation, you might find the PMI method easier and faster.

But before deciding to use a PMI module, compare it to the equivalent IPexpress module. Often IPexpress provides more options than PMI does. IPexpress also assures that all of your option selections and parameter settings are legal. PMI offers no error checking.

Also be aware that PMI requires some extra steps for simulation and synthesis. PMI modules are treated as black boxes in design projects. So simulation outside of Diamond, with a third-party simulator, requires compiling a simulation library. And synthesis requires that a synthesis header file be added to the design project or to the project of a standalone synthesis tool, if using one. For more details, see "Requirements for Simulation and Synthesis with PMI" on page 201.

Creating IPexpress Modules and IP

IPexpress is an easy way to use a collection of functional blocks from Lattice Semiconductor. There are two types of functional blocks available through IPexpress: modules and IP. IPexpress enables you to extensively customize these blocks. They can be created as part of a specific project or as a library for multiple projects.

Modules: These basic, configurable blocks come with IPexpress. They provide a variety of functions including I/O, arithmetic, memory, and more. Open IPexpress to see the full list of what's available. Also see the Lattice Module Reference Guide.

IP: Intellectual property (IP) are more complex, configurable blocks. They are accessible through IPexpress, but they do not come with the tool. They must first be downloaded and installed as a separate step before they can be

accessed from IPexpress. To see all that's available and to learn about licensing and other vendors of IP, go to the Lattice Web site: www.latticesemi.com/ip.

Overview of the IPexpress Process Below are the basic steps of using IPexpress modules and IP. For details of performing these steps, see the following topics.

1. Start running IPexpress. It can be started from Diamond's Tools menu after you open your design project. If you want to create a library of configured modules or IP, IPexpress can be opened as a stand-alone tool to create a library of modules.
2. If you want to use a Lattice IP that's not visible, it must be downloaded and installed first. This can be done from IPexpress.
3. Customize the module/IP. These modules and IP can be extensively customized for your design. The options may range from setting the width of a data bus to selecting features in a communications protocol. At a minimum you need to specify the design language to use for the output.
4. Generate the module/IP and bring its .ipx file into your project. Prior to generating the module/IP, select the option "Import IPX to Diamond Project." This will then automatically bring the .ipx file into your project after the generation step completes. If you do not select this option, then after generation, add the .ipx file to your project as you would with any other source file (such as a Verilog or VHDL file). If using IPexpress standalone, there is no project to automatically add the .ipx file.
5. Instantiate the module/IP into the project's design. An HDL instance template is generated during the generation step to simplify this step.
6. IPexpress modules and IP can be further modified or updated later. After the .ipx file has been added to the Diamond project, it is visible in the project's file list. Double-clicking the .ipx file brings up the module/IP's configuration dialog box where changes can be made and the generation process repeated.

- "Downloading IPexpress IP" on page 192
- "Installing a Downloaded IP" on page 193
- "Generating a Module or IP with IPexpress" on page 194
- "IPexpress Output Files for Modules" on page 196
- "Regenerating a Module or IP with IPexpress" on page 196
- "Importing an IPexpress Module or IP into a Project" on page 197
- "Instantiating an IPexpress Module or IP" on page 198

Running IPexpress

IPexpress can be run as part of the open design project or as a separate, stand-alone tool. When run as part of a project, module selection is limited to modules that work with the project's FPGA. When run as a stand-alone tool, all modules are available and they can be created for any device type. IPexpress is usually run as part of a project. Stand-alone mode can be used to create a library of modules.

On Linux, IPexpress can also be run from the command line as a stand-alone tool.

To run IPexpress with your design project:

- Choose **Tools > IPexpress**.

To run IPexpress as a stand-alone tool, from your Windows desktop:

- From the Start menu, choose **Programs > Lattice Diamond > Accessories > IPexpress**.

To run IPexpress from the Linux command line:

- From the Linux command line, navigate to the <*install_path*>/bin/lin directory and enter **./ipexpress** on the command line.

  Note

  If this path has been included in your PATH environment variable definition, you do not have to navigate to it.

Downloading IPexpress IP

You can use IPexpress to download and install the latest IP available from Lattice Semiconductor. Before you can download any IP, you need to set up an Internet connection. If you haven't already, choose **Tools > Options**. In the Options dialog box, select **Environment > Network Settings** and fill in the dialog box.

The Web site also has links to other vendors of IP. To see all that's available and to learn about licensing and other vendors of IP, go to the Lattice Web site: www.latticesemi.com/ip.

To download Lattice IP:

1. If you are working on Linux and this is the first IP you have ever installed, go to your home directory and, with a text editor, create an empty file named **ipsetting_l.lst**. Enter no text: the file must be empty and must have this name. If you find you already have a file with this name, do not change it. This is a text file listing your IP and their path names.
2. In IPexpress, click the IP Server button, located at the upper-left of the tool.
3. Click **IP** in the left pane.

The software connects to the Lattice Semiconductor Web site.

4. Expand the folder tree and select the IP you want to download.

   Information about the IP appears in the right pane including links for additional information.

   IP that are not compatible with your version of Diamond have an X on their icons. You can still download and install these IP but you need to upgrade your Diamond software to use them. Look for software requirements in the right pane.

5. Do one of the following:

   - To download and install the IP, right-click the IP and choose **Install** in the pop-up menu.
   - To just download the IP for later installation, right-click the IP and choose **Download** in the pop-up menu.

6. Follow the on-screen instructions.

See Also ▶"Installing a Downloaded IP" on page 193

Installing a Downloaded IP

After downloading an IP, you must install it to make it available in IPexpress.

Installing on Windows **To install the IP:**

1. If IPexpress is open, close it.
2. Go to the location where you saved the IP.
3. Double-click the executable file (.exe).

   The Lattice Semiconductor Setup program opens.

4. Follow the on-screen instructions.
5. Open IPexpress to see the installed IP. Click the Local button and then expand the **IP** folder tree.

   Only IP that work with the selected device and your version of Diamond are available. Unavailable IP have a red X icon, , beside them.

   If you started IPexpress from Diamond's main window, the selection is automatically limited to the device of the design project.

   If you are running IPexpress in stand-alone mode and want access to all the IP, choose **All Device Families** from the menu in the toolbar.

Installing on Linux To install an IP that you downloaded earlier on Linux, the process depends on whether the download is a tar file (.tar.gz) or a shell file (.sh).

To install the IP from a tar file:

1. If this is the first IP you have ever installed, go to your home directory and, with a text editor, create an empty file named **ipsetting_l.lst**. Enter no

text: the file must be empty and must have this name. If you find you already have a file with this name, do not change it. This is a text file listing your IP and their path names.

2. Go to the location where you saved the IP.
3. Enter the following in a command line:

   tar -zxvf <*filename*>**.tar.gz**

4. In IPexpress, click the Import User Configurable IP button.
5. In the dialog box, browse to the installation directory for the IP and select **nodeinfo.cfg**.
6. Click **Open**.
7. To see the installed IP, click the Local button and then expand the **IP** folder tree.

To install the IP from a shell file:

1. Go to the location where you saved the IP.
2. Enter the following in a command line:

   sh <*filename*>**.sh** <*Diamond install path*>**/bin/lin** [<*destination path*>]

   The <*destination path*> is the full path name of where you want the IP to be installed. If not included, the IP will be installed in the current directory.

   The first time you install an IP, IPexpress creates a file, ipsetting_l.lst, in your home directory. This is a text file listing your IP and their path names.

3. To see the installed IP, click the Local button and then expand the **IP** folder tree.

Generating a Module or IP with IPexpress

Use IPexpress to generate a customized functional block from any module or installed IP.

Note

Lattice Synthesis Engine (LSE) is not currently used to generate IP. When LSE is selected to be used for your design, the IP generation step (done within IPexpress) will use Synplify Pro.

ROM modules require that a memory initialization (.mem) file be available before generating a customized module. The memory initialization file is optional with RAM modules. See “Creating a Memory Initialization File with Memory Generator” on page 202.

To generate an IP or module:

1. If you are running IPexpress as a stand-alone tool, then choose a device family from the menu in the toolbar. Only modules and IP that work with

that device and your version of Diamond will be available. Unavailable modules will have a red X icon,  or  , beside them.

If you started IPexpress from a Diamond project (Diamond's main window), the functional block selection is automatically limited to the device of the design project.

2. In the Module/IP tree, select the module or IP that you want to generate.
3. To get more information about the module or IP, click the **About** tab.
4. In the Configuration tab, specify general project information and the base file name for the module or IP. If you started IPexpress from a Diamond project (Diamond's main window), all but File Name and Module Output have been filled in from the design project. You can still change Project Path if you want.
   - Project Path is the location for the customized module's files.
   - File Name is the base name for the module's files (that is, with no extension).
   - Module Output is how the module will be coded.
   - Device Family is the device family that the module will be optimized for. This can be different from the device family selected in the toolbar.
   - Part Name is the exact device that the module will be optimized for.
   - Synthesis is the synthesis tool that will be used while generating the module.
5. Click **Customize.**

   The module's dialog box opens.
6. In the dialog box, choose desired options. To get information about the options, click **Help**. Also, check the About tab in IPexpress for links to technical notes and user guides. IP may come with additional information.

   As the options change, the schematic diagram of the module changes to show the ports and the device resources the module will need.
7. To automatically import the .ipx file into your project when the module/IP is generated, select **Import IPX to Diamond project** (not applicable in IPexpress stand-alone mode). If you do not select this option, the .ipx file must be added to the project. See "Importing an IPexpress Module or IP into a Project" on page 197.
8. Click **Generate**.
9. Click the **Generate Log** tab to check for warnings and error messages.

See Also

- "Creating a Memory Initialization File with Memory Generator" on page 202
- "IPexpress Output Files for Modules" on page 196

IPexpress Output Files for Modules

IPexpress creates the following output files for modules under the specified Project Path. The <*file_name*> comes from the File Name specified in the Configuration tab.

IPexpress creates some different files for IP. These are documented in the IP's associated user guide.

Table 3:

File Name	Description
<*file_name*>.ipx	Manifest file. This file is loaded into IPexpress so that modifications can be made to the module.
<*file_name*>.lpc	Parameter file.
<*file_name*>.naf	Internal file. Do not edit.
<*file_name*>.srp	Report file.
<*file_name*>.sym	Internal file. Do not edit.
<*file_name*>.tmpl.v	Instantiation template for Verilog netlist.
<*file_name*>.tmpl.vhd	Component/instantiation template for VHDL netlist.
<*file_name*>.txt	Configuration file for PCS and System Bus modules.
<*file_name*>.v	Verilog HDL file for both synthesis and simulation. Verilog output files declare implicit wire types.
<*file_name*>.vhd	VHDL file for both synthesis and simulation.
<*file_name*>_generate.log	IPexpress log file.
msg_file.log	Log message file.
tb_<*file_name*>_tmpl.v	Verilog test bench template.
tb_<*file_name*>_tmpl.vhd	VHDL test bench template.

Regenerating a Module or IP with IPexpress

By regenerating a customized module or IP you can modify any of its settings including: device type, design language, and any of the options specific to the module. You can also update older modules or IP to the latest version.

Regenerating can be done to modify an existing module or to create a new but similar one.

Note

If the module was originally customized with ispLEVER, you may see an .lpc file but no .ipx file. The .ipx file is new with Diamond. However, Diamond also supports .lpc files for backward compatibility. When you regenerate a module from ispLEVER, the .lpc file is replaced with an .ipx file.

To just change the option settings of a module or IP that is already in a design project, double-click the module's .ipx file in the File List view. This opens IPexpress and the module's dialog box showing the current option settings. Then go to step 6 below.

To regenerate a module or IP:

1. In IPexpress, click the Regenerate button.
2. In the Regenerate view of IPexpress, choose the IPX source file of the module or IP you wish to regenerate.
3. IPexpress shows the current settings for the module or IP in the Source box. Make your new settings in the Target box.
4. If you want to generate a new set of files in a new location, set the location in the IPX Target File box. The base of the file name will be the base of all the new file names. The IPX Target File must end with an .ipx extension.
5. Click **ReGenerate**.

   The module's dialog box opens showing the current option settings.
6. In the dialog box, choose desired options. To get information about the options, click **Help**. Also, check the About tab in IPexpress for links to technical notes and user guides. IP may come with additional information.

   As the options change, the schematic diagram of the module changes to show the I/O and the device resources the module will need.
7. To import the module into your project, if it's not already there, select **Import IPX to Diamond project** (not available in stand-alone mode).
8. Click **Generate**.
9. Check the **Generate Log** tab to check for warnings and error messages.
10. Click **Close**.

Importing an IPexpress Module or IP into a Project

After generating module source files using IPexpress, you can import the module by importing the IPexpress manifest file (.ipx). Modules and IP have several files of different types but you only need to import the .ipx. The .ipx file identifies the components needed to make up the module or IP.

Note

If the module was originally customized with ispLEVER, you may see an .lpc file but no .ipx file. The .ipx file is new with Diamond. However, Diamond also supports .lpc files for backward compatibility. If there's no .ipx file, select the .lpc file.

Importing the module may not be necessary if the "Import IPX to Diamond project" option was selected when the module was generated.

To import a module:

1. In the File List view, right-click the implementation folder () and choose **Add > Existing File**.
2. Browse for the customized module's .ipx file, <*file_name*>**.ipx**, and select it.
3. Click **Open**.

   The .ipx file is added to the File List view.
4. Check the Output Panel for error messages. If the module is not targeted for the current device, try double-clicking the file to regenerate the module.

After importing the module, you can further customize it for your design project including changing the device type, design language, and any of the options specific to the module. You can also update older modules or IP to the latest version. See "Regenerating a Module or IP with IPexpress" on page 196.

Instantiating an IPexpress Module or IP

IPexpress modules and IP are instantiated the same way other modules are in your HDL. When you generate modules and IP in IPexpress, the tool also produces a Verilog or VHDL file with the necessary instantiation commands. You can copy and paste the contents of this file into one of your source files.

Before you instantiate any IPexpress module, check that it is compatible with your design project's device. When they were created, the modules were optimized for a specific device and may depend on that device's architecture. A module may not work with a different type of device and may need to be regenerated. If so, see "Regenerating a Module or IP with IPexpress" on page 196.

The instantiation file is located in the folder that the module was created in. The file name is based on the module's name: <*module name*>_tmpl.v or <*module name*>_tmpl.vhd.

Copy the instantiation command and paste it into one of your source files. Then add an instance name and signal names to the module ports.

Note

The following I/O modules from IPexpress cannot be used as the top level of a design. These must be instantiated within another module: DDR, DDR_GENERIC, DDR_MEM, DQS, and SDR.

Before running any processes on the design, make sure that the IPexpress module or IP has been imported into the project. See "Importing an IPexpress Module or IP into a Project" on page 197.

Using PMI

PMI (Parameterized Module Instantiation) is an alternate way to use some of the modules that come with IPexpress. With PMI, instead of using IPexpress, you directly instantiate a module into your HDL and customize it by setting parameters in the HDL. You may find this easier than using IPexpress if your design requires many variations of the same module.

But PMI requires some extra steps for simulation and synthesis. PMI modules are treated as black boxes in design projects. So simulation outside of Diamond, with a third-party simulator, requires compiling a simulation library. And synthesis requires that a synthesis header file be added to the design project or to the project of a standalone synthesis tool, if using one.

See Also

- “Use PMI or IPexpress?” on page 190
- List of PMI modules, see Table 142 on page 1401
- “PMI Process Steps” on page 199
- “Instantiating a PMI Module” on page 200
- “Requirements for Simulation and Synthesis with PMI” on page 201

PMI Process Steps

This section provides a brief listing of the process steps you take when using PMI.

1. Using Source Editor, insert PMI modules in the HDL source files. This is the recommended method because it includes the PMI instance templates, which require minimal editing.
2. Observe the PMI requirements to ensure successful functional simulation.

   Since PMI block generation occurs post-synthesis, functional simulation uses simulation models for these blocks. If you are running simulation in Aldec Active-HDL, these models are automatically used. If you are using another simulator, you must first compile the simulation library.

   See “Requirements for Simulation and Synthesis with PMI” on page 201 for more details.
3. Add the PMI synthesis header files to your design project or to your stand-alone synthesis tool’s project.

   When synthesis is run, your PMI block instance will pass through the process as a black box definition. The PMI synthesis header file contains a comprehensive list of all necessary module/component declarations. This saves you from having to create these declarations yourself or to obtain them from some other source.

   See “Requirements for Simulation and Synthesis with PMI” on page 201 for details.
4. After synthesis, run the Translate Design process (EDIF2NGD and NGDBUILD). Note: If you are using LSE as the synthesis tool, Translate

Design is automatically included with synthesis. During this step, the module generation that is required to implement the various instances in your design is performed. This process will result in the output of multiple .ngo files that are then input into one output .ngd file.

5. Perform the remaining implementation steps as you would normally.

Instantiating a PMI Module

PMI modules are instantiated the same way other modules are in your HDL. The Diamond software provides a template for the Verilog or VHDL instantiation command that specifies the customized module's ports and parameters. You customize the module by changing the parameters.

To instantiate a PMI module:

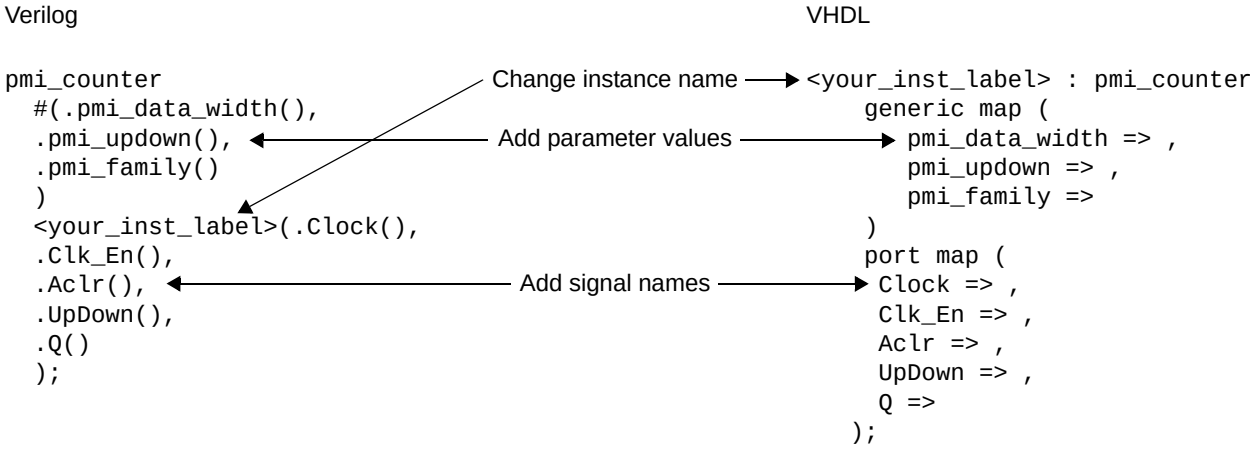
1. With Source Editor, open the source file that will receive the module. See "Running Source Editor" on page 166.
2. Place the cursor in the desired spot for the instantiation command.
3. Choose **View > Template Editor**.

   The Template Editor view appears.
4. In Template Editor, open the **System Templates > PMI** folder and select the module.

   The code of the template shows in the lower box of the Template Editor view.
5. Right-click the template and choose **Insert to text**.

   The instantiation command is copied into your source file.
6. Add an instance name, set parameter values, and add signal names to the corresponding module ports in the instantiation command. For information about allowed parameter values, see the section on the module in the "Lattice Module Reference Guide" on page 1399.

Figure 20: PMI Instantiation Command Example



7. Save and close the source file.

Note

Simulation and synthesis require additional preparation. VHDL also has some additional requirements. See “Requirements for Simulation and Synthesis with PMI” on page 201.

Requirements for Simulation and Synthesis with PMI

Unlike IPexpress module generation, which produces source files that contain all of the necessary code for simulation, the PMI module code is a black box definition of an IPexpress module. For this reason, simulation models for these blocks must be available to supplement the code for simulation. For synthesis, a PMI synthesis header file needs to be added to the project.

VHDL designs have a few additional requirements for both synthesis and simulation.

PMI Simulation Models For Aldec Active-HDL, the PMI models are automatically available. When using ModelSim, or any other simulator, you must first compile the simulation library (pmi_work) from the sources, which are in:

<*install_dir*>/cae_library/simulation/verilog/pmi

Note

No VHDL PMI models exist. The pmi_work library is compiled from Verilog modules and used in both Verilog and VHDL simulation. The VHDL simulation must run in a mixed-HDL environment.

PMI Synthesis Header Files The PMI synthesis header files for Verilog and VHDL, respectively, are at:

<*install_dir*>/cae_library/synthesis/verilog/pmi_def.v
<*install_dir*>/cae_library/synthesis/vhdl/pmi_def.vhd

If you are running synthesis from inside Diamond (the integrated flow), add the PMI synthesis header file to your design project by right-clicking the implementation folder ( ) in the File List view and choosing **Add > Existing Source**.

If you are running the synthesis tool outside Diamond (the interactive or stand-alone flows), add the PMI synthesis header file to your synthesis tool project.

VHDL Requirements When performing simulation for VHDL PMI, you also need to compile the PMI component declaration file into your work library. The file is at:

<*install_dir*>/cae_library/simulation/vhdl/pmi/pmi_def.vhd

At the top of your source file, add two lines:

```
use work.pmi_components.all;
library pmi_work;
```

The first line includes the PMI components defined in the header file. The second line is required by some simulators, such as Active-HDL, for successful library binding.

Creating a Memory Initialization File

A memory initialization (.mem) file is an ASCII text file that specifies the initial contents for the memory modules in your design. A .mem file is required to create ROM and optional when creating RAM modules with IPexpress or PMI.

A .mem file can be most easily created or edited using Diamond's Memory Generator. But you can also create a .mem file using any text editor. Use the file format described in the following section.

See Also

- "Creating a Memory Initialization File with Memory Generator" on page 202
- "Memory Initialization File Format" on page 203

Creating a Memory Initialization File with Memory Generator

Diamond's Memory Generator is the easiest way to create or edit a memory initialization file.

To create a memory initialization file:

1. Choose **File > New > File**.

   The New File dialog box opens.
2. Under Categories, click **Other Files**.
3. Under Source Files, click **Memory Files**.
4. Fill in a name and location for the new memory initialization file.
5. Click **New**.

   The Memory Generator tab opens showing the file name that you specified.
6. In the Options view, set file format and memory size in the File Format, Depth, and Width boxes. See "Memory Initialization File Format" on

page 203 for more information. Then click **Update** to apply your changes and refresh the display.

Note

If you close the Options view and want to get it back, choose **View > Options View**.

7. In the Options view, choose the Address Radix and Data Radix for the display.

Note

The Radix settings only specify in which format the addresses and data values are displayed and entered in the Memory Generator window. They do not affect the memory data format recorded in the .mem file. The data format in the .mem file depends on the File Format option.

8. Fill in the memory contents in the right pane using the following methods:
   - Click in a cell and type in the value. You can use the arrow and Tab keys to move between cells.

     The values you enter should match the format specified in the Data Radix box. Values that are too large are displayed in blue. You are not allowed to save a file with blue values.
   - To find a location in a large memory, type the address into the “Jump to” box and click **Go**.
   - To fill a block of memory with the same value, type the first and last addresses of the block into the From and To boxes (under Filling). Type the memory value into the Fill box. Then click **Fill**.
9. When you finish, choose **File > Save** <*filename*>.

See Also ▶“Memory Initialization File Format” on page 203

Memory Initialization File Format

A memory initialization (.mem) file is an ASCII text file that consists of a header followed by lines of memory data. The data must be in one of the following formats: Bin (binary), Hex (hexadecimal), or Address-Hex (described below).

For hexadecimal values, both upper and lower case can be used. If the data has fewer bits than the specified data width, the most significant bits are filled with 0. Any address not specified will be filled with 0.

Comments can be added at any point after the header (defined below) by starting the comment with a pound sign (#) or two slashes (//). The comment then includes everything to the end of the line. Comments may be added to any of the data, but never add comments to the header.

Header A .mem file starts with a header, which declares the file format, memory size, and address and data display radix for Memory Generator. The syntax of the header is:

#Format=Bin | **Hex** | **AddrHex**
#Depth=<*1-65536*>
#Width=<*1-256*>
#AddrRadix=<*index_number*>
#DataRadix=<*index_number*>
#Data

The <*index_number*> can be one of the following numbers. AddrRadix and DataRadix can have different values.

Binary: 0
Octal: 1
Decimal: 2
Hexadecimal: 3

For example, the following header says the .mem file is using the binary format for a 32x8 memory. When displayed in Memory Generator, the address will be shown in hexadecimal and the data will be shown in binary.

```
#Format=Bin
#Depth=32
#Width=8
#AddrRadix=3
#DataRadix=0
#Data
```

Bin and Hex Formats The data is represented in binary or hexadecimal format. Each line of data specifies the contents for one memory location, starting with address 0. That is, the first line is for address 0, the second line is for address 1, and so on. For each line, the data is interpreted as least significant bit on the right.

For example, in the Bin format, the following lines will initialize address 0 to “00011011”, address 1 to “11111010” (assuming it is a 32x8 memory).

```
# for a 32x8 memory
11011
11111010
```

In the Hex format, the following lines will initialize address 0 to “003B”, address 1 to “FB0A” (assuming it is a 32x16 memory).

```
# for a 32x16 memory
3B
FB0A
```

AddrHex The data is represented in hexadecimal format. Each line consists of an address followed by a colon and then any number of data words, separated by spaces:

<*address*>:<*data*> <*data*> <*data*> ...

The data will be applied starting at <*address*> and filling in sequentially from there.

For example:

```
A0:03 F3 3E 4F
B2:3B 9F
```

will initialize A0 with 03, A1 with F3, A2 with 3E, A3 with 4F, B2 with 3B, and B3 with 9F. The other addresses will be initialized to 0. So A4 through B1 will be set to 0.

See Also ▶"Creating a Memory Initialization File with Memory Generator" on page 202

Creating Your Own Black Box Modules

In some cases, you may not want to distribute HDL source code because of the risk of changes or of exposing proprietary information. So, Lattice Semiconductor offers a compiled Native Generic Object (NGO) netlist format as an alternative to HDL.

Advantages and Disadvantages An NGO netlist has the following advantages over HDL source code:

- Hides details of internal logic
- Easy to distribute
- Optimized to meet timing or area requirements
- Optional grouping and floorplan constraints

On the other hand, an NGO netlist:

- May not be portable across all device families
- Cannot be parameterized

Overview of the Black Box Process The following are the basic steps for creating and using a black box module. For details about performing these steps, see the topics listed under "See Also."

1. Create an NGO netlist.

   Start with a design project just for the module and add some attributes. Then run the synthesis and Translate Design processes.

2. Create support files.

In addition to the NGO netlist, users of the black box module will need additional information such as declaration and instantiation templates, a data sheet, a simulation model, and timing attributes.

Note

NGO blocks will be given a unique name which is constructed by appending the parameter value to the name of the NGO module as in the following example.

For the following module :

```
module my_add_sub (DataA, DataB, Add_Sub, Result);
parameter bit_width = 6;
...
endmodule
```

After generating the NGO file, the ngo must be renamed with the parameter value appended to the module name as shown below:

```
"my_add_sub_6.ngo"
```

3. Instantiate the module.

   Following the instructions from the module's data sheet, copy the declaration and instantiation templates into your design project.

See Also

- "Creating an NGO Netlist" on page 206
- "Support Files for the Black Box Module" on page 207
- "Instantiating a Black Box Module" on page 208

Creating an NGO Netlist

To create an NGO netlist for a black box module, you just need to add synthesis attributes to the ports and run the synthesis and Translate Design processes. The exact procedure depends on your synthesis tool: Translate Design runs as a part of Lattice Synthesis Engine (LSE); Translate Design is a separate step with Synplify Pro.

To create an NGO netlist for a module:

1. Create a design project for the module.
2. If using:
   - LSE, set "Use IO Insertion" to False in the Synthesis options.
   - Synplify Pro, set "Disable IO Insertion" to True in the Synthesis options.
3. If you want to include floorplan information, add grouping (UGROUP/HGROUP) or placement (REGION, LOC) attributes.

   Floorplan constraints can improve performance with some designs but may make the NGO netlist less portable across devices.
4. Synthesize the design.

If using LSE, an NGO netlist (.ngo) file is created.

5. If using Synplify Pro, double-click **Translate Design** in the Process view.

   An NGO netlist (.ngo) file is created.

Support Files for the Black Box Module

To maximize the value of a black box module, you need to create additional material such as declaration and instantiation templates, a data sheet, a simulation model, and timing attributes. The declaration and instantiation templates are the minimum information someone else will need to use the module. The other items are recommended but not required.

Declaration Templates Users will need to know how to declare the module in their designs. The simplest way to is to supply a file with the code. In the file, create an empty Verilog module or VHDL architecture declaration. Add “black box” synthesis attributes for the module and any ports that must attach to external PIOs. See Figure 21 on page 207 for an example (the synthesis attribute is for Synplify Pro).

Figure 21: Verilog Sample Declaration

```
module top (DAT_B, DAT_A, CD, CK, DAT, OE)
/* synthesis syn_black_box black_box_pad_pin="DAT_B[15:0]" */;
input CD;
input CK;
input OE;
input [15:0] DAT;
inout [15:0] DAT_B;
output [15:0] DAT_A;
endmodule
```

Instantiation Template Users will also need a template for instantiating the module. In another file, create a Verilog or VHDL instantiation template such as shown in Figure 22 on page 207. Include the “FILE=” attribute for the .ngo file name. The synthesis attribute is for Synplify Pro.

Figure 22: Verilog Sample Instantiation Template

```
// Register/Bidirectional Circuit (Lattice NGO)
top top_1_ (
.DAT_B (DAT_B),
.DAT_A (DAT_A),
.CD (CD),
.CK (CK),
.DAT (cnt),
.OE (OE))
/* synthesis FILE="top.ngo" */;
```

Data Sheet Users will probably need more information to use the module effectively. So create a data sheet for the module with details about what the module does, I/O port function and format, and support contacts.

Simulation Model To fully simulate their designs, users will need a simulation model of the module. Base the model on RTL code. If there are restrictions on how the module is used, pre-compile the model for the target simulator. If you provide the RTL itself, make it clear that the RTL should not be re-synthesized unless you are willing to risk timing changes.

Timing Attributes To fully analyze the timing of their designs, users will need timing information for the module. Create an example use of the module and run static timing analysis. Then add “black box timing” attributes to the Verilog module or VHDL component declaration file.

Instantiating a Black Box Module

A black box module may come with a few files besides the .ngo file. The module should come with a template for the instantiation command and an empty Verilog module or VHDL component declaration. The module may also come with a datasheet, a simulation model, or an example implementation. See “Support Files for the Black Box Module” on page 207.

If there’s a datasheet, refer to it for information about the module and instructions for its use.

Note

Check what device the module was created for. If your design project is not using the same or a very similar device, the module may not work.

To instantiate an NGO module:

1. Do one of the following:
   - Copy the .ngo file to the local project folder.
   - Specify the file’s location in the Macro Search Path setting of the Translate Design process in the project’s strategy.
2. Copy and paste the instantiation template and the module declaration into your design files. This can be done with Diamond’s Source Editor or you can use any text or HDL editor.
3. In the instantiation command, add an instance name and signal names to the corresponding module ports.

Designing with Lattice Library Primitives

Any Lattice library primitive described in the “FPGA Libraries Reference Guide” on page 1664 can be instantiated as a Verilog module or VHDL component in your RTL design. This sort of “gate-level” design can be error-prone and should be limited to a small number of primitives if attempted at all. In general, Lattice recommends you rely on IPexpress to generate modules that are built with Lattice library primitives.

To minimize the amount of code overhead required to design with a library primitive, Lattice provides a Verilog and VHDL synthesis header library file for each major FPGA device family. Refer to the “Lattice Synthesis Header Libraries” on page 577 topic for details. Typically the module is treated as a “black box” which causes the synthesis tool to pass instances of the library primitive into the target netlist untouched.

Global signals for global set/reset (GSR), power-up reset (PUR), tri-state all (TSALL), and the internal oscillator (OSCA, OSCC, OSCD, OSCE, OSCF) can be used within structural models built with Lattice library primitives. For more information, see “How to Use the Global Set/Reset (GSR) Signal” on page 1174, “How to Use the Tristate Interface (TSALL) Global Signal” on page 1190, and “How to Use the Internal Oscillator” on page 1192

The “FPGA Libraries Reference Guide” on page 1664 contains descriptions, pinouts, and schematic diagrams of all library primitives for Lattice FPGA libraries.

See Also ▶“FPGA Libraries Reference Guide” on page 1664

- “How to Use the Tristate Interface (TSALL) Global Signal” on page 1190

Creating Clarity Designer Modules

Improving design entry has been a goal for many generations of software tools. Early tools used only designer entered source and very small basic cell library blocks. Later tools expanded the area for pre-made or generated blocks. But these tools only provide single-block generation. As multiple complex blocks are used in devices, resource allocation problems often occur. These issues require blocks to be planned together and potentially can even require blocks to be generated with certain options to allow maximum utilization. To solve these problems tools that can provide capabilities beyond simple module generation are required.

Clarity Designer Benefits and Features

Clarity Designer is a tool within the Lattice Diamond software environment that addresses the need to be able to generate and plan multiple blocks together. Clarity Designer is used for configuration of blocks, building the connections between blocks, and planning the resources used by the PCS and DDR blocks in the design. For device families supported by Clarity Designer, IPexpress functionality is accomplished along with functionality for building and planning. The IPexpress tool is disabled when using a device family supported by Clarity Designer. Device families that are not supported yet by Clarity Designer still require the use of IPexpress. Clarity Designer is currently only available for the ECP5 device family. A comparison chart between IPexpress and Clarity Designer features is shown in Table 4.

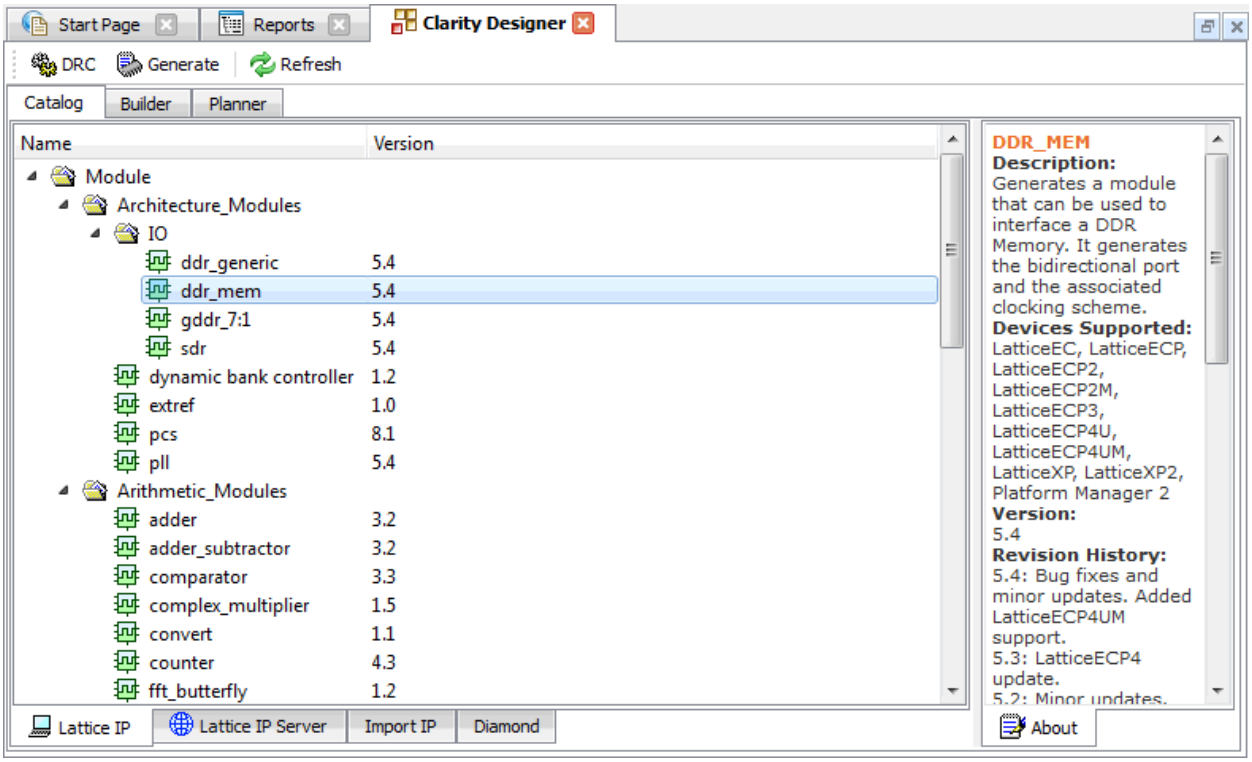
Table 4: IPexpress versus Clarity Designer

		IPExpress	Clarity Designer
Configuration / Generation			
	Modules	Yes	Yes
	IP	Yes	Yes
	Download IP	Yes	Yes
Building			
	Rule checking	No	Yes
	Generate Connectivity	No	Yes
	Connection Assistance	No	Yes
	Design Reuse	No	Yes
Planning (PCS & DDR)			
	Pre-Synthesis	No	Yes
	Placement Assistance	No	Yes
	Rule checking	No	Yes
	Graphical usage	No	Yes

Configuration and Importing

Clarity Designer produces design (.sbx) files that can be used in the design project like an HDL file or an IPexpress generated (.ipx) file. A key difference compared to IPexpress generated files is that Clarity Designer files can contain multiple modules or IP blocks, not just a single block and can represent a subsystem. With IPexpress, the process is to generate a module or IP. This is one step since an IPexpress file can only contain one module or IP. For Clarity Designer, the saving of a file is a separate step. Modules or IP are configured and then more modules or IP can optionally be added within the same file. Additionally, since building and planning can also be done, saving the file and generating the blocks needs to be done as a later step.

Figure 23: Clarity Designer Module and IP Configuration



Configuring modules is done by going to the **Catalog** tab, selecting the **Lattice IP** tab at the bottom of the window, and selecting a module or IP and then double-clicking. A separate dialog box will open that allows the appropriate options to be set and, when the configure button is pressed, this information will be added to the Clarity Designer file that is currently open.

To add new IP, when the **Catalog** tab is selected, select the **Lattice IP Server** tab at the bottom of the window, and click the IP folder to get an updated list of the available IP. Select the IP you want to download from the available list and click the **Download** or **Install** button. Once the IP is installed, it can be configured as explained above.

If an existing project is being migrated to Clarity Designer from IPexpress, existing IPexpress files in the design must be imported and saved as Clarity Designer files. To import existing .ipx files, in the **Catalog** tab, select the

Import IP tab at the bottom of the window. In the window you can now select the existing file and include the name of the converted module for use in Clarity Designer. After completing the necessary fields, press the Import button to complete the process. Each existing IPexpress file must be imported individually.

A unique feature in Clarity Designer compared to IPexpress is the ability to use an RTL module within the design as a block within the Clarity Designer file. This is the same as instantiating a block within an HDL module. It is important to understand that RTL modules are imported into Clarity Designer are not automatically updated when the RTL is changed. The tool must be manually refreshed if the RTL is updated. To import an RTL module, the HDL source code must already be in the Diamond project and showing in the file list. Then from the **Catalog** tab, select the **Diamond** tab at the bottom of the window. This will show an elaborated view of the design hierarchy. Double-click the instance that should be imported. The imported module will be available in the Builder tab for connecting to the rest of the design.

Building

Once one or more modules or IP have been configured, then any connections between them or to the top of the subsystem (file) can be set. Each Clarity Designer file is the equivalent of a subsystem like an HDL module. Information in the file can be self-contained within the subsystem or connected to the top where it can connect to a higher level of the design hierarchy. The Builder function allows blocks to be connected to each other or to the top of the design file (equivalent to an HDL module description of the blocks and connections). The Builder tab provides two ways to approach this task. See Figure 24 on page 213.

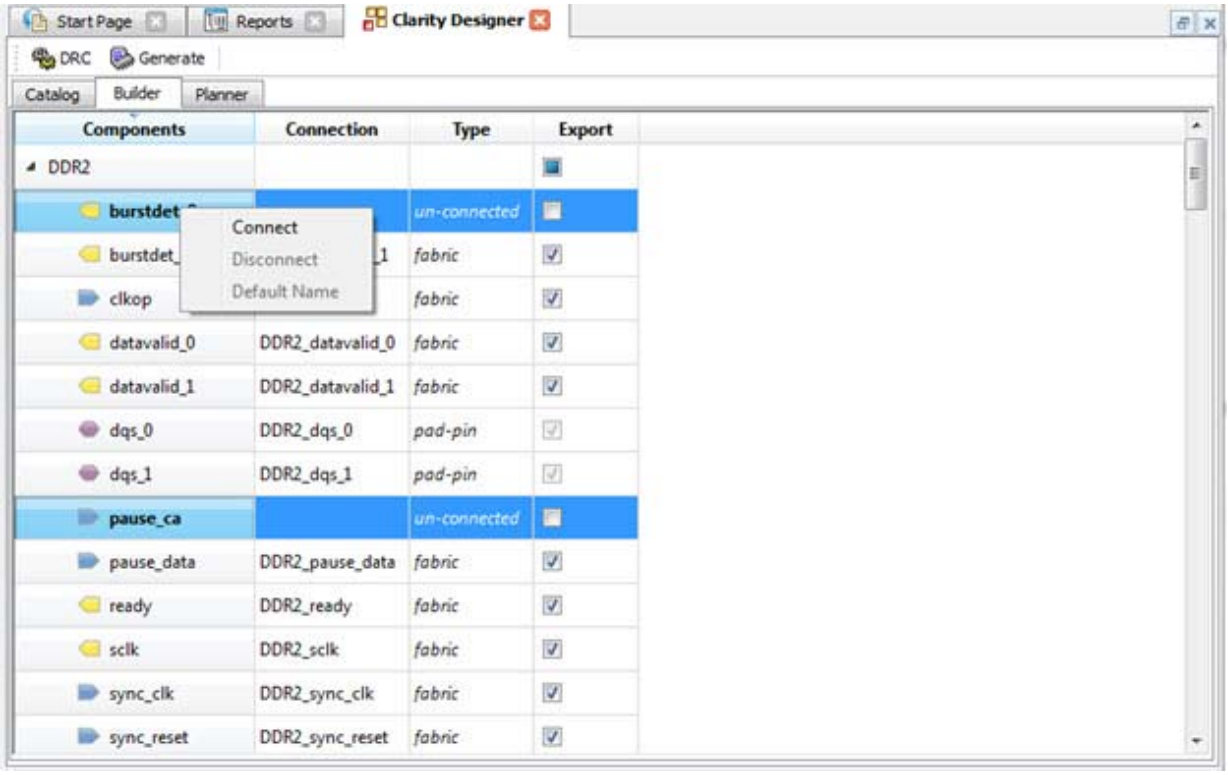
In the Components view, there are columns showing the components used, connections, connection type, and a column named “Export.” The Export column is for connecting a signal to the top of the Clarity Design file. Checking this column for a signal means that signal connects to the top of the file so it can be used at a higher level in the hierarchy. By default the Export column is checked when a module is created in order to mimic the behavior with IPexpress for creating a file with a single module. The Export column should be unchecked for signals that are connections between modules.

The Schematic view provides a schematic of the Clarity Designer module including a block for each module that you’ve added, external ports, and wires connecting them all.

Ports can be connected to each other or to the top of the Clarity Designer module in one of two ways in the Schematic view:

- Selecting them and then choosing from the right-click menu. To connect signals between modules, select the first signal, then Control-click on the second signal. Right-click on either signal name and then select **Connect** from the popup menu to complete the connection. Multiple signals can be connected by selecting them in this manner. To disconnect signal connections between modules, right-click on the signal and select **Disconnect** in the popup menu. Signals can be renamed by double-

Figure 24: Clarity Designer Building



clicking the signal name and typing in the new name. Refer to “Building with the Schematic View” on page 225.

- Using right-click and drag- and-drop functionality to connect available components, ports, and pins to other available components, ports, and pins. Refer to “Building with the Schematic View” on page 225.

The primary use of the builder functionality is to improve ease of use for connecting multiple modules. To connect signals between modules, select the first signal, then Control-click on the second signal. Right-click on either signal name and then select **Connect** from the popup menu to complete the connection. Multiple signals can be connected by selecting them in this manner. To disconnect signal connections between modules, right-click on the signal and select **Disconnect** in the popup menu. Signals can be renamed in the Property and Design tabs by double-clicking the signal name and typing in the new name. Signals cannot be renamed in the Schematic View.

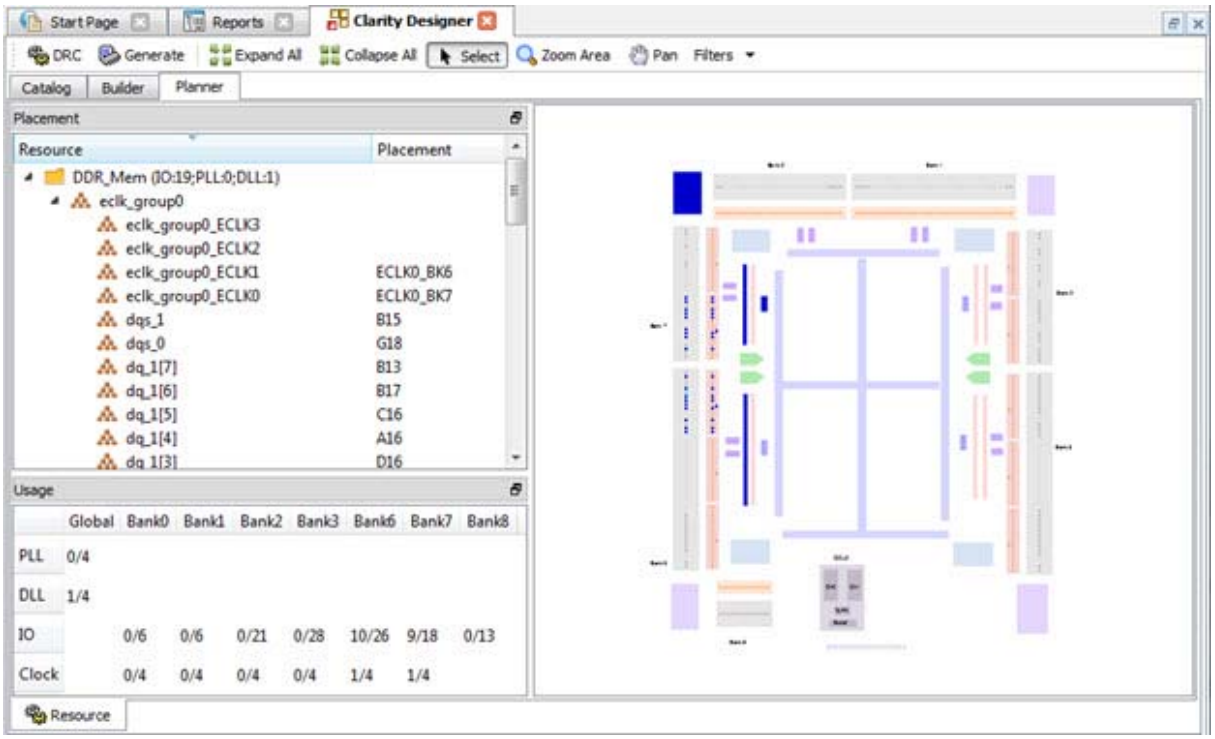
Planning and Determining Usage

After configuring and connecting modules, modules and IP can be placed in the Planner tab. Currently only PCS-based modules and IP, and DDR-based modules and IP are supported for placement. Other design elements should still be placed using Spreadsheet View or through LPF constraints.

In addition, the real-time resource usage report allows you to monitor the resource usage during the Planning phase. The usage information is updated

after each planning operation. The report displays used resources and total available resources, as shown in Figure 25.

Figure 25: Clarity Designer Planning



Design elements that can be placed are shown in the left panel and a chip-level view of the FPGA and available resources are shown on the right. Elements can be dragged from the left panel onto the appropriate resource on the right panel to be placed. When an element is dragged onto a resource that can be used, the cursor will change to a “+” to show a valid solution is possible. The chip view on the right can be zoomed in and out to help with placing the design elements. Design elements can be dragged as a group or as individual elements to be placed.

For details on how to do placement on PCS/SERDES and DDR modules, “PCS/SERDES Planning” on page 226 and “DDR I/O Planning” on page 232.

Diamond Integration

Clarity Designer outputs source files that are used in a Diamond project like other source file types such as VHDL, Verilog, EDIF, or IPexpress files. Clarity Designer files must be added to the file list in order to be used for a project.

To be added to the file list, the file must be generated. This should be done after the configuration, building, and planning steps. To generate the file, click the Generate button in the Clarity Designer window toolbar.

Currently Diamond projects support using Clarity Designer files either as a module for a level of hierarchy within a design project using HDL as the top level or as the top level of the design project.

Usage 1—Used as a Module If a Clarity Designer file is used as a module within an existing design, it must be instantiated within an HDL file, similar to how IPexpress modules are instantiated within an existing HDL design. Within an HDL design, multiple Clarity Designer files can be used. However, within a Clarity Designer file, an instantiated module cannot be another Clarity Designer file.

Currently, using Clarity Designer files as modules within an HDL design is recommended. This allows the current hierarchy of a design to be used without significant changes. If a Clarity Designer file is used as the top-level of the design, the design hierarchy must meet the requirements specified for top-level use.

Note that when instantiating generated subsystems in an HDL module, it is important to use the instance template generated by Clarity Designer. Top-level I/Os in the subsystem use port names based on instance and port names by default. Additionally, the instance needs an HDL attribute to indicate it is a Clarity Designer instantiation. Templates can be found in the directory in which the .sbx file was saved.

Usage 2—Top-Level of Design If a Clarity Designer file is used as the top-level of the design, the following requirements must be followed.

- All modules and IP must be directly instantiated within this file. Modules cannot be instantiated within an HDL file. For example, a PLL module must be in the top-level Clarity file. It cannot be instantiated within an HDL file.
- Any HDL in the design must be imported into the file as a module. HDL files can contain a hierarchy of other HDL modules, but no Clarity Designer modules or IP can be instantiated within the HDL.
- Clarity Designer files cannot be used as modules within another Clarity Designer file.

Basic Tasks

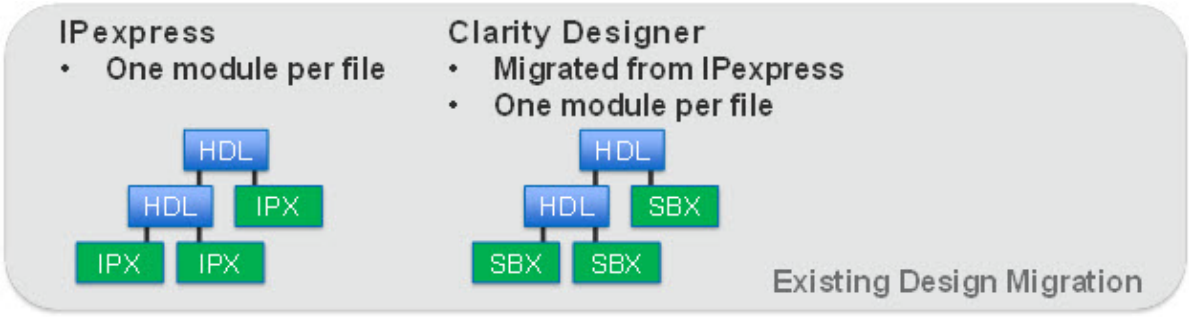
Tool usage falls into two primary methods: migrating existing designs in Clarity Designer and starting new designs in the tool.

Design Migration versus New Designs

When migrating an existing design into Clarity Designer, it is recommended that the design hierarchy should be unchanged and each existing IPexpress (.ipx) file should be imported into Clarity Designer and replaced with a new Clarity Designer (.sbx) file as illustrated in Figure 26 on page 216. The exceptions to this are PCS/SERDES and DDR modules and IP. Since these should be placed together for efficient resource use, the PCS/SERDES modules need to be in one Clarity Designer file and DDR modules in another

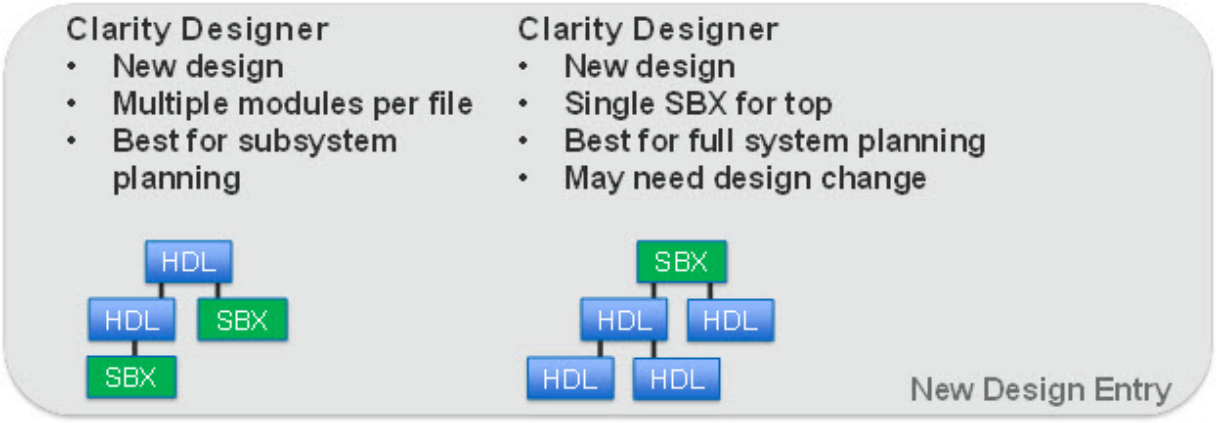
file. This means one module should be imported and then the existing Clarity Designer file should have the other modules copied and instantiated within it. See “Importing Existing PCS or DDR Modules or IP” on page 219 on steps needed for this.

Figure 26: Migrating Existing Designs in Clarity Designer



New designs can be optimized for efficient use in Clarity Designer. Modules that have a high amount of interconnection should be placed in the same Clarity Designer file. Modules at the same hierarchy level even though they are not interconnected can also be placed within the same file, as shown in Figure 27 on page 216. This will reduce the effort to configure, generate, and save them independently. The goal for new designs should be to use the tools most efficiently for your design structure rather than follow the same method needed for using IPexpress.

Figure 27: New Design Entry in Clarity Designer



Running Clarity Designer

To run Clarity Designer, first ensure that your device supports it. If it does not, it may support IPExpress instead.

To open the Clarity Designer startup dialog, do one of the following:

- Choose Tools > Clarity Designer

- Click  Clarity Designer in the toolbar

The tool can also be launched by choosing **File > New >**  **File** to create a new Clarity Designer file. Double-clicking an existing Clarity Designer file in the File List view will open that file and launch the tool. Only one Clarity Designer file can be open at a time.

Clarity Designer allows you to do the following tasks:

- Configure modules and IP from the Catalog tab
- Download and install new IP from the Catalog tab
- Import IPexpress (.ipx) files from an existing project and convert them into Clarity Designer format
- Import HDL modules from the project for use as modules within Clarity Designer
- Connect modules from the Builder tab
- Place PCS/SERDES and DDR elements into FPGA resources from the Planner tab

Using Single Module Generation The **Start Clarity Designer to generate a single Component SBX** option that appears when launching Clarity Designer provides a streamlined interface for generating single modules. This mode hides the Builder and Planner interfaces in Clarity Designer's main interface, as well as the DRC and Generate toolbar menus in Clarity Designer's toolbar menu. When customizing a module/IP, the Instance Path is editable and the Module Output does not have a default value.

To generate a module with Single Module Generation:

1. Open the Clarity Designer startup dialog
2. Select **Start Clarity Designer to generate a single Component SBX**
3. Click **Start**
4. Double-click an item in the Clarity Designer catalog to open the "Customize" dialog
5. Set the configuration options and click Configure to generate the module

   Clarity Designer will use this information to create and save the SBX file. If it does not exist in the Diamond File List, a pop-up dialog box will appear to confirm whether the file should be added to the File List.

To modify a module with Single Module Generation:

1. Open the Clarity Designer startup dialog
2. Select Open Clarity Design
3. Choose a Single Module/IP SBX file from the "Design File" list

4. Click Open

Note

You can also open a project by double-clicking it in the main window's File List tab.

5. Modify the configuration options
6. Click Configure

   Diamond will process the project file if the new SBX file is the project file. After the Configuration dialog closes, Clarity Designer will stay open in Single Component Mode.

Importing Existing Modules and IP from an Existing Design

Modules and IP that were generated with IPexpress and are in the project can be imported into Clarity Designer. They must be imported and configured, and the file generated and saved in the file list. Once the Clarity Designer (.sbx) file is saved in the file list, the existing IPexpress files must be deleted from the file list in order to successfully implement the design. The steps are shown below.

To import an IPexpress module:

1. Open Clarity Design using the toolbar, Tools menu, or by creating a new file.
2. In Clarity Designer, click the **Catalog** tab.
3. Click the **Import IP** tab (at the bottom of the view).
4. Click **Browse**.
5. In the Open IPX File dialog box, browse to the **.ipx** or **.lpc** file of the module. Use the .ipx if it is available.
6. Click **Open**.

   Most of the Import IP view is filled in.

7. Type in a name for Target Instance. This is the name that will be used for the configured module in the Clarity Designer project.
8. In the Target area, choose a Core Version. Usually you will leave it with the latest version.
9. Click **Import**.

   The module's dialog box opens.

10. In the dialog box, choose desired options. To get information about the options, click **Help**. Also, check the About tab in the Lattice IP view for links to technical notes and user guides. Downloaded IP may come with additional information.

    As the options change, the schematic diagram of the module changes to show the ports and the device resources the module needs.

11. Click **Configure**.
12. Click the **Generate Log** tab to check for warnings and error messages.
13. Click **Close**.
14. Click **Generate** in the Clarity Designer toolbar and import the Clarity Designer file into the File List view.
15. Delete the original IPexpress file from the File List view.

The module or IP is now configured and is available in the Builder tab for connections. It is recommended that the Clarity Designer file be saved and the process repeated for each existing IPexpress file. This will allow the original design hierarchy to be reused without changes. However, if any of the modules or IP use PCS/SERDES or DDR resources, use the procedure below.

Importing Existing PCS or DDR Modules or IP

Modules and IP that were generated with IPexpress and are in the project can be imported into Clarity Designer. They must be imported and configured, the file generated and saved in the file list. Once the Clarity Designer (.sbx) file is saved in the file list, the existing IPexpress files must be deleted from the file list in order to successfully implement the design. The steps are shown below for when an existing module or IP uses PCS/SERDES or DDR resources. This procedure is different because PCS modules or DDR modules should be in the same Clarity Designer file to allow proper planning of the resources in the FPGA.

To import a PCS or DDR module:

1. Open Clarity Design using the toolbar, Tools menu, or by creating a new file.
2. In Clarity Designer, click the **Catalog** tab.
3. Click the **Import IP** tab (at the bottom of the view).
4. Click **Browse**.
5. In the Open IPX File dialog box, browse to the **.ipx** or **.lpc** file of the module. Use the .ipx if it is available.
6. Click **Open**.

   Most of the Import IP view is filled in.
7. Type in a name for Target Instance. This is the name that will be used for the configured module in the Clarity Designer project.
8. In the Target area, choose a Core Version. Usually you will leave it with the latest version.
9. Click **Import**.

   The module's dialog box opens.
10. In the dialog box, choose desired options. To get information about the options, click **Help**. Also, check the About tab in the Lattice IP view for

links to technical notes and user guides. Downloaded IP may come with additional information.

As the options change, the schematic diagram of the module changes to show the ports and the device resources the module needs.

11. Click **Configure**.
12. Click the **Generate Log** tab to check for warnings and error messages.
13. Click **Close**.
14. Repeat steps 2 - 13 for each existing module using the same resources (all PCS/SERDES modules should be in one Clarity Designer file and all DDR modules in another Clarity Designer file).
15. Click **Generate** in the Clarity Designer toolbar and import the Clarity Designer file into the File List view.
16. Delete the original IPexpress file from the File List view.

The modules or IP are now configured and are available in the Builder tab for connections. They will also show in the Planner tab to allow those resources to be placed. Consolidating multiple modules within a single hierarchy level in a Clarity Designer file may require the original design hierarchy to be modified. This will vary for different designs on a case by case basis. Although this may cause design changes, there is a benefit to doing this. By putting the DDR modules, for example, in the same file these resources can now be planned together and feedback given on whether a valid placement is possible. Previously, constraints would need to be entered and if the solution was not valid, later implementation engine stages would generate errors. This new methodology is a faster and easier solution to placing resources within an FPGA and getting feedback if the solution is possible.

Current Restrictions

Clarity Designer contains several restrictions in this release. The list below lists the general usage restrictions. Restrictions within each module or IP are dependent upon the FPGA target and the use of that module or IP.

- Using Clarity Designer file as the top level of a design
  - All modules and IP must be directly instantiated within this file. Modules cannot be instantiated within an HDL file.
  - Any HDL in the design must be imported into the file as a module. HDL files can contain a hierarchy of other HDL modules, but no Clarity Designer modules or IP can be instantiated within the HDL.
  - Clarity Designer files cannot be used as modules within another Clarity Designer file.
- Builder tab connections
  - Cannot set HDL parameters of user modules.
  - Cannot tie ports with constants.
  - Cannot connect ports to logic equations.
- Implementation process

- No IPexpress (.ipx) files are allowed in the File List view.
- Clarity Designer (.sbx) files must be generated before they can be put into the File List view.
- Clarity Designer files must be in the File List view in order to correctly implement the design.

IP or Module Generation

IP or Module configuration is accomplished in the Catalog tab. Existing modules and installed IPs are listed in the Lattice IP sub-tab in the Catalog tab.

Downloading Additional IP

All available modules are installed with the Lattice Diamond software installation. Additional IP are downloaded from a Lattice IP site within the Clarity Designer tool. To add additional IP, the Lattice IP Server tab is used to download and install them.

To download Lattice IP:

1. If you are working on Linux and this is the first IP you have ever installed, go to your home directory and, with a text editor, create an empty file named **ipsetting_l.lst**. Enter no text: the file must be empty and must have this name. If you find you already have a file with this name, do not change it. This is a text file listing your IP and their path names.
2. In Clarity Designer, click the **Catalog** tab.
3. Click the **Lattice IP Server** sub-tab, located at the bottom of the tool.
4. Click **IP** in the left pane.

   The software connects to the Lattice Semiconductor Web site.
5. Expand the folder tree and select the IP you want to download.

   Information about the IP appears in the right pane including links for additional information.
6. Do one of the following:
   - To download and install the IP, right-click the IP and choose **Install** in the pop-up menu.
   - To just download the IP for later installation, right-click the IP and choose **Download** in the pop-up menu.
7. Follow the on-screen instructions.

Installing a Downloaded IP

After downloading an IP, you must install it to make it available in Clarity Designer.

Installing on Windows To install the IP:

1. If Clarity Designer is open, close it.
2. Go to the location where you saved the IP.
3. Double-click the executable file (.exe).

   The Lattice Semiconductor Setup program opens.
4. Follow the on-screen instructions.
5. Open Clarity Designer to see the installed IP. Click the **Catalog** tab and then the **Lattice IP** tab. Then expand the **IP** folder tree.

Installing on Linux To install an IP that you downloaded earlier on Linux, the process depends on whether the download is a tar file (.tar.gz) or a shell file (.sh).

To install the IP from a tar file:

1. If this is the first IP you have ever installed, go to your home directory and, with a text editor, create an empty file named **ipsetting_l.lst**. Enter no text: the file must be empty and must have this name. If you find you already have a file with this name, do not change it. This is a text file listing your IP and their path names.
2. Go to the location where you saved the IP.
3. Enter the following in a command line:

   tar -zxvf <*filename*>**.tar.gz**
4. In Clarity Designer, click the Import User Configurable IP  button.
5. In the dialog box, browse to the installation directory for the IP and select **nodeinfo.cfg**.
6. Click **Open**.
7. To see the installed IP, click the **Catalog** tab and then the **Lattice IP** tab. Then expand the **IP** folder tree.

To install the IP from a shell file:

1. Go to the location where you saved the IP.
2. Enter the following in a command line:

   sh <*filename*>**.sh** <*Diamond install path*>**/bin/lin** [<*destination path*>]

   The <*destination path*> is the full path name of where you want the IP to be installed. If not included, the IP will be installed in the current directory.

   The first time you install an IP, the installer creates a file, ipsetting_l.lst, in your home directory. This is a text file listing your IP and their path names.

3. To see the installed IP, click the **Catalog** tab and then the **Lattice IP** tab. Then expand the **IP** folder tree.

Configuring Modules or IP

To customize a module or IP with Clarity Designer, go to the Catalog tab. After the module or IP has been configured, it will be available in the Builder tab and, if it uses PCS/SERDES or DDR resources, the Planner tab.

To configure a module or IP:

1. In the Catalog tab, double-click the IP that you want to configure.

   A dialog box opens with some general information about the IP. To get more information about the IP, see the About tab to the right in Clarity Designer.

2. In the dialog box, specify the Instance Name. Instance Name is the base name for the module's files (that is, with no extension).
3. Choose from the Module Output menu. This is how the IP will be coded.
4. Click **Customize.**

   The IP's dialog box opens.

5. In the dialog box, choose desired options. To get information about the options, click **Help**. Also, check the About tab in Clarity Designer for links to technical notes and user guides. Downloaded IP may come with additional information.

   As the options change, the schematic diagram of the module changes to show the ports and the device resources the IP needs.

6. Click **Configure**.
7. Click the **Generate Log** tab to check for warnings and error messages.
8. Click **Close**.

   The IP is added to the Builder tab and, if it uses PCS/SERDES or DDR resources, to the Planner tab.

Building

After configuring modules and IP, they need to be connected to each other and to the top of the Clarity Designer subsystem. The Builder tab provides two ways to approach this task:

- The Components view provides a spreadsheet listing all of the modules and their ports. The columns show how the ports are connected.
- The Schematic view provides a schematic drawing of the modules and their ports. You can drag the parts to see how they fit together.

Click the tab at the bottom of the Builder view to select the mode that you want to start with. You can change mode anytime you want.

Once building is complete, the subsystem can be planned or generated and saved if no planning is required. Once the subsystem has been generated, the design can be implemented with the design flow in the Lattice Diamond software.

Building with the Components View

The Components view lists all of the modules in the Clarity Designer project along with all of their ports. For each port there are three fields:

- Connection is the name of the connecting net that you will define in Builder.
- Type is how the port was connected:
  - “un-connected” indicates the signal has not been connected yet.
  - “fabric” indicates a user-defined connection.
  - “internal” indicates a connection made in the Planner tab.
  - “pad-pin” indicates a connection to the I/O of the FPGA.
- Export is checked when the signal is connected to the top of the subsystem.

To connect a port to the top of the Clarity Designer subsystem:

- Select the check box in the Export column.

  The default name of the connecting net appears in the Connection column for the selected port. This will also be the name of the port in the Clarity Designer subsystem. The default name is based on the module and port names of the port. You can change the name by double-clicking it and typing over it.

To connect module ports to each other:

1. If you want to change a connection, right-click one of the ports and choose **Disconnect**.
2. Select the ports that you want to connect together. You can select several input ports if they will all use the same source. There can be no more than one output port selected. There can be zero output ports selected if one of the input ports has its Export box selected.

   Output ports have yellow arrows that point left. Input ports have dark blue arrows that point right.
3. Right-click the name of one of the selected ports and choose **Connect**.

   The default name of the connecting net appears in the Connection column for each of the selected ports. The default net name is based on the module and port names of the output port. You can change the net name by double-clicking it in any row and typing over it.

Building with the Schematic View

The Schematic view provides a schematic of the Clarity Designer module including a block for each module that you've added, external ports, and wires connecting them all. The Schematic view also has two additional panes:

- The Design pane provides a nested list of all modules, their ports, and the ports of the Clarity Designer module.
- The Property pane provides information about the selected object (in the General tab) and a list of related wires (in the Connections tab).

To connect a port to the top of the Clarity Designer subsystem:

1. Select the port.
2. Right-click in the schematic and choose **Export**.

   The default name of the connecting net appears in the Connections tab of the Property pane. This will also be the name of the port in the Clarity Designer subsystem. The default name is based on the module and port names of the port.

To connect module ports to each other using right-click:

1. If you want to change a connection, select one of the ports. Then right-click in the schematic and choose **Disconnect**.
2. Select the ports that you want to connect together. You can select several input ports if they will all use the same source. There can be no more than one output port selected. There can be zero output ports selected if one of the input ports has its Export box selected.

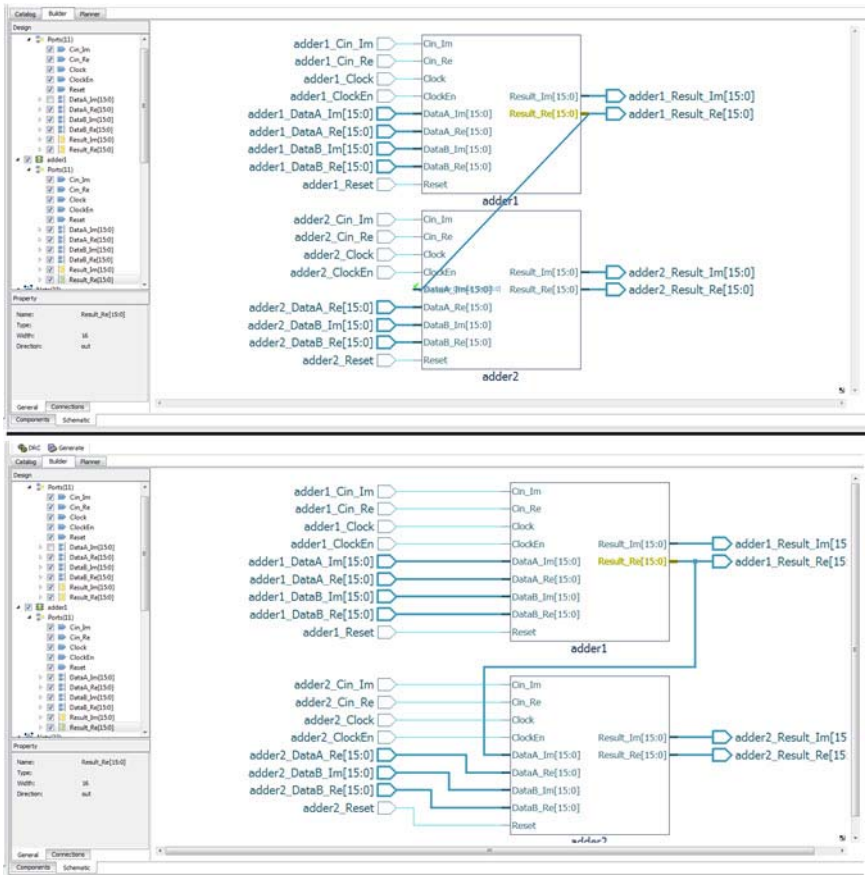
   In the Design pane, output ports have yellow arrows that point left. Input ports have dark blue arrows that point right.
3. Right-click the name of one of the selected ports and choose **Connect**.

   The default name of the connecting net appears in the Connection column for each of the selected ports. The default net name is based on the module and port names of the output port.

To connect module ports to each other using drag-and-drop:

1. If you want to change a connection, select one of the ports. Then right-click in the schematic and choose **Disconnect**.
2. Select the output pin of the port you wish to connect, and using the left mouse button, drag-and-drop it onto the pin of the input port you wish to which you wish to connect. A green check mark appears if the connection is allowed.
3. Release the left mouse button to make the connection. In the top portion of the example shown in Figure 28 on page 226, the adder1_Result_Im[15] output bus is dragged and dropped onto the available DataA-Im[15:0] input of adder2. The bottom portion of the figure shows the resulting connection when the left mouse button is released.

Figure 28: Drag and Drop Connections in Schematic Editor



PCS/SERDES Planning

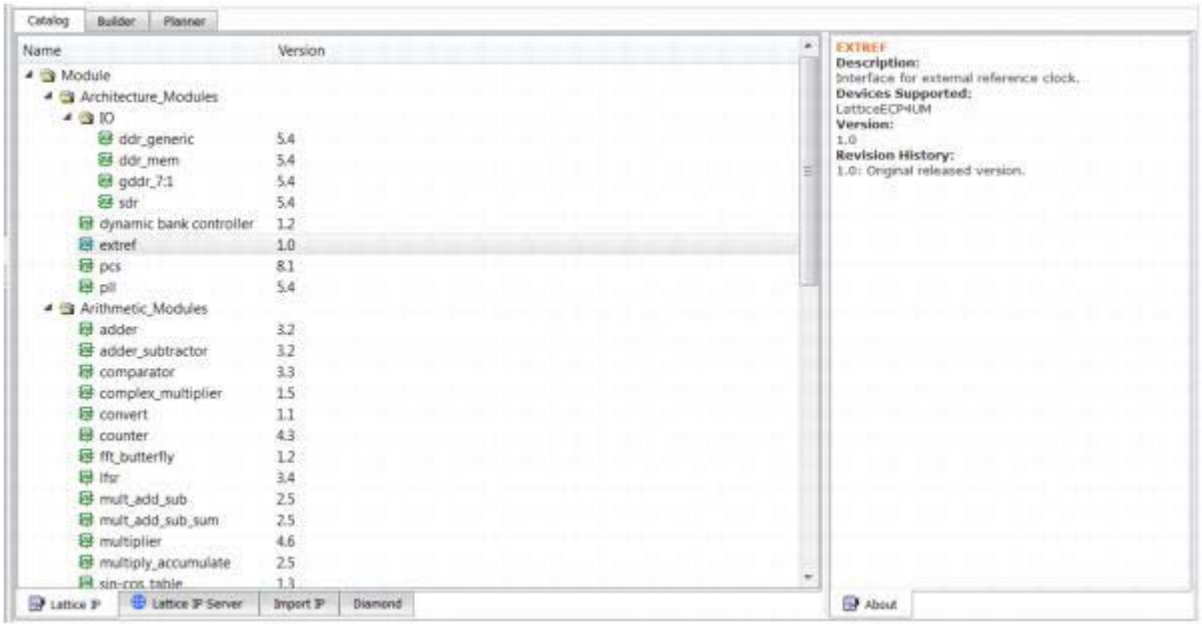
In order to plan the PCS/SERDES resources, the PCS or SERDES modules must be generated using the Catalog tab. If there is any connectivity between these modules, these connections must be completed in the Builder tab. “IP or Module Generation” on page 221 and “Building” on page 223 describe how these tasks can be accomplished. Once the modules are generated, the placement of the PCS or SERDES modules can be planned in the Planner tab.

PCS Configuration

An example for creating the SERDES Eye Demo using ECP5 is shown in Figure 29 on page 227. For this application both the Extref and PCS modules must be selected and configured from the Catalog tab.

Each module must be configured independently. Once both modules have been configured, they will appear in the Builder tab. They can then be connected to other modules in the subsystem or exported to the level above for connection in RTL code to the rest of the design. See “IP or Module

Figure 29: PCS Configuration Example



Generation" on page 221 and "Building" on page 223 for details on module configuration and building.

PCS Planning

To place the generated PCS module and the Extref modules, they can be dragged and dropped from the Resource listing on the left side of the Planner tab to the resources in the chip view on the right. The PCS-related resources are shown in the bottom section of the chip view as show in Figure 30 on page 228.

By placing the PCS module and the Extref, Clarity Designer will incorporate the placement of PCS module and the Extref block to the location automatically without any additional constraints or editor preferences.

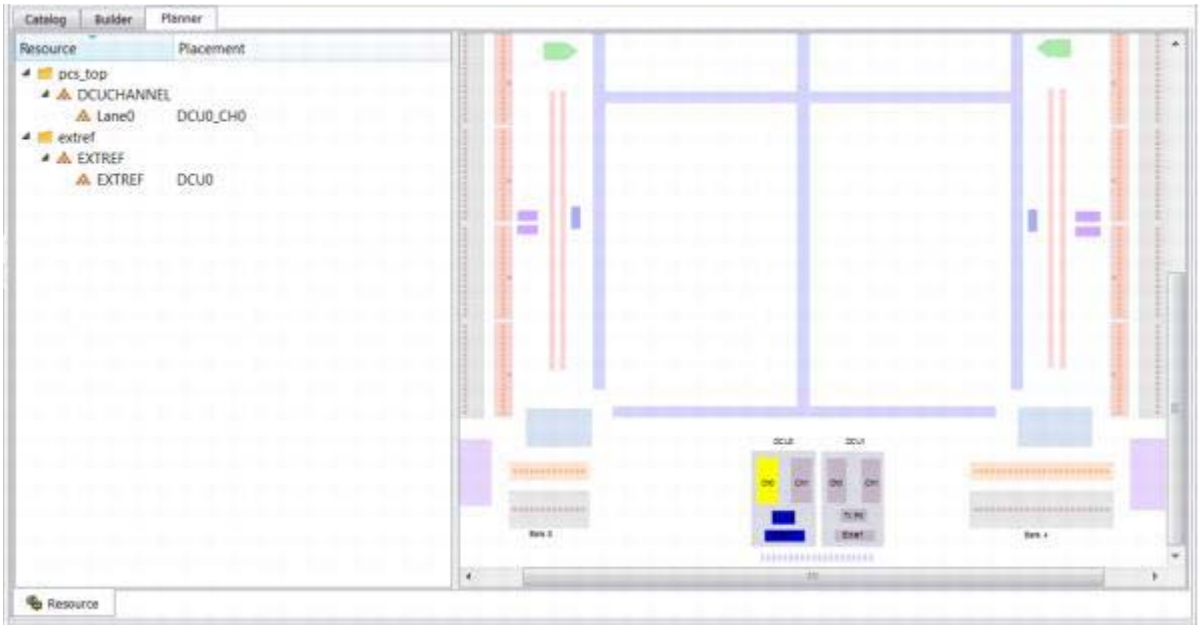
Once all PCS related resources are placed, then the DRC can be used to check that there are no DRC errors and use the generate button to complete the Clarify Designer subsystem and incorporate it into the Diamond project design flow.

Using Multiple PCS Modules in a Single DCU

To place multiple PCS channels in the same DCU, proper care must be taken to ensure that the two PCS blocks used in the design should be using the same external reference clock frequency and TXPLL settings for both the channels in the same DCU.

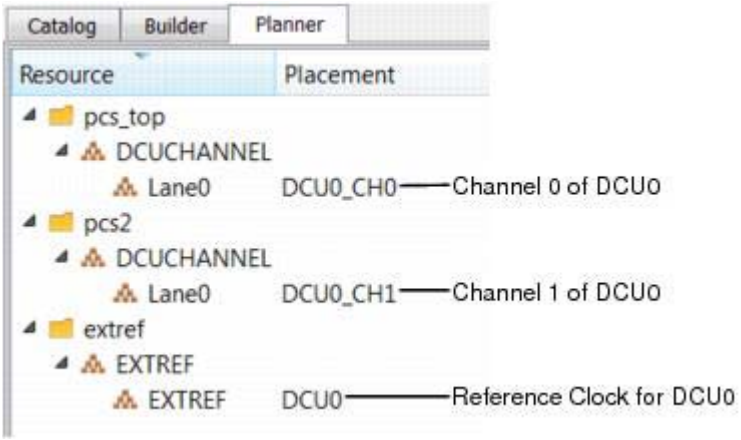
For example, a PCI Express x1 at 2.5 Gbps and a Gigabit Ethernet channel can share the same DCU using the half-rate option on the Gigabit Ethernet channel. When a DCU shares a PCI Express x1 channel with a non-PCI

Figure 30: PCS-Related Resources



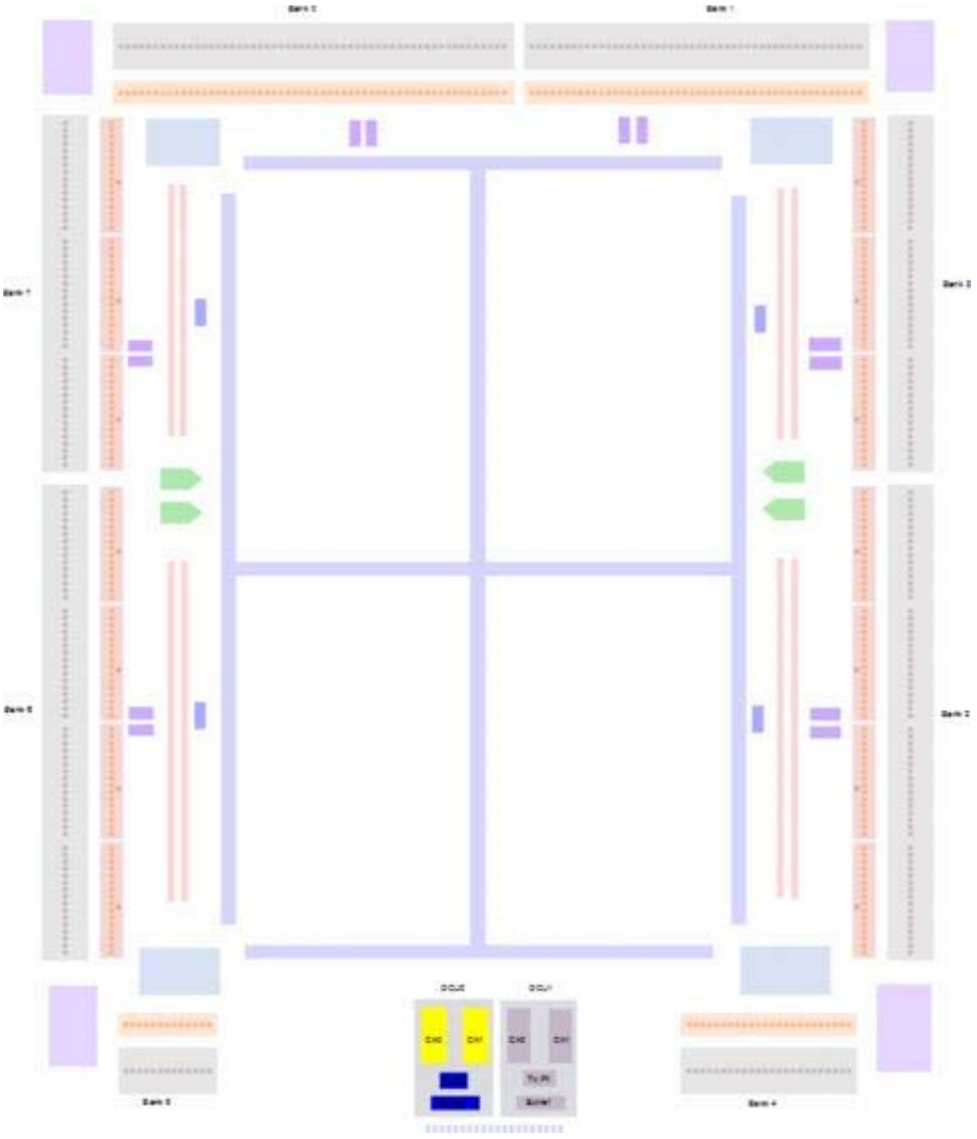
Express channel, the reference clock for the DCU must be compatible with all protocols within the DCU.

Figure 31: Using Multiple PCS Modules in a Single DCU



The placed DCU channels will be displayed as shown in Figure 32 on page 229.

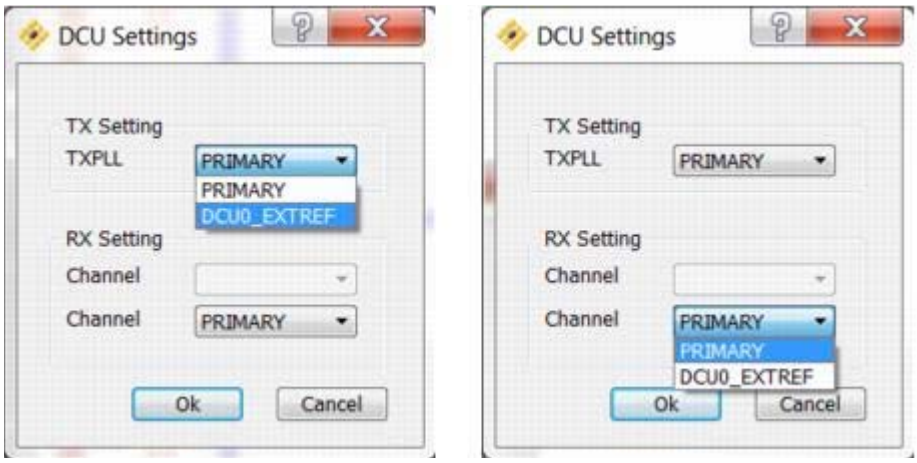
Figure 32: Placed DCU Channels



DCU Settings

In order to choose the TX and RX settings for the DCU, double-click the placed channel of the DCU and choose the input clock to the TXPLL inside and the reference clock for the RX side of the DCU as shown below:

Figure 33: Setting DCU Clocks



If there are multiple protocols that use the same reference clock or one protocol with a single reference clock frequency, choose the input to the TX and RX input clocks (TXPLL and RX setting clock) on the DCU. Either the Primary Clock input from the FPGA logic or a clock input from Extref components of DCU0 can be used.

Multiple Protocols on the Same Device

If multiple protocols have to be supported using a single ECP5 device that has different reference clocks, then the same DCU cannot be supported. A different DCU has to be implemented with its own external reference clock and Tx PLL settings with a PCS block to support multiple protocols as shown in Figure 34 on page 231.

The placed DCU channels will be displayed as shown in Figure 35 on page 231.

DCU Settings with Multiple Protocols

In order to choose the TX and RX settings for the DCU, double-click the placed channel of the DCU and choose the input clock to the TXPLL inside and the reference clock for the RX side of the DCU as shown in Figure 36 on page 232.

If there are multiple protocols, choose the input to the TX and RX input clocks (TXPLL and RX setting clock) on the second DCU. Use either the Primary Clock input from the FPGA logic or inputs from the Extref components of DCU0 or DCU1.

Figure 34: Using Multiple Protocols in the Same Device

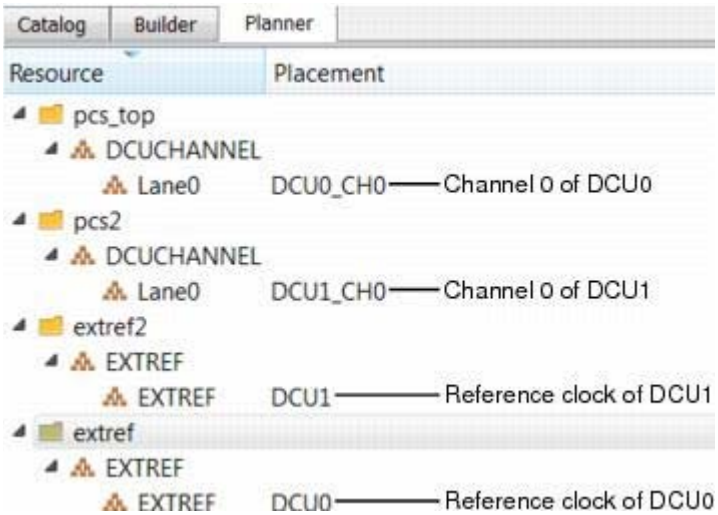


Figure 35: Placed DCU Channels

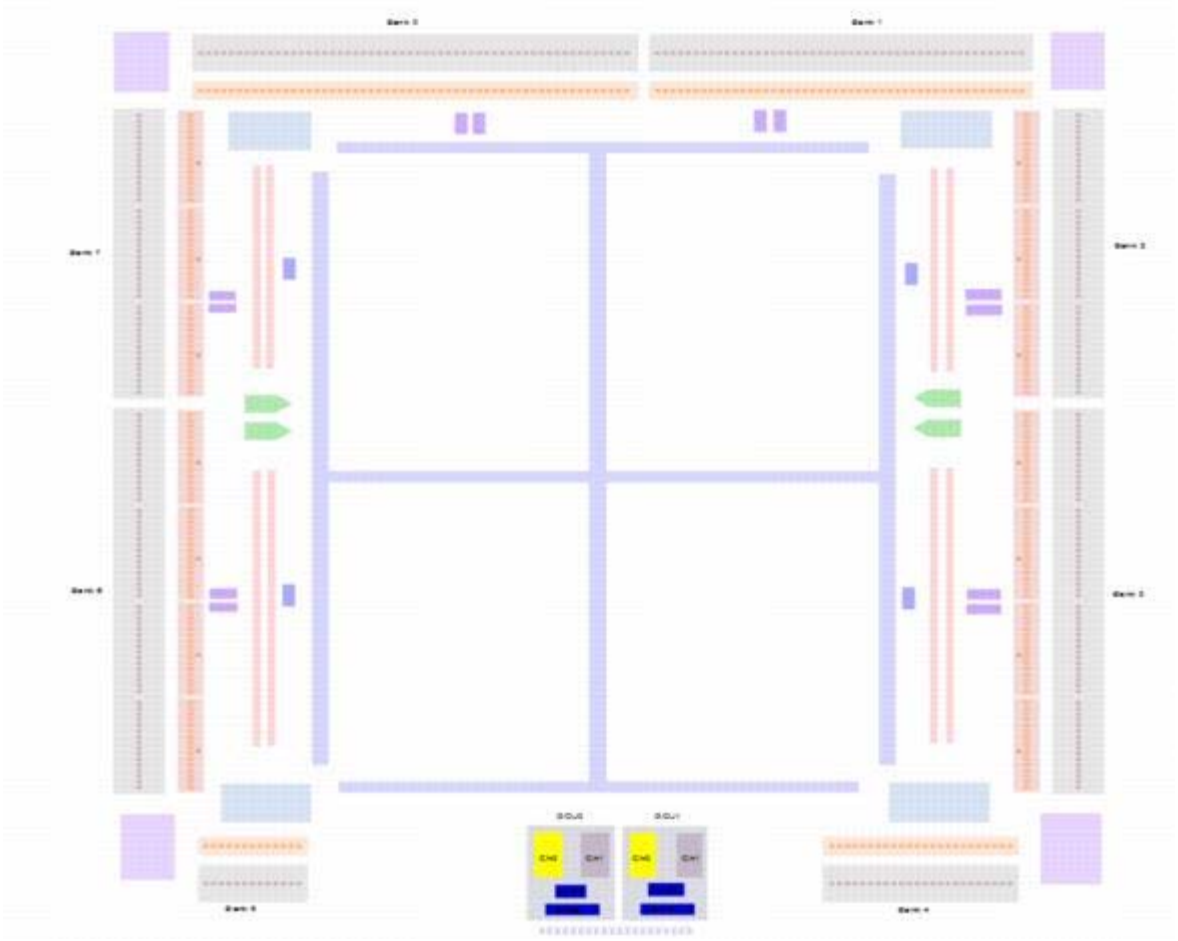

Figure 36: Setting DCU Clocks

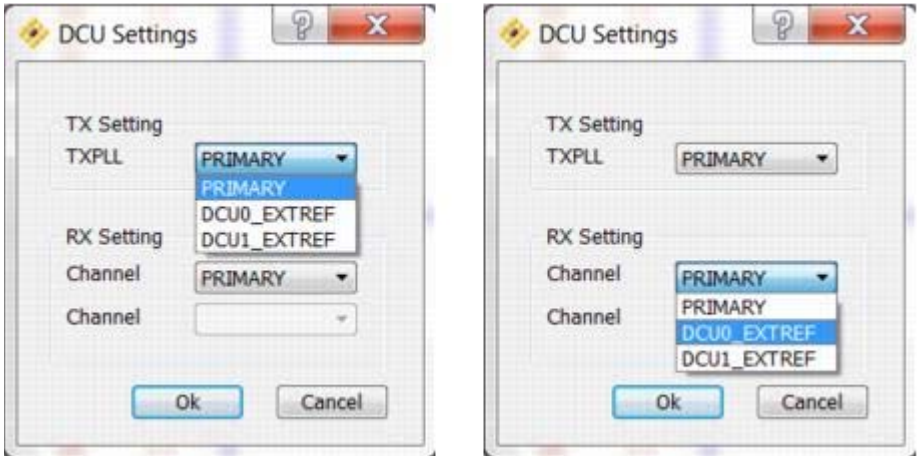


DDR I/O Planning

In order to plan the DDR I/Os, the DDR modules must be generated using the Catalog tab. If there is any connectivity between these modules, these connections must be completed in the Builder tab. "IP or Module Generation" on page 221 and "Building" on page 223 describe how these tasks can be accomplished. Once the modules are generated, you can plan the placement of the DDR modules in the Planner tab.

Planner View for DDR Modules

Once DDR modules are generated, they are listed in the Planner. The resources required by each of the DDR modules are listed next to the module name. This includes the number of I/O required, number of PLLs used, and number of DLLs used by that module.

Each DDR module, when expanded, will show the clock groups under that module. The ports and primitives in each of the DDR modules is grouped based on the clocking requirement. All ports and elements clocked by the same clock are listed in a given clock group. This clock group could be a high speed "ECLK" (edge clock) group for interfaces that use a gearbox (x2 or x4) or a slower speed "SCLK" (primary clock) group for interfaces that do not use a gearbox (x1).

Each clock group will include:

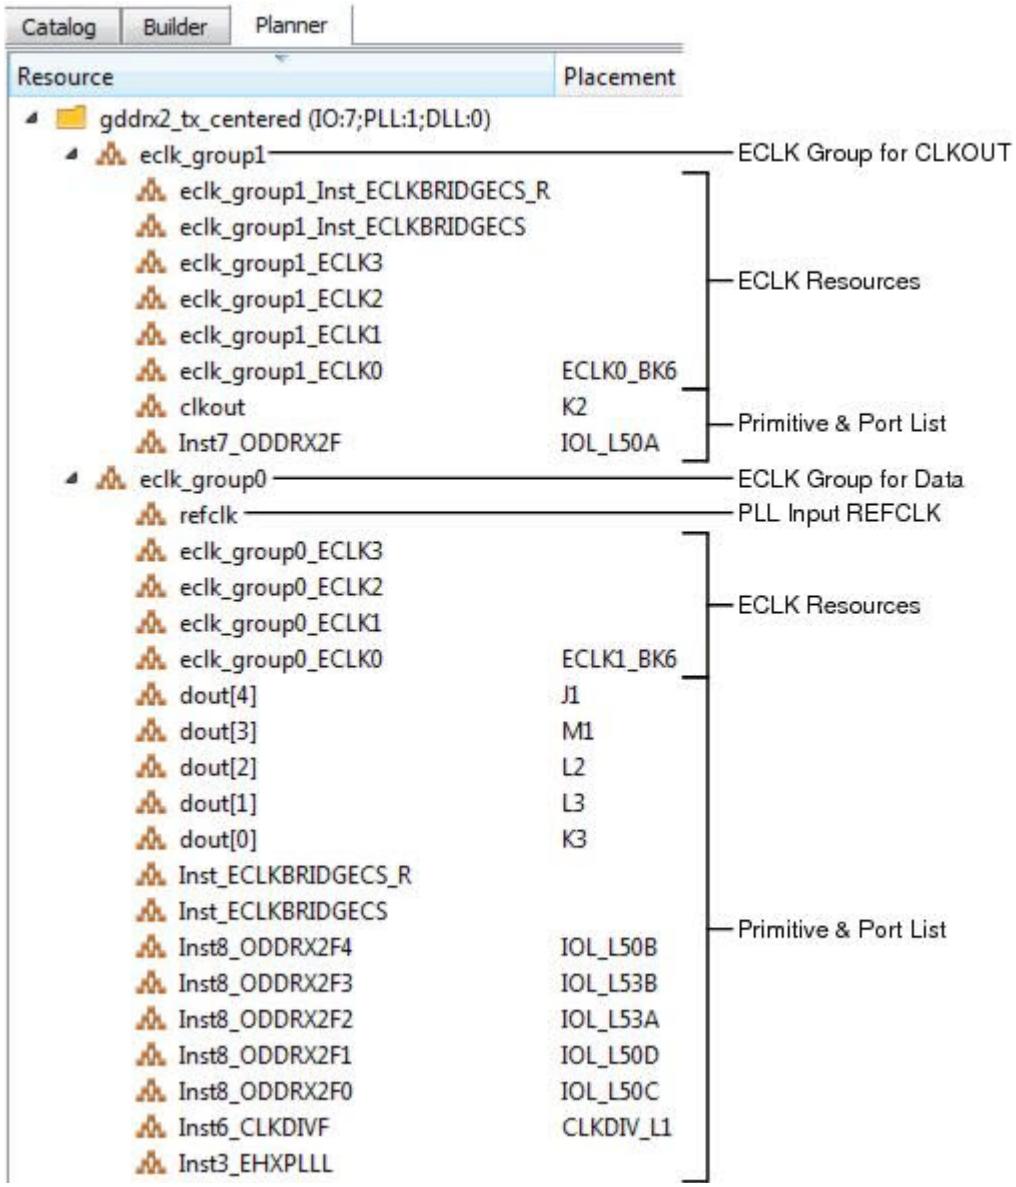
- Port list
- Primitive list
- ECLK and ECLKBRIDGE resources (if used by that module)

Once a port is placed, the Placement column shows pin numbers next to each of the ports and the ECLK resources shows the ECLK that was used for that interface.

The figure below shows how an interface will look when listed in the Planner tab. This interface is used for an example to show the clock grouping and port list. This Interface has two ECLK groups. Each group lists the ports clocked by that ECLK, the primitives that are clocked by that clock, and the ECLK resources.

Note that in this release, the ECLK resource section lists all the ECLKs and ECLKBRIDGEs available on the device even though only one ECLK is used in the clock group. Once the interface is assigned it will only show placement information for the ECLK that is used by that interface.

Figure 37: DDR Modules in the Planner View



Reconfiguration of an Interface

An interface can be reconfigured by right-clicking and selecting **Config**. This will allow you to change the interface parameters by opening the dialog box for that module.

Placing a DDR Interface

The following steps should be used to place any of the generated DDR interfaces.

1. Select the clock group under a given interface and then drag and drop onto the chip view. A valid location is indicated by a “+” symbol. Once the location is selected, the interface pins will be placed in a counterclockwise direction.

   The following also happens:

   - The pins used are displayed in the chip view.
   - The corresponding IOLOGIC cell will be highlighted.
   - If the group is an ECLK group, the ECLK tree used will be displayed.
   - The left pane will also display the locations of the Ports, ECLKs, and Primitives.

2. Drag and drop of a clock group will only place the data pins of that interface. The clock input pins in that interface will have to be placed manually. Expand the clock group and select the clock input pin. Drag it onto the dedicated clock pin. Right-click in the chip view to get the option to filter out all the dedicated clock pins.

   The following happens:

   - Once the clock pin is placed, the PLL, DLL, CLKDIV, and ECLKBRIDGE used by the DDR module will be displayed in the chip view.
   - The left pane will also display the locations of these modules.

If an interface cannot be placed in the location when the ports are dropped due to architectural limitations, all the data ports will be placed in the next available location. If it is a clock input port, Planner will not place the port and will issue a DRC message in the Output view.

DDR Interface Planning Guidelines

Here are some general rules to follow when placing DDR modules. Refer to the “High Speed Interface” technical note for the device for details on placement of each type of DDR interface using Clarity.

- On DDR interfaces, the data ports have to be placed before placing the clock input ports. Once the data ports are placed, manually drag and drop the CLKIN port to the desired location. The PLL, DLL, and CLKDIV used with the clock are not placed until the input CLK port is placed. This also applies to REFCLK input ports of PLL modules when generated with the DDR modules.

- On drag-and-drop of any interface, only data pins are placed. You have to manually place the clock input to any of the GDDRX interfaces as explained in “Placing a DDR Interface” on page 234.
- When placing the data ports, Planner does not use the dedicated clock sites on the device. These are reserved for the clock inputs.
- You must try to place all the data and clock ports of a given interface on one side. If there is a requirement to go around the corner to the other side, Planner uses the ECLKBRIDGE if it is available on that device. You must enable the ECLKBRIDGE when configuring the IP. Refer to the “High Speed I/O Interfaces” technical note for the device for details on how to use Planner to plan an interface with an ECLKBRIDGE.
- There are only a limited number of high speed clock (PLL, DLL, and ECLK) and I/O logic elements on each device. Planner does not allow interfaces to be placed if it runs out of resources.
- Planner always places the pins in a counterclockwise direction. You must drag and drop interfaces at the optimum location so that pins are not lost during planning. For example, if you require that all pins be placed in a single bank, the interface should be dropped at the first valid location of that bank counting counterclockwise so pins do not overflow to the next bank. Similarly, if all pins need to be on the same side, you must drag and drop at the first valid pin of the side. If you drag it into the edge of the side, the ports will automatically overflow to the other side, which forces Planner to use an ECLKBRIDGE when it is not required.
- When placing a GDDRX or DDR_MEM module that requires a PLL module, you can either choose to generate a PLL with the interface module or use a stand-alone module. If you choose to generate a PLL with the DDR interface, you must also choose the input buffer standard for the CLKI input of the PLL. This is required for Planner to correctly place the PLL. This will apply for GDDR.TX “centered” and DDR Memory modules.
- If planning the DDR Memory IP Cores, refer to the IP Core user manual for guidelines on placement of each IP module.

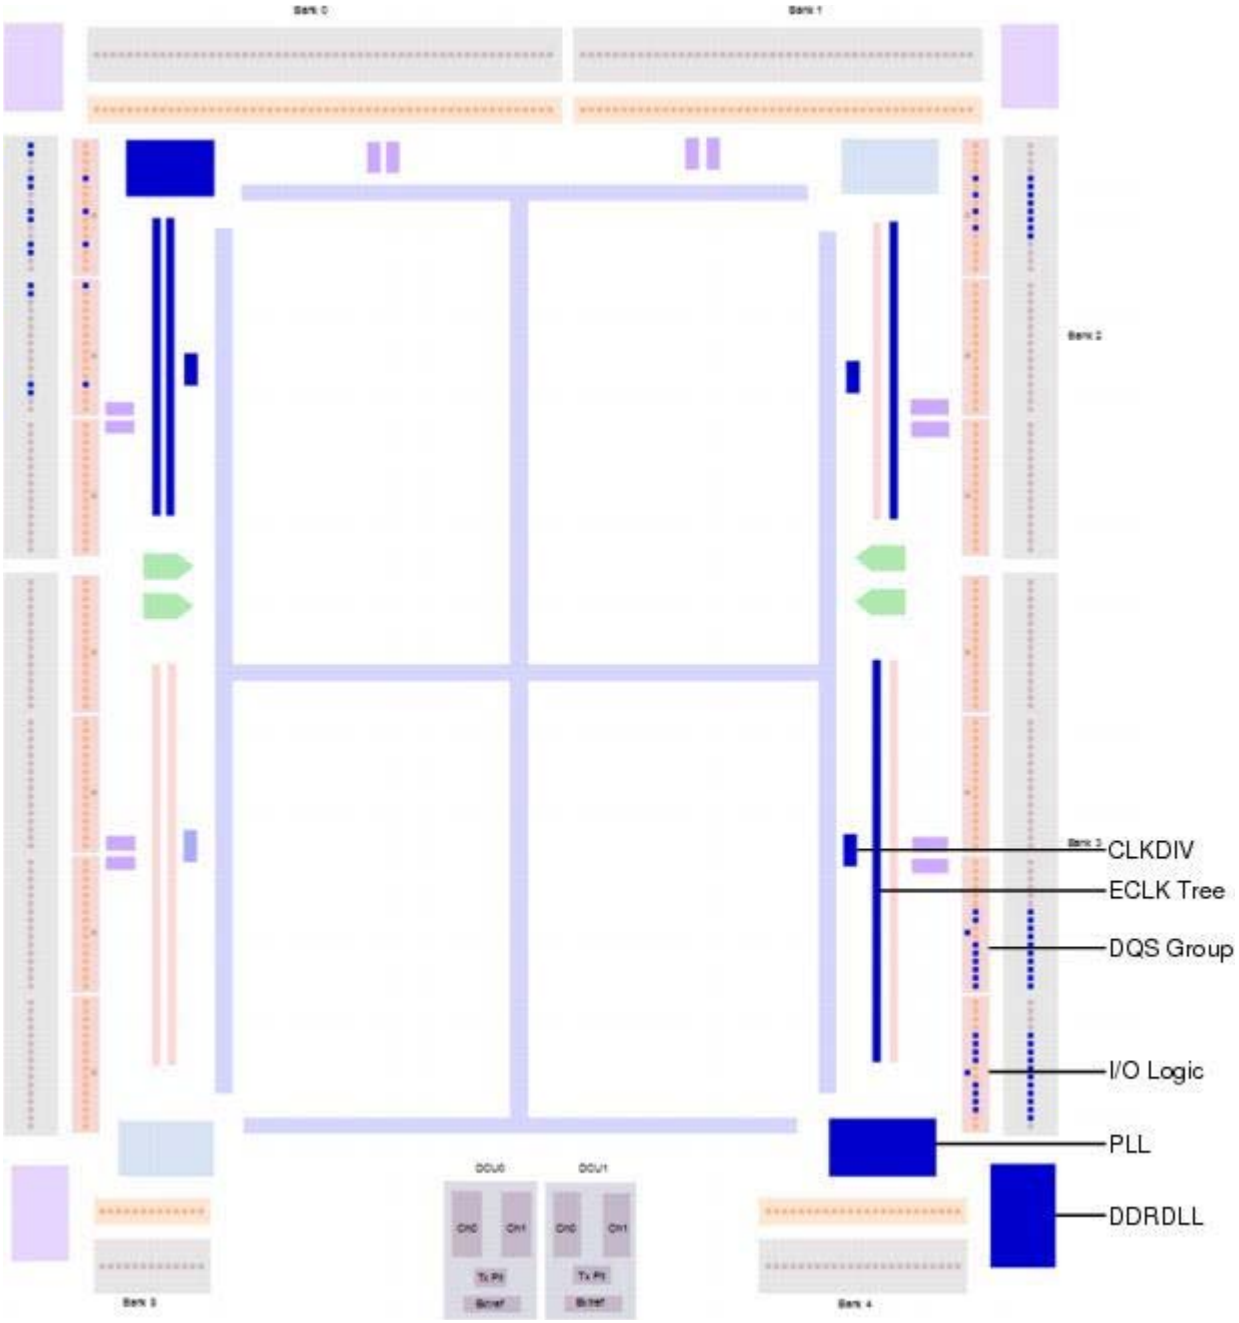
The chip view after placement of interfaces is shown in Figure 38 on page 236. This figure highlights some of the DDR resources that get used for an interface. For more details on the DDR resources, refer to the “High Speed I/O Interface” technical note for the device.

Viewing Interface Placement

Once an interface has been placed, you can view the placement by:

- Clicking on the port in the left pane to locate it in the chip view. The location of this port is highlighted in the chip view.
- Clicking on the placed pin in the chip view, which will highlight the port in the left pane.

Figure 38: DDR Resources in the Planner View



Resetting or Modifying Placement

Once the interface has been placed, it can be reset or modified using the following methods:

- If the entire interface placement has to be reset, right-click on the Interface name in the left pane and choose **Reset**.
- If the assignments for one of the clock groups under the interface have to be reset, right-click on the clock group in the left pane and choose **Reset**.

- If placement for a signal port has to be modified, choose the port in the left pane and drag and drop it to its new location.
- If placement for a signal port has to be reset, right-click on the port in the left pane and choose **Reset**.

Note

Clarity does not support multiple select on ports. The workaround is to modify placement of each port or modify placement of the entire clock group

Filtering Pin Types

You can get to the filter by either right-clicking on the chip view or on the toolbar. Planner allows filtering of dedicated PCLK pins, PLL/DLL clock pins, True LVDS pins, VREF pins, and so on. These will vary for each device. Refer to the “High Speed Interface” technical note for the device to see the options available.

Design Rule Check

Once all the interfaces are placed, you can click  **DRC** in the toolbar to see the list of warning and error messages.

Current Restrictions

- Planner does not see the signal connectivity in Builder. The workaround is to export the ports to the SBX file and make the connectivity outside of the SBX module. So any clock sharing between different DDR modules has to be external to the SBX.
- Stand-alone PLL are not available in Planner for placement or connection. Any connections to stand-alone PLL have to be done externally to the SBX.

Designing with LatticeMico Platforms

Lattice Diamond allows you to import a platform that you have created in LatticeMico System. Such a platform includes a microprocessor and peripheral components that can be implemented in a Lattice FPGA device.

LatticeMico System is included as an optional installation with Diamond, through an open IP core licensing agreement. It can also be downloaded from the Lattice web site. LatticeMico System enables you to build the embedded processor platform using MicoSystem Builder and afterwards incorporate the platform's source files into a Diamond project. After generating the data file, you can use the Programmer tool to program the FPGA device or boot memory device on your target system.

For complete information about building a LatticeMico platform, see the Mico System Builder section of the LatticeMicoSystem online Help.

About LatticeMico System

LatticeMico System is based on the Eclipse C/C++ Development Tools, which provide an open-source framework for building software. It contains two integrated tools and a debugger that combine with the Diamond software to build the microprocessor platform on an Lattice FPGA device and write the software code to drive it.

Lattice Mico System Builder (MSB) The Mico System Builder enables you to generate a platform description and associated HDL for a hardware implementation, choose peripheral components to attach to the LatticeMico32 microprocessor or LatticeMico8 microcontroller, and specify connectivity between peripheral components.

After generating the platform in MSB, you can import the HDL files into Diamond, perform functional and timing simulation, place and route the design, and download the bitstream to the Lattice FPGA device using the Programmer tool.

For complete information about using MSB to generate a platform, refer to the Mico System Builder section of the LatticeMico System online Help.

Lattice Software Project Environment (SPE) and Debugger The Lattice Software Project Environment enables you to develop the C or C++ application code that runs on platforms created with MSB, use the debugger to validate the code, and deploy the application code to on-chip or flash memory.

For complete information about using SPE to develop an application for tthe LatticeMico32 microprocessor or LatticeMico8 microcontroller, refer to the Lattice Software Project Environment section of the LatticeMico System online Help.

- "Adding a LatticeMico Platform" on page 38

Running LatticeMico System

If you are using Microsoft Windows, you can start LatticeMico System from the Windows Start menu. If you are using Linux, you can start LatlticeMico System from the command line.

To open LatticeMico System using the Windows Start menu:

- Choose **Start > Programs > Lattice Diamond > Accessories > LatticeMico System**

To open LatticeMico System using Linux:

1. Navigate to the following directory in the installation:

   <install_path>ispcpld/bin

2. Type the command **`source setup_lv.csh`**.

   Or, if you are using the Korn shell, type **`source setup_lv.sh`**.

3. Change to the LatticeMico installation directory.
4. Type **LatticeMicoLauncher**.

LatticeMico System opens in a separate window. To create a new platform for your design, click the MSB button to open the Mico System Builder perspective.

Schematic Design Entry

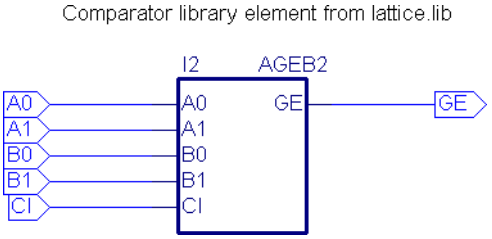
The Diamond schematic design environment is a set of tools that allows you to capture the structure of a design as either a flat description or a hierarchical set of components and the connectivity between these components. Then you can use this description to drive logic synthesis, implementation, and verification tools of the FPGA design flow. Schematics can be drawn on multiple “sheets” and be a variety of sizes.

Schematic Editor works in conjunction with Symbol Editor and Symbol Library Manager. You design by laying out symbols for basic functions and other modules and drawing wires between their ports. You can also create your own library of custom schematic symbols.

Schematic Overview

Unless you're using them just for documentation, schematics are actually the starting point of the development process, not the goal. The schematic will eventually be used to analyze the device's behavior using logic simulation and implement the logic into the target device using place and route. The Lattice Diamond software includes a Schematic Editor for creating and editing schematic sources. The figure below is an example schematic that represents 2-bit comparator gate.

Figure 39: Schematic Sample of a 2-bit Comparator



In the above schematic there are five inputs (labeled A0, A1, B0, B1, and CI) and one output (GE). The function of I2 is to perform a comparison of A[1:0] and B[1:0] with CI serving as carry-in.

In the FPGA design flow, Diamond creates a structural HDL model of the schematic in terms of component instances as in the following Verilog and VHDL.

Depending on the target device and version of the software, a symbol library may be provided or you may create your own symbols using Symbol Editor. A symbol library, lattice.lib, is provided for gate-level design of Lattice FPGA device families. The Lattice FPGA symbol library represents a sub-set of the library elements documented in the “FPGA Libraries Reference Guide” on page 1664. In addition, IPexpress automatically produces schematic symbols

Figure 42 on page 242 is a much more complex schematic.

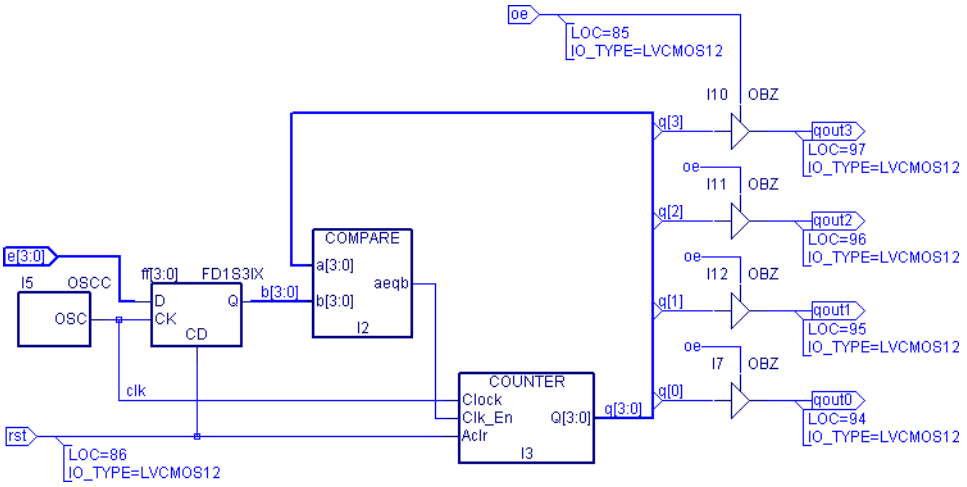
What is a Schematic?

The schematic file (saved as a .sch file) describes your circuit in terms of the components used and how they connect to each other. The schematic can be used to create HDL structural models for logic simulation or synthesis. A schematic can represent a simple logic process (such as an AND gate) or a more complex component in your design (such as a memory function). It can also represent the top-level of your design.

Figure 42: Complex Schematic Sample



What do Schematics Consist of? A schematic is composed of the following items:

Symbols - These can be symbols from the standard symbol libraries, symbols representing other schematics you have drawn (Block symbols), or symbols you have created from scratch.

Wires - Wires connect the symbols. They can be single-signal (nets) or multiple-signal (buses).

I/O Ports - I/O ports show where signals enter or exit the schematic and the direction (polarity) of the signal. That is, whether it is an input, output, or bi-directional signal.

Attributes – Attributes are used to add functional characteristics such as user constraints to wires or symbols that are interpreted by tools like logic synthesis and place and route. Schematic attributes are translated into Verilog or VHDL attributes by the schematic netlister.

Graphics and Text - Graphics and text are usually added to display explanations. They are optional and have no electrical meaning.

A valid schematic must contain at least the first three components—symbols, wires, and I/O ports. For instance, a single, isolated component symbol cannot be the only element in a schematic. The schematic must include I/O ports for the external connections to the schematic, and these ports must be connected to the symbol with wires.

Symbols Symbols are graphic representations of components. The term “symbol” usually refers to an electrical symbol, such as a gate or a sub-circuit. You can draw graphic-only symbols (such as title blocks) with Symbol Editor, but these have no electrical meaning.

Figure 43: A Valid Schematic

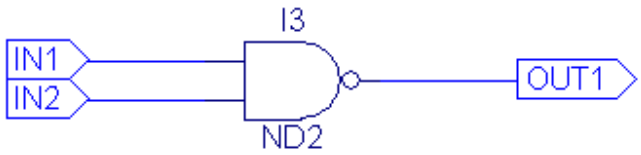


Figure 44: Invalid Schematic (No Wires or I/O Ports)

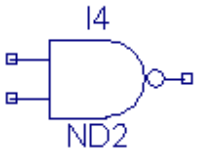


Symbols are the most basic elements of a schematic. Symbols represent primitive design elements, whether those elements are complete gates or a complex macro. A symbol can also be the hierarchical representation of a sub-circuit, or a “Block” symbol.

Each schematic symbol is a file ending with a .sym extension, and may be included in a library file with a .lib extension. The symbol file contains four types of information: graphics, text, pins, and attributes.

Pins Symbol pins are the connecting points between the symbol and the schematic wiring. If the symbol represents an individual component, the symbol pin represents the physical pin where a conductor can be attached. If the symbol represents a subcircuit (block symbol), the symbol pin represents a connection to an internal net of the subcircuit.

Wires Wires are the lines that electrically connect the symbol pins. Symbol pins are the only connection points for wires. You cannot connect wires to the symbol body itself.

There are two types of wires: single-wire nets and multiple-wire buses. Buses allow more than one signal to be routed as a single line.

Wires (both nets and buses) are added to schematics using the **Edit > Add > Wire** or the **Edit > Add > Net Name** commands of Schematic Editor.

There is only one kind of wire you can add (using the **Edit > Add > Wire** command). Whether it is a net or a bus depends on how you name the wire (using the **Edit > Add > Net Name** command). For instance, buses are named as <*busname*> [<*numberlist*>] where <*busname*> is the name of the

bus and <*numberlist*> is an optional list of numbers separated by commas representing each net in the bus.

You would normally name all wires that connect to inputs or outputs and any internal nets with signals you want to view during simulation. You can use any name you like, but you usually choose a name that suggests the name or function of the signal carried by that wire. If you do not give a wire a name, Schematic Editor automatically supplies one, of the form N_<*n*> (where <*n*> is an integer).

Giving a single wire a compound name creates multi-wire buses. You can then tap off any signal you want anywhere along the bus.

Buses are most often used to group related signals, such as a 16-bit data path. However, a bus can be any combination of signals, related or not. Buses are especially useful when you need to route a large number of signals from one side of the schematic to the other.

Buses also make it possible for a single I/O port to connect more than one signal to a Block symbol. The signal names do not have to match, but both pins must carry the same number of signals.

I/O Ports I/O ports mark the points at which signals leave or enter the schematic. They are required. Any unconnected wire without an I/O port will eventually be flagged as an error when you try to create a netlist or run the simulator.

I/O ports are added to schematics using the **Edit > Add > IO Port** command in Schematic Editor.

The I/O port automatically takes the name of the wire it is attached to. If the wire is a bus, the port will have the same compound name as the bus.

When a Block symbol and its matching schematic are created, the I/O ports for the signals that enter and leave the schematic must have the same names as the corresponding pins on the Block symbol. The matching names identify which signal attaches to which pin.

Attributes Attributes of the schematic specify characteristics of the design that are interpreted by implementation tools in the design flow. Often attributes specify directives or preferences for logic synthesis or place and route in the FPGA design flow. See “Schematic Attributes” on page 280 for more details.

Each symbol has a number of predefined attributes that describe its component type and other unchanging characteristics. Other attributes can be given values after the symbol is placed in the schematic.

Like symbols and symbol pins, nets (the wiring that connects symbols to each other and makes external connections) can also have attributes. These attributes include the net's name, as assigned in the schematic.

Note

Net attributes for a sub-set of sysIO Buffer preferences are supported for the FPGA design flow.

Graphics and Text Graphics are pictures of the symbols. Symbol graphics have no electrical meaning and show only the position of the component in the circuit. A symbol’s attributes and pins, not the graphics that represent it, define the electrical behavior of a symbol. Explanatory or descriptive text displayed with a symbol is also considered “graphic” information without electrical meaning.

Although symbols, wires, and I/O ports are visible, graphical items, they also have a functional or electrical meaning. In this context, “graphics” refers to the non-functional graphical parts of the schematic.

For example, you might add graphics showing the expected waveforms at different points in the circuit. Or, you could draw the company's logo and add it to each schematic for identification.

The most common use of graphics is to create a title block. The block shows the name and address of your company, and can include the company logo and blank spaces for the project name, schematic sheet number, and so on.

Title block symbols are available in the title.lib or lattice.lib libraries. You can modify the symbols in Symbol Editor and save the file (with the same name) in the project directory, or you can use Symbol Library Manager to add the revised symbol to your own custom symbol library file.

Text, like graphics, can provide additional information about the schematic or its project. Text can be placed anywhere on a schematic, even if it overlaps symbols or wires.

Text is added to schematics using the Edit > Add > Text command.

Naming Schematic and Symbol Files When you name schematic or symbol files, observe the following rules:

- Observe DOS file naming conventions. The dollar sign ($) cannot be the first letter of a file name, however.
- Do not type a file name extension; Schematic Editor will add it automatically. If you enter a non-standard extension, Schematic Editor will replace it with the correct extension (.sch for schematics, .sym for symbols, and .lib for symbol libraries).
- Symbol files must have the same name as the schematic file or HDL module that the symbol represents. For example, if you create a symbol for a Verilog module named “foo,” the symbol’s file must be named “foo.sym.”

- Instances of a symbol in a design cannot use the same name as the symbol itself.

Symbols

Symbols are graphic representations of components. The term “symbol” usually refers to an electrical symbol, such as a gate or a sub-circuit. You can draw graphic-only symbols (such as title blocks) with Symbol Editor, but these have no electrical meaning.

Wires

Wires electrically connect schematic symbols. The symbol pins are the connection points for the wires. They can be single-signal (nets) or multiple-signal (buses).

I/O Ports

An I/O port is a special indicator that identifies a net name as a device input, output, or bidirectional signal. This establishes net polarity (direction of signal flow) and indicates that the net is externally accessible. An I/O port can either denote an I/O port of a design if it is in the top level schematic or denote an I/O marker in a lower level schematic.

Bus Taps

Signals enter or exit a bus at points called bus taps. A bus tap can be added to any existing bus, net, or wire. If a net or wire is not already a bus, adding the tap automatically promotes it to a bus.

Selecting the Type of HDL Files Generated for Schematic

To select the HDL file type generated from your schematic:

1. In the File List view, right-click the Project name and choose **Properties**.

   The Project Properties dialog box opens with the project name is selected at the top of the left pane.

2. In the right pane of the Project Properties dialog box, find Schematic HDL Type and select its Value cell.
3. Click the Value cell again to reveal a menu. Choose the desired HDL type. The default is Verilog.
4. Click **OK**.

Basic Schematic Editor Operation

Schematic Editor uses an *action–object* command structure. That is, you select the action you want to perform (usually from a menu), and then you select the object you want to act on.

For example, to move a symbol from a schematic, you first select the Move command from the Edit menu. Then you drag the symbol to move it.

Almost all commands remain in effect until you select a different command. For example, if the Add Wire command is active, you can continue to draw wires until you select a different command.

Edit Menu

The Edit menu consists of the following commands:

Table 5: Edit Menu Commands

Command	Description	Available	Shortcuts
Undo	Allows you to reverse the edit process. The Undo command operates on all commands that change a schematic or symbol (such as Cut, Paste, Add, Move, Drag, Attribute Window, Object Properties, and Clear), but it does not reverse those commands that do not change the drawing. The Undo command backs up one event each time it is issued. It can reverse all changes since the file was opened or saved. Saving a file discards the record of the preceding changes, and they cannot be undone or redone.	Schematic Editor Symbol Editor	Toolbar:  Keyboard: Ctrl+Z
Redo	Reverses the effects of the Undo command. The Redo command can go forward, playing back the undone events until it reaches the end of the Undo log (the point when the first Undo in the sequence was issued). The Redo log is discarded whenever the current version of a symbol or schematic is saved. Once the log is discarded, the Redo command cannot recover undone commands.	Schematic Editor Symbol Editor	Toolbar:  Keyboard: Ctrl+Y
Cut	Removes data (nets, graphics, symbols, or text) from the schematic and places it in the clipboard. The previous contents of the clipboard are erased. The items can then be pasted from the clipboard into another schematic.	Schematic Editor Symbol Editor	Toolbar:  Keyboard: Ctrl+X
Copy	Copies items from the schematic to the clipboard. The items can then be pasted in another schematic.	Schematic Editor Symbol Editor	Toolbar:  Keyboard: Ctrl+C
Paste	Places the contents of the clipboard into the schematic. When you select this command, the pasted contents are attached to the mouse pointer. Click the mouse pointer to place the contents to the right spot.	Schematic Editor Symbol Editor	Toolbar:  Keyboard: Ctrl+V
Find	Finds wire and symbol instances on the schematic.	Schematic Editor	Toolbar:  Keyboard: Ctrl+F

Table 5: Edit Menu Commands (Continued)

Command	Description	Available	Shortcuts
Clear	Deletes the selected items from the schematic drawing. Deleted items are not copied to the clipboard and the clipboard's contents are not affected.	Schematic Editor Symbol Editor	Keyboard: Delete
Select All	Selects all the items in the schematic.	Schematic Editor Symbol Editor	Keyboard: Ctrl+A
Add	Opens a menu for adding objects. See “Add Menu” on page 249.	Schematic Editor Symbol Editor	
Move	Enables the Move mode. Moves one or more elements (wire or symbol) to a different location within the schematic. You can move items in three ways. See “Moving Symbols” on page 279.	Schematic Editor	Toolbar: 
Drag	Enables the drag mode. Moves portions of objects while the rest of the object remains in place. The effect is to stretch or reposition the item, altering its basic shape or direction.	Schematic Editor	Toolbar: 
Move, Drag	In Symbol Editor, Drag has the same function as Move. After selecting an item, you can move the cursor to the selected item, press the right mouse button, and move the item to the desired place when the cursor becomes a cross.	Symbol Editor	
Mirror	Works with items already attached to the cursor with the Add > Symbol command, Edit > Paste, or Edit > Move. The object is reflected through an imaginary vertical line each time the Mirror command is selected. The Mirror command can be combined with the Rotate command to produce eight standard orientations. See “Transforming Symbols” on page 279.	Schematic Editor	Keyboard: Ctrl+M
Rotate	Works with items already attached to the cursor with the Add > Symbol command, Edit > Paste, or Edit > Move. The object is rotated 90° counter-clockwise each time the Rotate command is selected. The Rotate command can be combined with the Mirror command to produce eight standard orientations. See “Transforming Symbols” on page 279.	Schematic Editor	Keyboard: Ctrl+R
Highlight	Selects the whole wire if a segment of the wire has been selected.	Schematic Editor	Toolbar:  Keyboard: Ctrl+L
Sheet	You can control your sheets in this dialog box.	Schematic Editor	
Symbol Origin	Assigns an origin or changes the current origin. See “Setting the Symbol Origin” on page 274.	Symbol Editor	
Expand page	Increases the work area for the symbol. See “Expand Page” on page 250.	Symbol Editor	
Attribute Window	Selects the attribute names for the symbol. See “Adding an Attribute Window to a Symbol” on page 277.	Symbol Editor	
Symbol Type	Selects the symbol type. See “Schematic Symbol Overview” on page 267.	Symbol Editor	
Object Properties	Assigns attribute values for symbols and wires. See “Assigning Attribute Values in a Schematic” on page 285.	Schematic Editor Symbol Editor	

Add Menu

The Add menu consists of the following commands:

Table 6: Add Menu Commands

Command	Description	Available	Shortcuts
Select	Enables the selection mode, allowing you to select items on the schematic.	Schematic Editor Symbol Editor	Toolbar: 
Zoom Area	Enables you to zoom in on the schematic by pressing the left mouse button and drawing a box around the area of interest. See “Using the Zoom and Pan Tools” on page 452.	Schematic Editor Symbol Editor	Toolbar: 
Pan	Enables you to see another part of the schematic by clicking and dragging. See “Using the Zoom and Pan Tools” on page 452.	Schematic Editor Symbol Editor	Toolbar: 
Wire	Adds wires between symbol pins. See “Wiring a Schematic” on page 288.	Schematic Editor	Toolbar: 
Net Name	Gives each net an unique reference name. Net names can contain only letters, numbers, apostrophes (single quote), and underscores. Net names are not case-sensitive. When you save your schematic, Schematic Editor automatically assigns names to unnamed nets. These names are in the form N_*nn*, where *nn* is an integer. You can override the Editor-assigned names by assigning your own names. See “Entering a Net Name” on page 292.	Schematic Editor	Toolbar: 
Bus Tap	Adds a bus tap to a bus, net, or wire. See “Adding a Bus Tap” on page 297.	Schematic Editor	Toolbar:
Symbol	Opens the Add Symbol dialog box, which lets you select a symbol and place it on a schematic. Symbols come from symbol libraries or folders. Click on the schematic to place the symbol. See “Adding Symbols to the Schematic” on page 277.	Schematic Editor	Toolbar: 
Instance Name	Names an instance symbol. Opens the Add Instance Name dialog box where you can enter an instance name. Then click on the instance symbol to name it. The instance name cannot be the same as a symbol name in the Lattice schematic library. Each symbol that is placed in a schematic is called a symbol “instance.” Each instance of a symbol must have an unique reference name. Schematic Editor automatically assigns names to unnamed symbols each time the schematic is saved. These names are in the form I_*nn*, where *nn* is an integer.	Schematic Editor	Toolbar: 
IO Port	Adds an I/O port to a net. Before this operation, the net should already have a name. After you select an I/O port in the Add IO Port dialog box, click on the net’s name, then the I/O port is placed on the schematic. See “Specifying Signal Direction” on page 294.	Schematic Editor	Toolbar: 
Big Bubble	Adds a big bubble to the layout. See “Drawing Negation Bubbles” on page 273.	Symbol Editor	Toolbar: 
Bubble	Adds a bubble to the layout. See “Drawing Negation Bubbles” on page 273.	Symbol Editor	Toolbar: 

Table 6: Add Menu Commands (Continued)

Command	Description	Available	Shortcuts
Pin	Assigns pins that correspond to I/O markers on the underlying schematic and connects the device represented by the symbol to the rest of the circuit. See “Adding Pins to a Symbol” on page 275.	Symbol Editor	Toolbar:
Arc	Adds arcs to the drawing. These arcs are graphics only and have no electrical meaning in either the schematic or symbol. You can draw as many arcs as you like until you select another command. An arc is drawn from a starting to an ending point. These points can be defined by dragging the mouse from the starting point to the end point. Then release the button. You see an arc that starts and ends on the selected points and passes through the cursor. Move the cursor to change the shape of the arc. When the arc has the shape you want, click to add the arc to the drawing. If you decide not to draw the arc, right-click anywhere in the window to discard the selected points and restart the command. If you move the cursor outside of the schematic’s borders, the arc disappears until you move the cursor inside. See “Drawing Circles and Arcs” on page 273.	Schematic Editor Symbol Editor	Toolbar:
Circle	Lets you draw circles, which are graphics and have no electrical significance. You can draw as many circles as you like until you select another command. See “Drawing Circles and Arcs” on page 273.	Schematic Editor Symbol Editor	Toolbar:
Line	Lets you add individual line segments to the drawing. These line segments are graphics and have no electrical meaning in the schematic or symbol. You can draw as many lines as you like until you select another command. See “Drawing Lines” on page 272.	Schematic Editor Symbol Editor	Toolbar:
Rectangle	Lets you add rectangles to the drawing. These rectangles are graphics only and have no electrical meaning in the schematic or symbol. You can draw as many rectangles as you like until you select another command. See “Drawing Rectangles” on page 273.	Schematic Editor Symbol Editor	Toolbar:
Text	Adds fixed text to the drawing. Text is used for adding notes, title blocks, and other information to the symbol or schematic. Text has no electrical meaning. The size and justification of the text is set by parameters in the dialog box. See “Drawing Text” on page 273.	Schematic Editor Symbol Editor	Toolbar:

Expand Page

The initial work area is 40 x 40 primary grids. After a symbol has been created, Symbol Editor provides a work area that is approximately twice the height and width of the symbol.

When a symbol grows too large to fit, choose this command to enlarge the work area. Its initial use increases the size to 80 x 80 Primary grids. Subsequent use adds increments of 20 grids, up to a maximum of 400 x 400 grids.

The extra area is added at the right and bottom of the symbol. If more space is needed on the left or top, choose the Move command to shift the entire symbol.

Pay attention that the origin is not part of the symbol. If you move the symbol, the origin does not move with it. Be sure to reposition the Origin if you move the symbol.

Hierarchical Design with Schematics and HDL

A design with more than one level is called hierarchical. A single-level design is referred to as being flat. Converting a section of circuitry to a block makes a flat design hierarchical. This is commonly referred to as “hierarchical” design.

The Lattice Diamond software supports full hierarchical design by using schematics, HDL modules, or a mix of both. Hierarchical structuring permits a design to be broken into multiple levels, either to clarify its function or to permit the reuse of functional blocks. For instance, a large, complex design does not have to be created as a single module. By using a hierarchical design, each component or piece of a complex design can be created as a separate module.

A design is hierarchical when it is broken up into functional blocks, or modules. For example, you could create a top-level schematic describing an integrated circuit. In the schematic, you could place a Block symbol (a Block symbol represents a functional block) that provides a specific function of the chip. You can then elaborate the underlying logic for the Block symbol as a separate schematic or as a separate HDL module.

The module represented by the Block symbol is said to be at one level below the schematic in which the symbol appears. Or, the schematic is at one level above the Block's module. Regardless of how you refer to the levels, any design with more than one level is called a hierarchical design.

Advantages of Hierarchical Design

The most obvious advantage of hierarchical design is that it encourages modularity. A careful choice of the circuitry that composes your module will give you a Block symbol that can be reused.

Another advantage of hierarchical design is the way it lets you organize your design into useful levels of abstraction and detail. For example, you can begin a project by drawing a top-level schematic that consists of nothing but Block

symbols and their interconnections. This schematic shows how the project is organized but does not display the details of the modules (Block symbols).

You then draw the schematic for each Block symbol. These schematics can also contain Block symbols for which you have not yet drawn schematics. This process of decomposition can be repeated as often as required until all components of the design have been fully described as schematics.

Breaking the schematic into modules adds a level of abstraction that lets you focus on the functions (and their interaction) rather than on the device that implements them. At the same time, you are free to view or modify an individual module.

Although there are many ways of “breaking apart” a complex design, some may be better than others. In general:

- Each module should have a clearly defined purpose or function and a well-defined interface.
- Look for functions or component groupings that can be reused in other projects.
- The way in which a design is divided into modules should clarify the structure of the project, not obscure it.

Hierarchy vs. Sheets

Creating a hierarchical design is not the same as creating a schematic with multiple sheets. In a schematic, you can add as many sheets as desired to extend beyond the original sheet. However, regardless of how many sheets you add, all the components of the design are still at a single level; all sheets are still contained in the same module.

Approaches to Hierarchical Design

Hierarchical designs consist of one top-level module. This module can be of any format, such as VHDL, Verilog HDL, or schematic. Lower-level modules can be of any supported sources and are represented in the top-level module by functional blocks or other “place-holders.”

Following are some rules you need to follow when creating a hierarchical design in Diamond for a FPGA design.

- The top-level source can be of any format, such as VHDL, Verilog HDL, schematic, or EDIF netlist.
- For hierarchical Schematic/VHDL or Schematic/Verilog HDL designs:
  - If the upper-level source is a schematic file, the lower-level source can be either a HDL file or a schematic file.
  - If the upper-level source is a HDL file, the lower-level source can only be a HDL file.
- For EDIF designs:

- Hierarchical EDIF design is not allowed.

You can create the top-level module first, or create it after creating the lower-level modules. For example, in Schematic Editor you can create schematic project components in any order and then combine them into a complete design. You can draw a schematic first and create a Block symbol for it afterwards; or you can specify the Block first and create the schematic for it later.

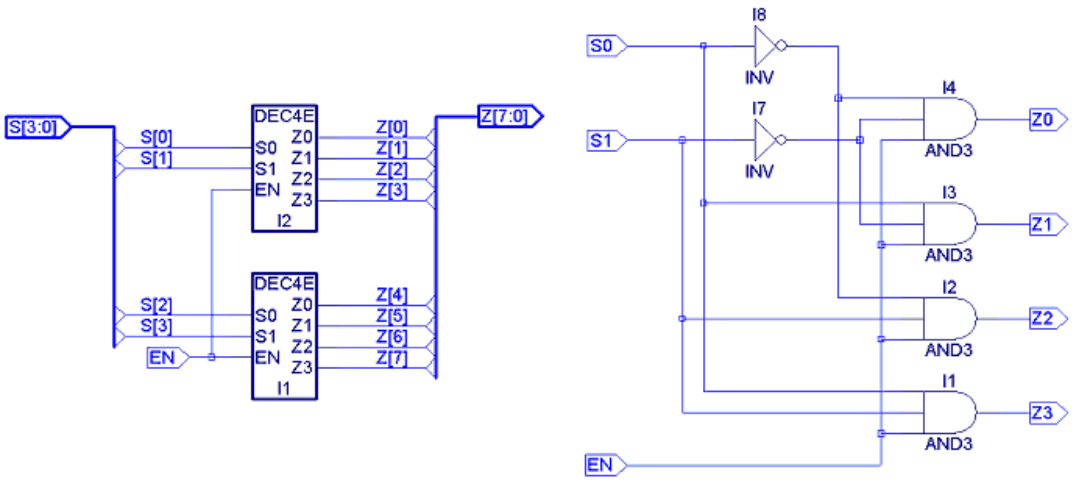
Hierarchical Design Structure Considerations

Apply the following considerations when using hierarchical design techniques. We take a hierarchical schematic design as an example (shown below). The rules implied in the example are also applicable to other types of hierarchical designs.

Hierarchical Design Structure The example below shows a 8-bit decoder circuit (DEC8E) constructed from two DEC4E symbols. The right side of the figure shows the underlying components. The two decoder symbols represent a total of eight AND gates and four inverters.

This hierarchical building process could be repeated by using Schematic Editor's **Design > Generate Symbol** command to create a symbol for schematic DEC8E, and then placing the DEC8E symbol in a higher-level schematic. If you created a schematic for a 16-bit decoder, DEC16E, by placing two copies of symbol DEC8E, you would be defining a circuit with a total of 24 gates. But instead of having to view 24 gates on a single level, you can work with symbols that represent gates, at the appropriate level of detail.

Hierarchical Naming In the DEC4E schematic example below, an AND3 gate has the instance name I1. In schematic DEC8E, two copies of the symbol DEC4E are placed and assigned instance names I1 and I2. Schematic DEC8E, therefore, contains two copies of AND3 gate I1.



Automatic Aliasing of Nets When a design is loaded, nets take the name of the highest (top-level) net in the design. That is, the name of top-level net propagates downward through the hierarchy to override the local name. By forcing all nets to the same name, this aliasing feature greatly speeds signal tracing in a multi-level design.

In the preceding example, the net name S[0] and S[1] of I1(DEC4E) is overridden by the higher-level external reference to become S[2] and S[3]. This override becomes the reference at all levels of the hierarchy.

Note

The hierarchical HDL output produced by the schematic system will retain the local names as defined by the schematic.

Creating a Hierarchical Schematic Design

You can generate a hierarchical design in the following way:

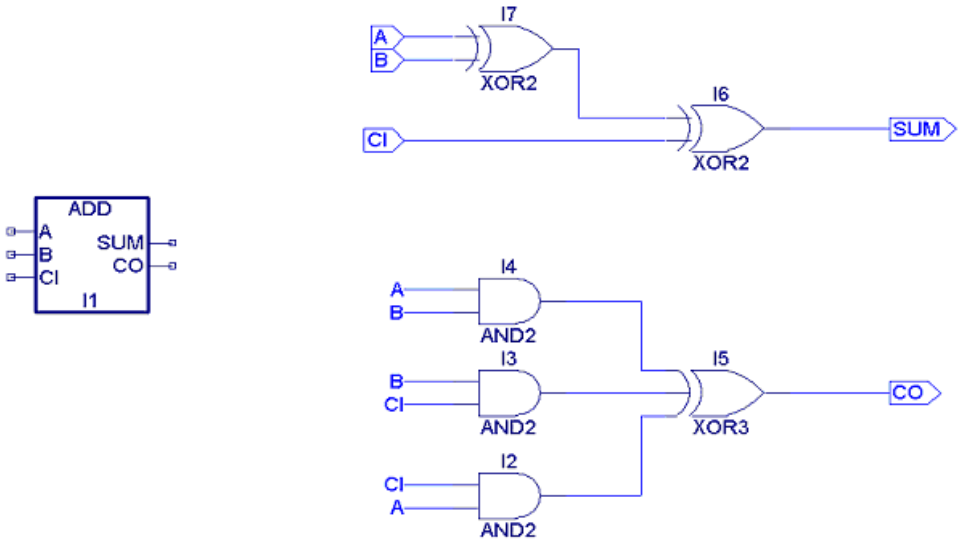
1. Create a schematic or HDL design for a lower level module.
2. Generate a schematic symbol for the lower level module. See:
   - “Creating a Block Symbol from a Schematic” on page 273
   - “Creating a Symbol from an HDL Module” on page 274
3. Store the new symbol in one of three ways:
   - Move the symbol to the same folder as the project file or the upper level schematic file.
   - Add the symbol to a library (see “Using Lattice Symbol Library” on page 257). Make sure the library is specified the User Defined Symbol Libraries strategy option. Choose **Tools > Options** to check. See “Adding Symbol Libraries to Schematic Editor” on page 266.
   - Add the folder of the symbol into the User Defined Symbol Libraries strategy option. Choose **Tools > Options** to check. See “Adding Symbol Libraries to Schematic Editor” on page 266.
4. Choose **Edit > Add > Symbol** to add the symbol to an upper level schematic. See “Adding Symbols to the Schematic” on page 277.

Schematic Hierarchy Example

The figure below shows an example of how a symbol corresponds to an underlying schematic. In this figure, pin A on the Block symbol corresponds to the net in the schematic, which is also named A. The other pins, B, CI (Carry In), CO (Carry Out) and SUM, also correspond to named nets in the schematic.

A Block Symbol and its Underlying Schematic

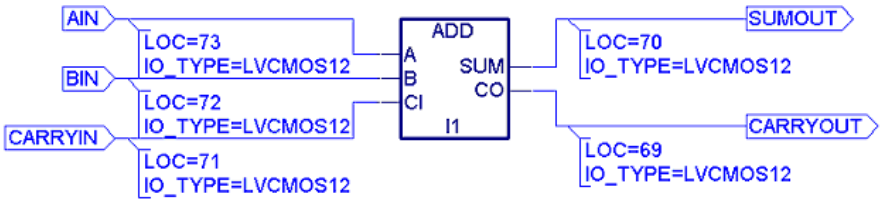
This following figure shows one top-level schematic with module I/Os and net attributes to specify sysIO Buffer preferences.



Top-level Schematic for Top (top.sch)

The name of the lower-level schematic must match the block name (schematic) in the upper-level schematic. This associates the lower-level schematic with the symbol representing it. The above schematic must be named add.sch.

The net names in the lower-level schematic corresponds to the pin names in the upper-level module. The symbol should be a Block symbol.



Beginning a New Schematic Design

To begin a new schematic design:

1. In the Diamond window, choose **File > New > File**.

   The New File dialog box opens.

2. In the New File dialog box, do the following:

a. Under Categories, select **Source Files**.

b. Under Source Files, select **Schematic Files**.

c. Specify Name and Location for the new schematic file.

d. Click **New**.

Schematic Editor opens with a new, untitled sheet.

Converting a Schematic Design to Another Device

You can first target this design to the new device. As some symbols are only valid for some specific devices, you may find that some symbols cannot be used for the new device. Replace these symbols with new symbols that support the new device, according to the list of Schematic Symbols. See “List of Schematic Symbols” on page 258.

Opening Schematic Editor

To open Schematic Editor, you can either open an existing Schematic Design (see “Opening an Existing Schematic Design” on page 256) or create a new schematic file (see “Creating a New Source File” on page 35).

Opening an Existing Schematic Design

You can open schematic design files through the File List view of a design project or directly, outside of any design project.

To open a schematic design from within a design project:

1. In the File List view, find the schematic file under the Input Files folder. The entry looks like this:

    *<path>*/*<filename>*.sch

2. Double-click the schematic file.

   Schematic Editor opens with the selected file.

To open a schematic design outside of any design project:

1. Choose **File > Open >** **File**.
2. In the Open File dialog box, in the file type menu at bottom-right, choose **Schematic Files (*.sch)**.
3. Browse to the desired schematic file.
4. Click **Open**.

   Schematic Editor opens with the selected file.

Network Operation

When schematics, symbol files, and other project components are shared on a network, some form of overwrite protection is required. The system does not allow two people to work on the same file at the same time.

Schematic Editor uses the crash-recovery log file (described in the preceding section) to ensure single-user access. If you try to open a file and Schematic Editor finds a log file for it, you are asked if someone else is using the file. If you answer **Yes**, you cannot access the file.

If you answer **No**, you will be allowed to open the file, even if someone else is editing it. Check with anyone who might be using the file before answering **No**.

Using Lattice Symbol Library

The Lattice FPGA Symbol Library provides Boolean logic gates and synchronous elements for gate-level design. For macro-sized elements like architectural blocks, arithmetic, or memories it is recommended that you use the IPexpress interface to configure and generate schematic symbols and files for implementation. The Lattice schematic library provides dozens of library elements for gate-level schematic design.

The library file, lattice.lib, is composed of library elements compatible with most Lattice FPGA device families.

Symbol Library Manager allows you to manage libraries of symbols (.sym files) used in your designs. With Symbol Library Manager, you can view two types of symbol libraries: **folder** and **binary**. Folder libraries are simply directories that contain symbols. Binary libraries are .lib files that contain many symbols. You can clean up your folder structure and save disk space by organizing your symbols into binary libraries. Symbol Library Manager allows you to create your own binary libraries and maintain them by adding, extracting, deleting, copying, and renaming the symbols in the libraries.

Symbol Categories The Lattice FPGA Symbol Library for schematic design is based on a sub-set of the library elements documented in the “FPGA Libraries Reference Guide” on page 1664. The Libraries Guide is organized into functional categories by device family and provides details on function, I/O, and device compatibility.

For a complete list of all the symbols provided in the Lattice FPGA Symbol Library, see “List of Schematic Symbols” on page 258.

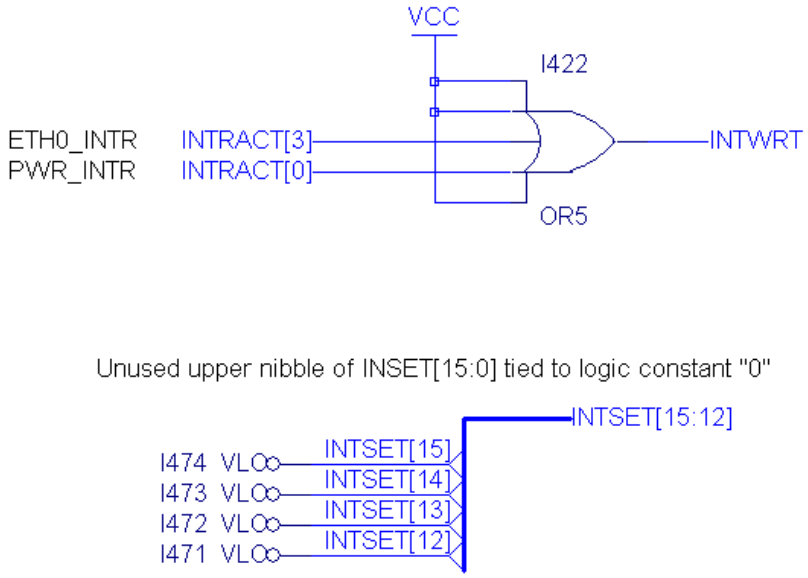
Attributes Schematic Editor for FPGA and MachXO Crossover Programmable devices supports the ability to specify HDL Attributes as schematic symbol attributes or net attributes. For more information, see “List of Schematic Attributes” on page 281.

Logic Constants Logic constants are a common construct in digital design to represent a static value.

Schematic Editor provides two special nets named VCC or GND that produce logic constants in the HDL output. To create a VCC or GND net, use the Edit > Add > Net Name feature to name a wire stub. Specify VCC or GND. Depending on the orientation of the wire, a special symbol for the net will appear as shown in the first sample circuit below.

The FPGA Symbol Library provides two symbols: VHI and VLO to represent bit value 1 or 0 respectively. To create a multi-bit value constant, use a combination of buses and symbols as shown in the second sample circuit below.

Figure 45:



Bus Declarations Schematic Editor allows you to create discontinuous bus ranges, for example MyBus [15:12] and MyBus [3:0], in separate regions of the schematic design. To avoid semantic problems in the resulting Verilog HDL or VHDL model of the translation process, the HDL model writer will create one bus declaration to cover the range: MyBus [15:0].

I/O Cell Usage The Lattice FPGA Symbol Library contains several I/O cell library elements (such as IB, OB, and BB) to help define the sysIO Buffer interface to the design. However, in general, it is not necessary to add these library elements to your schematic design. The logic synthesis process (Precision RTL or Synplify Pro) will automatically add them.

I/O Buffer Usage The Lattice FPGA Symbol Library for schematic design is based on a sub-set of the “FPGA Libraries Reference Guide” on page 1664.

List of Schematic Symbols

The Lattice schematic library, lattice.lib, is composed of library elements compatible with most Lattice FPGA device families. The following table lists all the schematic symbols included in the library file. Click the symbol name to learn its functionality and device compatibility.

In addition there are four more title blocks available in title.lib: FPTITLE, REV_BLK, SPTITLE, STITLE.

Creating a New Symbol Library

One of the first things you will probably want to do with Symbol Library Manager is to create a binary library for storing your own symbols or for storing symbols specific to a design.

To create a new symbol library:

1. In the Diamond window, choose **File > New >** **File**.

   The New File dialog box opens.
2. Under Categories, select **Other Files**.
3. Under Source Files, select **Symbol Library Files**.
4. Specify the file name without any extension. The .lib extension is added automatically.
5. Click **Browse**.
6. In the Location dialog box, browse to where you want to put the file.
7. Click **Select Folder**.
8. In the New File dialog box, click **New**.

   Symbol Library Manager opens, allowing you to create a symbol library. Now you can open other libraries and add symbols to your new library.

See Also ▶"Adding Symbols to a Library" on page 263

▶ "Copying Symbols to a Library" on page 264

Opening an Existing Symbol Library

You can open an existing symbol library file from the Diamond main window. There are additional methods for symbol library files and folders from the Symbol Library Manager window.

To open a symbol library file:

This method is only for symbol library (.lib) files, not library folders. This method can be used from the Diamond main window or from a detached Symbol Library Manager window.

1. Choose **File > Open > File**. (**File > Open File** if in a detached Symbol Library Manager window.)
2. In the Open File dialog box, in the file type menu at bottom-right, choose **Symbol Library Files (*.lib)**
3. Browse to the desired symbol library file.
4. Click **Open**.

   Symbol Library Manager opens with the selected symbol library.

To open a symbol library (file or folder) that is in your search path:

1. Select an open Symbol Library Manager view and choose **File > Open From Search Paths**.

   The Open Library From Search Paths dialog box opens.
2. In the dialog box, select the library you want to open.

   Selecting a folder that contains more than one .sym file allows you to access all of those .sym files. However, selecting a folder that contains a .lib file will not let you edit that .lib file unless the file name is specified in the search paths.
3. Click **OK**.

   The selected symbol library opens and the first symbol in the list is selected.

To open a folder library that is not in your search path:

1. Select an open Symbol Library Manager view and choose **File > Open Folder**.
2. In the dialog box, browse to the desired folder.
3. Click **Select Folder**.

   The selected symbol library opens and the first symbol in the list is selected.

Adding Symbols to a Library

To add symbols to a library in Symbol Library Manager:

1. Open the library to which you want to add a symbol.
2. Choose **Edit > Add Symbol(s)** or right-click any symbol in the library and choose **Add Symbol(s)** from the pop-up menu.

   The Add Symbols to Library dialog box opens.

3. Go to the location of the folder that has the symbol you want to add, and then select the symbol. You can select more than one symbol at a time by using the Shift and Ctrl keys on your keyboard.
4. Click **Open**.

   Symbol Library Manager copies the symbol into the current library. The original symbols still exist and may be deleted if so desired.

Extracting Symbols from a Library

You can copy a symbol from a binary library to a folder library with the Extract Symbol(s) command.

To extract symbols from a library:

1. Open the binary library (.lib) from which you want to extract a symbol and select the symbol. You can select more than one symbol at a time by using Shift and Ctrl keys on your keyboard.
2. Choose **Edit > Extract Symbol(s)** or right-click the symbol and choose **Extract Symbol(s)** from the pop-up menu to open the dialog box.
3. Type the path where you want to extract the file, or click **Folders** to browse for the path.
4. Click **OK**.

   Symbol Library Manager copies the selected symbol from the binary library to the folder library. You can use the File > Open Folder command to verify that the symbol was, in fact, copied.

Copying Symbols to a Library

You can copy a symbol to either a binary library or a folder library with the Copy Symbol(s) command.

To copy symbols to a library:

1. Open the library from which you want to copy a symbol and select the symbol. You can select more than one symbol at a time by using Shift and Ctrl keys on your keyboard.
2. Choose **Edit > Copy Symbol(s)** or right-click the symbol(s) and choose **Copy Symbol(s)** from the pop-up menu.

   The Copy Symbols dialog box opens.
3. Type the path to the folder library or binary library, or click **Folders** or **Libraries** to browse for the path.
4. Click **OK**.

   Symbol Library Manager copies the selected symbol from the current library to the new library.

Deleting Symbols from a Library

You can delete a symbol from a binary or folder library.

To delete a symbol from a library:

1. Open the library from which you want to delete a symbol and select the symbol. You can select more than one symbol at a time by using Shift and Ctrl keys on your keyboard.
2. Choose **Edit > Delete Symbol(s)**, press the Delete key on your keyboard, or right-click the symbol(s) and choose **Delete Symbol(s)** from the pop-up menu.

   Symbol Library Manager deletes the selected symbol from the current library.

Renaming Symbols in a Library

There are times when you want to change the name of a symbol.

To rename a symbol:

1. Open the library that contains the symbol you want to rename and select the symbol.
2. Choose **Edit > Rename Symbol(s)** or right-click the symbol and choose **Rename Symbol(s)** from the pop-up menu.

   The Rename Symbol dialog box opens.
3. Type the new name for the selected symbol.
4. Click **OK**.

   The selected symbol will now appear with the new name.

Note

Symbol names will be converted to module names in HDL. It is recommended that you follow the module name rules in HDL when naming symbols.

Saving a Symbol Library

The Save File command in Symbol Library Manager saves the changes to the existing library file. You can use the Save File As command to save the library with another file name.

Symbol library files have the extension .lib. Below shows the steps of saving a symbol library with the Save File As command.

To save a symbol library with the Save File As command:

1. In Symbol Library Manager, choose **File > Save** <*filename*> **As**.

   The Save As dialog box opens.

2. Go to the folder in which you want to save the library.
3. Type in a base name for the library.

   Symbol Library Manager adds the .lib extension automatically when you specify the base name.
4. Click **Save**.

Viewing Symbol Properties from Symbol Library Manager

You can view properties associated with any symbol in a library with the Symbol Properties dialog box. However, you cannot edit symbol properties in this dialog box.

To view symbol properties from Symbol Library Manager:

1. Open a library and select the symbol whose properties you want to view.
2. Choose **Edit > Properties** or right-click the symbol and choose **Properties** from the pop-up menu to open the Symbol Properties dialog box.

The dialog box has three tabs: General, Pins, and Attributes. The General tab has information on the name of the symbol and the location of the library it is in. The Attributes tab displays various attributes of the symbol. The Pins tab displays pin attributes. A pin's attributes may be viewed by selecting the pin whose attributes you wish to view.

Adding Symbol Libraries to Schematic Editor

After creating a symbol library, you need to tell Schematic Editor about it. Then the library and its collection of symbols will appear in Schematic Editor’s Add Symbol dialog box.

To add a symbol library to Schematic Editor:

1. In the Diamond window, choose **Tools > Options**.
2. In the left-hand pane of the Options dialog box, look under Schematic Editor and select **User Defined Symbol Libraries**.

   The right-hand pane shows a list of user-defined symbol libraries. The libraries that come with Diamond are not shown.
3. Click **Add Library** (for a .lib file) or **Add Folder**.

   The Add Symbol Library dialog box opens.
4. Browse to the library file (.lib) or folder that you want to add.
5. Click **Open**.

   The selected library is added to the list.

6. To change the order of the libraries in the Add Symbol dialog box, select a library and click **Up** or **Down**.
7. When you finish, click **Apply** or **OK**.

Creating Schematic Symbols

You can use Symbol Editor to construct schematic symbols. Besides the various lines, arcs, and boxes needed to create a symbol. You can add text to give information about the symbol and its relationship with the rest of the circuit.

You can also use Schematic Editor to create a block symbol from a schematic.

Schematic Symbol Overview

Symbol Types Four types of symbols can be created in Symbol Editor. Use the Symbol Type command on the Edit menu to select symbol types.

- Cell Symbol

  Cell symbols represent the primitive cells (transistors, resistors, diodes, and so on) used to design integrated circuits. The pins on cell symbols are named for identification in netlists.

- Block Symbol

  Block symbols are used to build a hierarchical design. Each block symbol represents a schematic or HDL module at the next-lower level of the hierarchy. Bus pins are permitted on block symbols.

- Graphic Symbol

  Graphic symbols add information that is not part of the circuitry. Graphic symbols are typically used for tables and notes. No pins are associated with graphic symbols, and they are never included in the hierarchy or netlists.

- Master Symbol

  Master symbols are used for title blocks, logos, revision blocks, and other standardized graphic symbols. You can add text to a master symbol to display the company name, address, project description, date, and so on.

Symbol Elements Schematics are constructed from symbols. A symbol can represent any logic component. Symbols are connected with wires (in Schematic Editor) to create a complete schematic whose behavior can be verified and simulated.

A symbol is a picture; it has no inherent electrical meaning. Its electrical characteristics are supplied by attributes that describe the symbol's behavior. (The behavior of a Block symbol is described by the schematic file associated with that Block symbol.).

The Lattice Diamond software supplies you with an extensive set of symbols. You can also use Symbol Editor to create Block symbols that represent a complete schematic, or part of one.

Symbols are composed of graphic, pin, and attribute elements.

- Graphic elements are the picture of the symbol. They have no electrical meaning; they show only the location of the component in the schematic.
- Pin elements on a symbol are points where a wire can be attached. The pins and wires are connected between symbols to circuit elements.

  Buses cannot be connected to pins unless the pin is a bus pin. Only ordered buses can be connected to bus pins.
- Attribute elements are properties of a symbol, pin, or net. Attributes can describe how the Fitter will optimize the symbol, or where it is placed in the device.

Pins Symbol pins are connection points for wires. Pins on Gate, Component, and Cell symbols represent the connection points on the device (pins or pads). Pins on a Block symbol represent connections from one level of the hierarchy to the level below. Because Graphic and Master symbols do not represent electrical components, you cannot attach pins to them.

Pins are the only symbol elements restricted to locations on the Primary grid, since wires must begin and end on Primary grid points.

Bus Pins A bus pin is used to connect a bus to a symbol. Naturally, a bus pin must have as many nets or signals as the bus that connects to the pin.

One way to create a bus pin is to give a pin a name of the form:

bus_name[*index1–index2*]

Where *bus_name* is the name of an internal bus, and *index1* and *index2* specify the range of signals you want to connect. For example, if you need to connect nine signals, *index1* could be 5 and *index2* could be 13.

Alternatively, a bus pin can be defined by giving it a *compound name*—a list of bus names separated with commas (,):

```
name1, clk, mux[0-3], toggle
```

Bus pins are allowed only on Block, Cell, and Component symbols. When a bus pin is created on a Component symbol, the numbers of the physical pins must be specified in the symbol definition.

These pin numbers are a list of pins assigned to the pin attributes BusPin_A through BusPin_H. When assigning bus pins, the normal PinNumber pin attribute *must not* have an assigned value.

The pin list can be divided sequentially among the eight attributes. Each individual attribute can hold about 200 characters. The list is delimited with

commas or spaces, and can specify sequences of pins in parentheses **( )** or square brackets **[ ]**. Examples are

```
BusPin_A = 1, 3, 5, (7:10)
  7 pins: 1, 3, 5, 7, 8, 9, 10
BusPin_B = A1 B[2:4] C1
  5 pins: A1, B2, B3, B4, C1
```

Attributes A symbol and each of its pins can have attributes. An attribute has a name and a value.

- Symbol Attributes

  Symbol Attributes are characteristics or properties associated with a symbol. Examples of symbol attributes are *PartNum*, *InstName*, *Width*, and *Type*.

  You can edit symbol attributes in the Object Properties Setting dialog box.

- Pin Attributes

  Pin Attributes are characteristics or properties associated with a pin. *PinName*, *Polarity*, and *PinNumber* are examples of Pin Attributes.

More on Pin Attributes Pin attributes generally have no meaning except as literal text. It is only when other programs read this text that it acquires any other meaning. There are a few exceptions:

- The Pin Name on Block symbols must match the name of the net connected to this pin on the underlying schematic in the hierarchy. The Pin Name can represent a single signal, or it can be a compound name representing a bus. All signals represented by a pin must exist on the underlying schematic.
- The Use or Polarity attribute has a default value of Input. You need to assign a value only if the Use or Polarity is other than Input. The other legal values are Output and Bidir (bidirectional).
- The values for Load and Drive attributes must be integers and use consistent units. Input pins use the attributes LoadLow and LoadHigh. Output pins use the attributes DriveLow and DriveHigh, while bidirectional pins use both the Drive and Load attributes.
- For gate symbols, pin numbers should be added in Symbol Editor as a list of pin numbers. For component symbols, a single pin number should be specified.

Opening Symbol Editor

To open Symbol Editor, you can either open an existing symbol (see “Opening an Existing Symbol” on page 270) or create a new symbol file (see “Creating a New Symbol File” on page 270).

Opening Symbol Library

To open a symbol library, you can either open an existing library (see "Opening an Existing Symbol Library" on page 262) or create a new library file (see "Creating a New Symbol Library" on page 262).

Opening an Existing Symbol

You can open an existing symbol file from Diamond's main window.

To open an existing symbol file:

1. In the Diamond window, choose **File > Open > File**.
2. In the Open File dialog box, in the file type menu at bottom-right, choose **Symbol Files (*.sym)**
3. Browse to the desired symbol file.
4. Click **Open**.

   Symbol Editor opens with the selected symbol.

Creating a New Symbol File

You can open Symbol Editor to create a new symbol.

To create a new symbol:

1. In the Diamond window, choose **File > New > File**.

   The New File dialog box opens.
2. Under Categories, select **Other Files**.
3. Under Source Files, select **Symbol Files**.
4. Specify the file name without any extension. The .sym extension is added automatically.
5. Click **Browse**.
6. In the Location dialog box, browse to where you want to put the file.
7. Click **Select Folder**.
8. In the New File dialog box, click **New**.

   Symbol Editor opens allowing you to create the symbol.

See Also "Creating a Block Symbol from a Schematic" on page 273

"Creating a Symbol from an HDL Module" on page 274

Saving a Symbol

You can store a symbol in a library for use in many designs, or keep it in the design directory for use in a specific design.

The Save File command in Symbol Editor saves the changes to the existing symbol file. You can use the Save File As command to save the symbol with another file name, which is useful when you're designing several similar symbols. Save the original, modify it, then save the new version with a new name.

Symbol files have the extension .sym. Below shows the steps of saving a symbol with the Save File As command.

To save a symbol with the Save File As command:

1. In Symbol Editor, choose **File > Save** <*filename*> **As**.

   The Save as Symbol File dialog box opens.
2. Go to the folder in which you want to save the symbol.
3. Type in a base name for the symbol.

   Symbol Editor adds the .sym extension automatically when you specify the base name.
4. Click **Save**.

Printing a Symbol

You can print a symbol using the Print command.

To print a symbol:

1. In Symbol Editor, choose **File > Print**.

   The Print dialog box opens.
2. Select the print options that you want and click **OK**.

Checking a Symbol for Errors

You can check symbols for errors at any time. Symbol Editor writes an error report to a file and opens it after the check is run. Clicking an error in the list highlights the error in the drawing.

The following types of errors are detected and reported:

- Block symbols should have a schematic with the same name in the current directory.
- Symbols of type other than Block are usually primitives and should not have a schematic of the same name in the current directory.
- Each pin should have a PinName in a Block or Cell, and a PinNumber in a Gate or Component.
- Pins in Component and Pin symbols can only have one PinNumber.
- Pins in the same group of a Gate must all have the same Polarity, Load and Drive.

- Pins on Block symbols should not have Load or Drive specifications.
- Pins on non-Block symbols should have Load or Drive specified. Input pins should specify Load but not Drive. Output pins should specify Drive, unless the pin is tristate. In that case, Load should also be specified, representing the load in the High-Z state. Bidirectional pins should specify both Load and Drive.

To check a symbol for errors:

1. In Symbol Editor, choose **Design > Drc Check**.

   Symbol Editor opens an error report.

2. Select an error from the list.

   The system displays the corresponding location of the error with a cross mark over it.

Drawing Operations

This section describes the operations that are generally applicable to drawing the graphic for a symbol.

Setting the Line Weight Graphic objects can be drawn in two line weights: normal and wide.

Normal lines (default) are the same width as the wires in a schematic. You might use this weight for drawing all elements.

Wide lines are twice the width of Normal lines, the same weight as schematic buses. For example, you might use this weight to illustrate a bus pin connection.

To set the line weight:

1. In the Diamond window, choose **Tools > Options**.

   The Options dialog box opens.

2. In the dialog box, click **Graphic Options** under Symbol Editor.
3. To draw wide lines, select **Use Wide Line**.

   All elements you enter are drawn as wide lines until you change this setting. Changing the line width does not alter the width of elements already drawn. It only affects the elements drawn after the change.

4. Click **Apply** or **OK**.

Drawing Lines When clicking to place the end points, lines are constrained to three principal directions: vertical, horizontal, and 45°. When you drag the line, the line can be at any angle as long as the end points fall on the grid being used. To show or hide the grid, choose **Tools > Options** in the Diamond window. Then select **Show Grid** in Symbol Editor Graphic Options.

Use the Add Line command to draw a line or an outline. When you draw a line, the line can be at any angle.

Drawing Rectangles Many symbols are based on a rectangular body. For non-rectangular symbols such as inverters or multiplexers, use the Line command to draw the outline.

Drawing Circles and Arcs You can place full circles with the Add Circle command and create portions of circles with the Add Arc command. Arcs are useful for the curved sections of NAND and NOR gates.

Drawing Negation Bubbles Negation bubbles are graphical and have no electrical significance. (Adding a negation bubble to a symbol does not change its logic. You must modify the symbol's attributes or the underlying schematic file.) You can add small or large bubbles:

- Click  on the Drawing Toolbar to draw a bubble one-half the Primary grid unit in diameter
- Click  on the Drawing Toolbar to draw a bubble one Primary grid unit in diameter

With either command, a bubble is attached to the cursor. Click the desired position in the schematic to place a bubble.

Drawing Text Text can be added anywhere in the drawing window. Typical uses of text include:

- Notes about the symbol
- Title blocks
- Cross references

Fixed text (as opposed to text appearing in attribute windows) can be drawn in up to eight sizes. (In the Windows version of the Diamond software, eight sizes are available. In the Linux version, three sizes are available.) Text can be left justified, right justified, or centered. Use the Add Text command to specify font size and text content and justification in the Add Text dialog box.

Creating a Block Symbol from a Schematic

Block symbols are used to build a hierarchical design. Each block symbol represents a schematic or HDL module at the next-lower level of the hierarchy. You can create a block symbol from the currently loaded schematic in Schematic Editor or for an HDL module selected in the Hierarchy view (see “Creating a Symbol from an HDL Module” on page 274).

To create a block symbol from the currently loaded schematic:

1. Open the schematic design in Schematic Editor.
2. Choose **Design > Generate Symbol**.

A generic block symbol is created at:
<*install dir*>/tmp/<*schematic name*>.sym.

3. Use Symbol Editor to customize the new block symbol.

See Also ▶"Adding Symbols to the Schematic" on page 277

Creating a Symbol from an HDL Module

The Lattice FPGA Symbol Library provides dozens of pre-defined symbols for gate-level schematic design. You can also create customer symbols (*.sym) from an existing Verilog or VHDL module. These symbols can later be added to your schematic design source.

Once a symbol is created, you can modify it in Symbol Editor.

To create a schematic symbol from an existing HDL module:

- In the Hierarchy view, right-click the module that you want to create a symbol for, and choose **Generate Schematic Symbol**.

  The Diamond software writes a new schematic symbol file (*.sym) into the project directory using the interface ports defined by your HDL module.

See Also ▶"Adding Symbols to the Schematic" on page 277

Preparing Symbols for Schematics

A symbol needs special *links* so that it can be recognized and placed in a schematic. These links consist of *pins*, *attributes*, *attribute windows*, and the *symbol origin*. You can define these links before adding symbols to schematics.

Setting the Symbol Origin

When a symbol is placed in Schematic Editor, the symbol is attached to the cursor. The point on the symbol attached to the cursor is called the *origin* of the symbol.

A newly created symbol has no origin. When the symbol is saved, the origin defaults to the upper-left corner of the symbol. You can assign an origin or change the current origin with the Symbol Origin command in Symbol Editor.

To set the symbol origin:

- Choose **Edit > Symbol Origin** and click the desired location. (The origin does not have to be on or within the symbol; it can be outside.)

  After you assign a new origin, the symbol coordinate tick marks relocate.

The Origin is not part of the symbol. If you move the symbol, the Origin does not move with it. Be sure to reposition the origin if you move the symbol.

Positioning Master Symbols

Master symbols cannot be freely placed on a schematic sheet. Instead, they are automatically positioned at one of the corners. This permits resizing the sheet without having to move the title block or other annotations.

The sheet corner is determined by the location of the symbol's origin. If the origin is placed at the upper-right corner of the Master symbol, for example, the symbol will be positioned at the upper-right corner of the sheet.

Master symbols do not have pins.

Adding Pins to a Symbol

Symbol pins correspond to I/O markers on the underlying schematic and connect the device represented by the symbol to the rest of the circuit.

Pins are usually attached to the symbol on short lines extending outward from the symbol's body. However, pins can be attached anywhere inside or outside the symbol, with or without connecting lines.

Pins are electrical elements and are therefore restricted to locations on major grid intersections. There can be only one pin at any location.

To add a pin to a symbol:

1. In Symbol Editor, choose **Edit > Add > Pin**, or click  on the Drawing Toolbar.
2. Click where you want to place a pin.

   If that point already has a pin, the system displays an error message. Pins appear in Symbol Editor as small squares.

Adding a Pin Name

You can use the Object Properties command to add pin names.

To add pin names:

1. In Symbol Editor, select the pin for which you want to add a name.

   The pin appears highlighted in red.
2. Choose **Edit > Object Properties**.

   The Object Properties Setting dialog box opens.
3. In the left-hand list, select the pin from the Pins list.

   The corresponding pin attributes are displayed in the right-hand table in alphabetical order.
4. Double-click the Value cell for the PinName attribute, and type in the name you want.

5. Click **Apply**.

Note

If you want the pin names to be displayed, use the Name Location field in the Object Properties Setting dialog box to set the display position of pin names. See "Setting the Display Position of Pin Names" on page 276 for details.

See Also ▶"Adding Pins to a Symbol" on page 275

Setting the Display Position of Pin Names

You can use the Object Properties Setting dialog box to control the pin name position relative to the pin.

To set the display position of pin names:

1. In Schematic Editor, select the pin you want to work with.
2. Choose **Edit > Object Properties**.

   The Object Properties Setting dialog box opens.
3. In the left-hand list, select the pin from the Pins list.
4. Under Name Location, select an option among the available choices: showing the pin name on the left, top, right, or bottom of the pin; or showing the pin name vertically. Also, you can set the offset value, the distance of the pin name from the pin.
5. Click **Apply**.

   The pin name appears at the specified position.

   Note

   The Offset is measured in Secondary grid units. The maximum Offset is 127.

See Also ▶"Adding a Pin Name" on page 275

Adding or Changing a Pin Attribute Value

Pin Attributes are characteristics or properties associated with a pin. *PinName*, *Polarity*, and *PinNumber* are examples of Pin Attributes.

To add or change pin attribute values:

1. In Symbol Editor, select the pin for which you want to add or change attributes.
2. Choose **Edit > Object Properties**.

   The Object Properties Setting dialog box opens.
3. In the left-hand list, select the pin from the Pins list.

The attributes for the selected pin are displayed in the right-hand table in alphabetical order.

4. Double-click the Value cell for the desired attribute, type in a new value, and click **Apply**.

   The attribute value is assigned to the selected pin.

See Also ▶"Pin Attributes" on page 269

Adding an Attribute Window to a Symbol

Attribute windows are predefined areas on or near a symbol or pin in which attribute values are displayed. In Symbol Editor, the window only contains the attribute name. When the symbol is instantiated in a schematic drawing, the attribute window contains the attribute value for that instance, rather than the attribute name.

Attribute windows do not have a visible outline. If no value is displayed, there is no indication that an attribute window has been defined.

To add an attribute window to a symbol in Symbol Editor:

1. Choose **Edit > Attribute Window**.

   The Attribute Window dialog box opens. It contains all attribute names.

2. Select the desired attribute name from the list.

   The attribute name is attached to the cursor.

3. Click to place the symbol attribute window at the desired position on (or near) the symbol.

   Two narrow bars appear beside the window's name, in a position indicating the text justification. For example, a right-justified name has the bars at the right end of the name.

4. Close the dialog box when you finish.

Adding Symbols to the Schematic

You can use the Add Symbol command on the Edit menu to select and add symbols to a schematic. Symbols come from a symbol library, or you can create your own symbols using Symbol Editor. Symbol files have the file extension .sym. Symbol libraries have the file extension .lib.

To select and add a symbol to a schematic:

1. In Schematic Editor, choose **Edit > Add > Symbol**.

   The Add Symbol dialog box opens.

2. In the dialog box, choose a library from the Library list.

   Tip

   If you want your own library of custom schematic symbols to appear in the Library list, you need to specify them in advance. See “Adding Symbol Libraries to Schematic Editor” on page 266.

3. From the Symbols list, select a symbol.

   The symbol is attached to the cursor.

4. After the symbol is attached to the cursor, click the location in the schematic where you want to place the symbol. If you pick the wrong symbol or change your mind, right-click anywhere in the window to remove the symbol from the cursor. You can then select a different symbol.

   Note

   The symbol remains attached to the cursor, so that you can place multiple copies without having to reselect the symbol.

See Also ▶“Using Lattice Symbol Library” on page 257

Deleting Symbols

To delete a symbol from a schematic:

1. In Schematic Editor, click the symbol that you want to delete.
2. Choose **Edit > Clear**.

   The symbol is deleted from the schematic.

Copying Symbols

If an instance of the symbol you want already appears in the schematic, you can copy it to another location.

To copy a symbol:

1. In Schematic Editor, choose **Add > Symbol**.
2. Click the instance that you want to copy.

   A copy of that symbol is attached to the cursor.

3. Click the location in the schematic where you want to place the symbol.

   Schematic Editor places a copy of the symbol at that location. The symbol remains attached to the cursor, so that you can place multiple copies without having to reselect the symbol.

Selecting Symbols

You can select one or more symbols in Schematic Editor. The selected symbols are highlighted in red.

To select symbols:

1. Choose **Edit > Add > Select**, or click on the drawing toolbar.
2. Do either of the following:
   - Click the symbol.
   - Draw a rectangle area around the desired symbols.

   You can continue to select symbols, in either of the above mode, as long as you hold down the Shift key.

Note

You cannot deselect a symbol by clicking it again. To deselect symbols, click any empty space on the schematic sheet.

Transforming Symbols

You can *mirror* or *rotate* symbols in Schematic Editor before you place them.

To mirror a symbol before placing it:

- When the symbol is attached to the cursor, choose **Edit > Mirror**.

To rotate a symbol before placing it:

- When the symbol is attached to the cursor, choose **Edit > Rotate**.

Moving Symbols

You can move symbols in Schematic Editor in three ways.

To move a single symbol:

1. Select from the drawing toolbar.
2. Choose **Edit > Move**.
3. Click the symbol that you want to move.
4. Drag it to a new location to move the symbol there.

Net names, attributes, and instance names are moved as well as the physical representation of the symbol. A priority list determines which item is selected if the cursor points at two or more items when the mouse button is clicked.

To move all symbols in an area:

1. Select from the drawing toolbar.

2. Choose **Edit > Move**.
3. Drag the mouse to define a rectangle area around the symbols that you want to move.

   When the mouse button is released, all items totally enclosed by the rectangle are selected.
4. Drag the selected symbols to a new location.

   All items totally enclosed by the rectangle are moved.

To move a group of symbols:

1. Select from the drawing toolbar.
2. Choose **Edit > Move**.
3. Select one or more items, as either a single item or area.

   As each item or area is selected, it is highlighted. You can continue to select items, in either single item or area-selecting mode, as long as you hold down the Shift key.
4. Drag the selected group to a new location.

   All items in the group are moved. The relative position of the items in the group is maintained.

Schematic Attributes

You use attributes to describe the characteristics or properties belonging to, or associated with, a *symbol*, *pin*, or *net*. Attributes only apply to describing characteristics in schematics. HDL source files have their own syntax for describing characteristics.

For pre-defined schematic attributes supported by FPGA and MachXO devices, see “List of Schematic Attributes” on page 281.

For more information on attribute usage, see the sysIO User Guides on the Lattice Web site.

Attribute Use Attributes are primarily used to control certain aspects of design optimization and signal placement. You can also use attributes to control design implementation.

Attribute Types There are two types of attributes used in Schematic Editor: *symbol* and *net*.

- **Symbol** attributes describe features related to a whole symbol. Symbol attributes usually apply only to the symbol on which they appear.
- **Net** attributes describe characteristics associated with nets.

Setting Attribute Values In the FPGA device flow, Schematic Editor passes attribute information to the output netlist as Verilog HDL or VHDL attributes depending on the project type specified when you define a project. For those attributes that can be edited, you can set or override the values as follows.

- You can set *symbol* and *pin* attribute values for all occurrences of a symbol in Symbol Editor.
- You can override the attribute values in any schematic where the symbol appears by using Schematic Editor.

Default Values Attribute values in a symbol definition become the default values for each symbol instance. These values are frequently overridden in the completed design to reflect the design's application.

When you are in Symbol Editor, any attribute values you set in Symbol Editor will be used.

When you are in Schematic Editor, any attribute values you set in Schematic Editor will be used. If you did not specify attributes for the symbol in Schematic Editor, Schematic Editor will use the values set for the symbol in Symbol Editor.

Attributes that apply to all instances of a symbol are generally assigned values when the symbol is created. Attributes that apply to a single instance (such as the instance name) are assigned after a symbol has been placed in the design.

The symbol libraries supplied with the Diamond software have predefined values for all the attributes required by most simulators and netlisters.

Displaying Attribute Values on a Schematic Attribute values are displayed in attribute windows. Before an attribute can be displayed on a schematic, an attribute window number must be assigned to the attribute in Symbol Editor.

List of Schematic Attributes

Schematic Editor for FPGA and MachXO Crossover Programmable devices supports the ability to specify HDL attributes as schematic symbol or net attributes. HDL attributes are interpreted by place and route implementation software.

Schematic Editor supports schematic attributes summarized in the following tables for Precision RTL Synthesis, Synplify Pro, and Diamond. For detailed

information on the above Synplify attributes, see “Synthesis Attributes and Directives” in the Synplify and Synplify Pro for Lattice Reference Manual.

Table 8: Table of FPGA HDL Attributes for Precision RTL Synthesis

HDL Attribute	Attribute Type	Description and Syntax
black_box	Symbol	Tells Precision RTL Synthesis that the module should not be compiled or optimized. Only the interface need be defined for synthesis. Values: True | False
don’t_touch	Symbol	Tells Precision RTL Synthesis to pass the module through synthesis without optimizing or unmapping. Values: True | False
hierarchy	Symbol	Tells Precision RTL Synthesis to maintain the hierarchy of the module. Values: Preserve | Flatten
noopt	Symbol	Tells Precision RTL Synthesis that an instance should not be optimized or changed. Values: True | False
nopad	Net	Tells Precision RTL Synthesis to not place an I/O pad on the specified port when the design is mapped to the technology. Values: True | False
preserve_driver	Net	Tells Precision RTL Synthesis to preserve the specified signal and the driver in the design. Specifies that both a signal and the signal name must survive synthesis. Values: True | False
preserve_signal	Net	Tells Precision RTL Synthesis to preserve the specified signal in the design. Values: True | False

Table 9: Table of FPGA HDL Attributes for Synplify Pro

HDL Attribute	Attribute Type	Description and Syntax
syn_black_box	Symbol	Tells Synplify Pro to treat the module as a black box during synthesis. Values: 1 | 0; True | False
syn_direct_enable	Net	Tells Synplify Pro to use the signal as the enable input to an enable flip-flop when multiple candidates are possible. (LatticeECP/EC, LatticeECP2/M, LatticeSC/M, LatticeXP, and MachXO only) Values: 1 | 0; True | False
syn_force_pads	Net	Tells Synplify Pro to enable or disable I/O insertion on a port level or a global level. Values: 1 | 0; True | False

Table 9: Table of FPGA HDL Attributes for Synplify Pro

HDL Attribute	Attribute Type	Description and Syntax
syn_hier	Symbol	Tells Synplify Pro how to control the amount of hierarchical transformation that occurs across boundaries on module or component instances during optimization. Values: Soft (default) | Firm | Hard | Remove | Macro | Flatten | Flatten,Soft | Flatten,Firm | Flatten,Remove
syn_keep	Net	Tells Synplify Pro to not remove the internal signal during synthesis and optimization. Values: 1 | 0; True | False
syn_netlist_hierarc	Symbol	Tells Synplify Pro whether or not to generate the hierarchy in the EDIF output when you assign the attribute to the top-level module of your design. The default (true) is to allow hierarchy generation. Values: 1 | 0; True | False
syn_noarrayports	Symbol	Tells Synplify Pro to treat the ports of a design unit as individual signals (scalars), not as buses (arrays) in the EDIF file. Values: 1 | 0; True | False
syn_noclockbuf	Net	Tells Synplify Pro to disable automatic clock buffer insertion. Values: 1 | 0; True | False
syn_noprune	Symbol	Tells Synplify Pro whether or not to remove instances that have outputs that are not driven. Values: 1 | 0; True | False
syn_maxfan	Net	Tells Synplify Pro the fanout limit for an individual input port or register output. (LatticeECP/EC, LatticeECP2/M, LatticeSC/M, LatticeXP, and MachXO only) Values: *integer*
syn_preserve	Net	Tells Synplify Pro to prevent sequential optimizations across a flip-flop boundary during optimization and preserves the signal. Values: 1 | 0; True | False
syn_useioff	Net	Tells Synplify Pro to pack flip-flops in the I/O ring to improve input/output path timing. (LatticeECP/EC, LatticeECP2/M, LatticeSC/M, LatticeXP, and MachXO only) Values: 1 | 0; True | False

Table 10: Table of FPGA HDL Attributes for Diamond

HDL Attribute	Attribute Type	Values
BBOX	Symbol	*<height>.<width>*
BBOXTYPE	Symbol	Obsolete. Do not use.
BLOCKNET	Net	*<name>*
BUS	Net	*<bus_name>*
COARSE	Symbol	CDEL0 | CDEL1 | CDEL2 | CDEL3

Table 10: Table of FPGA HDL Attributes for Diamond

HDL Attribute	Attribute Type	Values
COMP	Symbol	<*comp_name*>
DCSMODE	Symbol	NEG | POS | HIGH_LOW | HIGH_HIGH | LOW_LOW | LOW_HIGH | CLK0 | CLK1
DELAYTYPE	Symbol	CFGBIT | DLL | PCLK | ECLK
DIFFCURRENT	Symbol/Net	NA | 2 | 3.5 | 4 | 6
DIFFRESISTOR	Symbol/Net	Off (default) | 100 | 150 | 200 (only for differential buffers)
DIN	Symbol	<*cell_name*>
DOUT	Symbol	<*cell_name*>
DRIVE	Net	NA | 2 | 4 | 8 (default) | 12 | 16 | 24
ENDPOINT	Symbol/Net	Obsolete. Use Spreadsheet View to apply the TO keyword in the BLOCK, MAXDELAY, and MULTICYCLE constraints instead.
FINE	Symbol	FDEL0 | FDEL1 | FDEL2 | ... | FDEL47
FIXEDDELAY	Net	False | True
FREQUENCY	Net	<*value*> (expressed in MHz)
GSR	Symbol	ENABLE | DISABLE | FORCEENABLE | IPENABLE
HGROUP	Symbol	<*identifier*>
HULOC	Symbol	R<*row_number*>C<*column_number*>
HURLOC	Symbol	R<*row_number*>C<*column_number*>
IMPEDANCE	Symbol/Net	Off (default) | 25 | 33 | 50 | 100
IMPEDANCEGND	Symbol	Off (default) | 16.7 | 20 | 25 | 33 | 50 | 100 (Impedance down)
IMPEDANCEVCCIO	Symbol	Off (default) | 16.7 | 20 | 25 | 33 | 50 | 100 (Impedance up)
INBUF	Symbol	Off | On
IO_TYPE	Net	<*buffer_type*>
LOAD	Symbol	<*integer*>.<*integer*>
LOC	Symbol/Net	<*string*> Default is None (floating).
MAXDELAY	Net	<*value*> (expressed in ns)
NOCLIP	Net	1
NOMERGE	Net	<*net_name*>
NORETIME	Symbol	<*string*>
OPENDRAIN	Net	On | Off (default)
PCICLAMP	Net	On | Off (default)
PERIOD	Net	<*value*> (expressed in ps)

Table 10: Table of FPGA HDL Attributes for Diamond

HDL Attribute	Attribute Type	Values
POWERSAVE	Net	Obsolete. Do not use.
PULLMODE	Net	Up (default) | Down | None | Keeper | PCIClamp
PWRSAVE	Symbol	Off (default) | On
RBBOX	Symbol	*<height>.<width>*
REFCIRCUIT	Symbol/Net	Off (default) | Internal | External (for differential buffer)
REGION	Symbol	*<identifier>*
SLEW	Symbol	1-100
SLEWRATE	Net	Fast | Slow | NA (LatticeSC/M only)
STARTPOINT	Net	Obsolete. Use Spreadsheet View to apply the FROM keyword in the BLOCK, CLOCK_TO_OUT, MAXDELAY, and MULTICYCLE constraints instead.
TERMINATEGND	Symbol/Net	Off (default) | 50 | 100 | 120
TERMINATEVCCIO	Symbol/Net	Off (default) | 50 | 100 | 120
TERMINATEVTT	Symbol/Net	Off (default) | 60 | 75 | 120 | 150 | 210
UGROUP	Symbol	*<identifier>*
VCMT	Symbol/Net	OFF (default) | VCMT | VTT | DDR_II

Assigning Attribute Values in a Schematic

Schematic Editor enables you to assign attribute values for symbols and nets. See “List of Schematic Attributes” on page 281 for schematic attributes supported by Lattice FPGA devices.

Following the steps below, you can assign attribute values in a schematic (the procedure takes assigning the DOUT symbol attribute as an example).

To assign an attribute value in a schematic:

1. In Schematic Editor, open the schematic you want to work with.
2. In the Schematic area, select the symbol for which you want to assign the DOUT attribute.
3. Choose **Edit > Object Properties**.
4. In the pop-up dialog box, click the plus sign before **Symbols** to show the symbol name.
5. Select the symbol name. All its symbol attributes are displayed in the right-hand table.
6. In the attributes list, double-click the Value cell for **DOUT**, type **1** in the cell, and then click **Apply** to save the assignment.

   The value 1 is assigned to the DOUT attribute.

7. Click **OK** to close the dialog box.

The above example takes assigning symbol attribute values as an example. If you want to assign a net attribute value, select a net in Step 2, and then perform the same operations to show the net attributes list and assign attribute values.

The net attribute LOC is used to lock pins. Double-click the Value cell for **LOC** in the net attributes list, type in a pin name in the edit box, and then click **Apply**. The selected net will be locked to the pin.

Net attributes also include I/O configuration attributes such as IO_Type, Drive, Slewrate, Pullmode, PCIClamp, OPENDRAIN, and various synthesis tool attributes. See “List of Schematic Attributes” on page 281 for schematic attributes supported by Lattice FPGA devices.

Schematic Sheets

A sheet is a page of a schematic. A schematic file can consist multiple sheets. The schematic sheets can be added, deleted, resized, and renumbered.

Adding a New Sheet

You can add new (blank) sheets to an existing schematic.

To add a new sheet to a schematic:

1. Choose **Edit > Sheet**.
2. In the Sheet Operating dialog box, click **New**.
3. In the pop-up dialog box, enter a sheet number, select a sheet size, and click **OK**.
4. In the Sheet Operating dialog box, click **OK**.

   Schematic Editor adds the new sheet to the list.

Resizing Sheets

You can change the sheet size to any of several sizes that are based on the standard paper sizes of the American National Standards Institute (ANSI).

Table 11: Schematic Sheet Sizes

Paper Size	In Inches	In Millimeters	Similar ISO Size
ANSI A (letter)	11 x 8.5	279 x 216	A4
ANSI B (ledger or tabloid)	17 x 11	432 x 279	A3
ANSI C	22 x 17	559 x 432	A2

Table 11: Schematic Sheet Sizes

Paper Size	In Inches	In Millimeters	Similar ISO Size
ANSI D	34 x 22	864 x 559	A1
ANSI E	44 x 34	1118 x 864	A0

To resize a sheet:

1. Choose **Edit > Sheet**.
2. In the Sheet Operating dialog box, select the Size cell of the sheet that you want to change.
3. Click **Resize**.

   The Resize Sheet dialog box opens, displaying the current size of the selected sheet.
4. Select the desired new size from the drop-down menu.
5. Click **OK**.
6. In the Sheet Operating dialog box, click **OK**.

Renumbering Sheets

You can change the number of any sheet in the schematic.

To renumber a sheet:

1. Choose **Edit > Sheet**.
2. In the Sheet Operating dialog box, select the sheet number that you want to change, and click **Renumber**.

   The Change Sheet Number dialog box opens.
3. Type the new sheet number in the dialog box and click **OK**.
4. In the Sheet Operating dialog box, click **OK**.

   Schematic Editor changes the number of the sheet to the new number.

Re-sequencing Sheets

You can use the Resequence Sheet command to sequentially renumber, starting at sheet 1, all the sheets in the drawing and remove any skipped numbers.

To resequence sheets in your schematic:

1. Choose **Edit > Sheet**.
2. In the Sheet Operating dialog box, click **Resequence**, and then click **OK**.

   Schematic Editor resequences the sheets and deletes all unused (skipped) numbers.

Printing Sheets

For schematic sheets, the Print command prints whatever is showing in the Schematic Editor window. Print acts much like a screen capture tool. You may need to experiment with Print Preview to get the printout that you want.

To print schematic sheets:

1. Click to detach Schematic Editor from Diamond's main window.
2. Click **View >** **Zoom Fit**.
3. Adjust the height or width of the Schematic Editor window so the sheet fills the window with the same small margin on all sides.
4. Choose **File >** **Print Preview**.

   The Print Preview window opens.
5. Expand the Print Preview window until you are comfortable with the display of the page.
6. To maximize the printout, click for landscape mode.
7. Click the **Page Setup** button and adjust the paper size and margins if necessary.
8. If you are not happy with the way the page looks, close Print Preview, adjust the Schematic Editor window, and open Print Preview again.
9. Click the **Print** button.
10. Adjust the printer settings if necessary and click **Print**.

With a little experience, you will be able to skip using Print Preview and just choose **File >** **Print** after adjusting the Schematic Editor window.

Wiring a Schematic

Wires electrically connect schematic symbols. The symbol pins are the connection points for the wires. The Add Wire command is used to add wires between symbol pins. However, you can also use the Add Net Name and Add Bus Tap commands to add single wire segments.

Wiring Constraints

Schematic Editor enforces a number of wiring constraints. Most are intended to encourage clean layout and prevent ambiguous wiring patterns.

- All wire segments must end on Primary grid points.
- Wire segments must be oriented on the 90° axes.
- A maximum of three wires can connect at a pin or I/O port.
- A net can have only one name (simple or compound).
- Two I/O ports with different net names cannot be connected by a wire.

- An I/O port can connect only to a wire segment, never a pin. (Add a wire segment if you want a marker to be near a pin.)
- An I/O port cannot be placed in the middle of a diagonal line, only at the end.
- An I/O port cannot be placed at the crossing point of two wires, even if the wires are connected.
- A tap can only be placed on a vertical or horizontal section of a wire.
- Only one bus tap can be made at any point on a bus.
- A bus can contain only individual signals, not other buses. Attempting to give a net in a bus either a compound name or the name of another bus is flagged as an error.
- The relationship between an ordered bus (that is, a bus with a compound name) and the signals in that bus is strictly enforced. Naming the bus or one of its signals in a way that breaks this relationship is not permitted. For example, you cannot assign a bus tap a name that is not in the bus.

Drawing a Wire Using the Point-to-point Method

To draw a wire using the point-to-point method:

1. Choose **Edit > Add > Wire**.
2. Click the first point of the wire. Two dotted lines, horizontal and vertical, stretch from the selected point to the cursor. As you move the cursor, the lines change from horizontal to vertical (or vertical to horizontal) depending on the position of the cursor relative to the first point.
3. When the first dotted section has the length and direction you want, click a second time.

   The first dotted section changes to the wire color and its position is fixed. A new dotted section is now added to the “rubber band” line. You can add additional wire segments by repeating steps 2 and 3.
4. To end the wire, click twice at the same point (or right-click).

   The wire terminates automatically if the point you click falls on a pin terminal.

Drawing a 4-way Connection

To form an intersecting connection:

1. Start with a single wire.
2. Add one or two additional wires at right angles to the first wire from a point on the first wire. This type of connection is automatically marked with a connect dot to distinguish it from unconnected crossing wires.

Selecting Wires

You can select one or more wires in Schematic Editor. The selected wires are highlighted in red.

To select wires:

1. Choose **Edit > Add > Select**, or click on the drawing toolbar.
2. In the schematic, do either of the following:
   - Click a wire to select it. You can continue to select more wires by holding down the Shift key.
   - Draw a rectangle area to enclose the desired wires. The wires inside the area are selected.

Note

- When selecting wires, the area-selecting method only allows you to select one area. You cannot use the Shift key to select additional areas.
- You cannot deselect a wire by clicking the wire again. To deselect wires, click any empty space on the schematic sheet.

Changing Wire Length or Direction

After wires are placed to the schematic, you can drag the wire ends to lengthen or shorten them, or change their routing directions.

To change wire length or direction:

1. Choose **Edit > Add > Select**, or click on the drawing toolbar.
2. Choose **Edit > Drag**.
3. Select one or more wires that you want to change.
4. Place the mouse cursor near the wire end of the selected wire(s). When the cursor changes to , click and drag the wire end to the desired place.

Note

- If the node connected with the wire end that you drag only has one linked connection, dragging the wire end moves the entire wire instead of changing its length or direction.
- You cannot shorten wires if you have selected too many wires which are very close to each other. Shortening wires by dragging requires enough space to avoid wire overlapping. In such cases, you can shorten the wires one by one or adjust their positions before shortening them.

Deleting a Wire Connection

You can delete wires from the schematic in two ways using the Clear command.

To delete a single wire or wire segment:

1. Click the wire or wire segment that you want to delete.
2. Choose **Edit > Clear**.

   The wire is deleted. If the cursor points at more than one item, the items are deleted based on a priority list.

To delete wires enclosed in an area:

1. Drag a rectangle area to enclose the wires that you want to delete.
2. Choose **Edit > Clear**.

   All totally enclosed wires are deleted when you release the mouse. Portions of wires enclosed by the rectangle are also deleted. All wire segments outside the rectangle remain. All wires that cross the rectangle are cut into wire segments.

Nets and Buses

This section introduces the concepts of nets and buses, as well as procedures on creating and naming nets and buses.

Nets

Any single- or multi-wire connection between pins is called a *net* (“network”). The following topics explain how nets are named and how multi-wire nets (called *buses*) are created and named.

Net Names

The nets (networks) form the electrical connections among the components. Every net has a name, either assigned by you or by Schematic Editor. Net names have two principal functions: *identification* and *interconnection*.

Note

If your instance names use brackets **[ ]**, parentheses **( )**, or curly braces **{ },** the software replaces these characters with an underscore (_) because they are illegal characters in HDL.

Meaningful net identifiers make a design easier to understand. Nets are usually given the names of the signals they carry.

If you do not assign a name, Schematic Editor automatically assigns a unique name when you save the file, in the form of N_*nn*, where *nn* is an integer.

You can override any name assigned by Schematic Editor and assign one of your own by using the Add Net Name command from the Edit menu.

Interconnection If a wire segment attached to a symbol pin is given the name of a net or bus, the pin is attached to that net or bus, even if you haven't drawn the connection on the schematic.

Two or more wires with no visible connection on the schematic are automatically connected if they have the same net name. Each wire is called a *branch* of that net. Inter-sheet connections are created in this way.

You can easily find implicit net connections with the Drc Check command from the Design menu. Click any net or bus. All wires with the same name are highlighted, on all sheets of the current schematic.

Nets with different names cannot be connected. Schematic Editor will warn you if you try to “short” them.

Legal Characters in Net Names The following characters can be used in net names:

Table 12:

Character	Description
A–Z, a–z, 0–9	All alphanumeric characters. Case is not significant.
'	Apostrophe (single quote)
_	Underscore

Reserved Names If B is the first character of a net name, the underscore cannot follow it as the second character (as in B_). The underscore cannot be used in a net name of the form “N_*nn”* (where “*nn”* is any integer). These names are reserved by Schematic Editor for nets that have not been named by the user.

Entering a Net Name

Use the Add Net Name command from the Edit menu to assign a name of your own choice to a net. Your name replaces any name Schematic Editor may already have assigned. If you assign the same name to two separate nets (“branches”), *they are connected*, even though no connection appears on the schematic. This feature makes it easy to connect widely spaced components without having to draw long wires across the schematic.

Net names you assign are always displayed; Editor-assigned names are not displayed. To avoid cluttering the schematic, you should name only these nets:

- That connect to other schematics.
- Whose functions need documentation or clarification.
- Whose signals you want to reference in simulation or timing analysis.
- Whose signals you want to identify in the Fitter report.

To enter a net name:

1. In Schematic Editor, choose **Edit > Add > Net Name**.
2. In the pop-up dialog box, enter a name. The name is attached to the cursor. You can then place it to the schematic.

Placing a Net Name

Once a net name (or group of names) is attached to the cursor, there are three ways to place it.

- **Click an empty space** to place the net name at an empty point on a sheet. This will be an error unless a net is eventually connected to the name flag.
- **Click a net** to place the net name on the selected net. If you click at the end of a net, the net name extends from the end. If you click the middle of a net, the net name is centered just above the net.
- **Drag to create the net** and place the net name on the newly created net. The net name and a single net segment can be placed *simultaneously*. You can then place subsequent wires and names by clicking a pin.

Note

- You can only define a horizontal or vertical net segment in this way. If either end of the segment connects to a perpendicular net or bus, a bus tap is created at that end of the segment. If the net was not a bus, it is promoted to one.
- The position of the name is determined by the segment ends at the time of placement. If both ends are connected, the name is placed in the middle. If neither end of the segment is connected, the name is placed at the starting point. If only one end of the segment is connected, the name is placed at the unconnected end.
- After you drag the mouse to or from a pin, you can place subsequent net names by clicking a pin**.** You do not need to drag. A wire segment is automatically added, of the same length as the one previously dragged. The name is attached as described above.

The segment ends determine the position of the name at the time of placement. If both ends are connected, the name is placed in the middle. If neither end of the segment is connected, the name is placed at the starting point. If only one end of the segment is connected, the name is placed at the unconnected end.

After you drag the mouse to or from a pin, you can place subsequent net names by clicking a pin. You do not need to drag. A wire segment of the same length as previously dragged is automatically added. The name is attached as described above.

Renaming a Net

To rename a net:

1. In Schematic Editor, choose **Edit > Add > Net Name**.
2. In the pop-up dialog box, type the new net name. The new name is attached to the mouse cursor.
3. To rename the net (that is, all branches of the net, across all sheets), press and hold down **Shift** as you click. You can click anywhere on the net.

   The new net name replaces the old one.

   If the renamed net has an I/O port:

   - The I/O port is removed if you click to rename a specific branch.
   - The I/O port is kept if you hold down **Shift** to rename all branches.

Important

Remember that renaming a single branch disconnects that branch from the rest of the net and connects it to the net (if any) with the new name.

Note

If the name of a branch is displayed two or more times on a single branch, you cannot rename the branch. You must first use the Clear command to remove the extra name(s).

Specifying Signal Direction

An I/O port is a special indicator that identifies a net name as a device input, output, or bidirectional signal. This establishes *net polarity* (direction of signal flow) and indicates that the net is externally accessible.

The Schematic Editor Drc Check command uses I/O ports to flag any discrepancies in the polarity of marked signals and the symbol pins.

To add a port:

1. Make sure the net has a name. Nets must be named before ports can be attached.
2. Choose **Edit > Add > IO Port**.

   The Set IO Type dialog box appears.
3. In the drop-down menu on the left of the dialog box, choose the port direction. (Or select **None** to remove an existing port.)
4. If the net name is not at the end of the net where the port will go, choose **Edit > Add > Net Name**. The Set IO Type dialog box changes to the Set Wire Name dialog box. In the text box, type the name of the net. The port must be given the same name as the net.

5. Click the end of the wire. Or you can draw a box around one or more net names if the names are attached to the ends of their wires.

   The port, along with the net name, appears extending from the end of the wire.

Note

- You can place, remove, or change several ports at one time by dragging a box around the wire ends.
- A net should only have one I/O port per sheet.

To change a port:

1. Choose **Edit > Add >** **IO Port**.

   The Set IO Type dialog box appears.

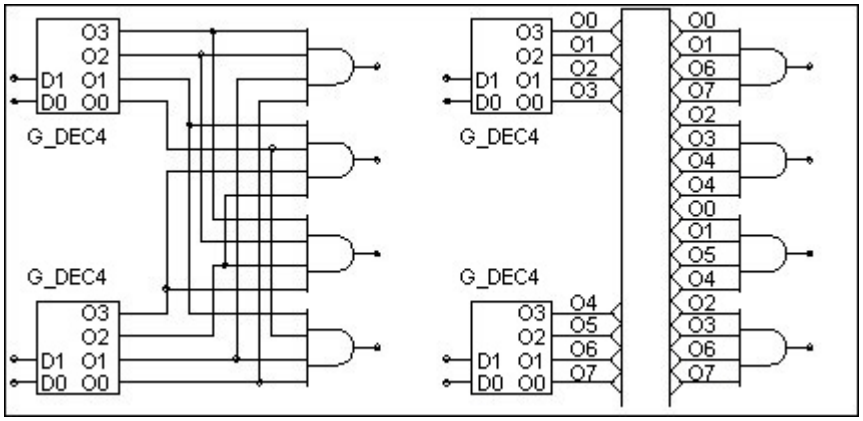
2. In the drop-down menu on the left of the dialog box, choose the new port direction. (Or select **None** to remove an existing port.)
3. Click the end of the wire. Or you can draw a box around one or more ports.

Buses

A *bus* combines two or more signals into a single wire. Buses are a convenient way to group related signals. This grouping can produce a less cluttered, functionally clearer drawing and clarify the connection between the main circuit and a Block symbol.

The figure below shows how a circuit appears before and after a bus has replaced individual wires. The two schematics are electrically equivalent.

Circuit before and after a bus has replaced individual wires.



Ordered Buses An ordered bus has a compound name consisting of the names of the signals that comprise the bus. Any signals can be combined into an ordered bus, whether they are related.

A net becomes an ordered bus when it is given a compound name. The net is *promoted* to an ordered bus containing the nets listed in the compound name. (The net is redrawn at twice its regular thickness to indicate that it's now a bus.)

A compound name is a list of two or more net names, separated by commas. For example:

```
READ,WRITE,MYNAME
```

represents the three signals READ, WRITE, and MYNAME. Spaces in compound names are ignored.

Adding a sequence of numbers to a name can also form a compound name. The sequence is specified as a starting number, an ending number, and an optional increment (default = 1). The numbers are positive integers, and are delimited by commas (**,**), dashes (**–**), or colons (**:**). The sequence is enclosed in brackets **[ ]**, parentheses **( )**, or curly braces **{ }**.

The following are examples of sequential compound names.

Table 13:

Sequential Name	Signals
DATA[0-7]	DATA[0] DATA[1] ... DATA[7]
ADDR(0,14,2)	ADDR(0) ADDR(2) ADDR(4) ... ADDR(14)
IO{4:23:3}	IO{4} IO{7} IO{10} ... IO{22}

If the increment is greater than one, the ending number will not appear in the sequence if it does not equal the starting number plus an integral multiple of the increment (as in the third example above).

A compound name can also combine individual names and compound names in any order.

Table 14:

Sequential Name	Signals
CS,DATA{0:7},WR	CS DATA{0} DATA{1} ... DATA{7} WR

The order of the signals in the bus is the same as the order in which they are specified. The order is significant only when the bus is connected to a bus pin. (Bus pins are described in a later section, “Bus Pins” on page 298.”)

Note

If your instance names use brackets **[ ]**, parentheses **( )**, or curly braces **{ },** the software replaces these characters with an underscore (_) because they are illegal characters in HDL language.

Unordered Buses An unordered bus is nothing more than an unnamed wire with *bus taps*. A net with a single name (or any unnamed wire) is promoted to an unordered bus by attaching one or more bus taps to it. The order of the signals within an unordered bus is not defined and has no significance.

Although the order of the signals in an unordered bus has no significance, *you must name the wires connecting to the bus taps*, because Schematic Editor would otherwise have no way of determining which symbol pin at one end connects to which symbol pin at the other end

Unordered buses provide a convenient way to route signals through the schematic with a minimum of visual clutter. They have no other function.

Unordered buses cannot connect to bus pins, because bus pins represent an ordered sequence of signals.

Adding a Bus Tap

Signals enter (or exit) a bus at points called *bus taps*. A bus tap can be added to any existing bus, net, or wire. If a net or wire is not already a bus, adding the tap automatically promotes it to a bus.

To add a bus tap:

1. Choose **Edit > Add > Bus Tap**.
2. Position the cursor on the bus or wire where the tap is required.
3. Drag the mouse to draw a wire perpendicular to the bus.
4. Release the mouse button when the wire is the desired length.

Bus taps can be made only on vertical or horizontal sections of a bus. Tap connections are shown as two diagonal lines.

More than one tap can be taken from the same signal, to simplify routing or permit a cleaner layout. But you cannot add a bus tap to an existing bus tap. You will get the error message “Forming Multilevel Bus.”

Naming the Tap

Once the tap has been added, choose the **Edit > Add > Net Name** command to name it. If the tap is from an ordered bus, the tap's name must match the name of a signal in the bus. If it does not, Schematic Editor will flag it as an error.

Note

Wires entering and leaving any bus (ordered or unordered) must be tagged with a net name to indicate which signal is being tapped. Unnamed taps will eventually be flagged as errors.

Bus Pins

A *pin* represents either a physical pin on a real component or a signal from a lower-level schematic.

A *bus pin* represents a group of pins or signals. You create a bus pin by giving a pin a compound name. That is, a list of signals. If the pin connects to a Block symbol, each of the signals listed in the bus pin name must also appear in the schematic. This defines the connection between the Block symbol and its underlying schematic.

Ordered buses can connect directly to bus pins. The number of bits or signals attached to the bus must match the number of bits or signals attached to the bus pin.

The first signal in the bus (by definition, the first signal in the bus's name) is connected to the first signal represented by the pin. The remaining signals in the bus are connected to the remaining pins in the same order you assigned the signal names to the pins.

Connecting to Pins

A tapped signal connects to an ordinary symbol pin in the usual way. An ordered bus connects to a *bus pin* (a pin with multiple connections) directly. No taps are needed; the connections are made automatically. The first signal in the bus connects to the first signal in the bus pin, the second to the second, and so forth. Both the bus and the bus pin must contain the same number of signals.

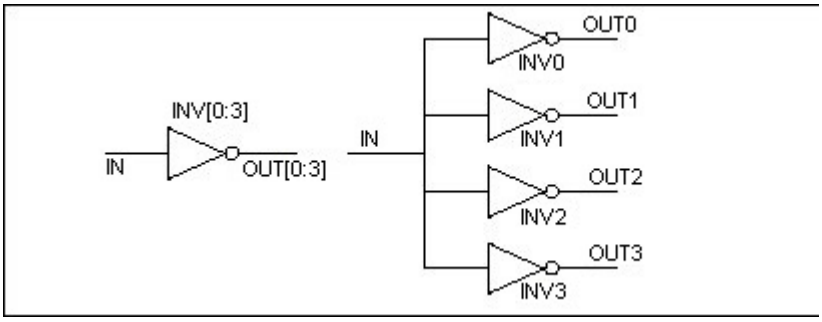
Compound Names

The input and output nets of an iterated instance can be given either single names or compound names. If the inputs or outputs are given a compound name, their nets are promoted to buses in which each instance's input or output is a separate signal.

Iterated buses work like any other bus. You can attach a bus (with the same number of signals) directly to them, as you would any other bus.

Single Names

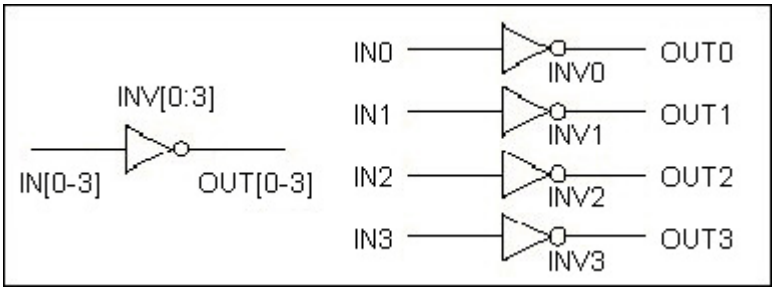
If an iterated input or output is given a single net name, there is only one input or output net, and all the inputs or outputs connect in parallel to that single net. In the figure below, the input net is given a single name and the inputs of all four gates are connected in parallel to the net.



This feature is used most often on inputs, not outputs. Paralleled outputs represent a “wired-OR” configuration, which is usually drawn as separate gates, rather than as an iterated instance.

Nets on Iterated Instances

Iterated instances allow a single symbol instance to represent multiple instances in a parallel connection. The figure below shows two ways of representing four parallel buffers. On the right, four separate inverters are added to the schematic. On the left, one symbol with the instance name of INV[0:3] represents the bank of four inverters.



Bus and Net Connections to Iterated Instance

You can make an iterated instance of any symbol. A simple (non-bus) pin on an iterated instance remains a simple pin. The iteration does not convert the pin to a bus pin. The same rules of connection to a simple pin still apply.

Connections to the nets of iterated instances are made according to the following rules.

Table 15: Rules for Connection to Nets of Iterated Instances

Connection	Rule
Simple net to simple pin	The net connects to corresponding pin on each instance.
Bus to bus pin	Successive bus signals connect to successive bus pins on successive instances. The bus and bus pin must have the same number of nets.
Simple net to bus pin	Not permitted. Only a bus can connect to a bus pin.
Bus to simple pin	The Nth signal of the bus connects to the scalar pin of the Nth instance. The width of the bus and the number of instances must match.

Creating a Tap, Wire, and Net Name At Once

You can use the Net Name command in Schematic Editor to create the tap, a wire, and the net name at once.

To create a tap using the Net Name command:

1. In Schematic Editor, choose **Edit > Add > Net Name**.
2. In the pop-up dialog box, type a net name contained in the bus to be tapped. The name is attached to the mouse cursor.
3. Point to the place on the schematic where you want the free end of the bus tap.
4. Drag the mouse to the bus and release the mouse button.

   The tap is made, and the free end is labeled with the signal name.

Saving a Schematic

The Save File command in Schematic Editor saves the changes to the existing schematic file. You can use the Save File As command to save the schematic with another file name.

Schematic files have the extension .sch. Below shows the steps of saving a schematic with the Save File As command.

To save a schematic with the Save File As command:

1. In Schematic Editor, choose **File > Save File As**.

   The Save as Schematic File dialog box opens.
2. Go to the folder in which you want to save the schematic.
3. Type in a base name for the schematic.

   Schematic Editor adds the .sch extension automatically when you specify the base name.

4. Click **Save**.

Debugging a Schematic

Schematic Editor has two levels of checking that report or prevent errors early in the design process.

First level errors are detected as you enter your schematic. For example, Schematic Editor will not let you draw an isolated wire that forms a closed loop without connecting to anything else. It won't let you short together nets with different names.

Second level errors are recognized in the context of a complete design. An unconnected wire or pin, or an unnamed signal tapped from a bus, are normal during the first stages of a design. Some potential errors are always indicated, such as the dots on open pins and hanging line ends. Otherwise, errors of this type are reported only when schematics and symbols are combined in the design hierarchy.

You can check for errors and potential errors at any time.

See Also ▶"Checking a Schematic for Errors" on page 301

Checking a Schematic for Errors

You can use the Drc Check command to detect errors that are only meaningful in a completed schematic or symbol.

Schematic Errors The following schematic errors are detected:

- Bus Taps should be named.
- Isolated Net Name Flags are not permitted.
- If the ShowSymbolPins option is enabled, each pin on symbols in this schematic should be connected to a net.
- If the MarkOpenEnds option is enabled, there should not be any unconnected net ends.
- Only ordered buses can be connected to a bus pin on a symbol.
- Only ordered buses can be marked with I/O ports.
- Nets should not be marked with more than one I/O port.
- A bus tap and its bus should not both be marked with an I/O port.
- If there is a symbol for this schematic, the following errors are detected by the schematic checker:
- Each pin must have a corresponding net with an I/O port whose direction matches the Polarity of the pin.
- Each net marked with an I/O port must correspond to a pin.

Symbol Errors The following symbol errors are detected:

- Block symbols should have a schematic with the same name in the current directory.
- Symbols of a type other than Block are primitives and should not have a schematic of the same name.
- Each pin in a Block or Cell must have a Name. Each pin in a Gate or Component should have a PinNumber.
- Every pin in a Gate must appear in the same number of sections. Therefore, all PinNumber attributes must have the same count of pin numbers.
- Pins in Component and Pin symbols can have only one PinNumber.
- Pins in the same Gate group must have the same Polarity, Load and Drive.
- Pins on symbols that are not Blocks should have Load or Drive specifications. Input pins should have Load but not Drive. Output pins should have Drive, but not Load, unless the pin is tristate, in which case it should have a Load that represents the load in the High-Z state. Bidirectional pins should have both Load and Drive.
- Pins on Blocks should not have Load or Drive specifications.

Checking Errors

To check a schematic for errors:

- Choose **Design > Drc Check**.

  The software opens an error report in a pop-up text window and writes the information to a file.

Highlighting a Net

You can use the Select icon to trace nets in a schematic. Selecting a net changes its color (or turns it into a dashed line on a monochrome monitor). If the net is a signal in a bus, the bus is also highlighted.

To highlight a net:

1. Click on the drawing toolbar.
2. Click the net that you want to highlight.

   The color of the net changes.
3. To remove highlighting, click any blank area in the schematic.

Troubleshooting FPGA Schematic Design

This section describes common problems and solutions for the schematic design flow.

Verilog Functional Simulation Model (vericode.exe) or VHDL Functional Simulation Model (vhdl.exe):

```
ERROR: Missing I/O marker for pin <pin name>
ERROR: Missing pin for I/O marker on net <net name>
```

Caused by a mismatch between I/O ports of a schematic (.sch) and a related schematic symbol (.sym). A common mistake is to overlook creating a symbol for the top-level schematic of a project.

```
ERROR: Polarity mismatch on pin – I/O marker for net <net name>
```

Caused by a polarity (or type) mismatch between an I/O port and symbol pin. A common mistake is attempting to read or feedback a signal marked with an Output marker.

```
ERROR: --- Pins in symbol - <symbol name>.sym
ERROR: --- IOs in schematic  - <schematic name>.sym
```

Caused by a mismatch between I/O ports and a related schematic symbol. A common mistake is modify the I/O ports and not update the related schematic symbol (.sym). A common mistake is to overlook creating a symbol for the top-level schematic of a project.

Schematic Editor > DRC:

```
Different I/O marks on net <net name>
```

Caused by multiple I/O ports on the same net.

```
Pin <pin name> has wrong I/O mark
```

Caused by a mismatch between I/O ports and a related schematic symbol. A common mistake is that you modified the I/O ports and not updated the related schematic symbol (.sym). A common mistake is to overlook creating a symbol for the top-level schematic of a project.

```
Bus <bus name> and signal <signal name> marked as I/O
```

Caused by multiple I/O ports on the same net.

```
Unconnected pin <instance name>-<pin name>
```

Caused by an unwired pin. In general it is good practice to tie unused inputs to a logic constant such as the VHI or VLO library element. Unused outputs can remain unconnected.

```
Signal count mismatch on pin <instance name>-<pin name>
```

Caused by a range mismatch between the bus pin of a symbol instance and the bus wire.

ModelSim:

```
Unresolved reference to GSR_INST
Unresolved reference to PUR_INST
Unresolved reference to TSALL_INST
```

ModelSim reports:

```
** Error: (vsim-3043) <path>/cae_library/simulation/verilog/
machxo/FL1S3AY.v(15): Unresolved reference to 'PUR_INST'
```

Many synchronous library elements from the Lattice FPGA Symbol Library contain references to global signals related to Global Set/Reset (GSR), Power Up Reset (PUR), or Tri-State All (TSALL). To establish a driver on these “global” nets you must instantiate the related library element in your design or test fixture. For more information, refer to the following topics:

- “How to Use the Global Set/Reset (GSR) Signal” on page 1174
- “How to Use the Power Up Set/Reset (PUR) Global Signal” on page 1189
- “How to Use the Tristate Interface (TSALL) Global Signal” on page 1190

Customizing Work Environment

You can use the Options dialog box to set schematic display and work environment for the schematic tools.

To access Schematic Editor or Symbol Editor options, choose **Tools > Options** in the Diamond main window. Then select **Schematic Editor** or **Symbol Editor** in the Options dialog box.

Turning On/Off Grid Display

You can use the Options dialog box to turn on or off the grid display in Schematic Editor and Symbol Editor.

To turn grid display on or off:

1. In the Diamond window, choose **Tools > Options**.

   The Options dialog box opens.
2. In the dialog box, click **Graphic Options** under Schematic Editor or Symbol Editor.
3. Select **Show Grid**.
4. Click **Apply** or **OK**.

Changing the Color Scheme

You can change the current color scheme for Schematic Editor and Symbol Editor.

To change the current color scheme:

1. In the Diamond window, choose **Tools > Options**.

   The Options dialog box opens.

2. In the dialog box, select **Color Options** under Schematic Editor or Symbol Editor.
3. Select the colors you want to use as the new scheme.
4. Click **Apply** or **OK**.

Tool Options for Schematic Editor Colors

You can change the colors for the following items in the dialog box:

Background: Color of sheet background

Wire: Color of wire on sheet

Symbol: Color of symbol on sheet

Add Wire: Not used

Add Bustap: Not used

Highlight: Color of highlighted objects

Selected: Color of selected objects

Drc Check: Color of cross line which marks errors

Panel: Color of sheet panel including frame and pixels

Selected Box: Not used

Tool Options for Symbol Editor Colors

You can change the colors for the following items in the dialog box:

Background: Color of sheet background

Wire: Color of wire on sheet

Symbol: Color of symbol on sheet

Add Wire: Not used

Add Bustap: Not used

Highlight: Color of highlighted objects

Selected: Color of selected objects

Drc Check: Color of cross line which marks errors

Panel: Color of sheet panel including frame and pixels

Selected Box: Not used

Simulating the Design

This topic explains how to perform functional and timing simulation by using the Diamond tools and third-party simulators.

Simulation in Diamond

Diamond provides you with an interface to create a new simulation project file that you can import into a standalone simulator. Diamond supports Active-HDL and ModelSim simulation file for file exports. To create testbenches for simulation in Diamond, generate all testbenches in your third-party tool using an imported simulation project (.spf) file.

Functional Simulation

Functional simulation is the process of verifying that the model of the design matches the functional specification. Functional simulation helps identify logic errors in a design before it is programmed into a device.

In the Diamond design flow, to perform functional simulation on designs modeled with Verilog HDL or VHDL, you can peform pre-synthesis functional simulation on your source HDL or netlist using a third party simulator. In Diamond use the subprocesses **Verilog Simulation File** and **VHDL Simulation File** to produce a post-map source simulation file for functional simulation of primitive gate-level logic during that stage in the flow..

HDL Simulators The Diamond software and model libraries are qualified with a variety of popular HDL simulators, including Aldec Riviera Pro®, Aldec Active-HDL®, Cadence® NC-Verilog®, Cadence® NC-VHDL®, Cadence® NCSim®, Mentor Graphics® ModelSim®, Mentor Graphics Questa®,and Synopsys® VCS®.

See Also ▶"Simulation in Diamond" on page 307

Simulation Environment

In the Diamond software environment provides library model resources in both Verilog HDL and VHDL formats to support stand-alone simulation with Aldec, Cadence, Mentor Graphics, and Synopsys simulators. Using the simulation wizard inside of the Diamond software, you can create simulation project files that can be exported and brought into standalone simulators.

In addition, you can use Diamond's backannotation tools to extract gate-level models and the timing data. This type of simulation is convenient if you want to simulate a design file outside the current project. Stand-alone operation enables you to choose your own settings and preferences.

You can customize the simulation by creating a different script (.do) file that contains commands equivalent to the ModelSim or Active-HDL graphical user interface (GUI) commands. For information about creating your own simulation scripts, see Aldec's Active-HDL online Help.

See Also ▶"Simulation in Diamond" on page 307

Design Source Files

The third-party simulators enable you to simulate the operation of your design in the following design entry formats:

- Schematic format (<*design*>.sch) – Describes the circuit in terms of the components used and how they connect to each other. These schematics are automatically translated into Verilog or VHDL format.
- VHDL format (<*design*>.vhd) – Describes the circuit in Very High-Speed IC hardware description language (VHDL) format.

- Verilog HDL format (<*design*>.v) – Describes the circuit in Verilog format, which is an industry-standard hardware description language used to describe the behavior of hardware that can be implemented directly by logic synthesis tools.

See Also "Simulation in Diamond" on page 307

Creating a New Simulation Project in Diamond

This topic describes how to use the Diamond Simulation Wizard to create a simulation project (.spf) file so you can import it into a standalone simulator.

1. In Diamond, click **Tools > Simulation Wizard** or click the  icon in the toolbar. The Simulation Wizard opens.
2. In the Preparing the Simulator Interface page click **Next**.
3. In the Simulator Project Name page, enter the name of your project in the Project Name text box and browse to the file path location where you want to put your simulation project using the Project location text box and Browse button.

   When you designate a project name in this wizard page, a corresponding folder will be created in the file path you choose. If you add a subdirectory to the default file path the wizard will prompt you to create a new directory. Click **Yes** in the popup dialog that asks you if you wish to create a new folder.
4. Click either the **Active-HDL** or **ModelSim** simulator check box and click **Next**. Note that if ModelSim is not installed, it will appear grayed out and will not be selectable.

   Note

   Please note here that if you want to use ModelSim that you must precompile all of the Lattice library files in the simulator before you proceed through the Simulation Wizard. Diamond provides precompiled library files for Active-HDL.
5. In the Process Stage page choose what type of Process Stage of simulation project you wish to create. Valid types are RTL, Post-Synthesis Gate-Level, Post-Map Gate-Level, and Post-Route Gate-level+Timing. Only those process stages that are available are activated.

   Note that you can make a new selection for the current Strategy if you have more than one defined in your project.

   The software supports multiple strategies per project implementation which allows you to experiment with alternative optimization options across a common set of source files. Since each strategy may have been processed to different stages, this dialog allows you to specify which stage you wish to load.
6. In the Add Source page, select from the source files listed in the Source Files list box or use the browse button on the right to choose another desired source file.

- By default, the **Analyze HDL and test bench** option is checked. This option allows you to specify a top level simulation testbench. Uncheck this box if you do not wish to specify a top level simuation testbench.
- If you wish to keep the source files in the local simulation project directory you just created, check the Copy Source to Simulation Directory option.

7. Click **Next**. If the **Analyze HDL and test bench** option was checked in the previous page, specify a name for the top level simulation test bench in the Simulation top box the Parse HTL and Test Bench page.
8. Click **Next**, and a Summary page appears and provides information on the project selections including the simulation libraries. By default the **Run simulator, Add top-level signals to waveform display, and Run simulation** check boxes are enabled. Their functionality is as follows:
   - The **Run simulator** option will launch the simulation tool you chose earlier in the wizard in the Simulator Project Name page when you perform Step 9.
   - The **Add top-level signals to waveform display** option can only be selected if the **Run simulator** box is checked. This option adds top-level signals to the waveform in the simulation tool when you perform Step 9.
   - The **Run simulation** option can only be selected if the **Add top-level signals to waveform display** option is checked. This option causes your simulation tool to run the simulation automatically when you perform Step 9.
9. Click **Finish**. The Simulation Wizard Project (.spf) file and a simulation script DO file are generated after running the wizard. You can import the DO file into your current project if desired. If you are using Active-HDL, the wizard will generate an .ado file and if you are using ModelSim, it creates and .mdo file.

Exporting VHDL and Verilog Simulation Files

In Diamond, you can export project simulation source files to simulate into your third-party vendor simulation tool for timing simulation.

To export a VHDL or Verilog file in Diamond:

1. In the Process view, under the **Export Files** process check either the **VHDL Simulation File** or **Verilog Simulation File** subprocess.
2. Double click the **Export Files** process to run the export feature. This will generate a back-annotated version of your design file in an .ldb file, a VHDL netlist (.vho) simulation file, and an SDF timing file.

Note:

You can also use Tcl Diamond commands in the Tcl Console to accomplish this task as shown below:

```
prj_run Export -task TimingSimFileVHD
prj_run Export -task TimingSimFileVlg
```

See Also ▶"Simulation in Diamond" on page 307

Timing Simulation

The Diamond software supports two types of timing verification: dynamic timing simulation and static timing analysis. See the Static Timing Analysis topic and related information for more information on that type of design verification.

To facilitate timing simulation, Diamond allows you to export simulation files that you can import into a simulator for design verification using dynamic timing simulation. In the Process view under **Export Files** use the **Verilog Simulation File** and **VHDL Simulation File** to export a simulation project file to a standalone Aldec Active-HDL® or Mentor Graphics® ModelSim® hardware design language (HDL) simulator. Some simulators allow a combination of both languages to be simulated concurrently. This scenario is common when mixing IP cores.

See Also ▶"Verifying Designs with Timing Simulation" on page 311

▶ "Timing Simulation in the FPGA Process Flow" on page 312

Verifying Designs with Timing Simulation

Timing simulation is based on an event-driven simulator and requires you to specify a test vector (waveform). Where timing analysis returns partial timing information, dynamic timing simulation (timing simulation) gives you detailed information about gate delays and worst-case circuit conditions. Because the total delay of a complete circuit depends on the number of gates the signal sees and on the way the gates have been placed in the device, you can only perform timing simulation after you have implemented the design. Timing simulation also requires several input files to run.

Diamond simulation files can be imported into HDL simulators (e.g., Aldec's Active-HDL or Mentor Graphics' ModelSim) for dynamic timing simulation. You can simulate FPGA devices by using any popular third-party HDL

simulator. Dynamic simulation analyzers have considerably longer run times than a static timing analysis tool like the Diamond TRACE program.

Note

You cannot generate text fixtures in Diamond. All simulation must be done outside of the Diamond software using simulation files in a supported simulator. For guidelines using third-party EDA simulators with Diamond software, see your vendor documentation or the following references.

See Also ▶"Timing Simulation" on page 311

Timing Simulation in the FPGA Process Flow

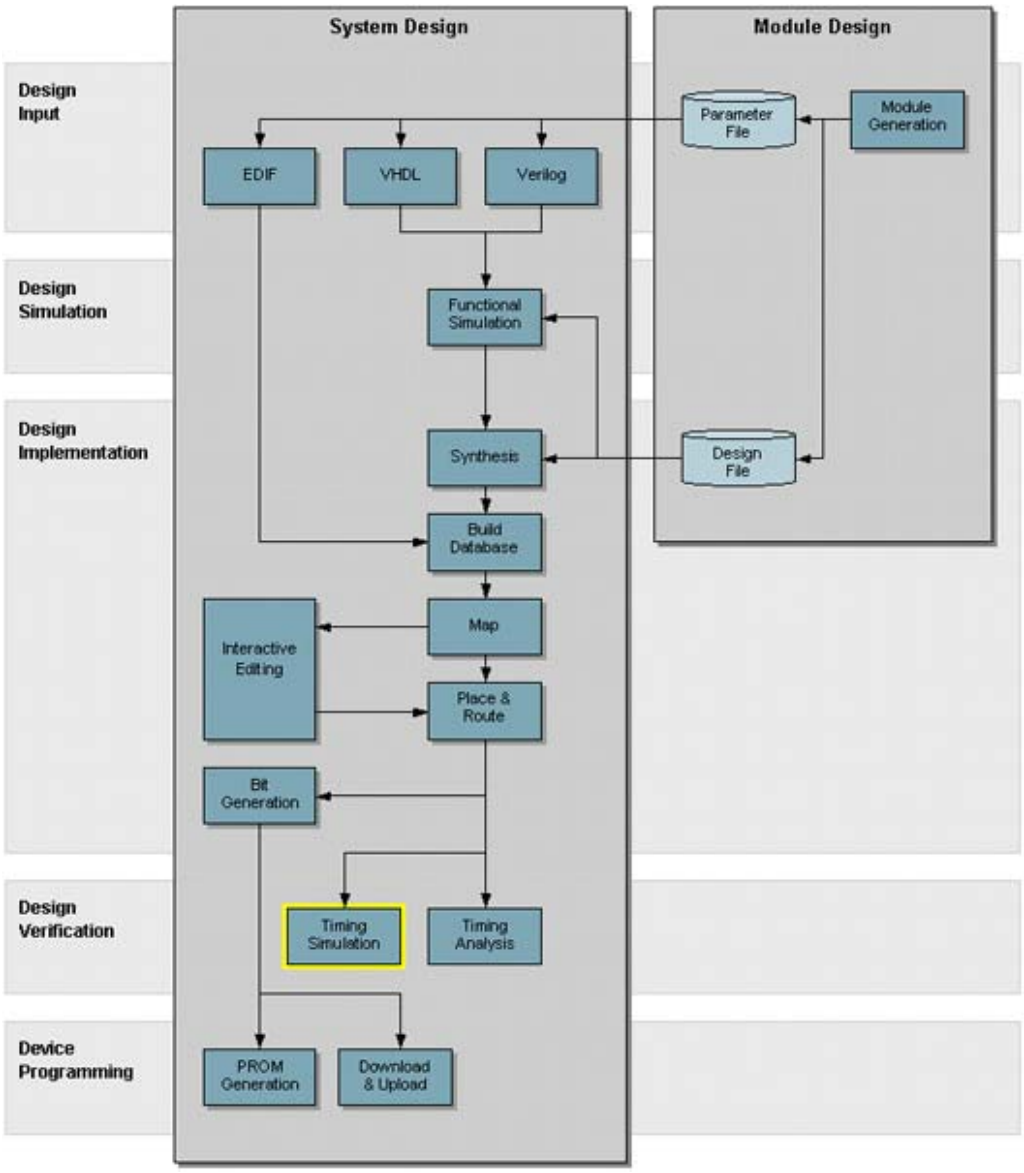
The following figure shows the place of timing simulation in the FPGA process flow as a part of design verification. To learn more about timing analysis using static timing analysis tools, see the appropriate topics in this Help system.

See Also "Timing Simulation" on page 311

Third-Party Simulators

This section explains how to use Aldec Active-HDL, Aldec Riviera Pro, Cadence NC-Verilog, Cadence NC-VHDL, Cadence NCSim, Mentor Graphics ModelSim / Questa, and Synopsys VCS software to simulate designs that target Lattice Semiconductor FPGAs. It shows you how to use these

Figure 46: Timing Simulation Flow Chart



simulators to perform functional register-transfer-level (RTL) simulation, post-map simulation, and place-and-route gate-level simulation with and without timing simulation.

Note

Lattice Semiconductor does not supply the Synopsys VCS, Cadence NC-Verilog, Cadence NC-VHDL, Cadence NCSim, Aldec Riviera Pro, or Mentor Graphics ModelSim / Questa simulators. You must obtain them independently.

See Also ▶"Simulation Library Files" on page 314

▶ "Performing Simulation with Aldec Riviera Pro" on page 318

Simulation Library Files

This section describes where to find the source simulation library files for FPGA device families. In addition to source files, compiled versions of the simulation library files are available for Aldec Active-HDL Lattice Edition (LE). When you install Active-HDL LE, precompiled libraries are automatically installed in the Diamond installation directory.

There are no precompiled library files available for ModelSim / Questa. If you choose to associate your Diamond project with the ModelSim / Questa simulator in the Simulation Wizard, you need to precompile all of the source libary files in ModelSim / Questa before using the Simulation wizard.

VHDL and Verilog library source files are also installed in the cae_library directory. These source files are always installed, whether or not you install Active-HDL LE.

The sources of some of the library models are not provided, so Lattice delivers them as black-boxes. This means for those models, Lattice provides either precompiled libraries (ModelSim / Questa) or encrypted HDL sources (Riviera Pro, NCSim, and VCS). For further details, refer to "Referencing Black-Box Models" on page 338.

Verilog Source Library Files The Verilog functional and behavioral simulation library files are installed with the Diamond software in the locations shown in the following table.

Table 16: Verilog Functional and Behavioral Simulation Library File Locations

FPGA Family	Library Location
ECP5U/UM	<*install_dir*>**/**cae_library**/**simulation/verilog/ecp5u
LatticeEC	<*install_dir*>**/**cae_library**/**simulation/verilog/ec

Table 16: Verilog Functional and Behavioral Simulation Library File Locations

lptm	<*install_dir*>/active-hdl/Vlib/lptm	*.vhd	Platform Manager
lptm2	<*install_dir*>/active-hdl/Vlib/lptm2	*.vhd	Platform Manager 2
sc/scm	<*install_dir*>/active-hdl/Vlib/sc	*.vhd	LatticeSC/M
xp	<*install_dir*>/active-hdl/Vlib/xp	*.vhd	LatticeXP
xp2	<*install_dir*>/active-hdl/Vlib/xp2	*.vhd	LatticeXP2

Compiled Mixed-Language Libraries for Aldec Active-HDL The next table shows the location of the compiled mixed-language simulation libraries for Aldec Active-HDL.

Table 20: Aldec Active-HDL Compiled Mixed-Language Simulation Libraries

pmi_work	<*install_dir*>/active-hdl/vlib/pmi_work	*.v	Not device-specific. These are for parameterized module Instantiation.

See Also "Third-Party Simulators" on page 312

Performing Simulation with Aldec Riviera Pro

This section explains how to perform simulation with the Aldec Riviera Pro simulator.

Creating or Updating Lattice Semiconductor's FPGA Vendor Libraries

Create VHDL or Verilog libraries by following the procedures in this section.

Creating VHDL Libraries If you do not have Lattice Semiconductor's FPGA VHDL libraries as pre-compiled vendor libraries, the following steps are required to create them:

1. Create Lattice Semiconductor's FPGA VHDL libraries:

```
# create new VHDL libraries
alib ecp5u
alib sc
alib ec
alib xp
alib ecp
alib machxo
alib ecp2
alib xp2
alib ecp3
alib machxo2
alib machxo3d
alib machxo3l
alib lptm
alib lptm2
alib lifmd
amap scm ./sc
amap ecp2m ./ecp2
amap ecp5um ./ecp5u
```

Note

The VHDL library names are strict.

2. For each of the above VHDL libraries compile the source files by using the `acom` command:

```
acom -work <library_name> -reorder <vhdl_lib_src_folder>/
*.vhd
```

where:

- *<vhdl_lib_src_folder>* is the folder containing VHDL source files for the appropriate Lattice Semiconductor library *<library_name>*.

For the ecp5u library, there is an extra step required. You must also compile the Verilog source files by using the `alog` command:

```
alog -work <library_name> <vhdl_lib_src_folder>/*.v
```

where:

- <*vhdl_lib_src_folder*> is the folder containing VHDL source files for the appropriate Lattice Semiconductor library <*library_name*>.

If you want to place the debugging information in the library, use the –dbg switch. Debugging may slow down simulation.

3. Set the status of the newly created library as read-only to prevent accidental overwriting:

```
setlibrarymode -ro <library_name>
```

Creating Verilog Libraries If you do not have Lattice Semiconductor's FPGA Verilog libraries as pre-compiled vendor libraries, the following steps are required to create them:

1. Create Lattice Semiconductor's FPGA Verilog libraries:

```
# create new Verilog libraries
alib ovi_ecp5u
alib ovi_sc
alib ovi_ec
alib ovi_xp
alib ovi_xp2
alib ovi_ecp
alib ovi_ecp2
alib ovi_ecp3
alib ovi_machxo
alib ovi_machxo2
alib ovi_machxo3d
alib ovi_machxo3l
alib ovi_lptm
alib ovi_lptm2
alib ovi_lifmd
amap ovi_scm ./ovi_sc
amap ovi_ecp2m ./ovi_ecp2
amap ovi_ecp5um ./ovi_ecp5u
```

Note

The Verilog library names are not strict, but they conform to Aldec's naming convention for Verilog vendor libraries.

2. For each of the above Verilog libraries, compile the source files by using the alog command:

```
alog -quiet -work <library_name> <verilog_lib_src_folder>/
*.v
```

where <*verilog_lib_src_folder*> is the folder containing the Verilog source files for the <*library_name*> library.

If you want to place the debugging information in the library, use the –dbg switch. Debugging may slow down simulation.

Note

Ignore the warning messages.

3. Set the status of the newly created library as read-only to prevent accidental overwriting:

   ```
   setlibrarymode -ro <library_name>
   ```

Updating Lattice Semiconductor's Vendor Libraries If you obtained the updated source code of Lattice Semiconductor's FPGA libraries, you can update the VHDL libraries, Verilog libraries, or both by using the following procedure (for each one of the VHDL or Verilog libraries):

1. Using the cd command, navigate to the directory where your vendor library resides. The vendor libraries are usually located in the <*install_dir*>/vlib folder when pre-compiled by Aldec.
2. Set the library mode to read-write by using the setlibrarymode command:

   ```
   setlibrarymode -rw <library_name>
   ```

3. Compile the source code into the library. Use the acom command for VHDL source files and the alog command for Verilog source files.

   ```
   acom -work <library_name> -reorder <library_src_folder>/
   *.vhd
   ```

   or

   ```
   alog -quiet -work <library_name> <library_src_folder>/*.v
   ```

   Note

   For the ecp5u VHDL library, you must perform both of the above steps.

4. Set the library to the read-only mode to prevent accidental overwriting:

   ```
   setlibrarymode -ro <library_name>
   ```

   Note

   You can enter the commands either in command-line mode or in the graphical console. Alternatively, you can write a macro that will prepare and compile the libraries, as follows:

   1. Include in the macro the appropriate commands for the libraries that you want to create or update.
   2. Run the runvsimsa script (Linux) or the runvsimsa.bat batch file (Windows) command with the macro as a command-line argument.

Performing Verilog Simulation Use the procedures described in this section to perform a Verilog simulation.

Functional RTL Simulation Use the following commands to perform a functional RTL simulation with one of the libraries shown in Table 16:

```
alib work
alog -v2k -work work <design_name>.v <test_bench>.v
```

```
asim work.<test_bench>
```

Note

If you have a pre-existing work library, you can clear its contents by using the following command:

```
adel -lib work -all
```

Post-Map and Place-and-Route Gate-Level Simulation Use the following commands to perform post-map and place-and-route gate-level simulation:

```
alib work
alog -quiet -v2k -work work -l <library_name> <design_name>.vo
<test_bench>.v
asim -O5 +access +rw -L <library_name> work.<test_bench>
```

where <*library_name*> is the FPGA Verilog library to be searched for the low-level units.

Post-Map and Place-and-Route Gate-Level Simulation with Timing Use the following procedure to perform post-map and place-and-route gate-level simulation with timing:

1. Add the `sdf_annotate` line at the top-level test bench:

   ```
   $sdf_annotate ("<design_name>.sdf", <instance_name>,
   ,<sdf_log>, "MAXIMUM");
   ```

2. Use the following commands to perform the simulation:

   ```
   alib work
   alog -quiet -v2k -work work -l <library_name>
   <design_name>.vo <test_bench>.v
   asim -O5 +access +rw -L <library_name> work.<test_bench>
   ```

Performing VHDL Simulation Use the procedures described in this section to perform a VHDL simulation.

Functional RTL Simulation Use the following commands to perform a functional RTL simulation with one of the libraries shown in Table 17:

```
alib work
acom -work work <design_name>.vhd <test_bench>.vhd
asim -t ps work.<test_bench>
```

Note

If you have a pre-existing work library, you can clear its contents by using the following command:

```
adel -lib work -all
```

Post-Map and Place-and-Route Gate-Level Simulation Use the following commands to perform post-map and place-and-route gate-level simulation:

```
alib work
acom -work work <design_name>.vho <test_bench>.vhd
```

```
asim -t ps -noglitchmsg work.<test_bench>
```

Post-Map and Place-and-Route Gate-Level Simulation with Timing Use the following commands to perform post-map and place-and-route gate-level simulation with timing:

```
alib work
acom -work work <design_name>.vho <test_bench>.vhd
asim -t ps -noglitchmsg -sdfmax
/<instance_name>="<design_name>.sdf" work.<test_bench>
```

Note

The "/" character is Aldec's default hierarchy separator.

See Also "Third-Party Simulators" on page 312

Performing Simulation with Aldec Active-HDL

You can use the same procedure as in "Performing Simulation with Aldec Riviera Pro" on page 318 for creating or updating Lattice Semiconductor's FPGA (vendor) libraries and simulating Verilog or VHDL designs in Active-HDL with a few modifications. Refer to the *Active-HDL On-line Documentation* for more details.

An alternative and easy way recommended for updating the Lattice Semiconductor FPGA libraries with Active-HDL is to obtain the pre-compiled Lattice Semiconductor FPGA libraries directly from the following directory:

```
<Diamond_installation_folder>/active-hdl/Vlib
```

You can either copy these libraries, along with the Library.cfg file, to your Active-HDL Vlib folder, overwriting any old libraries, or you can modify the Active-HDL Vlib/Library.cfg file to map to the Lattice Semiconductor FPGA libraries installed with Diamond (you can instead perform the mapping with the amap command).

Running Aldec Active-HDL in Stand-Alone Mode If you are running Active-HDL in stand-alone mode—that is, you are not accessing it through the Diamond graphical user interface—you should do the following to avoid elaboration (ELBREAD) errors when selecting top-level unit or compiling files from the design pop-up menu:

1. From the top-level menu, select **Design > Settings**.
2. Under Category in the left pane of the Design Settings dialog box, select **General > Compilation > Verilog**.
3. In the right (Verilog) pane under Verilog libraries, click the **Add Library** button  .
4. Select the reference Verilog libraries that are needed in your design. You can select multiple libraries by holding the CTRL key.

5. Click **OK**.
6. Click **OK** in the Design Settings dialog box.

This design setting also adds the -l <*verilog_library_name*> option to the vlog command, then it recognizes (or allows you to set) the top-level unit.

After setting the top-level unit (or testbench), you can start the simulation by clicking **Simulation > Initialize Simulation** from the top-level menu.

Note

If you are compiling and simulating your design by using a .do file, the steps just given are not needed. Instead, you should add -l with vlog, add -L with vsim, or both in your .do file.

If you are running Active-HDL in stand-alone mode and you are using at least one of the ASIC blocks, such as PCS or SYSBUS, in your design, you must do the following:

1. Change the directory to the design folder, that is, where the PCS or SYSBUS configuration file resides:

   ```
   cd <design_folder>
   ```

2. Set the simulation directory to the design (current) folder:

   ```
   set SIM_WORKING_FOLDER .
   ```

Setting the SIM_WORKING_FOLDER option forces the Active-HDL simulator to look for the configuration or input files in the design folder (by default Active-HDL looks for input files in the <*work*> and <*work*>/src folders only, where <*work*> is the Active-HDL working library folder). If you do not set this option, the simulation will fail and Active-HDL will issue an error about a missing configuration file.

This option is also necessary if your simulation is expecting any input files in the design folder rather than in the <*work*> or <*work*>/src folders, unless you place the input file path in your HDL code.

See Also "Third-Party Simulators" on page 312

Performing Simulation with Cadence NC-Verilog

This section explains how to perform simulation with Cadence NC-Verilog.

Setting Lattice Semiconductor Libraries Before simulating Lattice Semiconductor FPGA designs in the Cadence NC-Verilog simulator, you must perform the following steps to specify the Lattice Semiconductor simulation libraries.

Creating Library Definition Files Before using the NC-Verilog simulator to simulate your design project, you must first create two library definition files named hdl.var and cds.lib in your project folder. The hdl.var and cds.lib files define which libraries are accessible and where they are located. The hdl.var file contains optional statements that can be used to define variables such as the default work library, and the cds.lib file contains statements that map logical library names to their physical directory paths.

For example, your local hdl.var file may include the following:

```
DEFINE work work
```

Your local cds.lib file can include the following:

```
DEFINE ecp5u_vlog <compile_dir>/ecp5u_vlog
DEFINE ecp5um_vlog <compile_dir>/ecp5u_vlog
DEFINE ec_vlog <compile_dir>/ec_vlog
DEFINE ecp_vlog <compile_dir>/ecp_vlog
DEFINE ecp2_vlog <compile_dir>/ecp2_vlog
DEFINE ecp2m_vlog <compile_dir>/ecp2_vlog
DEFINE ecp3_vlog <compile_dir>/ecp3_vlog
DEFINE xp_vlog <compile_dir>/xp_vlog
DEFINE xp2_vlog <compile_dir>/xp2_vlog
DEFINE machxo_vlog <compile_dir>/machxo_vlog
DEFINE machxo2_vlog <compile_dir>/machxo2_vlog
DEFINE machxo3d_vlog <compile_dir>/machxo3d_vlog
DEFINE machxo3l_vlog <compile_dir>/machxo3l_vlog
DEFINE lptm_vlog <compile_dir>/lptm_vlog
DEFINE lptm2_vlog <compile_dir>/lptm2_vlog
DEFINE lifmd_vlog <compile_dir>/lifmd_vlog
DEFINE sc_vlog <compile_dir>/sc_vlog
DEFINE scm_vlog <compile_dir>/sc_vlog
DEFINE work ./work
```

Note

<*compile_dir*> refers to the location of the compiled device libraries.

Cadence provides a utility called NCLaunch to set up the necessary initialization files and to compile the Verilog source libraries. NCLaunch is available as part of the 2.1 and later releases. Otherwise, setting up the initialization files and compiling the Verilog source libraries is a manual process.

You can create the hdl.var and cds.lib files with any text editor. You must map the physical locations to the logical names before proceeding to the next step. On the Linux platform, you can create these names by using the mkdir command as follows:

```
mkdir -p <compile_dir>/ecp5u_vlog
mkdir -p <compile_dir>/ec_vlog
mkdir -p <compile_dir>/ecp_vlog
mkdir -p <compile_dir>/ecp2_vlog
mkdir -p <compile_dir>/ecp3_vlog
mkdir -p <compile_dir>/xp_vlog
mkdir -p <compile_dir>/xp2_vlog
mkdir -p <compile_dir>/machxo_vlog
```

```
mkdir -p <compile_dir>/machxo2_vlog
mkdir -p <compile_dir>/machxo3d_vlog
mkdir -p <compile_dir>/machxo3l_vlog
mkdir -p <compile_dir>/lptm_vlog
mkdir -p <compile_dir>/lptm2_vlog
mkdir -p <compile_dir>/lifmd_vlog
mkdir -p <compile_dir>/sc_vlog
```

If you want the logical library names to be available for all designs, use INCLUDE or SOFTINCLUDE in the location of your master hdl.var and cds.lib files.

For example, you can add the following line to your master cds.lib file:

```
INCLUDE $path/cds.lib
```

Note

The *path* variable specifies the location of your own cds.lib file.

Or, you can directly include the library definitions in the master hdl.var and cds.lib files.

Now the master hdl.var and cds.lib files include the Lattice Semiconductor library definitions. The next time that you want to simulate Lattice Semiconductor designs in the NC-Verilog simulator, you do not need to create you own hdl.var and cds.lib files again.

Parsing and Analyzing Lattice Semiconductor Simulation Libraries
After creating your own hdl.var and cds.lib files, you must parse and analyze the Lattice Semiconductor simulation libraries by using the NC-Verilog simulator. These libraries must be parsed and analyzed only once.

To parse and analyze Lattice Semiconductor Verilog simulation libraries, run the following commands in the NC-Verilog simulator:

- ECP5U Verilog:

  ```
  ncvlog -messages -work ecp5u_vlog
  $Diamond_install_path/cae_library/simulation/verilog/ecp5u/
  *.v
  ```

- LatticeEC Verilog:

  ```
  ncvlog -messages -work ec_vlog
  $Diamond_install_path/cae_library/simulation/verilog/ec/*.v
  ```

- LatticeECP Verilog:

  ```
  ncvlog -messages -work ecp_vlog
  $Diamond_install_path/cae_library/simulation/verilog/ecp/*.v
  ```

- LatticeECP2 Verilog:

  ```
  ncvlog -messages -work ecp2_vlog
  $Diamond_install_path/cae_library/simulation/verilog/ecp2/
  *.v
  ```

- LatticeECP3 Verilog:

```
ncvlog -messages -work ecp3_vlog
$Diamond_install_path/cae_library/simulation/verilog/ecp3/
*.v
```

- LatticeXP Verilog:

```
ncvlog -messages -work xp_vlog
$Diamond_install_path/cae_library/simulation/verilog/xp/*.v
```

- LatticeXP2 Verilog:

```
ncvlog -messages -work xp2_vlog
$Diamond_install_path/cae_library/simulation/verilog/xp2/*.v
```

- MachXO Verilog:

```
ncvlog -messages -work machxo_vlog
$Diamond_install_path/cae_library/simulation/verilog/machxo/
*.v
```

- MachXO2 Verilog:

```
ncvlog -messages -work machxo2_vlog
$Diamond_install_path/cae_library/simulation/verilog/
machxo2/*.v
```

- MachXO3D Verilog:

```
ncvlog -messages -work machxo3d_vlog
$Diamond_install_path/cae_library/simulation/verilog/
machxo3d/*.v
```

- MachXO3L Verilog:

```
ncvlog -messages -work machxo3l_vlog
$Diamond_install_path/cae_library/simulation/verilog/
machxo3l/*.v
```

- Platform Manager Verilog:

```
ncvlog -messages -work lptm_vlog
$Diamond_install_path/cae_library/simulation/verilog/lptm/
*.v
```

- Platform Manager 2 Verilog:

```
ncvlog -messages -work lptm2_vlog
$Diamond_install_path/cae_library/simulation/verilog/lptm2/
*.v
```

- LatticeSC Verilog:

```
ncvlog -messages -work sc_vlog
$Diamond_install_path/cae_library/simulation/verilog/sc/*.v
```

- LIFMD Verilog:

```
ncvlog -messages -work lifmd_vlog
$Diamond_install_path/cae_library/simulation/verilog/lifmd/
*.v
```

Functional RTL Simulation Use the following commands to perform a functional RTL simulation with one of the libraries shown in Table 16:

```
rm –rf work
mkdir work
ncvlog -work work <design_name>.v <test_bench>.v
```

```
ncelab -lib_binding –access +rwc work.<test_bench>
ncsim -GUI work.<test_bench>
```

Note

If you are using NCSim version 5.4 or older, remove the –lib_binding option from the ncelab command.

Post-Map and Place-and-Route Gate-Level Simulation Use the following commands to perform post-map and place-and-route gate-level simulation:

```
rm –rf work
mkdir work
ncvlog -work work <design_name>.vo <test_bench>.v
ncelab -lib_binding –access +rwc work.<test_bench>
ncsim -GUI work.<test_bench>
```

Post-Map and Place-and-Route Gate-Level Simulation with Timing Use the following procedure to perform post-map and place-and-route gate-level simulation with timing:

1. Add the sdf_annotate line at the top-level test bench:

   ```
   $sdf_annotate ("<design_name>.sdf", <design_name>,
   ,<sdf_log>, "MAXIMUM");
   ```

2. Use the following commands to perform the simulation:

   ```
   rm –rf work
   mkdir work
   ncvlog -work work <design_name>.vo <test_bench>.v
   ncelab -lib_binding –access +rwc work.<test_bench>
   ncsim -GUI work.<test_bench>
   ```

See Also "Third-Party Simulators" on page 312

Performing Simulation with Cadence NC-VHDL

This section explains how to perform simulation with Cadence NC-VHDL.

Setting Lattice Semiconductor Libraries Before simulating Lattice Semiconductor FPGA designs in the Cadence NC-VHDL simulator, you must perform the following steps to set the Lattice Semiconductor simulation libraries.

Creating Library Definition Files Before using the Cadence NC-VHDL simulator to simulate your design project, you must first create two library definition files named hdl.var and cds.lib in your project folder. The hdl.var and cds.lib files define which libraries are accessible and where they are located. The hdl.var file contains optional statements that can be used to define variables such as the default work library, and the cds.lib file contains statements that map logical library names to their physical directory paths.

For example, your local hdl.var file can include the following:

```
DEFINE work work
```

Your local cds.lib file may include the following:

```
DEFINE ecp5u <compile_dir>/ecp5u_vhdl
DEFINE ecp5um <compile_dir>/ecp5u_vhdl
DEFINE ec <compile_dir>/ec_vhdl
DEFINE ecp <compile_dir>/ecp_vhdl
DEFINE ecp2 <compile_dir>/ecp2_vhdl
DEFINE ecp2m <compile_dir>/ecp2_vhdl
DEFINE ecp3 <compile_dir>/ecp3_vhdl
DEFINE xp <compile_dir>/xp_vhdl
DEFINE xp2 <compile_dir>/xp2_vhdl
DEFINE machxo <compile_dir>/machxo_vhdl
DEFINE machxo2 <compile_dir>/machxo2_vhdl
DEFINE machxo3d <compile_dir>/machxo3d_vhdl
DEFINE machxo3l <compile_dir>/machxo3l_vhdl
DEFINE lptm <compile_dir>/lptm_vhdl
DEFINE lptm2 <compile_dir>/lptm2_vhdl
DEFINE lifmd <compile_dir>/lifmd_vhdl
DEFINE sc <compile_dir>/sc_vhdl
DEFINE scm <compile_dir>/sc_vhdl
DEFINE work ./work
```

Note

<*compile*_dir> refers to the location of the compiled device libraries.

Cadence provides a utility called NCLaunch to set up the necessary initialization files and to compile the VHDL source libraries. NCLaunch is available as part of the 2.1 and later releases. Otherwise, setting up the initialization files and compiling the VHDL source libraries is a manual process.

You can create the hdl.var and cds.lib files with any text editor. You must map the physical locations to the logical names before you proceed to the next step. On the Linux platform, you can create these names by using the mkdir command as follows:

```
mkdir -p <compile_dir>/ecp5u_vhdl
mkdir -p <compile_dir>/ec_vhdl
mkdir -p <compile_dir>/ecp_vhdl
mkdir -p <compile_dir>/ecp2_vhdl
mkdir -p <compile_dir>/ecp3_vhdl
mkdir -p <compile_dir>/xp_vhdl
mkdir -p <compile_dir>/xp2_vhdl
mkdir -p <compile_dir>/machxo_vhdl
mkdir -p <compile_dir>/machxo2_vhdl
mkdir -p <compile_dir>/machxo3d_vhdl
mkdir -p <compile_dir>/machxo3l_vhdl
mkdir -p <compile_dir>/lptm_vhdl
mkdir -p <compile_dir>/lptm2_vhdl
mkdir -p <compile_dir>/lifmd_vhdl
mkdir -p <compile_dir>/sc_vhdl
```

If you want the logical library names to be available for all designs, use INCLUDE or SOFTINCLUDE in the location of your master hdl.var and cds.lib files.

For example, you can add the following line to your master cds.lib file:

```
INCLUDE $path/cds.lib
```

Note

The *path* variable specifies the location of your own cds.lib file.

Or, you can directly include the library definitions in the master hdl.var and cds.lib files.

Now the master hdl.var and cds.lib files include the Lattice Semiconductor library definitions. The next time that you want to simulate Lattice Semiconductor designs in the NC-VHDL simulator, you do not need to create you own hdl.var and cds.lib files again.

In addition to defining Lattice Semiconductor VHDL libraries, you must map the vital2000 logical library to the IEEE library location by adding the following line to your cds.lib file:

```
DEFINE vital2000 <NC_VHDL_Libraries_Folder>/IEEE
```

Note

The <*NC_VHDL_libraries_folder*> variable specifies the folder containing the NC-VHDL libraries.

Parsing and Analyzing Lattice Semiconductor Simulation Libraries

After creating your own hdl.var and cds.lib files, you must parse and analyze the Lattice Semiconductor simulation libraries by using the NC-VHDL simulator. These libraries must be parsed and analyzed only once.

To parse and analyze Lattice Semiconductor VHDL simulation libraries, run the following commands in NC-VHDL simulator.

- ECP5U VHDL:

  ```
  ncvhdl -messages -work ecp5u -smartorder
  $Diamond_install_path/cae_library/simulation/vhdl/ecp5u/src/
  *.vhd

  ncvlog -messages -work ecp5u $Diamond_install_path/
  cae_library/simulation/vhdl/ecp5u/src/*.v
  ```

- LatticeEC VHDL:

  ```
  ncvhdl -messages -work ec -smartorder
  $Diamond_install_path/cae_library/simulation/vhdl/ec/src/
  *.vhd
  ```

- LatticeECP VHDL:

  ```
  ncvhdl -messages -work ecp -smartorder
  ```

```
$Diamond_install_path/cae_library/simulation/vhdl/ecp/src/
*.vhd
```

- LatticeECP2 VHDL:

```
ncvhdl -messages -work ecp2 -smartorder
$Diamond_install_path/cae_library/simulation/vhdl/ecp2/src/
*.vhd
```

- LatticeECP3 VHDL:

```
ncvhdl -messages -work ecp3 -smartorder
$Diamond_install_path/cae_library/simulation/vhdl/ecp3/src/
*.vhd
```

- LatticeXP VHDL:

```
ncvhdl -messages -work xp -smartorder
$Diamond_install_path/cae_library/simulation/vhdl/xp/src/
*.vhd
```

- LatticeXP2 VHDL:

```
ncvhdl -messages -work xp2 -smartorder
$Diamond_install_path/cae_library/simulation/vhdl/xp2/src/
*.vhd
```

- LIFMD VHDL:

```
ncvhdl -messages -work lifmd-smartorder
$Diamond_install_path/cae_library/simulation/vhdl/lifmd/src/
*.vhd
```

- MachXO VHDL:

```
ncvhdl -messages -work machxo -smartorder
$Diamond_install_path/cae_library/simulation/vhdl/machxo/
src/*.vhd
```

- MachXO2 VHDL:

```
ncvhdl -messages -work machxo2 -smartorder
$Diamond_install_path/cae_library/simulation/vhdl/machxo2/
src/*.vhd
```

- MachXO3D VHDL:

```
ncvhdl -messages -work machxo3d -smartorder
$Diamond_install_path/cae_library/simulation/vhdl/machxo3d/
src/*.vhd
```

- MachXO3L VHDL:

```
ncvhdl -messages -work machxo3l -smartorder
$Diamond_install_path/cae_library/simulation/vhdl/machxo3l/
src/*.vhd
```

- Platform Manager VHDL:

```
ncvhdl -messages -work lptm -smartorder
$Diamond_install_path/cae_library/simulation/vhdl/lptm/src/
*.vhd
```

- Platform Manager 2 VHDL:

```
ncvhdl -messages -work lptm2 -smartorder
$Diamond_install_path/cae_library/simulation/vhdl/lptm2/src/
*.vhd
```

- LatticeSC VHDL:

```
ncvhdl -messages -work sc -smartorder
$Diamond_install_path/cae_library/simulation/vhdl/sc/src/
*.vhd
```

Functional RTL Simulation Use the following commands to perform a functional RTL simulation with one of the libraries shown in Table 2:

```
rm –rf work
mkdir work
ncvhdl -work work <design_name>.vhd <test_bench>.vhd
ncelab -lib_binding –access +rwc work.<test_bench>
ncsim –GUI work.<test_bench>
```

Note

If you are using NCSim version 5.4 or older, remove the –lib_binding option from the ncelab command.

If you receive warning messages during compilation, see “Warning Messages Caused by Std_Logic Declarations” on page 332.

Post-Map and Place-and-Route Gate-Level Simulation Use the following commands to perform post-map and place-and-route gate-level simulation:

```
rm –rf work
mkdir work
ncvhdl -work work <design_name>.vho <test_bench>.vhd
ncelab -lib_binding –access +rwc work.<test_bench>
ncsim –GUI work.<test_bench>
```

If you receive warning messages during compilation, see “Warning Messages Caused by Std_Logic Declarations” on page 332.

Post-Map and Place-and-Route Gate-Level Simulation with Timing Use the following procedure to perform post-map and place-and-route gate-level simulation with timing:

1. Compile the SDF file:

   ```
   ncsdfc <design_name>.sdf
   ```

   This command generates the compiled SDF file, <*design_name*>.sdf.X.

2. Create an <*sdf_cmd*> file with the following contents:

   ```
   COMPILED_SDF_FILE = “<design_name>.sdf.X”, SCOPE =
   :<instance_name>,
   LOG_FILE = “<sdf_log>”, MTM_CONTROL = "MAXIMUM";
   ```

3. Use the following commands to perform the simulation:

   ```
   rm –rf work
   mkdir work
   ncvhdl -work work <design_name>.vho <test_bench>.vhd
   ncelab -lib_binding –access +rwc –sdf_cmd_file <sdf_cmd>
   work.<test_bench>
   ncsim –GUI work.<test_bench>
   ```

If you receive warning messages during compilation, see "Warning Messages Caused by Std_Logic Declarations" on page 332.

Warning Messages Caused by Std_Logic Declarations When you set vital_level1 as an attribute for the architecture, Cadence NC-VHDL issues several warning messages during compilation about an unapproved type in the vital2000 library models. These messages are caused by Cadence NC-VHDL's strict interpretion of std_logic signal declarations in the architecture as signal types. You can make this interpretation less strict by using the following option:

```
ncvhdl -relax
```

This option does not affect the actual simulation.

See Also "Third-Party Simulators" on page 312

Performing Mixed-Language (Verilog and VHDL) Simulation with Cadence NCSim

The steps involved in performing Verilog/VHDL mixed-language simulation with Cadence NCSim are straightforward and use most of the information provided in the previous two sections ("Simulation Library Files" on page 314 and "Performing Simulation with Cadence NC-VHDL" on page 327):

1. Set up your local cds.lib and hdl.var files to include all the libraries that you use in your design. Each library can be Verilog only, VHDL only, or a mixed-language library containing both VHDL entities and Verilog modules. The libraries can be Lattice Semiconductor FPGA libraries, protected libraries (for example, special-block or IP libraries), or your own design libraries.
2. Compile your Verilog files, using the ncvlog command.
3. Compile your VHDL files, using the ncvhdl command.
4. Elaborate the top-level unit (or test bench) in your mixed-language design, using the ncelab command.
5. Simulate the top-level unit (or test bench), using the ncsim command.

Following is an example of the procedure used for simulating a mixed-language design that consists of your own VHDL design files, the LatticeSC VHDL source files, and the Lattice PCSA encrypted Verilog module:

1. Compile the LatticeSC VHDL source files into the LatticeSC VHLD library, as explained in "Performing Simulation with Cadence NC-VHDL" on page 327.
2. Compile the Lattice PCSA encrypted Verilog source file into the same LatticeSC VHDL library as follows:

   ```
   ncvlog -messages -work sc <install_dir>/cae_library/
   simulation/blackbox/pcsa-ncv.vp
   ```

3. Create a local folder for the work library:

   ```
   mkdir work
   ```

4. Add the following lines to your local hdl.var file:

   ```
   DEFINE WORK work
   ```

5. Add the following lines to your local cds.lib:

   ```
   DEFINE sc <Path to NCSim-compiled SC VHDL lib>
   DEFINE work ./work
   ```

6. Compile your VHDL design and test bench files:

   ```
   ncvhdl <design_name>.vhd <test_bench>.vhd
   ```

7. Elaborate your top-level unit (test bench):

   ```
   ncelab -lib_binding –NOMXINDR –access +rwc <test_bench>
   ```

   The –NOMXINDR option is added to ncelab to avoid MXINDR errors. This option is necessary for mixed-language designs.

8. Simulate your test bench:

   ```
   ncsim –GUI <test_bench>
   ```

Performing Simulation with Mentor Graphics ModelSim / Questa

This section explains how to perform simulation with the Mentor Graphics ModelSim / Questa simulator.

Setting Lattice Semiconductor Libraries Before simulating Lattice Semiconductor FPGA designs in the Mentor Graphics ModelSim / Questa simulator, you must compile the Lattice Semiconductor simulation libraries using the cmpl_libs command available from the Diamond's TCL console.

For details about using this command, refer to “Simulation Libraries Compilation Tcl Command” on page 2574.

To enable Diamond’s batch interface to ModelSim / Questa, change the default simulation tool setup and directory reference as follows:

1. Choose **Options > Environment Options**.
2. Click on the **Directories** tab.
3. Change the path setting to the ModelSim / Questa executable on the tab to the new version.
4. Click **OK**.

Mapping to ModelSim / Questa Libraries The library compilation target folder should also be your simulation working directory. Otherwise, you need to copy the library mappings from modelsim.ini at the target folder (or the file itself) into your local or master modelsim.ini.

After running simulation libraries compilation using the cmpl_libs TCL command, a modelsim.ini file will be created at the target folder chosen for the compiled libraries. That file will have the proper mappings for these compiled libraries.

Performing Verilog Simulation Use the procedures described in this section to perform a Verilog standalone simulation with ModelSim / Questa.

Functional RTL Simulation Use the following commands to perform a functional RTL simulation with one of the libraries shown in Table 16:

```
vlib work
vlog -work work <design_name>.v <test_bench>.v
vsim work.<test_bench>
```

Note

If you have a pre-existing work library, you can clear its contents by using the following command:

```
vdel -lib work -all
```

Post-Map and Place-and-Route Gate-Level Simulation Use the following commands to perform post-map and place-and-route gate-level simulation:

```
vlib work
vlog -work work <design_name>.vo <test_bench>.v
vsim -L <library_name> work.<test_bench>
```

where <*library_name*> is the FPGA Verilog library to be searched for the low-level units.

Post-Map and Place-and-Route Gate-Level Simulation with Timing Use the following procedure to perform post-map and place-and-route gate-level simulation with timing:

1. Add the `sdf_annotate` line at the top-level test bench:

   ```
   $sdf_annotate ("<design_name>.sdf", <instance_name>,
   ,<sdf_log>, "MAXIMUM");
   ```

2. Use the following commands to perform the simulation:

   ```
   vlib work
   vlog -work work <design_name>.vo <test_bench>.v
   vsim -L <library_name> work.<test_bench>
   ```

Performing VHDL Simulation Use the procedures described in this section to perform a VHDL standalone simulation with ModelSim / Questa.

Functional RTL Simulation Use the following commands to perform a functional RTL simulation with one of the libraries shown in Table 17:

```
vlib work
vcom -work work <design_name>.vhd <test_bench>.vhd
```

```
vsim -t ps work.<test_bench>
```

Note

If you have a pre-existing work library, you can clear its contents by using the following command:

```
vdel -lib work -all
```

Post-Map and Place-and-Route Gate-Level Simulation Use the following commands to perform post-map and place-and-route gate-level simulation:

```
vlib work
vcom -work work <design_name>.vho <test_bench>.vhd
vsim -t ps +no_glitch_msg work.<test_bench>
```

Post-Map and Place-and-Route Gate-Level Simulation with Timing Use the following commands to perform post-map and place-and-route gate-level simulation with timing:

```
vlib work
vcom -work work <design_name>.vho <test_bench>.vhd
vsim -t ps +no_glitch_msg -sdfmax
<instance_name>="<design_name>.sdf" work.<test_bench>
```

See Also "Third-Party Simulators" on page 312

Performing Simulation with Synopsys VCS

This section explains how to perform simulation with Synopsys VCS for Verilog-only designs.

For VHDL designs, refer to "Performing Mixed-Language (Verilog and VHDL) Simulation with Synopsys VCS-MX" on page 336.

For SystemVerilog designs, refer to "Performing Mixed-Language (Verilog and SystemVerilog) Simulation with Synopsys VCS-MX" on page 337.

Functional RTL Simulation Use the following vcs command to perform a functional RTL simulation with one of the libraries shown in Table 16:

```
vcs -RI <design_name>.v <test_bench>.v
-y <Lattice_verilog_library_location> +libext+.v +v2k
```

Post-Map and Place-and-Route Gate-Level Simulation Use the following vcs command to perform post-map and place-and-route gate-level simulation:

```
vcs -RI <design_name>.vo <test_bench>.vo
-y <Lattice_verilog_library_location> +libext+.v +v2k
```

Post-Map and Place-and-Route Gate-Level Simulation with Timing Use the following procedure to perform post-map and place-and-route gate-level simulation with timing:

1. Add the `sdf_annotate` line at the top-level test bench:

```
$sdf_annotate ("<design_name>.sdf", <instance_name>,
,<sdf_log>, "MAXIMUM");
```

2. Use the following `vcs` command to perform the simulation:

```
vcs -RI <design_name>.vo <test_bench>.v
-y <Lattice_verilog_library_location> +libext+.v +v2k
```

See Also "Third-Party Simulators" on page 312

Performing Mixed-Language (Verilog and VHDL) Simulation with Synopsys VCS-MX

In order to run mixed-language simulation with VCS, you must have a special license for VCS-MX. Contact Synopsys if you do not have one.

"Performing Simulation with Synopsys VCS" on page 335 describes how to simulate a Verilog-only design by simply using the vcs command. In order to simulate a VHDL-only or a Verilog/VHDL mixed-language design, extra steps are required (with extra commands). In general, if your design contains VHDL source code, you must analyze it by using the vhdlan utility. And, if your VHDL design instantiates a Verilog design within it, you must use the vlogan utility. Mixed-language designs are categorized into either VHDL-top or Verilog-top designs, where each one has its own procedure for running the simulation with VCS-MX tools. For more details, refer to the *VCS MX/VCS MXi User Guide*.

Following is an example of the procedure used for simulating a Verilog/VHDL mixed-language design that consists of your own VHDL design files, the ECP5U VHDL library source files, and the ECP5U black boxes encrypted Verilog source file.

1. Create local folders for the ECP5U VHDL and the work libraries:

```
mkdir ecp5u_vhdl work
```

2. Create (or modify) your local synopsys_sim.setup file, and add the following lines:

```
WORK > DEFAULT
DEFAULT : ./work
ECP5U: ./ecp5u_vhdl
```

3. Analyze the ECP5U VHDL library:

```
vhdlan –work ECP5U <ecp5u_vhdl_src_folder>/ECP5UCOMP.vhd \
<ecp5u_vhdl_src_folder>/ECP5U_SEQ.vhd \
<ecp5u_vhdl_src_folder>/ECP5U_IO.vhd \
<ecp5u_vhdl_src_folder>/ORCA_CMB.vhd \
<ecp5u_vhdl_src_folder>/ORCA_MEM.vhd \
<ecp5u_vhdl_src_folder>/ORCA_MISC.vhd \
<ecp5u_vhdl_src_folder>/ORCA_LUT.vhd \
<ecp5u_vhdl_src_folder>/gsr_pur_assign.vhd
```

```
vlogan –work ECP5U <ecp5u_vhdl_src_folder>/*.v
vhdlan –work ECP5U <ecp5u_vhdl_src_folder>/ECP5U_SL.vhd
```

where <*ecp5u_vhdl_src_folder*> refers to <*install_dir*>*/*cae_library*/*simulation/vhdl/ecp5u/src.

4. Analyze the Lattice black box modules from the encrypted Verilog source as follows:

```
vlogan –work ECP5U <install_dir>/cae_library/simulation/
blackbox/ecp5u_black_boxes-vcs.vp
```

5. Analyze your VHDL design and test bench files:

```
vhdlan <design_name>.vhd <test_bench>.vhd
```

6. Compile the simulation executable from your top-level unit (test bench):

```
scs –mhdl <test_bench>
```

7. Simulate your test bench by running the simulation executable:

```
scsim
```

See Also "Third-Party Simulators" on page 312

Performing Mixed-Language (Verilog and SystemVerilog) Simulation with Synopsys VCS-MX

In order to run mixed-language simulation with VCS, you must have a special license for VCS-MX. Contact Synopsys if you do not have one.

"Performing Simulation with Synopsys VCS" on page 335 describes how to simulate a Verilog-only design by simply using the vcs command. In order to simulate a Verilog/SystemVerilog mixed-language design, extra steps are required. In general, if your design contains SystemVerilog code, then you need first to compile the Lattice library sources and/or encrypted modules using the vlogan utility. For more details about running mixed-language designs, refer to the *VCS MX/VCS MXi User Guide*.

Following is an example of the procedure used for simulating a Verilog/ SystemVerilog mixed-language design that consists of your own SystemVerilog design files, modules from the MachXO2 Verilog source files and the machxo2_black_boxes encrypted Verilog source file.

1. Create local folder for the work library:

```
mkdir work
```

2. Create (or modify) your local synopsys_sim.setup file, and add the following lines:

```
WORK > DEFAULT
DEFAULT : ./work
```

3. Analyze the machxo2_black_boxes modules from their encrypted Verilog source file as follows:

   ```
   vlogan +v2k <install_dir>/cae_library/simulation/blackbox/
   machxo2_black_boxes-vcs.vp
   ```

4. Compile your SystemVerilog files and simulate your design with top-level unit (test bench):

   ```
   vcs -mhdl -RI <design_name>.v <test_bench>.v -y
   <install_dir>/cae_library/simulation/Verilog/machxo2
   +libext+.v
   ```

See Also "Third-Party Simulators" on page 312

Referencing Black-Box Models

Some high-value models, such as ECP5UM DCU, are not distributed as HDL open source. In these cases, either HDL encrypted sources or pre-compiled libraries are provided for the respective simulator. By default, Diamond installs archives for each encrypted or pre-compiled model in the following directory:

```
<install_dir>\cae_library\simulation\blackbox
```

For older devices (LatticeSC, LatticeEC, LatticeECP, LatticeECP2, LatticeECP3, LatticeXP, LatticeXP2, Platform Manager and MachXO), each file or folder name indicates the model and simulator supported using the following format:

```
<model>[-aldec|-ncv|-vcs].vp | folder <model>/
```

where:

- <model> is the name of the Verilog simulation model.
- -aldec indicates that the model is provided as encrypted Verilog source for the Aldec Riviera Pro simulator. These models can also be compiled for Aldec Active-HDL simulator, but it is recommended to use the Lattice-provided pre-compiled libraries for Aldec Active-HDL simulator.
- -ncv indicates that the model is provided as encrypted Verilog source for the Cadence NCSim simulator.
- -vcs indicates that the model is provided as encrypted Verilog source for the Synopsys VCS simulator.
- <model>/ is a folder indicating that the model is available as a pre-compiled library for the Mentor Graphics ModelSim / Questa simulator.

For example, the file JTAGA-vcs.vp contains the JTAGA encrypted Verilog model for Synopsys VCS.

For newer devices (ECP5U, MachXO2, MachXO3D, MachXO3L and Platform Manager 2), all the black-box models for each device family are contained in a single .vp file or a single folder for each simulator, in the following format:

```
<device>_black_boxes[-aldec|-ncv|-vcs].vp | folder
<device>_black_boxes/
```

Some Verilog models are pre-compiled or encrypted differently for VHDL. Those models will have the following format:

```
[<model>|<device>_black_boxes]_vhdlib[-aldec|-ncv|-vcs].vp |
folder [<model>|<device>_black_boxes]_vhdlib/
```

If the models are supplied as encrypted Verilog models, you must compile them with other source files for the same device into the same library (both Verilog and VHDL) for the respective simulator. Refer to each respective section for each third-party simulator in "Third-Party Simulators" on page 312.

For ModelSim / Questa pre-compiled libraries, if you have a higher version of ModelSim / Questa simulator, you need to refresh the library as follows:

```
vlog -refresh -work <library_name>
```

For VCS encrypted sources, make sure you compile the files for Verilog, but not for SystemVerilog. For example, use the +v2k option.

If a README file is provided, examine it in each archive file for any further compilation instructions.

See Also "Third-Party Simulators" on page 312

Using the Global Set/Reset (GSR) Signal

Lattice FPGA device simulation models provide the Global Set/Reset Interface (GSR) signal for use with all Lattice FPGAs.

Details regarding the architecture of global signals are described in the data sheet for each device family on the Lattice Web site.

For more information on the GSR library element, see "FPGA Libraries Reference Guide" on page 1664.

For more information on GSR and RTL Functional Simulation, see "RTL Functional Simulation and the GSR Resource" on page 1179.

For more information on how to use the GSR signal, see "How to Use the Global Set/Reset (GSR) Signal" on page 1174.

Creating Waveform Test Stimulus

Once you have completed your design (or a module of the design), you will want to test it to confirm that it behaves the way you expect it to. Simulation requires a test stimulus file that specifies the input waveforms.

You can graphically create a waveform test stimulus file with the Waveform Editor. You see exactly what each waveform will look like, as well as its timing relationship to all the other waveforms.

The Waveform Editor window consists of two panes. The left-hand Waveform Editing area is used for graphically creating and editing waveforms. The right-hand pane includes three views for setting pulse/waveform properties and using patterns.

The following design flow illustrates how you would typically create a stimulus file with the Waveform Editor.

1. Create a waveform file (.wdl).
2. Set Time Unit for the simulation.
3. Select the signals for which you want to define stimuli.
4. Draw the stimulus for each input.
5. Export the waveform information to a stimulus file.

Creating a Waveform File

You can create a new waveform file (.wdl) in Lattice Diamond.

To create a new .wdl file:

1. In the Diamond window, choose **File > New > File**.
2. In the New File dialog box, do the following:
   - Under Source Files, select **WaveForm Files**.
   - Specify the file name and location.
   - Select **Add to project** if you want to include the new file in the current project directory.
   - Select an implementation name from the Implementation name drop-down list.
   - Click **New**.

   The Waveform Editor opens with a blank window.

Setting Simulation Time Unit

You can select the Time Unit for the simulation database. In the simulation stimulus file, stimulus values are specified at intervals of the specified Time Unit.

All stimulus events occur at, and have lengths of, integral multiples of the Time Unit. This feature makes it easier to draw waveforms because all Transitions are automatically forced to occur at multiples of the Time Unit.

Note

A long Simulation Time combined with short Time Units may require an excessive amount of computer resources. Be sure you have selected duration values appropriate for your design before you begin simulation.

To set simulation time unit:

1. In the Waveform Editor, choose **Edit > Timing Settings**.

   The Time Settings dialog box opens.

2. Select the time units you want and click **OK**.

Creating Waveforms

Before drawing waveforms in the Waveform Editor, you may need to specify time unit for the simulation. See “Setting Simulation Time Unit” on page 340.

If you make an error when creating waveforms, choose **Edit > Undo**. The Waveform Editor allows you to perform an unlimited number of Undos and Redos until you save the file.

To create a waveform:

1. Be sure you are in the Edit mode. If not, choose **Edit > Edit Mode** or click the  icon on the toolbar to switch to the Edit mode.
2. At the bottom of the right-hand pane, click the **Pulse** tab to display the Pulse Properties view.

   Note

   If the Pulse tab is not available, choose **View > Pulse Properties View** to display it.

3. Choose **Edit > New Wave**.

   The Add New Wave dialog box opens.

4. In the dialog box, do the following:

   - Type a name for the new wave in the Wave Name box.
   - Select the polarity for the new waveform.
   - Click **Add**.

     The new waveform name is displayed in the Waveform Editing area. The letter behind the waveform name indicates its polarity. “I” stands for Input, “O” for Output, “B” for Bidirectional, “T” for Test Point, and “G” for Global. A pattern name begins with a dollar sign ($).

- You may keep the dialog box open and continue to add more waveform names. When you finish, click **Close**.

5. In the Waveform Editing area, click the new waveform name to highlight it.
6. Move the mouse to the waveform section of the window and click where you want the first Transition. (You must click inside the area next to the highlighted name.)

   A blue line is drawn showing the first section (called a Pulse) of the waveform. You can also see two black horizontal lines above and below the new pulse, indicating it is currently selected.
7. Keep the pulse selected. Then do the following in the Pulse Properties view.
   - In the State box, select a state for the selected pulse and press **Enter**.

     If you are adding a bus pulse, you can select **Set Value** in the State box, and then enter the value in the Value box below it. The value entered in the Value box must be in hexadecimal format.
   - In the Duration box, enter a time value.

     You don't have to enter the time unit. The Waveform Editor automatically appends the time unit specified in the Time Settings dialog box to the time value. To apply a different time unit, see "Setting Simulation Time Unit" on page 340.
8. In the Waveform Editing area, click again to create the second Transition.

   The pulse drawn has the opposite state of the first pulse.
9. Set the properties for the second pulse.
10. Continue clicking and setting properties to complete the waveform.
11. Choose **File > Save File** to save the new waveform.

Note

The commands on the View menu allow you to zoom in and zoom out on the waveforms, to view them in more or less detail.

Creating Bus Waveforms

You can create bus waveforms in the Waveform Editor. Bus waveforms can be expanded to separate waveforms in the Waveform Editing area.

Bus waveform pulses are displayed as elongated hexagons, as shown below.

Figure 47:

Tip

You can double-click the plus sign before a bus name to display the individual waveforms included in the bus. However, you cannot edit those individual waveforms. You can only edit the bus waveform.

To create a bus waveform:

1. Be sure you are in the Edit mode. If not, choose **Edit > Edit Mode** or click the icon on the toolbar to switch to the Edit mode.
2. At the bottom of the right-hand pane, click the **Pulse** tab to display the Pulse Properties view.

   Note

   If the Pulse tab is not available, choose **View > Pulse Properties View** to display it.

3. Choose **Edit > New Wave**.

   The Add New Wave dialog box opens.
4. In the Wave Name box, enter the bus name by adding a bit range to the name. See the following examples:

   A[0:2], which you can expand to A[0], A[1], and A[2].

   A, B, C, D, which you can expand to A, B, C, and D.

   [A1...A3], which you can expand to A1, A2, and A3.
5. Select Polarity for the new bus waveform.
6. Click **Add** and then **Close**.

   The new bus name is displayed in the Waveform Editing area. You can double-click the plus sign before the bus name to expand the bus.
7. Click the new bus name to highlight it.
8. Move the mouse to the waveform section of the window and click where you want the first Transition. (You must click inside the area next to the highlighted name.)

   A bus pulse is drawn showing the first section of the bus waveform. You can also see two black horizontal lines above and below the bus pulse, indicating it is currently selected.
9. Keep the pulse selected. Then do the following in the Pulse Properties view.

   - In the State box, select **Don't Care** or **High-Z**, or select **Set Value** and then enter the bus value in the Value box below it. The value entered in the Value box must be in hexadecimal format.

     Bus pulses can have any value that can be represented by the number of bits in the bus. For example, any pulse in an eight-bit bus waveform can be assigned a value between 0 and 255. Bus pulses are given default values, in sequential order: 0, 1, 2, 3, and so on. You can change any of these values at any time.

The format of the bus value displayed in the Waveform Editing area is set by the Bus Radix option in the Options dialog box. To select a different Bus Radix format, see “Changing the Waveform Display Options” on page 356.

- In the Duration box, enter a time value.

  You don’t have to enter the time unit. The Waveform Editor automatically appends the time unit specified in the Time Settings dialog box to the time value. To apply a different time unit, see “Setting Simulation Time Unit” on page 340.

10. In the Waveform Editing area, click again to create the second Transition, and set the properties for the second bus pulse.
11. Continue clicking and setting properties to complete the bus waveform.
12. Choose **File > Save File** to save the new bus waveform.

Note

The commands on the View menu allow you to zoom in and zoom out on the waveforms, to view them in more or less detail.

Creating and Using Patterns

You may find yourself drawing the same waveform over and over again. The Waveform Editor allows you to name and define arbitrary waveforms, called Patterns, which you can then add to or insert in any other waveform. After a pattern is inserted to another waveform, it becomes a series of pulses, and loses its identity as a pattern. When you modify a pattern, the waveforms that use that pattern will not change.

A pattern name begins with a dollar sign ($). Patterns normally represent single-bit data. You can create a bus pattern by adding a bit range to the name, as shown below:

$buspat[7:0]

Bus patterns cannot be added to single-bit waveforms, or vice versa. Also, the number of bits in a bus pattern must match the number of bits in the bus waveform to which it is added.

To add a pattern name in the Waveform Editor:

1. In the Waveform Editor, choose **Edit > New Wave**.

   The Add New Wave dialog box opens.
2. In the Polarity drop-down box, select **Pattern**.
3. In the Wave Name box, type a name for the pattern. The name should begin with a dollar sign ($). If you do not include a dollar sign, the Waveform Editor automatically adds one.

4. Click **Add** to add the pattern's name to the Waveform Editing area. The dialog box remains open, so you can continue to add pattern names without having to reselect the command.
5. Click **Close**.

You can then draw the waveform for your pattern.

To draw a pattern:

1. Be sure you are in the Edit mode. If not, choose **Edit > Edit Mode** or click the icon on the toolbar to switch to the Edit mode.
2. At the bottom of the right-hand pane, click the **Pulse** tab to display the Pulse Properties view.

   Note

   If the Pulse tab is not available, choose **View > Pulse Properties View** to display it.

3. In the Waveform Editing area, highlight the pattern name for which you want to create a waveform.
4. Move the mouse to the waveform section and click where you want the first Transition. (You must click inside the area next to the highlighted name.)

   A blue line is drawn showing the first section (called a Pulse) of the waveform. You can also see two black horizontal lines above and below the new pulse, indicating it is currently selected.
5. Keep the pulse selected. Then do the following in the Pulse Properties view.
   - In the State box, select a state for the selected pulse and press **Enter**.

     If you are adding a bus pulse, you can select **Set Value** in the State box, and then enter the value in the Value box below it. The value entered in the Value box must be in hexadecimal format.
   - In the Duration box, enter a time value.

     You don't have to enter the time unit. The Waveform Editor automatically appends the time unit specified in the Time Settings dialog box to the time value. To apply a different time unit, see "Setting Simulation Time Unit" on page 340.
6. In the Waveform Editing area, click again to create the second Transition.

   The pulse drawn has the opposite state of the first pulse.
7. Set the properties fro the second pulse.
8. Continue clicking and setting properties to complete the waveform.
9. Choose **File > Save File** to save the new pattern.

Once the pattern is drawn, you can add it to a waveform or another pattern.

To add a pattern to a waveform or another pattern:

1. Be sure you are in the Edit mode. If not, choose **Edit > Edit Mode** or click the  icon on the toolbar to switch to the Edit mode.
2. At the bottom of the right-hand pane, click the **Pattern** tab to display the Pattern view.

   The Pattern List box lists all the patterns defined in the current waveform file in alphabetical order.

   Note

   If the Pattern tab is not available, choose **View > Pattern View** to display it.

3. In the Waveform Editing area, select the pulse where you want to insert the pattern.
4. In the Pattern view, select the name of the pattern you want to add and click **Insert**.

   The pattern is inserted before the selected pulse.

You can also use the Copy command on the Edit menu to copy a pattern to the clipboard, and then use the Paste command to insert it in another waveform. The pattern, however, is inserted only as a series of pulses, and loses its identity as a pattern.

Importing Signal Names from a NAF File

A NAF file is an intermediate file generated by the Generate Schematic Symbol command in the Hierarchy view. It is a text file that lists signal names and types in design modules. A typical NAF file looks like the following:

```
c[2]  o
c[1]  o
c[0]  o
clk  i
rst  i
ExtTrigOutPort0  o
```

Importing signal names from a NAF file is much quicker than adding waveform names one by one using the Edit > New Wave command.

Note

For detailed information on how to run **Generate Schematic Symbol** in the Hierarchy view, see “Creating a Symbol from an HDL Module” on page 274.

To import signal names from a NAF file:

1. In the Waveform Editor, select **Edit > Import Wave**.

   The Import Wave dialog box opens.

2. Click **Browse** to display the Open Existing Waveform File dialog box.
3. Select a .naf file and click **Open**.

   All the signals contained in the .naf file are then listed in the Imported Wave box. You can narrow the list by using the Filter options on the left.

   Next you will add signal names to the Selected Wave box. Only the names listed in the Selected Wave box will be added to the waveform display.
4. In the Imported Wave box, click to highlight the signal names that you want to import. You can use the Shift or Ctrl key to highlight multiple names.
5. Click **>** to add the highlighted signal names to the Selected Wave box.

   Tip

   You can use the four arrow buttons in the middle to add or remove signal names in the Selected Wave box.

   > – Adds the signal names highlighted in the Imported Wave box to the Selected Wave box.

   >> – Adds all the signal names in the Imported Wave box to the Selected Wave box.

   < – Deletes the signal names highlighted in the Selected Wave box.

   << – Clears all signal names from the Selected Wave box.
6. Click **OK**. The signal names in the Selected Wave box are added to the waveform display.

After adding signal names, you can then start drawing waveforms for them. See “Creating Waveforms” on page 341 for detailed information on how to draw waveforms.

Adding Test Points

You can add waveforms for internal nodes (that is, nets that do not have external connections or I/O markers) in the Waveform Editor window. These internal nodes are called test points.

Test points can be used to “force” internal nodes to specific values during simulation. However, not all simulators support this function. Check your simulator documentation to see if you can define arbitrary values for internal nodes.

To add a test points from the Waveform Editor:

1. In the Waveform Editor, choose **Edit > New Wave**.

   The Add New Wave dialog box opens.
2. In the Wave Name box, type the name of the test point.
3. In the Polarity box, select **Test Pt**.
4. Click **Add** to add the test point to the Waveform Editing area.

After adding the Test Points, you can then start drawing waveforms for them. See “Creating Waveforms” on page 341 for detailed information on how to draw waveforms.

Selecting Waveforms or Pulses

You can select waveforms or pulses (a Pulse is a section of a waveform between two Transitions) in the Edit operation mode. If you are not in the Edit mode, choose **Edit > Edit Mode** or click the icon on the toolbar to switch to the Edit mode.

To select a waveform:

- Click the name of the waveform you want to select.

To select pulses:

- To select a single pulse, click anywhere within a pulse.
- To select multiple successive pulses, drag the cursor across the waveform to cover several pulses.

  The selected pulse(s) will be marked with thick black lines above and below it.

Graphically Changing the Length of a Pulse

In the Waveform Editor, a section of a waveform between two Transitions is called a Pulse. You can graphically change the length of any pulse. The length of a pulse can also be changed by specifying the pulse duration in the Pulse Properties view. See “Setting Pulse State and Duration” on page 349 for details.

To change the length of a pulse graphically:

1. Click the pulse you want to lengthen or shorten.

   The pulse becomes selected, marked with thick black lines above and below it.

2. Click and hold down the mouse button on the selected pulse.

   The selected pulse and its preceding or succeeding pulse (depending on where you click) both change to dotted lines.

3. Drag the mouse to the left or right to change the length of the pulse.
   - If you select the last pulse in a waveform, dragging changes the length of that pulse and extends or shortens the waveform.
   - If you select a pulse within the waveform, dragging alters the start or ending time of the Transition. The preceding or succeeding pulse is lengthened and the selected pulse shortened (or vice versa). The total

length of both pulses (and of the complete waveform) does not change.

- If you press and hold **Shift** before you click a pulse, dragging only changes the length of the selected pulse. The preceding or succeeding pulse lengths do not change. Any pulses to the left or right of the selected pulse are moved (without modification) to accommodate the lengthened or shortened pulse. Use this mode to adjust a pulse without changing anything else in the waveform.

Remember that pulses always have a length that is an integral multiple of the Time Units selected in the Timing Settings dialog box.

Setting Pulse Properties

In the Waveform Editor, a section of a waveform between two Transitions is called a Pulse. You can use the Pulse Properties view to change pulse properties, including state, duration, scaling, and repeat options.

To display the Pulse Properties view, click the **Pulse** tab at the bottom of the right-hand pane. If the Pulse tab is not displayed, choose **View > Pulse Properties View**.

Note

You cannot select a pulse or change pulse properties for individual waveforms included in a bus. However, you can select pulses on a bus waveform and change pulse properties.

Setting Pulse State and Duration

Before setting pulse state and duration, make sure you are in the Edit operation mode. If not, choose **Edit > Edit Mode** or click the icon on the toolbar to switch to the Edit mode.

To change the state of a pulse:

1. In the Waveform Editor, select a pulse by clicking anywhere within the pulse.
2. In the Pulse Properties view, select the desired state in the State box. If you are working with a bus pulse, you can select **Set Value** in the State box, and then enter the value in the Value box below it. The value entered in the Value box must be in hexadecimal format.

   Changing a pulse from Low to High or High to Low effectively removes it from the waveform, since it now has the same value as the pulses on either side.

To change the duration of a pulse:

1. In the Waveform Editor, select a pulse by clicking anywhere within the pulse.

2. In the Pulse Properties view, click inside the Duration edit box and type a time value.

   You don't have to enter the time unit. The Waveform Editor automatically appends the time unit specified in the Time Settings dialog box to the time value. To apply a different time unit, see "Setting Simulation Time Unit" on page 340.

Repeating Pulses

You can use the Pulse Properties view to repeat successive pulses in a waveform. The pulses at the end of a waveform can be repeated forever in the Waveform Editor.

Note

- A single pulse cannot be repeated. To repeat pulses, you must select more than two successive pulses.
- Pattern pulses cannot be repeated forever.

To repeat pulses:

1. Be sure you are in the Edit operation mode. If not, choose **Edit > Edit Mode** or click the icon on the toolbar to switch to the Edit mode.
2. In the Waveform Editing area, select the pulses that you want to repeat by dragging the cursor across the waveform to cover several successive pulses. The selected pulses are marked with thick black lines above and below them.
3. In the Pulse Properties view, do either of the following:
   - In the Repeat edit box, type any integer larger than 1, and then press **Enter**.

     The selected pulses are repeated by the specified multiple.
   - If the selected pulses are located at the end of a waveform, you can select **Forever** to repeat the selected pulses forever.

   Note

   The simulation time for the Repeat Forever waveform can be controlled by the run time or conditional settings in a simulator.

Scaling Patterns and Waveforms

You can use the Pulse Properties view to make any pattern, pulse(s), or an entire waveform longer by scaling it.

To scale patterns and waveforms:

1. Be sure you are in the Edit operation mode. If not, choose **Edit > Edit Mode** or click the icon on the toolbar to switch to the Edit mode.

2. In the Waveform Editing area, select the pulse(s) that you want to scale by clicking anywhere within the pulse or dragging the cursor across the waveform to cover several successive pulses. The selected pulses are marked with thick black lines above and below them.

   If you want to scale an entire pattern or waveform, select all its pulses.

3. In the Pulse Properties view, click inside the Scale edit box.

4. Type any integer larger than 1, and press **Enter**.

   The length of the selection is multiplied by this value. (A pulse is multiplied only if it is not part of a Repeat Forever waveform.)

   If a complete waveform contains a pattern, that pattern is scaled along with the rest of the waveform. (The original definition of the pattern is unaffected by the scaling.)

See Also ▶"Selecting Waveforms or Pulses" on page 348

- "Graphically Changing the Length of a Pulse" on page 348

Setting Waveform Polarity and Offset

The Waveform Properties view allows you to change waveform polarity and add an offset at the beginning of a waveform.

You cannot change waveform polarity or offset for patterns.

To display the Waveform Properties view, click the **Waveform** tab at the bottom of the right-hand pane. If the Waveform tab is not displayed, choose **View > Waveform Properties View**.

Note

You cannot change waveform properties for individual waveforms included in a bus. However, you can set properties for the bus waveform.

To set waveform properties:

1. In the Waveform Editing area, select the waveform name for which you want to change properties.

   The Waveform Properties view displays the waveform details in the Wave Data box, including the state and duration for each pulse in the selected waveform.

2. In the Waveform Properties view, do the following:

   - To change polarity for the selected waveform, select a different polarity in the Polarity box.

     The letter behind the waveform name changes to indicate the updated polarity.

   - To add an offset at the beginning of the waveform, enter the offset value in the Offset box. The offset value must be a number greater than 0.

The waveform shifts to the right if the offset value was increased or to the left if the offset value was decreased.

Deleting, Cutting, Copying, Pasting, and Duplicating Pulses or Waveforms

Pulses or waveforms that can be selected (a single pulse, multiple successive pulses, or the entire waveform) can be deleted, cut, or copied to the clipboard for pasting elsewhere.

To delete, cut, or copy pulses or waveforms:

1. Select the waveform or pulse(s) that you want to edit.
2. Do any of the following:
   - Choose **Edit > Clear**.

     The selected waveform or pulse(s) is removed, but is not copied to the clipboard.
   - Choose **Edit > Remove Wave**.

     The Remove Waves dialog box opens. In the Wave List, select one or more waveforms to be deleted and click **Remove**. You can use the Shift or Ctrl key to select multiple waveforms or select and remove them one at a time.
   - To cut a waveform or pulse(s), choose **Edit > Cut**.

     The selected waveform or pulse(s) is removed, and is copied to the clipboard.
   - To copy a waveform or pulse(s), choose **Edit > Copy**.

     The selected waveform or pulse(s) is copied to the clipboard without being removed.

To paste the copied waveform or pulse(s) into the current waveform:

1. Select a single pulse, multiple successive pulses, or an entire waveform.
2. Choose **Edit > Paste**.

   The data in the Clipboard will replace the selected waveform or pulse(s).

To duplicate a waveform:

1. Select the waveform name that you want to duplicate.
2. Choose **Edit > Duplicate Wave**.

   The software adds an exact copy of the selected waveform to the display, and adds “_0” to the waveform name.

See Also ▶“Selecting Waveforms or Pulses” on page 348

Saving Waveforms

The first time you save a waveform file, the Waveform Editor creates a *project*.wdl file. The .wdl file contains the waveforms in WDL (waveform description language) format. You can use the Save As command to save the file under a different base name to create multiple stimulus files for a single project.

Caution

You can perform an unlimited number of Undos and Redos until you save the file. At that point, the files are updated and all Undo/Redo information is lost. Do not save the file if there are still changes you want to Undo or Redo.

The Waveform Editor can automatically save the file you are working on. You can use the Options dialog box to select an auto-save option.

To set auto-save options:

1. In the Diamond window, choose **Tools > Options**.

   The Options dialog box opens.

2. In the left-hand pane, select **Waveform Editor**.
3. In the right-hand pane, under Auto Save, select **1 Minute**, **5 Minutes**, or **10 Minutes** to let the system automatically save your file every 1, 5, or 10 minutes. Or select **Never Save** to cancel the auto-save function.
4. Click **OK**.

Showing Waveforms

Sometimes waveforms have been hidden from view. You can restore the view of hidden waveforms using the Show command.

To show a hidden waveform in the Waveform Editor:

1. Choose **Edit > Show Wave**.

   The Show Waves dialog box opens. The Wave List box displays all the available signals. You can use the Filter options on the left to narrow the signal list.

2. In the Wave List, select the name of the signal you want to show. You can use the Shift or Ctrl key to select multiple signal names.
3. Click **Show**.

   The software restores the view of the selected waveform.

Hiding Waveforms

If you decide not to display a particular waveform, you can temporarily hide it without deleting it from the Waveform Editor database.

To hide a waveform:

1. In the waveform Editing area, select the name of the waveform you want to hide.

   The Waveform Editor highlights the waveform name.

2. Choose **Edit > Hide Wave**.

   The Hide Wave command hides the highlighted waveform name and its waveform.

Viewing Waveform and Pulse Properties

When you are in the Edit mode, you can select a waveform or a pulse in the Waveform Editing area and view its properties.

Pulse properties like pulse state, duration, and scale are displayed in the Pulse Properties view. Waveform data, polarity, and offset are displayed in the Waveform Properties view.

To view pulse information in the Pulse Properties view:

1. Make sure you are in the Edit mode. If not, choose **Edit > Edit Mode** or click the icon on the toolbar to switch to the Edit mode.
2. At the bottom of the right-hand pane, click the **Pulse** tab to display the Pulse Properties view.

   Note

   If the Pulse tab is not available, choose **View > Pulse Properties View** to display it.

3. In the Waveform Editing area, select a pulse.

   The selected pulse is marked with thick black lines above and below it. The pulse information will appear in the Pulse Properties view.

To view waveform data in the Waveform Properties view:

1. At the bottom of the right-hand pane, click the **Waveform** tab to display the Waveform Properties view.

   Note

   If the Waveform tab is not available, choose **View > Waveform Properties View** to display it.

2. In the Waveform Editing area, select any waveform name on the left.

The selected waveform name is highlighted. The waveform data will appear in the Waveform Properties view.

Using a Marker

A marker is a red vertical line on the waveform time line. It is useful as a reference point to query the simulation data.

To place a marker:

1. In the Waveform Editing area, click the place on the time line where you want to insert a marker. You can use the Jump to commands on the View menu to locate the exact place.

   A query bar (a black vertical line) appears.

2. Choose **View > Place Marker**.

   A marker is inserted at the current location of the query bar. You may not see the red marker because it is covered by the black query bar. Click anywhere else to move the query bar, and then you will see the red marker.

To move the query bar to the marker:

1. In the Waveform Editing area, click anywhere on the time line to position a query bar.
2. Choose **View > Jump to > Marker**.

   The query bar is re-positioned at the marker.

   This is useful when you are displaying the time line at high magnification and you would have to press the Left or Right keys many times to return to the marker.

To hide a marker:

- In the Waveform Editor, choose **View > Hide Marker**.

  The marker is removed from the waveform display.

Positioning the Query Bar with the Jump to Commands

A query bar is a black vertical line on the waveform time line used to query the simulation data. You can use the Jump to commands on the View menu to position the query bar to a specific time.

To position a query bar:

1. In the Waveform Editing area, click anywhere on the time line to display a query bar.

2. Choose **View > Jump to**, and then select the required command to position the query bar to the specific time.

   The below table describes each Jump to command in detail.

Table 21:

Command Name	Description	Keyboard Shortcut
Next Change	Moves the query bar to the next transition in the currently selected signal. If the currently selected signal is a bus, the query bar moves to the next transition of any signal in the bus. This command is typically used to traverse the simulation data. Starting at a primary input (which is the most common activity initiator), you can jump from one initiating event to another. You can find later events on other signals that result from the changes on the primary input.	+
Marker	Positions the query bar at the marker. The principal use of this command is simply to return the query bar to the marker. This is especially useful when you are displaying the time line at high magnification and you would have to press Shift+Left or Shift+Right many times to return to the marker. For information on how to place a marker, see Figure on page 355.	-
Time...	Opens a dialog box that allows you to move the query bar to a specified time.	
Time=0	Moves the query bar to time=0. This is the left-most point on the time axis of the waveform.	Home
Time=End	Moves the query bar to the last time point of the simulation. This is the right-most point on the time axis of the waveform.	End
Tick Left	Moves the query bar one tick mark to the left (“backwards” in time). The interval between tick marks changes as you change the time scale with the Zoom commands.	Left
Tick Right	Moves the query bar one tick mark to the right (“forward” in time). The interval between tick marks changes as you change the time scale with the Zoom commands.	Right
10 Left	Moves the query bar one major tick mark to the left (“backwards” in time). The interval between tick marks changes as you change the time scale with the Zoom commands.	Shift+Left
10 Right	Moves the query bar one major tick mark to the right (“forward” in time). The interval between tick marks changes as you change the time scale with the Zoom commands.	Shift+Right

Changing the Waveform Display Options

You can use the Options dialog box to control the following waveform display options.

- **Bus Radix** – Controls how bus values are displayed in the Waveform Editor.

- **Show Grid Lines** – Shows or hides grid lines in the Waveform Editor.
- **Color** – Specifies the Waveform Editor color scheme.

To change the waveform display options:

1. In the Diamond window, choose **Tools > Options**.

   The Options dialog box opens.
2. In the left-hand pane, under Waveform Editor, select **General**.
3. In the right-hand pane, specify the Bus Radix and Show Grid Lines options as you want.
4. In the left-hand pane, under Waveform Editor, select **Color**.

   The current color settings are shown in the right-hand pane.
5. Click on the current color to open the Select Color dialog box, select the desired color, and click **OK**.
6. Click **OK** to apply your settings and close the Options dialog box.

Exporting the Stimulus File

The Waveform Editor saves the waveforms you create in it as a .wdl file. You can export (create) a Verilog (.tf) or VHDL (.vht or .tb) stimulus file from a .wdl file at any time. The Waveform Editor translates the waveform database in the .wdl file into the stimulus format in the appropriate output files. You can then use the exported stimulus file to simulate your design in a simulator.

To export the stimulus file:

1. In the Waveform Editor, choose **File > Export**.
2. In the Export Waveform File dialog box, do the following:
   - Click **Browse** to specify the existing .wdl file which includes the waveform information you want to export.
   - Click **Browse** to specify the name and location of the output file.
   - In the Export Type box, select an export format. This appends the appropriate file extension to the output file.
3. Click **OK**.

   The Waveform Editor exports the stimulus file to the specified location.

Chapter 6

Applying Design Constraints

Constraints are instructions applied to design elements to guide the design toward desired results and performance goals. They are critical to achieving timing closure or managing reusable intellectual property (IP). The most common constraints are those for timing and pin assignment, but constraints are also available for placement, routing, and many other functions.

Constraints can include timing constraints defined in synthesis constraint files (SDC) or HDL attributes. SDC is used for the synthesis tool. Post-synthesis constraints known as preferences can also be specified. The flow combines these together. All three sources of constraints specify design goals. Synthesis, map, and place-and-route work to meet these goals. Timing analysis reports whether or not the goals were met.

See Also ▶"Constraints Reference Guide" on page 1194

- "Setting Preferences" on page 457
- "Migrating Pin Assignments" on page 482
- "Integrated Synthesis" on page 581
- "Achieving Timing Closure" on page 569
- "Lattice Synthesis Engine (LSE) Constraints" on page 1338

Multiple Entry Constraint Flow

Constraints from mutiple sources can be used and modified in Lattice Diamond in multiple ways, such as: timing constraints from SDC or LDC synthesis files; constraints defined in HDL source files; or with post-synthesis constraints known as logical preferences that are defined in the logical preference file (.lpf).

You can set constraints using one or more of the following methods:

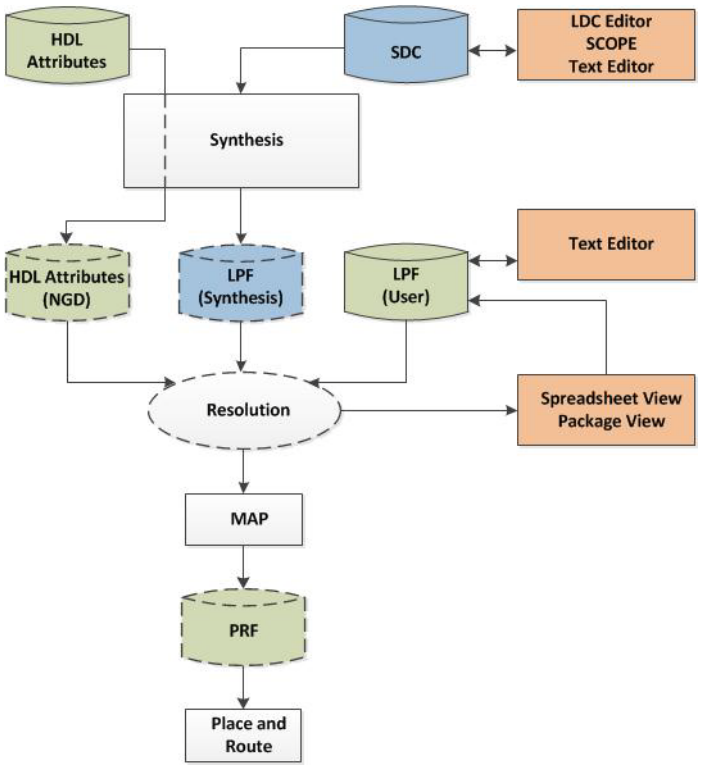
- You can assign HDL attributes in the HDL or schematic source files. After synthesis and translation, these defined attributes can be viewed and modified in Diamond's preference views, and the modifications can be saved to the logical preference file.

- If you are using the Lattice Synthesis Engine, you can assign SDC constraints using the Lattice Design Constraints (LDC) Editor and save them to an .ldc constraints file. If you are using Synplify Pro, you can assign SDC constraints using the SCOPE editor tool and save them to an .sdc file.
- You can apply SDC constraints added in Diamond by enabling the new "Use LPF Created from SDC in Project" strategy option. Refer to "Using SDC Constraints in Place and Route" on page 363.
- You can assign logical preferences in the logical preference file (.lpf) using a text editor or Diamond's preference-editing views: Device View, Spreadsheet View, Package View, Netlist View, NCD View, and Floorplan View.
- You can use Spreadsheet View to modify timing constraints that have been defined in Synplify Pro or Lattice Synthesis Engine (LSE) and save the modified constraints as preferences to the active .lpf file.

The constraints entered from multiple entry points are resolved in the Diamond software. Refer to "Resolving SDC Constraints with Other Constraints from Multiple Flow" on page 363.

The following figure shows a high-level flow of how constraints from mutiple sources can be used and modified in Lattice Diamond.

Figure 48:



See Also "Constraints Reference Guide" on page 1194

- "Using SDC Constraints" on page 362
- "Using Preferences" on page 373
- "Adding FPGA Attributes to HDL" on page 567

Constraint Implementation

The following steps illustrate how you might assign constraints and implement them at each stage of the design flow, using synthesis constraints, logical preferences and timing analysis.

1. Define the constraints in the pre-synthesis stage using one or both of the following methods:
   - Define constraints as attributes within the HDL or schematic model.
   - Define timing constraints using Synplify Pro or Lattice Synthesis Engine (LSE).
2. Synthesize and translate the design.

   When Synplify Pro is used, the synthesis process translates the design into an EDIF netlist. Run the **Translate Design** process to translate the EDIF netlist into a binary logical native generic database (.ngd) file, which will contain all HDL attributes.

   When LSE is used, the synthesis process both synthesizes the design and translates it into an .ngd file.

   The synthesis process writes timing constraints that were defined in Synplify Pro or LSE to a synthesis .lpf file in the project directory. The synthesis .lpf will not appear in Diamond, but the timing constraints will be displayed in Diamond's Spreadsheet View and color-coded as synthesis values.
3. Open one or more of the following views to define new constraints, called preferences, or to modify existing constraints from the source files and save them as preferences:

   Spreadsheet View – Modify timing constraints that were defined in the synthesis tool and save them as logical preferences to the active.lpf file. Set timing objectives such as fMAX and I/O timing. Define signaling standards and make pin assignments. Assign clocks to primary or secondary routing resources. Set parameters for simultaneous switching outputs and perform SSO analysis. Define groups of ports, cells, or ASIC blocks. Create UGROUPs from selected instances to guide placement and routing. Establish REGIONs for UGROUPs or to reserve areas of the floorplan. Run PIO design rule checking.

   Device View – Examine FPGA device resources. Reserve sites that should be excluded from placement and routing.

   Netlist View – View the design tree by ports, instances, and nets. Assign pins for selected signals. Set timing constraints. Define groups from selected ports or registers. Create UGROUPs from selected instances to guide placement and routing.

Package View – View the pin layout of the design. Modify signal assignments and reserve pin sites that should be excluded from placement and routing. Examine the status of SSO pins. Run PIO design rule checking.

Floorplan View – View the device layout. Draw bounding boxes for UGROUPs. Draw REGIONs for the assignment of groups or to reserve areas. Reserve sites and REGIONs that should be excluded from placement and routing. Run PIO design rule checking.

4. Save the preferences to the logical preference file (.lpf).
5. Run the **Map Design** process (map).

   This process reads the .ngd and .lpf files and produces a native circuit description (.ncd) file and a physical preference (.prf) file. The .prf file is derived from preference-related .ngd attributes and the .lpf file. Non-preference-related .ngd attributes are written directly into the .ncd file.

   The .prf file is an internal file generated by the Map engine that contains preferences used by the PAR engine. It should not be edited, because the changes will be lost when it is regenerated.
6. Run the **Map TRACE** process and examine the timing analysis report. Modify preferences as needed and save them.
7. Run the **Place & Route Design** process (par).

   This process reads the post-MAP .ncd file and the .prf file, and appends placement and routing to a post-PAR .ncd file.
8. Open one of the following views, as desired, to examine timing and placement and create new UGROUPs.

   Timing Analysis View – Examine details of timing paths. Cross-probe selected paths to Floorplan and Physical Views. Create one or more timing preference files (.tpf) and experiment with sets of modified preferences for the purpose of timing analysis, using the TPF Spreadsheet View. Select and export the desired timing preferences from TPF Spreadsheet View to the regular Spreadsheet View. From Spreadsheet View, save the timing preferences to the .lpf file.

   NCD View – Examine placement assignments. Create new UGROUPs, as needed, from selected instances.
9. Cross-probe to **Logic Block View** from NCD View, Floorplan View, or Physical View, to view logic details of a selected component.
10. Modify preferences or create new ones using any of the preference-editing views. Save the preference changes and rerun the **Place & Route Design** process.
11. Repeat Steps 3 through 10 until timing objectives are met.

You can repeat the flow using a new implementation of your design with a different set of preferences. See "Working with Run Manager" on page 93 and "Managing Project Sources" on page 33.

Note

Refer to Importing ispLEVER Projects to ensure the compatibility of designs that use the ispLEVER constraint data flow.

- "Analyzing Static Timing" on page 691
- "Achieving Timing Closure" on page 569

Using SDC Constraints

You can enter constraints in the synthesis design constraints (SDC) file using one of the following two synthesis tools:

- Lattice Synthesis Engine (LSE) LDC Editor

  For more information about entering constraints with LDC Editor, refer to "Applying Lattice Synthesis Engine Constraints" on page 364.

- Synplify Pro SCOPE Constraints Editor

  For more information about entering constraints with Synplify Pro SCOPE Constraints Editor, in the Synplify Pro online help, refer to "SCOPE Constraints Editor" help.

During synthesis, a read-only logical preference file (.lpf) is generated, which can be included and specified as the active preference file in your Diamond project.

The following Synopsis Design Constraints can be set in the SDC:

- "create_clock" on page 1340
- "create_generated_clock" on page 1342
- "set_clock_groups" on page 1343
- "set_false_path" on page 1344
- "set_input_delay" on page 1345
- "set_max_delay" on page 1346
- "set_min_delay" on page 1346
- "set_multicycle_path" on page 1347
- "set_output_delay" on page 1347

For more information about these constraints, refer to "Synopsys Design Constraints (SDC)" on page 1338.

Constraints entered from multiple entry points are resolved in the Diamond software. Refer to "Resolving SDC Constraints with Other Constraints from Multiple Flow" on page 363.

See Also ▶"Using SDC Constraints in Place and Route" on page 363

- "Conflicting HDL Attributes, Constraints, and Preferences" on page 399
- "Using Diamond's Preference Views" on page 404

Using SDC Constraints in Place and Route

When you chose the "Use LPF Created from SDC in Project" strategy setting, constraints set in Lattice Synthesis Engine (LSE) LDC Editor or Synplify Pro SCOPE Constraints Editor will be applied during the Diamond software Place & Route process.

To use SDC constraints in Place & Route

1. Specify "Use LPF Created from SDC in Project" in your project's strategy. Refer to "Specifying Strategy Options" on page 51.

   Note

   Refer to the "Strategy Reference Guide" on page 1113 for more information about LSE and Synplify Pro versions of the "Use LPF Created from SDC in Project" strategy.

2. Run the Synthesize the Design process. Refer to "Running Processes" on page 69.
3. Set the new LPF file as the active file. Refer to "Managing Constraint Files" on page 40.
4. Run the Place & Route Design process. Refer to "Running Processes" on page 69.

See Also ▶"Using SDC Constraints" on page 362

Resolving SDC Constraints with Other Constraints from Multiple Flow

When you have multiple sources of constraints, the Diamond software follows specific rules to resolve conflicting constraints. Refer to "Preference Conflict Resolution" on page 393.

See Also "Multiple Entry Constraint Flow" on page 358

Applying Lattice Synthesis Engine Constraints

Diamond's Lattice Synthesis Engine (LSE) enables you to set Synopsys® Design Constraints (SDC), which are directly interpreted by the synthesis engine. When you use LSE, these SDC constraints are saved to a Lattice Design Constraints file (.ldc). You can create several .ldc files and select one of them to serve as the active synthesis constraint file for an implementation. You can also cause a synthesis preference file to be generated when the design is synthesized. The synthesis preferences can then be merged with the logical preference file (.lpf).

Lattice Design Constraints (LDC) Editor, as well as Source Editor, are available for creating and editing .ldc files. LDC Editor provides a spreadsheet style user interface that enables you to quickly create and edit Synopsys Design Constraints.

See "Synopsys Design Constraints (SDC)" on page 1338 for descriptions of the SDC constraints that are supported by the Lattice Synthesis Engine and LDC Editor.

See Also "Defining Synthesis Constraints Using LDC Editor" on page 364

- "Creating a New LDC Synthesis Constraint File" on page 365
- "Integrated Synthesis" on page 581
- "Optimizing LSE for Area and Speed" on page 579

Defining Synthesis Constraints Using LDC Editor

LDC Editor presents the contents of a Lattice Design Constraints File (.ldc) in a spreadsheet style format. You can use LDC Editor to open and edit a current .ldc file or create a new one. Individual sheets are provided for defining clocks, setting input and output delays, and defining delay paths for multicycle, minimum and maximum delays, and false paths.

By default, LDC Editor is launched when you create a new .ldc file. Each sheet of LDC Editor allows you to define synthesis constraints by double-clicking a cell and selecting or typing a value.

Each row includes an Enabled check box, which is selected by default. If you clear this check box, the constraint is ignored by LSE. This can be an easy way to test different settings.

See Also "Creating a New LDC Synthesis Constraint File" on page 365

- "Defining Clocks Using LDC Editor" on page 367
- "Setting Input and Output Delays Using LDC Editor" on page 367
- "Defining Delay Paths Using LDC Editor" on page 368
- "Defining Clock Groups in LDC Editor" on page 369
- "Defining Generated Clocks in LDC Editor" on page 369

- "Setting Attributes in LDC Editor" on page 370
- "Generating a Synthesis Preference File" on page 372
- "Synopsys Design Constraints (SDC)" on page 1338

Running LDC Editor

Run LDC Editor by opening or creating an .ldc file for an implementation.

Note

In order to open or create an .ldc file, LSE must be the selected synthesis tool for the project. Choose **Project > Synthesis Tools** and select **Lattice LSE**.

You can have multiple .ldc files for an implementation, but only one can be opened in LDC Editor at a time.

To run LDC Editor, do one of the following:

- Double-click an .ldc file name in the Synthesis Constraints Files folder in the File List view.
- If you have set Source Editor to be the default program for .ldc files, right-click the .ldc file name in the File List view and choose **Open With**. In the Open With dialog box, choose **LDC Editor** and click **OK**.
- If no .ldc file exists yet for the active implementation, create an .ldc file as described in Creating a New LDC Synthesis Constraint File.

See Also
- "Managing Constraint Files" on page 40
- "Using Source Editor for LDC Files" on page 371

Creating a New LDC Synthesis Constraint File

Before you create a new .ldc file, verify that Lattice Synthesis Engine has been selected as the synthesis tool. In the Processes tab, "Lattice Synthesis Engine" should be listed under "Synthesize Design." If it is not listed, choose **Project > Synthesis Tool**, and select **Lattice LSE**.

To make sure that the LDC file opens in LDC Editor instead of Source Editor, verify that LDC Editor has been selected as the default program in Tool > Options > Environment > File Associations.

To create a new .ldc synthesis constraint file:

1. Choose **File > New > File**.

   Alternatively, right-click the **Synthesis Constraint Files** folder and choose **Add > New File**.

2. In the New File dialog box, select **Source Files** from the Categories list. Select  **LDC Files** from the Source Files list.

3. Type a name for the new .ldc file and specify the directory location.
4. Select the **Add to Implementation** option if you want to use the file with the currently active implementation.
5. Click **New**.

   LDC Editor opens and displays the spreadsheet and three tabs for creating and editing synthesis constraints. If you selected the Add to Implementation option, the new .ldc file will appear in the Synthesis Constraint Files folder.

   Drop-down menus of source elements are provided when you double-click the Clock Source cells or the Inputs/Outputs Ports cells.

   Note

   If manual compilation has been selected as the default, the lists of source elements might not be displayed. Choose **Design > Compile** to display them.

6. Enter or edit values for clocks, inputs and outputs, and delay paths:
   a. Double-click a cell and type a new value, or select a value from the drop-down list.
   b. Use the arrow keys or the Tab key to move to another cell and select it for editing.
   c. To add a new row, right-click inside a row and choose **Insert Row** from the pop-up menu.
7. Choose **File > Save**.

- "Managing Constraint Files" on page 40
- "Integrated Synthesis" on page 581
- "Optimizing LSE for Area and Speed" on page 579

Setting Design Rule Checks for LDC Editor

LDC Editor runs a design rule check (DRC) to verify that the constraints you enter are legitimate. You can control when these checks happen. By default, the DRC happens before saving the .ldc file. You can also set it to happen while you are creating the constraints for immediate feedback. The DRC marks any problems and gives you a chance to correct them.

To set when LDC Editor runs DRC:

1. Choose **Tools > Options**.

   The Options dialog box opens.

2. In the left frame, choose **LDC Editor**.
3. If you want to run DRC:
   - before saving the .ldc file, select **Run DRC check before saving**.
   - while creating constrains, select **Enable realtime DRC check**.

   If you clear both options, the DRC never runs. In that case, you may be saving incomplete or inaccurate constraints.
4. Click **OK**.

Defining Clocks Using LDC Editor

The Clocks tab of LDC Editor enables you to define an alias to be associated with an existing clock port or net from the source file. You can also define clocks by dragging-and-dropping from Netlist Analyzer into LDC Editor.

To define a clock using LDC Editor:

1. Double-click the **Source** cell to select an existing clock pin, port, or net.
2. If desired, enter an alias for the clock in the Clock Name cell.
3. Enter a clock period in nanoseconds in the Period(ns) cell.
4. If desired, you can specify the duty cycle. Double-click the Waveform Low Edge cell and enter the length of the high portion of the cycle in nanosecond. The default duty cycle is 50%. The waveform starts with the rising edge.

To define a clock in LDC Editor using Netlist Analyzer:

1. Start Netlist Analyzer. Refer to “About Netlist Analyzer” on page 57.
2. Select desired clock object (port or net) from Netlist Analyzer and drag-and-drop into Clock Name cell of the LDC Editor Clocks tab.
3. If desired, enter an alias for the clock in the Clock Name cell.
4. Enter a clock period in nanoseconds in the Period(ns) cell.
5. If desired, you can specify the duty cycle. Double-click the Waveform Low Edge cell and enter the length of the high portion of the cycle in nanosecond. The default duty cycle is 50%. The waveform starts with the rising edge.

See Also
- “create_clock” on page 1340
- “Creating a New LDC Synthesis Constraint File” on page 365
- “About Netlist Analyzer” on page 57

Setting Input and Output Delays Using LDC Editor

The Inputs/Outputs tab of LDC Editor enables you to specify input and output delays relative to a clock. You can also define input and output delays by dragging-and-dropping from Netlist Analyzer into LDC Editor.

To set an input or output delay using LDC Editor:

1. Double-click the **Type** cell to select the type of delay (input or output).
2. Select from the input or output ports in the Port cell.
3. In the Clock cell, select an existing clock or an alias name that has been defined for a clock.
4. Select either Max or Min or neither. Do not select both.
   - Max means that the delay value refers to the longest path.
   - Min means that the delay value refers to the shortest path.
   - Neither means that the maximum and minimum delays are assumed to be equal.
5. Enter a delay value in nanoseconds in the Value(ns) cell.

To set an input or output delay in LDC Editor using Netlist Analyzer:

1. Start Netlist Analyzer. Refer to "About Netlist Analyzer" on page 57.
2. Select from the input or output ports from Netlist Analyzer and drag-and-drop into the Port cell of the LDC Editor Input/Outputs tab.
3. In the Clock cell, select an existing clock or an alias name that has been defined for a clock.
4. Select either Max or Min or neither. Do not select both.
5. Enter a delay value in nanoseconds in the Value(ns) cell.

- "set_output_delay" on page 1347
- "Creating a New LDC Synthesis Constraint File" on page 365
- "About Netlist Analyzer" on page 57

Defining Delay Paths Using LDC Editor

The Delay Paths tab of LDC Editor enables you to define a Multicycle path, specify a Max_Delay or a Min_Delay for a timing path, and identify a False path that is to be excluded from timing analysis. You can also perform the same functions by dragging-and-dropping from Netlist Analyzer into LDC Editor.

To define a delay path using LDC Editor:

1. Double-click the **Delay Type** cell and select the type of delay.
2. Specify the path information, delay, and cycles as appropriate for the selected delay type.

To define a delay path in LDC Editor using Netlist Analyzer:

1. Start Netlist Analyzer. Refer to "About Netlist Analyzer" on page 57.
2. Select object (port, net, or register) from Netlist Analyzer and drag-and-drop into the From or To cell of the LDC Editor Delay Paths tab.
3. Specify the path information, delay, and cycles as appropriate for the selected delay type.

See Also
- "set_multicycle_path" on page 1347
- "set_max_delay" on page 1346
- "set_min_delay" on page 1346
- "set_false_path" on page 1344
- "Creating a New LDC Synthesis Constraint File" on page 365
- "About Netlist Analyzer" on page 57

Defining Clock Groups in LDC Editor

The Clock Groups tab of LDC Editor enables you to define clock groups that are mutually exclusive or asynchronous with each other in a design so that the paths between these clocks are not considered during timing analysis.

To define clock groups using LDC Editor:

1. Double-click the **Type** cell and select the type of clock group.
2. Specify the group information as appropriate for the selected clock group.

See Also
- "set_clock_groups" on page 1343
- "Creating a New LDC Synthesis Constraint File" on page 365

Defining Generated Clocks in LDC Editor

The Generated Clocks tab of LDC Editor enables you to define internally generated clocks. You can also perform the same functions by dragging-and-dropping from Netlist Analyzer into LDC Editor.

To define generated clocks using LDC Editor:

1. In the **Source** cell, select the source clock for the generated clock.
2. Specify the other values as appropriate for the generated clock.

To define generated clocks in LDC Editor using Netlist Analyzer:

1. Start Netlist Analyzer. Refer to "About Netlist Analyzer" on page 57.
2. Select the source clock from Netlist Analyzer and drag-and-drop into the Source cell of the LDC Editor Generated Clocks tab.

3. Specify the other values as appropriate for the generated clock. You can also specify the Master Clock and Object values by dragging from Netlist Analyzer.

See Also ▶"create_generated_clock" on page 1342

- "Creating a New LDC Synthesis Constraint File" on page 365

Setting Attributes in LDC Editor

The Attributes tab of LDC Editor enables you to specify Synplify Lattice Attributes that are supported by the Lattice Synthesis Engine (LSE). You can also define objects by dragging-and-dropping from Netlist Analyzer into LDC Editor.

To set attributes using LDC Editor:

1. Double-click the **Attribute** cell and select the desired attribute.
2. Specify object type, object, value type, and value, as appropriate for the attribute.

To set attributes in LDC Editor using Netlist Analyzer:

1. Start Netlist Analyzer. Refer to "About Netlist Analyzer" on page 57.
2. In LDC Editor Attribute tab, double-click the **Attribute** cell and select the desired attribute.
3. Specify object type and value, as appropriate for the attribute.
4. Select object (port, net, or register) from Netlist Analyzer and drag-and-drop into the Object cell of the LDC Editor Attribute tab.

Note

You can also drag-and-drop an object from Netlist Analyzer to the Object cell of LDC Editor Attribute tab before you specify the attribute. Object type will then be selected automatically. You can then specify attribute and value.

See Also ▶"Lattice Synthesis Engine-Supported HDL Attributes" on page 1348

- "Creating a New LDC Synthesis Constraint File" on page 365
- "About Netlist Analyzer" on page 57

Compiling the Design Using LDC Editor

By default, LDC Editor is set to compile the design automatically. With automatic compilation, LDC Editor automatically performs checks as to whether the design data is outdated. This happens whenever LDC Editor is launched or activated. If the design data is found to be outdated, the compilation will begin at once.

You can change this default setting to manual compilation, which will cause LDC Editor to check the data only when the Compile command is used.

To change to manual compilation:

1. Choose **Tools > Options**.
2. Select **LDC Editor** from the list of tools.
3. In the “Run LSE synthesis compile step” options, select **Manually**.
4. If you want the editor to run a check for any rule violations each time you save the .ldc file, select **Run DRC check before saving**.
5. Click **OK**.

To compile the design manually:

- Choose **Design > Compile** or click the Compile button on the toolbar.

  LDC Editor checks the design data. If the data is found to be outdated, it begins the compilation.

See Also ▶“Integrated Synthesis” on page 581

Using Source Editor for LDC Files

Any .ldc file that you have created using LDC Editor can be viewed and edited in Source Editor. Likewise, an .ldc file that you have created in Source Editor can be viewed and edited in LDC Editor.

One advantage of using Source Editor is that it allows you to open multiple .ldc files at once, whereas LDC Editor will load only one .ldc file at a time.

To open an .ldc file in Source Editor:

1. In the File List view, expand the Synthesis Constraints folder.
2. Right-click the name of the .ldc file you want to open and choose **Open With**.
3. In the dialog box, select **Source Editor** and click **OK**.

   The .ldc file opens in Source Editor window as an ASCII file.

See Also ▶“Changing the Default Editor for LDC Files” on page 371

Changing the Default Editor for LDC Files

Diamond gives you the option of setting Source Editor or LDC Editor as the default program for .ldc files.

To change the default editor for .ldc files:

1. Choose **Tools > Options**.

2. In the Environment section of the Options dialog box, select **File Associations**.
3. In the Extensions column of File Associations, scroll down to **ldc**.
4. In the Default Programs column, choose **Source Editor** or **LDC Editor** from the drop-down menu.

   The next time you create or select an .ldc file, it will open in the editor you selected as the default.

See Also ▶"Managing Constraint Files" on page 40

Optimizing for Timing

The SDC constraints that you set in the .ldc file will drive optimization of the design if you set the optimization goal for timing in the active strategy file.

To set the optimization goal for timing:

1. From the File List view, expand the Strategies folder and double-click the name of the active strategy.
2. In the Strategies dialog box, select **LSE** from the Synthesis Design folder in the Process pane.
3. In the LSE pane on the right, scroll down to Optimization Goal and select **Timing** in the Value column.
4. Click **OK**.

See Also ▶"Synopsys Design Constraints (SDC)" on page 1338

▶ "Optimizing LSE for Area and Speed" on page 579

Generating a Synthesis Preference File

You have the option of automatically generating a synthesis preference file for an implementation when you synthesize the design. The generated synthesis file includes preferences that are equivalent to those in the .ldc file. These synthesis preferences can later be merged with those of the active .lpf file.

To automatically generate a synthesis preference file:

1. From the File List view, expand the Strategies folder and double-click the name of the active strategy.
2. In the Strategies dialog box, select **LSE** from the Synthesis Design folder in the Process pane.
3. In the LSE pane on the right, scroll down to Output Preference File and select **True** in the Value column.

See Also ▶"Integrated Synthesis" on page 581

Adding an LDC File to an Implementation

You can add multiple .ldc files to an implementation and view each of them in LDC Editor.

To add an existing .ldc file to an implementation:

1. In the File List view, right-click the Synthesis Constraints Folder and choose **Add > Existing File**.
2. Browse to the directory that contains the desired .ldc file, select the file, and click **Add**.

   The file is added to the implementation and is displayed in the Synthesis Constraint Files list.

See Also ▶"Managing Constraint Files" on page 40

Activating an LDC File

To apply the synthesis constraints, you need to identify an .ldc file as the active one for the implementation.

To activate an .ldc file for an implementation:

- Right-click the file name and choose **Set as Active LDC**.

  By default, the active .ldc file is compiled when you synthesize the design.

See Also ▶"Managing Constraint Files" on page 40

Using Preferences

Preferences are constraints that guide the design toward performance goals. They can be created and edited using Diamond's six preference-editing views, or they can be created and edited manually in the logical preference file (.lpf) using a text editor. Preferences, unlike HDL attributes, are written to the .lpf file.

This section describes the major types of preferences and the role they play in the design flow. For complete descriptions of all preferences, see the "Constraints Reference Guide" on page 1194.

The Logical Preference File

The logical preference file (.lpf) is your source file for storing constraints. It is the constraint file used as input for developing and implementing the design. A new .lpf file is automatically generated when you create a new project. It is assigned the project file name by default and set as the active constraint file for the project's initial implementation.

The Map Design process depends on the .lpf file. If you map the design and then modify the active .lpf file, the map process and any downstream processes must be rerun.

You can create and modify logical preferences in the .lpf file using Diamond's preference-editing views, or you can modify the .lpf file directly using a text editor. Typically, you will start with a small .lpf file, which might contain basic timing preferences. For a complex design, the .lpf file might be modified several times during the course of design as timing and placement goals are refined.

The .lpf file can also be used to override attributes that exist in the HDL source. When you modify these constraints in the .lpf file, they will take precedence over those in the HDL file.

Unlike the .prf file, which is generated by the map process, the .lpf file contains only user-defined preferences.

Working with Multiple .lpf Files Diamond enables you to add new or existing preference files to your project and experiment with different sets of constraints. Each added .lpf file is listed in the LPF Constraint Files folder on Diamond's File List view. You can then activate a different .lpf file for a selected implementation.

Preference Flow

Diamond provides six views for editing preferences. You can also modify preferences manually in the logical preference file (.lpf) using a text editor. After routing, you can examine finer details in the read-only Physical View and Logic Block View.

Synthesis constraint files (SDC) can be processed using either Lattice Synthesis Engine (LSE) or Synplify. Refer to "Multiple Entry Constraint Flow" on page 358.

Figure 49:

Preferences and the Design Flow

Design constraints, including logical preferences and HDL attributes, work on design elements that are present in the logical domain, which is the user's netlist. In the design flow, logical preferences are specified in the logical preference file (.lpf), usually after synthesis and translation. HDL attributes are specified in the source files and are transferred into the binary native generic database (.ngd) file through logic synthesis and the Translate Design process

(ngdbuild). The mapping process maps logical .ngd elements to physical elements in the native circuit description file (.ncd), and it translates logical preferences to physical preferences in the physical preference file (.prf).

Logical Domain References The logical domain refers to the objects in the .ngd, which is a direct translation of the EDIF netlist. The following HDL example, “Verilog Hierarchical Design,” illustrates the objects that will be transferred to the .ngd by the synthesis and translation processes.

Figure 50:

```
module verilog_hierarchical_design(q, a, b, sel, r_l, clk,
rst);
output [7:0] q;
input [7:0] a, b;
input sel, r_l, clk, rst;
wire [7:0] mux_out, reg_out;

mux mux_1 (.out(mux_out), .a(a), .b(b), .sel(sel));

reg8 reg8_1 (.clk(clk), .data(mux_out), .q(reg_out),
.rst(rst));

rotate rotate_1 (q, reg_out, clk, r_l, rst);

endmodule
```

In the following .lpf file for the “Verilog Hierarchical Design” example, the timing, floorplan, and I/O preferences are defined in terms of objects of the logical domain—the ports, nets, or cell instances from the “verilog hierarchical design” cell in the EDIF file. The .lpf file illustrates package/floorplan locations of the FPGA device such as package locations P7, K4, and E13.

Figure 51:

```
COMMERCIAL ;
BLOCK RESETPATHS ;
BLOCK ASYNCPATHS ;
# Timing Preferences
FREQUENCY PORT "clk" 66 MHz;
INPUT_SETUP ALLPORTS 2.5ns CLKPORT "clk";
# Floorplan Preferences
UGROUP "Crit_Path"
  BLKNAME mux_1/out_4
  BLKNAME rotate_1/q_7
  BLKNAME reg8_1/q_1;
# I/O Preferences
LOCATE  COMP  "clk"  SITE  "P7";
LOCATE  COMP  "rst"  SITE  "K4";
LOCATE  COMP  "sel"  SITE  "E13";
```

While logic synthesis might rename or adjust the original design hierarchy, it is generally easy to relate logical domain references to the original HDL or schematic-based model of the design.

The Map Program The map program performs two major roles in the Diamond design flow:

- It maps the .ngd library elements into elements in the native circuit description file (.ncd), which is referred to as the physical domain. Logical elements of the .ngd (such as ports, flip-flops, and LUTs) are mapped to physical elements of the .ncd (such as slices and I/O components).
- It interprets all logical preferences from the .lpf and the .ngd files and, where appropriate, translates them into equivalent physical preferences in the physical preference file (.prf).

The map program also performs design rule checking when interpreting preferences. Logical constraints from the .lpf/.ngd are validated against the logical database (.ngd) file. Any logical references that do not exist in the .ngd are reported as semantic warnings and ignored by default. You can change the default by setting the “Ignore Preference Errors” property of the Map Design process to False in the project Strategy dialog box. This will cause the map program to error and will make these issues more visible.

When you update and save the .lpf during the design flow, the project gets initialized back to pre-map status and you must rerun the map process.

Note

If the time stamp of the .lpf for the project is newer than the post-map .ncd file, the Map Design and Place & Route Design processes will be reset. If you want to avoid resetting the project state, avoid saving any additions or changes to the .lpf file. You can still view the in-memory preferences in Preference Preview.

You can also use Timing Analysis View to experiment with sets of timing preferences and obtain quick analysis without rerunning Map and Place & Route. See “Using Timing Analysis View” on page 729.

Preferences in the .prf File The map process translates physical counterparts of logical preferences, as required, into the physical preference (.prf) file. Preferences listed in the .prf file result from both logical preferences and HDL attributes.

In the following .prf file for the “Verilog Hierarchical Design” example, the timing, I/O, and floorplan preferences of the .lpf have been translated by the design mapper to references that are compatible with the .ncd. In this example, most preferences appear unchanged; the object identifiers are common between the .ngd and .ncd. However, the UGROUP preference in the .lpf has been translated into a PGROUP with object references that reflect the post-map design and the consolidation of logical domain blocks into physical components.

Although it is possible to add preferences to the .prf file manually, this method is definitely not recommended because it would have to be done again each time after remapping.

Physical Domain References In cases where there is a one-to-one correlation between a logical object and a silicon device element, the physical domain reference uses the same identifier as the logical domain reference. This is common for objects such as ports, EBRs, PLL/DLLs, and DSP blocks. But objects that are consolidated into slices—such as ports, flip-flops and LUTs—are renamed with a SLICE identifier.

Floorplan View presents a graphical view of the physical placement of elements after the Place & Route process. The tool tips and status bar provide logic information and location for placed components. You can view the precise logical identifiers for a SLICE component by double-clicking the component on the Floorplan View layout to open Logic Block View. Logic Block View's schematic representation displays the logical names of registers within the slice.

You can also cross-probe to Netlist View to view the precise logical identifiers.

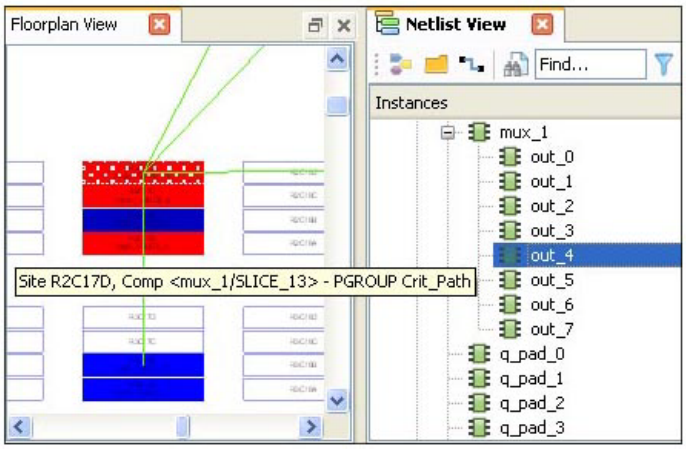
Preferences to Improve Timing

Timing preferences control the timed paths in an FPGA design. They are essential for good placement and routing results and for complete timing analysis. The following timing preferences are available in Spreadsheet View:

Figure 53:



Global Preferences Sheet – Block Path

- Block Asynchpaths – Blocks all paths from pads to FF inputs for the frequency and period preferences.
- Block Reset Paths – Blocks timing constraints on all asynchronous reset paths in the design.
- Block RD During WR Paths – Prevents timing analysis of RAM executing a read-during-write on the same address in a single clock period. This is recommended if your design contains PFU-based RAMs.

Timing Preferences Sheet

- FREQUENCY/PERIOD – Specify a frequency or period requirement on each clock net or clock port in the design. The PAR_ADJ keyword for PERIOD and FREQUENCY allows you to vary timing requirements for place-and-route results versus the requirements reported by TRACE, the timing analysis tool. This allows you to experiment more efficiently with over-constraining your design to achieve the best possible timing results.
- INPUT_SETUP – Each clocked input should have an input setup preference.
- CLOCK_TO_OUT – Each clocked output should have a clock-to-out preference.
- Block NET or PATH – All nets or paths specified should be ignored (blocked) by timing analysis.
- MULTICYCLE – Specify which paths' timing constraints can be relaxed.
- MAXDELAY – Identify a maximum total delay for a net, bus, or path in the design

After placement and routing, you can experiment with different sets of timing preferences using Timing Analysis View, which provides a timing preference

file (tpf) version of Spreadsheet View. Included in the TPF Spreadsheet View are Global, Timing, and Group preference sheets.

Note

The map report (.mrp) contains an “ASIC Components” section that lists the ASIC instances and type used in the design. All other registers in the report are CELLs. There might be times when you need to apply a timing preference, such as MULTICYCLE or MAXDELAY, that requires specification of CELL or ASIC; but you are not sure whether the specific instance is an ASIC or a CELL. In these situations, run the Map Report process.

Path Checking on Timing Preferences When a timing preference is specified, the software does a path check. The path checked depends upon the preference. The following table illustrates the path checks made for each timing preference:

Timing Preference	Description
PERIOD/FREQUENCY	On a clock net, generates a check for delays on all paths that terminate at a pin that has a setup or hold timing constraint relative to the clock net.
MAXDELAY PATHCLASS	Checks the delay of the specified class of paths: OUTPUTPATHS — all paths to primary output pins of the device CLOCKPATHS — all paths to clock inputs of SLICE/FSLICEs and PICs ENABLEPATHS — all paths to clock enable inputs of SLICE/FSLICEs SYNCPATHS — all paths to SLICE/FSLICE and PIC synchronous inputs ALLPATHS — a superset of these path classes
CLOCK_TO_OUT/ INPUT_SETUP	Specifies the delay offset for an external data input/ output relative to an external clock input, and generates delay checks on syncpaths and outputpaths.
BLOCK	Provides a means of blocking timing checks on specific nets, paths (containing the specified net), or path classes reported in the verbose report. RESETPATHS — specifies all asynchronous set/ reset paths, through an asynchronous set/reset pin on a design component. ASYNCPATHS — All paths from pads to FF inputs will be blocked for the frequency and period preference.
MULTICYCLE	Allows for relaxation of previously defined PERIOD or FREQUENCY constraints on a path.

Preferences for Floorplanning

Floorplanning involves the placement of logical component instances or signals of a synthesized design to package pins or other sites of the device floorplan to improve the design's performance.

I/O Assignments I/O planning involves both the configuration of the programmable sysIO buffers to meet signal standard requirements as well as package pin locations to meet signal routing specification of the printed circuit board design.

The FPGA's PIO buffer varies by location around the chip die and might support a subset of potential signal standards, depending on the location. Some pins might have special dedicated connections to programming or clocking circuits of the chip and put restrictions on how pin assignments can be made. Diamond's Package View and Spreadsheet View enable you to define the correct preferences for pin assignments (LOCATE COMP), port groups (DEFINE GROUP) and port attributes (IOBUF).

See the sections "Assigning Signals" on page 464; "Setting Port, Net, and Cell Attributes" on page 473; and "Defining Port, Cell, and ASIC Groups" on page 504.

Logical Groups One of the main floorplanning methods is to group logical instances into a universal group (UGROUP) or hierarchical group (HGROUP). UGROUP is intended for grouping blocks in hierarchies or no hierarchy. HGROUP, which is usually defined as part of a VHDL architecture or a Verilog module declaration, is used to infer a unique placement group for each instance of a block. UGROUPs and HGROUPs can include PFU, PFF, EBR, and DSP-based logic.

UGROUPs and HGROUPs are translated by the design mapper (map) into PGROUPs, which directs the placer algorithm of PAR to place the group members in proximity. Diamond's Spreadsheet View, Netlist View, and Floorplan View enable you to create and edit UGROUPs

Note

The Diamond preference views do not support the creation or editing of HGROUPs.

UGROUPs and HGROUPs and their related attributes facilitate partitioning the logical design. When a UGROUP or HGROUP is defined, the mapping program prevents logical elements of different groups from being mapped into the same block and achieves a natural partitioning of the mapped design.

After mapping, the place and route process interprets the groups and places the grouped physical elements in proximity, effectively minimizing the connections between them.

See "Grouping Logical Components" on page 504.

Placement Groups Placement groups (PGROUP) are inferred by the Map process from any HGROUP and UGROUP definitions that exist in the logical preference (.lpf). When you use UGROUPs and HGROUPs, you are using the logical domain, which gives you control over how functions are grouped relative to each other. After mapping, these groups appear in the physical preference (.prf) file as PGROUPs.

Note

The legacy PGROUP preference is no longer supported for grouping PFF, PFU, EBR, and DSP-based logic in the logical preference file. Use the UGROUP preference instead.

The DEFINE GROUP preference should be used instead of the legacy PIO-based PGROUP preference. Although you can still create a PIO-based PGROUP in the logical preference file using a text editor, this is not recommended. The Diamond preference views do not support the display or editing of PIO-based PGROUPs.

See Also "UGROUPs" on page 391

Preferences for Programming

The Global preferences sheet allows you to set configuration

The Lattice sysCONFIG feature is the non-JTAG interface supported by Lattice FPGA devices. The keywords for the sysCONFIG preference, which are available on the Global Preferences sheet, enable you to

Global Preferences

Global preferences are constraints that affect the entire design. They include preferences for setting voltage and temperature, preferences for blocking timing analysis on all paths of a certain type, configuration (sysCONFIG) preferences, and user code. Most of these preferences are available from the

Global sheet of Spreadsheet View. The list of available preferences varies by device family. See the references below the table for more information about sysCONFIG features for Lattice FPGA device families.

Table 22:

Preference Name	Supported Devices	Description
BACKGROUND_RECONFIG	ECP5U/UM, MachXO2, MachXO3D, MachXO3L	**NOTE:** The use of this preference is recommended for advanced users only. ON – Allows user to reconfigure device in user mode. OFF (default) – Disables this preference. SRAM_ONLY - specific for MachXO3D. SRAM_EBR - specific for MachXO3D.
BACKGROUND_RECONFIG_SECURITY	MachXO3D	ON - CFG can read/write to ESB. OFF (default) - CFG can read only.
BANK	All	Specifies the VCCIO voltage level of the IO bank.
BANDGAP	MachXO2	ON (default) – Statically enables analog PLL circuitry, power-on reset, oscillator, and referenced I/Os. OFF – Disables this preference.
BLOCK ASYNCHPATHS	All	ON (default) – Blocks timing analysis on all paths from pads to FF inputs for the FREQUENCY and PERIOD preference. OFF – Disables this preference.
BLOCK INTERCLOCK DOMAIN PATHS	All	**NOTE!** The use of this preference is risky and not recommended. ON – Specifies all paths involving data transfer between registers that are clocked by different clock nets—even when those clock nets are related. OFF (default) – Disables this preference.
BLOCK JITTER	All	ON – Blocks timing analysis on input and system jitter. OFF (default) – Disables this preference.
BLOCK RD DURING WR PATHS	All	ON – Globally blocks timing analysis on RAM read paths during the write operation. OFF (default) – Disables this preference.
BLOCK RESETPATHS	All	ON (default) – Blocks timing analysis on all asynchronous set/reset paths, through an asynchronous set/reset pin on a design component. OFF – Disables this preference.
BULK_ERASE	MachXO3D	YES (default) - Allows auto SRAM Bulk Erase for power cycling, refresh or PROGRAMN pin toggling. NO - Disables auto Bulk Erase.

Table 22:

Preference Name	Supported Devices	Description
COMPRESS_CONFIG	ECP5, LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeSC/M, MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2	ON (default) – Generates a compressed version of the bitstream file. The device will route the compressed bitstream through the decompression engine during configuration. OFF – Disables this preference. It is possible for the compressed bitstream to be larger than the uncompressed bitstream.
CONFIG_IOVOLTAGE	ECP5, LatticeECP3	Sets the voltage for the sysCONFIG bank. This attribute tells the software the voltage that is required in this bank to satisfy the sysCONFIG requirements.
CONFIG_MODE	ECP5, LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeXP, LatticeXP2, LatticeSC/M	Specifies the configuration mode. The configuration modes available, as well as the default mode, will depend on the targeted device.
CONFIG_SECURE	All	Allows you to set the security of the device. ON – Blocks Read Back of the configuration memory. OFF (default) – Enables Read Back through any port. **Note**: For LatticeECP2 devices, use the Security Settings interface from the Diamond Tools menu to set this preference.
CONFIGURATION	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2	Specifies settings for storing the configuration bitstream. CFG (default) – Stores the configuration bitstream, including EBR init, in the configuration flash array and does not allow it to overflow into the UFM. CFG_EBRUFM – Stores the configuration bitstream (not including EBR init) in the configuration Flash array and stores EBR init data in the lowest page addresses of the user flash memory (UFM). CFGUFM – Stores the configuration bitstream, including EBR init, in the configuration flash array and allows it to overflow into the UFM. EXTERNAL – Stores the configuration bitstream, including EBR init, in an external memory device.
CUR_DESIGN_BOOT_LOCATION	MachXO3D	Determines the.jed file downloaded to Flash memory: IMAGE_0 (default) - <project_name>_a.jed is generated. IMAGE_1 - <project_name>_b.jed is generated.
CUSTOM_IDCODE	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2	Specifies a 32-bit value to be used as the JTAG ID of the device when the MY_ASSP feature is enabled.
CUSTOM_IDCODE_FORMAT	MachXO3D	Specifies the CUSTOM_IDCODE format. The available formats are HEX and BINARY (default).

Table 22:

Preference Name	Supported Devices	Description
DONE_EX	ECP5, LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeXP, LatticeXP2, LatticeSC/M	Determines if the wake-up sequence is triggered by an external DONE signal. ON –- Delays wake-up until the DONE pin is driven high by an external signal and synchronous to the clock. OFF (default) – Synchronously wakes up when the internal Done bit is set and ignore any external driving of the DONE pin. If DONE_EX is set to ON, DONE_OD should be set to the default value of ON.
DONE_OD	ECP5, LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeXP, LatticeXP2	ON (default) – Configures the DONE pin as an open drain configuration. OFF – Disables this preference.
DONE_PULL	ECP5, LatticeSC/M	ON (default) – Configures the DONE pin with a pull up. OFF – Disables this preference.
DUALBOOTGOLDEN	MachXO3LF	INTERNAL (default) – Controls the Dual Boot Golden File Location. This setting specifies an internal location. EXTERNAL – Specifies an external Dual Boot Golden File Location.
ENABLE_NDR	LatticeECP2/M, LatticeECP3	OFF (default) – I/Os are tri-stated during reconfiguration. ON – Enables Non-disruptive Reconfiguration (NDR), which allows the device to be reconfigured while I/Os are in Leave-Alone mode.
ENABLE_TRANSFR	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2	DISABLE (default) – Leaves the Freeze_IO and Freeze_MIB fuses off and disables the TransFr function. ENABLE – Turns on the Freeze_IO and Freeze_MIB fuses to enable the TransFR function.
GSR_NET	All	Assigns a specified net as the input to the global set/reset (GSR) buffer inferred by the design mapper (MAP).
I2C ADDRESS	All	I2C ADDRESS SIZE - Specify 7 or 10 bit. I2C ADDRESS - Specify the starting address
I2C_PORT	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2	ENABLE – Makes the I^2C port active for configuration access by preventing the dual-purpose pins from being used as I/O pins. DISABLE (default) – Makes the dual-purpose pins related to the I^2C port available as user I/O pins.

Table 22:

Preference Name	Supported Devices	Description
INBUF	ECP5, LatticeECP/EC, LatticeECP2/M, LatticeXP, LatticeXP2, MachXO	On – Turns on the input buffers. You must set this preference to On when you need to perform boundary scan testing. Off – Disables all unused input buffers to save power. ECP5, LatticeECP/EC, LatticeECP2/M: defaults to Off LatticeXP, LatticeXP2, MachXO,: defaults to On
JTAG_PORT	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2	ENABLE (default) –- Prevents the JTAG pins from being used as ordinary I/Os. DISABLE – Allows the assigning of signals to the JTAG pins. A high signal on the JTAGENB would then be required to re-enable the JTAG port, after which the 4 pins would become dedicated JTAG pins.
MASTER_PREAMBLE_DETECTION_RETRY	MachXO3D	Sets the number of times the preamble detection should be retried in master mode. The attribute value is 0 to 3. 0 (default) - no retry 1 - try one time 2 - try two times 3 - try three times
MASTER_PREAMBLE_DETECTION_TIMER	MachXO3D	Sets the detection timer count value in master mode. The attribute value is 0 to 15. 0 (default) - approx. 126Kus 1 - 63 Kus, ... 13 - 15.4 us 14 - 7.7 us 15 - 3.85us
MASTER_SPI_PORT	ECP5, LatticeXP2, MachXO2, MachXO3D, MachXO3L, Platform Manager 2 except MachXO3D	ENABLE – Allows SRAM to be configured using the external Master SPI port. DISABLE (default) – Prohibits the use of the external Master SPI port for SRAM configuration. EFB_USER (MachXO2, MachXO3D, and MachXO3L only) – Reserves the SPI pins for user Master SPI mode in the embedded function block (EFB) In MachXO3D, MASTER_SPI_PORT is not open for user setting.

Table 22:

Preference Name	Supported Devices	Description
MCCLK_FREQ	ECP5, LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeXP, LatticeSC/M, MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2	When you have determined that the a device will be a Master Configuration device and will provide the clocking source for configuration, the CCLK will become an output clock with the frequency set by the user. At the start of configuration the device operates with the default Master Clock Frequency of 2.5MHz. One of the first configuration bits set will be the Master Clock. Once the Master Clock configuration bits are set, the clock will start operating at the user-defined frequency. MCCLK_FREQ is used to control the Master Clock frequency. It defaults to the lowest frequency depending on target device.
MUX_CONFIGURATION_PORTS	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2	ENABLE – Controls dynamic muxing of JTAG and IOs with JTAGEN. DISABLE (default) – Prevents the disabling of all configuration ports.
MY_ASSP	LatticeXP2, MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2	ON – For LatticeXP2 devices, causes the USERCODE to be used as a custom device ID. For MachXO2, MachXO3D, and MachXO3L devices, changes the JTAG IDCode of the device to the contents of the CUSTOM_IDCODE field. OFF (default) - Uses the regular Lattice device ID code.
ONE_TIME_PROGRAM	LatticeXP2, MachXO2, MachXO3D, MachXO3L, Platform Manager 2 except MachXO3D	ON – Protects the Flash memory from erasure or reprogramming. OFF (default) – Allows erasure and programming of the Flash memory.
PERSISTENT	LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeXP, LatticeSC/M	When using the sysCONFIG port, this keyword must be set to ON (except for LatticeECP3 devices) to reserve the dual-purpose pins for configuration. The ON option lets the software know that all the dual purpose configuration pins will NOT be available for the fitter to use. For LatticeECP3 devices, the SLAVE_PARALLEL option reserves all sysCONFIG pins; and the SSPI option reserves only the slave SPI port.
POR	MachXO2	ON (default) – Statically enables power-on reset when BANDGAP is turned on. OFF – Disables this preference.
PRIMARY_BOOT	MachXO3D	Sets the silicon boot option. IMAGE_0 (default) - for boot from CFG0/UFM0 IMAGE_1 - for boot from CFG1/UFM1 EXTERNAL - for external boot LATEST - during the dual internal boot, selects the last loaded bitsteam first FORMER - during the dual internal boot, selects the first loaded bitstream

Table 22:

Preference Name	Supported Devices	Description
SDM_PORT	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2	Self-download mode port. DISABLE (default) – Permits the SDM pins to be used as regular I/O pins. PROGRAMN – Retains the PROGRAMN pin as a dedicated SDM pin. PROGRAMN_DONE – Retains the PROGRAMN and DONE pins as dedicated SDM pins. PROGRAMN_DONE_INITN – Retains the PROGRAMN, DONE, and INITN pins as dedicated SDM pins. DONE - Retains the DONE pin as dedicated SDM pin. INITN - Retains the INITN pin as dedicated SDM pin.
SECONDARY_BOOT	MachXO3D	Sets the silicon boot option. NONE (default) - for single boot IMAGE_0 - for boot from CFG0/UFM0 IMAGE_1 - for boot from CFG1/UFM1 EXTERNAL - for external boot LATEST - during the dual internal boot, selects the last loaded bitsteam first FORMER - during the dual internal boot, selects the first loaded bitstream
SFDP_CHECK	MachXO3D	Check for Serial Flash Discoverable Parameter. DISABLE (default) - no SFDP check ENABLE_SFDP - SFDP checks and stops when SFDP fails ENABLE_SFDP_PREAMBLE - SFDP checks and continues PREAMBLE when SFDP fails.
SHAREDEBRINIT	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2	ENABLE – Allows sharing of the same init file used by multiple EBRs. DISABLE (default) – Does not allow sharing of the init file.

Table 22:

Preference Name	Supported Devices	Description
SLAVE_IDLE_TIMER	MachXO3D	Sets the Slave Idle Timer count value. 0 (default) - Infinite (disabled) 1 - 128,000 Ms 2 - 64,000 Ms 3 - 32,000 Ms 4 - 16,000 Ms 5 - 8,000 Ms 6 - 4,000 Ms 7 - 2,000 Ms 8 - 1,000 Ms 9 - 640 Ms 10 - 320 Ms 11 - 160 Ms 12 - 80 Ms 13 - 40 Ms 14 - 20 Ms 15 - 10 Ms
SLAVE_PARALLEL_PORT	ECP5	ENABLE – Makes the 8-bit slave parallel port available after configuration. DISABLE (default) – Prohibits the 8-bit slave parallel port from accessing the SRAM after configuration and allows the dual purpose pins to be used as general purpose IO's.
SLAVE_SERIAL_PORT	LatticeECP4U/M	ENABLE – Makes the slave serial port available after configuration. DISABLE (default) – Prohibits the slave serial port from accessing the SRAM after configuration, and allows the dual purpose pins to be used as general purpose IO's.
SLAVE_SPI_PORT	ECP5, LatticeXP2, MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2	ENABLE (default) – Allows on-chip Flash to be programmed and read back using the external Slave SPI port. DISABLE – Prohibits the use of the external Slave SPI port for on-chip Flash programming.
SPIM_ADDRESS_32BIT	MachXO3D	Extends the SPIM address. DISABLE (default) - 24-bit SPIM address ENABLE - 32-bit SPIM address
STRTUP	LatticeECP3	EXTERNAL (default) | TCLK | CCLK | MCLK Specifies the clock source to be used for synchronization with the start-up sequence.

Table 22:

Preference Name	Supported Devices	Description
SYSTEM_JITTER	All	Specifies the peak-to-peak system jitter for timing analysis. The value specified overwrites the default value. It should not be smaller than the default value for the device.
TEMPERATURE	All	Assigns an operating junction temperature for the part that changes the derating factor for timing.
TRACEID	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2	Specifies a code for storing device data, much like USERCODE but in binary format.
TRANSFR	ECP5	OFF (default) – Leaves the Freeze_IO and Freeze_MIB fuses off and disables the TransFr function. ON – Turns on the Freeze_IO and Freeze_MIB fuses to enable the TransFR function.
UNIQUE_ID	ECP5	Defines the upper sixteen bits of an automatic 32-bit USERCODE that will be used to identify the design.
USERCODE	All	Enter binary, hex, or ASCII values to program the Usercode bits. **Note**: The use of CHECKSUM as USERCODE is supported for LatticeXP2 devices. AUTO format, which enables UNIQUE_ID, is supported for ECP5 devices.
USERCODE_FORMAT	All	Specifies selected format of USERCODE. The available formats are Hex, Binary (default), and ASCII.
VOLTAGE	All	Assigns a value for nominal FPGA core voltage
WAKE_ON_LOCK	LatticeXP2, LatticeECP3	Determines whether the device will wait for the PLL to lock before beginning the wake-up process. OFF (default) – the device will wake up regardless of the state of the PLL lock signal. ON – the device will not wake up until the PLL lock signal for the given PLL is active.
WAKE_UP	ECP5, LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeXP, LatticeXP2, LatticeSC/M	Specifies the wake-up sequence. The default value is determined by the DONE_EX setting. DONE_EX = OFF: defaults to 21 and ranges between 1 and 25 DONE_EX = ON: defaults to 4 and ranges between 1 and 7

UGROUPs

A universal group (UGROUP) is a group of logical components that are to be packed close together. A UGROUP instructs the mapper not to pack unrelated logic into the same block. The UGROUP will be translated by the mapping process to a placement group (PGROUP) in the physical preference file (.prf), giving instructions to the placer to place the components in close proximity to each other. These groups are for mapping and placement only; they have no direct timing influence. See "DEFINE GROUP" on page 1213 for a different type of group that is usable for timing constraints.

Note

The Diamond preference views do not support the creation or editing of PGROUPs.

UGROUPs can be defined in the logical preference file (.lpf) or in the HDL source.

UGROUPs can include anchored or floating PFU, PFF, and EBR blocks, which can be bounded or unbounded. UGROUPs that include DSP blocks must be anchored. If a floating UGROUP includes a DSP block in the .lpf file, the system will issue a warning and ignore the block during mapping, placement and routing.

UGROUPs in the Logical Preference File

You can create or edit UGROUPs manually with a text editor using the ASCII .lpf file and the UGROUP preference syntax. You can also create UGROUPs using the Diamond preference views. UGROUPs from the HDL source are displayed in Spreadsheet View. If the UGROUPs are anchored (bounded or unbounded), they will also be displayed in Floorplan View. After being modified and saved, they will appear in the .lpf file. Use any of the following methods to create or edit UGROUPs:

- In the Group sheet of Spreadsheet View, create a new UGROUP and add instances; or modify an existing UGROUP.
- In Netlist View, create a new UGROUP from selected instances.
- In NCD View, create a new UGROUP from selected instances.

- In Floorplan View, draw a new UGROUP bounding box and add instances; modify an existing UGROUP; or create a new UGROUP from selected routed instances.

When you issue the “Save” command from any preference view, Diamond writes the new and modified UGROUPs to the currently active .lpf file.

UGROUPs in the HDL

Two main logical group preferences are available as attributes in the HDL and are displayed in the Group sheet of Spreadsheet View after the Translate Design process. They include:

UGROUP – The UGROUP attribute is used in the HDL for grouping components within hierarchies or across hierarchies. When you run the Translate Design process and open the design in Spreadsheet View, you will see these groups listed in the Group preference sheet. If you modify and save these groups, they will also appear in the .lpf file.

HGROUP – The UGROUP attribute is almost always the type of logical group that is used. However, the HGROUP attribute (also referred to as hierarchical group), can be used for grouping components within a module that is to be instantiated multiple times. During synthesis, the HGROUP is expanded into individual instances. Each instance is then displayed as a unique UGROUP in the Group sheet of Spreadsheet View. After you modify these groups and save the design, they will appear in the .lpf file. HGROUPS are not commonly used, and their functionality can be duplicated by assigning UGROUPs with a distinct name to each instance.

Note

The Diamond preference views do not support the creation or editing of HGROUPs.

Logical groups specified in the HDL design file are displayed in the Group sheet of Spreadsheet View. However, logical groups that are created in the Spreadsheet View are kept in the post-synthesized logical preference file (.lpf) and are not back annotated to the HDL design file.

Note

HDL groups that are modified and saved in Diamond are added to the .lpf file. Afterwards, the .lpf file takes precedence. If you want the original HDL preference to be honored, you must delete the conflicting preference in Diamond or you must delete it directly from the .lpf file using a text editor.

See Also ▶“Preferences for Floorplanning” on page 381

- “Creating UGROUPs” on page 507

Preference Conflict Resolution

When more than one preference is ascribed to a single design element, some preferences will take precedence over others, depending on the level of specificity, the order of the conflicting preferences, and redundancy between the HDL source and the logical preference file (.lpf). The software resolves such conflicts by adhering to the following rules of precedence:

- Timing preferences that have a higher priority than others take precedence when the same design objects are constrained in two or more preferences. For example, the higher-priority BLOCK preference takes precedence over the lower-priority MULTICYCLE preference.

  See "Timing Preference Priority" on page 393

- When more than one preference applies to a net or path, more specific preferences are honored before less specific ones. For example, individual net/path preferences supersede group (bus) preferences, and group preferences supersede global preferences.
- When more than one preference at the same specificity level exists for a block/comp/net/path, the preference that occurs last in the preference file takes precedence.

  Note

  MAXDELAY PATH (FROM/TO) preferences will supersede ALLPATHS, PERIOD, or FREQUENCY preferences where possible.

- When an attribute in the HDL conflicts with a preference in the logical preference file, the preference in the .lpf file has precedence. For example, when a given register is included in both a UGROUP attribute and a logical preference definition, the logical preference is honored.

  See "Conflicting HDL Attributes, Constraints, and Preferences" on page 399 and "Conflicting IOBUF Constraints" on page 396

- HGROUPs and UGROUPs in the HDL do not appear in the .lpf unless they have been modified and saved to the .lpf file. Afterwards, the groups in the .lpf file take precedence over those in the HDL. Conversely, logical groups created in the Diamond preference views are kept in the .lpf file and are not back annotated to the HDL design file.
- When two or more UGROUPs are identified with the same name in the .lpf file, the group that appears last is honored.
- When different UGROUPs in the .lpf file contain one or more of the same members, the UGROUP that appears last is honored.

Timing Preference Priority

The following list shows the priority of timing preferences, beginning with the highest priority BLOCK preference and ending with the lowest priority PERIOD/FREQUENCY preference:

1. BLOCK
2. INPUT_SETUP/CLOCK_TO_OUT

3. MULTICYCLE
4. MAXDELAY
5. PERIOD/FREQUENCY

In the following example, two preferences are assigned to port Q.

Figure 54:

```
MAXDELAY TO PORT "Q" 10 ns;
BLOCK PATH TO PORT "Q";
```

The BLOCK PATH TO PORT “Q” preference negates the MAXDELAY preference. The resulting TRACE Report (.twr) file lists both preferences:

Figure 55:

```
================================================================
   Preference: MAXDELAY TO PORT "Q" 10.000000 ns ;
               0 items scored, 0 timing errors detected.

  --------------------------------------------------------------------------------

================================================================

   Preference: BLOCK PATH TO PORT "Q" ;
    1 item scored, 0 timing errors detected.
  ----------------------------------------------------------
```

The TRACE report does not indicate that the MAXDELAY preference has passed the constraint requirements, and it was not scored. If you remove the BLOCK preference and retain just the MAXDELAY preference, the TRACE report will show that the preference passes the constraint of 10 ns.

For timing preferences with the same priority level, more specific preferences are honored over less specific ones. For example:

In this example, net W gets 10 ns because this preference is more specific than ALLNETS

Redundant Timing and I/O Assignments In the following timing preferences example, order and specificity determine the preference that will be honored.

In this example, the MAXDELAY priority is as follows:

- Net W gets 15 ns because this preference is more specific than BUS or ALLNETS and it comes after the 10 NS preference.
- Net X gets 25 ns because the BUS A preference is more specific than ALLNETS.
- Net Y gets 25 ns because the BUS A preference comes after the BUS B preference.

Figure 56:

```
================================================================
   Preference: MAXDELAY TO PORT "Q" 10.000000 ns ;
               1 item scored, 0 timing errors detected.
   ----------------------------------------------------------

Passed:  The following path meets requirements by 7.415ns

Logical Details:  Cell type  Pin type       Cell/ASIC name  (clock net +/-)

Source: FF         Q              Q_0io  (from CLK_c +)
      Destination:    Port       Pad            Q

Delay: 2.585ns  (66.8% logic, 33.2% route), 2 logic levels.

    Constraint Details:
2.585ns physical path delay d_MGIOL to Q meets
         10.000ns delay constraint by 7.415ns

    Physical Path Details:

Name    Fanout   Delay (ns)          Site               Resource
   C2OUT_DEL   ---     0.384   IOL_T24A.CLK to  IOL_T24A.INFF d_MGIOL (from CLK_c)
   ROUTE         1     0.858  IOL_T24A.INFF to      B14.PADDO Q_c
   DOPAD_DEL   ---     1.343      B14.PADDO to        B14.PAD Q
                     --------
                       2.585   (66.8% logic, 33.2% route), 2 logic levels.

  Report:    2.585ns is the maximum delay for this preference.
```

Figure 57:

```
MAXDELAY NET W 10 NS;
MAXDELAY ALLNETS 30 NS;
```

Figure 58:

```
MAXDELAY NET W 10 NS;
MAXDELAY ALLNETS 30 NS;
DEFINE BUS B NET Y NET Z;
DEFINE BUS A NET Y NET X NET W;
MAXDELAY BUS B 20 NS;
MAXDELAY BUS A 25 NS;
MAXDELAY NET W 15 NS;
```

- Net Z gets 20 ns because the BUS preference is more specific than ALLNETS.
- All other nets get 30 ns.

Note

MAXDELAY PATH (FROM/TO) preferences will supersede ALLPATHS, PERIOD, or FREQUENCY preferences if possible.

You can relax a global delay constraint with a more specific constraint under most conditions. For example, assume that there is a period preference of 50 ns on CLKB, which dictates that the maximum delay from STARTPOINT to ENDPOINT be 50 ns. You want to relax the period from STARTPOINT to ENDPOINT to 100 ns. To do this, you must define the STARTPOINT and the ENDPOINT, and then you must use the MAXDELAY FROM/TO preference.

Conflicting IOBUF Constraints

IOBUF constraints can sometimes conflict with one another, especially when they appear in both the HDL and the .lpf file or when they are used for individual ports as well as port groups. When there are conflicting IOBUF constraints, the following rules of precedence apply.

Attributes in the HDL and LPF for the Same Port or Port Group When conflicting IOBUF attributes exist in the .lpf file and in the HDL for the same port or port group, those in the .lpf file will take precedence.

Beginning with Diamond 3.2, IOBUF attribute changes that you make in Spreadsheet View for a specific port or port group will be combined with non-conflicting attributes that exist in the HDL for the same port or port group. When you save the changes, the combination will be recorded in the .lpf file.

For example, the HDL source assigns the following to Port A:

input A /* synthesis IO_TYPE=LVCMOS18 PULLMODE=UP LOC=12 */;

You open Spreadsheet View's Port Assignments sheet and change IO_TYPE to LVCMOS33 and set CLAMP to ON for Port A. When you save the changes, Diamond combines the non-conflicting HDL attributes with the Spreadsheet View changes and records them in the .lpf file as follows:

```
IOBUF PORT "A" CLAMP=ON IO_TYPE=LVCMOS33 PULLMODE=UP ;
```

The non-conflicting PULLMODE attribute from the HDL is added to the .lpf file, as is the CLAMP attribute that was set in Spreadsheet View. The LVCMOS18 IO_TYPE from the HDL is replaced by LVCMOS33 from Spreadsheet View.

The LOC=12 pin assignment from the HDL does not appear in the .lpf file, because it is a placement constraint. If you had changed the pin assignment to pin 14 in Spreadsheet View and saved it, it would appear in the .lpf file as a separate preference: `LOCATE COMP "A" SITE "14" ;`

When you set new IOBUF preferences manually using a text editor, conflicting IOBUF attributes in the .lpf file will completely override the HDL attributes for the same port or port group when the design is mapped. The exceptions to this rule are IO_TYPE and the placement constraint LOC.

- An IO_TYPE attribute that exists in the HDL will be honored unless the .lpf file contains an IO_TYPE constraint for the same port or port group.

- Beginning with Diamond 3.1, the placement constraint LOC does not get overridden by an IOBUF preference for the same port or port group unless it is redefined by a LOCATE preference in the .lpf file. See "Migrating Designs from Previous Releases" on page 398.

ALLPORTS Attribute and HDL Attributes All IOBUF attributes that exist in the HDL will get overridden by the Map process when the ALLPORTS attribute is used in the .lpf file. The one exception is IO_TYPE, which will be maintained unless the ALLPORTS attribute specifies a different IO_TYPE.

For example, the HDL source assigns PULLMODE=UP for Port A. Later, in Spreadsheet View, the IO_TYPE in the All Ports row is changed from LVCMOS25 to LVCMOS33. When the design is placed and routed, all of the ports are given the LVCMOS33 IO_TYPE, including Port A. But the PULLMODE for Port A reverts to DOWN, which is the default setting. The only way to return to the original PULLMODE=UP for Port A is to change it in the .lpf file and rerun Map and Place & Route.

When you use ALLPORTS in the .lpf file to make global IOBUF assignments, make sure that you move any existing HDL IOBUF assignments to the .lpf file.

Conflicting LPF Attributes for the Same Port or Group When two IOBUF preferences appear in the .lpf file for the same port or group, the one that occurs last will be honored and will override the one that appears earlier. The one exception is IO_TYPE, which be maintained unless the preference that occurs later specifies a different IO_TYPE. See "Combining Multiple IOBUF Preferences" on page 398.

For example, the following preferences for Port A appear in two different places in the .lpf file:

```
IOBUF PORT "A" SLEWRATE=SLOW PULLMODE=DOWN;

IOBUF PORT "A" SLEWRATE=FAST;
```

When the design is mapped, the SLEWRATE=FAST preference, which appears last, will be honored. The earlier preference will be completely overridden, which means that PULLMODE will revert to the default setting.

Conflicting LPF Attributes Between Ports, Groups, and ALLPORTS When the .lpf file contains IOBUF preferences that conflict among one or more ports, groups, and/or ALLPORTS, the more specific IOBUF preference takes precedence and will override the less specific preference. The one exception is IO_TYPE, which will be maintained unless the more specific preference specifies a different IO_TYPE.

For example, the following preferences show conflicting IOBUF attributes between Port A and a port group that includes Port A.

In the above example, a wildcard (A*) has been used to select ports for the "iogroup" port group, including Port A. When the design is mapped, the

```
DEFINE PORT GROUP "iogroup" "A*";
IOBUF GROUP "iogroup" IO_TYPE=LVCMOS33 PULLMODE=UP;
IOBUF PORT "A" IO_TYPE=LVCMOS18 CLAMP=OFF;
```

attributes for the more specific IOBUF Port A preference will be honored: IO_TYPE=LVCMOS18 and CLAMP=OFF.

In the following example, there is a conflict between the IOBUF preference for ALLPORTS and the IOBUF preference for Port A.

```
IOBUF ALLPORTS PULLMODE=UP;
IOBUF PORT "A" SLEWRATE=SLOW;
```

When the design is mapped, the more specific IOBUF preference for Port A will be honored. SLEWRATE will be set to SLOW for Port A, and the PULLMODE setting will revert to the default setting.

In the following example, there is a conflict between the IOBUF preference for ALLPORTS and the IOBUF preference for the “iogroup.”

```
IOBUF ALLPORTS IO_TYPE=LVCMOS33 CLAMP=ON;
IOBUF GROUP "iogroup" PULLMODE=UP;
```

When the design is mapped, only the IO_TYPE will be maintained from the ALLPORTS preference. PULLMODE will be set to UP for all ports in the “iogroup,” and CLAMP will revert to the default setting.

Migrating Designs from Previous Releases A design that was created with an earlier Diamond version might be affected by the following precedence rule change in Diamond 3.1:

- An IO_TYPE attribute in the .lpf file is no longer honored when there is a subsequent IOBUF preference in the .lpf file for the same port or port group. The IO_TYPE from the preference that appears first will either revert to the default or to one specified in the preference that appears last.
- A LOC attribute in the HDL will be honored. It will not get overridden by an IOBUF preference as long as there is no LOCATE preference for the same port or port group in the .lpf file.
- A BANK attribute in the HDL will be honored. It will not get overridden by an IOBUF preference as long as there is no IOBUF BANK preference for the same port or port group in the .lpf file.

When you use a design that was created in an earlier version, make sure that you move constraints from the HDL into the LPF file for the IOBUF attributes that you want to maintain.

Combining Multiple IOBUF Preferences When you have multiple IOBUF preferences in the .lpf file for the same port or port group, make sure that you combine them into one preference.

For example, the following two preferences appear in the .lpf file:

```
IOBUF PORT "a" IO_TYPE=LVTTL33 PCICLAMP=ON;

IOBUF PORT "a" PULLMODE=DOWN;
```

Except for the IO_TYPE, the second of these preferences, which appears last in the .lpf file, will override the first preference. This means that the PCICLAMP=ON will revert to the default OFF setting when the design is mapped. To maintain the PCICLAMP=ON setting, simply combine these two preferences into one.

```
IOBUF PORT "a" IO_TYPE=LVTTL33 PULLMODE=DOWN PCICLAMP=ON;
```

See Also ▶"Conflicting HDL Attributes, Constraints, and Preferences" on page 399

- "Defining I/O Defaults" on page 473
- "Defining Port, Cell, and ASIC Groups" on page 504

Conflicting HDL Attributes, Constraints, and Preferences

Using a combination of HDL attributes and preferences is a powerful technique for constraining the implementation tools. However, it is possible to introduce a combination of HDL attributes and logical preferences that are redundant and in conflict with each other. When such conflicts occur, the preference in the .lpf file takes precedence.

Conflicting Pin Assignments: When there is a conflicting pin assignment between the HDL and the preference file, the assignment in the preference file will take precedence. For example, SPI_PIN_D has a LOC attribute of W25 in the source file. Later, in Spreadsheet View, the pin is assigned to site U21 and saved to the .lpf file. When the design is placed and routed, the U21 location is honored instead of the W25 assignment. The only way to return to the original W25 site assignment is to delete the LOCATE preference from the .lpf file.

The following is an HDL example of conflicting pin assignments:

Input SPI_PIN_D /* synthesis LOC = "W25" */;

The following is an LPF example of conflicting pin assignments, which overrites HDL:

LOCATE COMP "SPI_PIN_D" U21; (this is LPF, it over-rides HDL))

The same is true for IOBUF attributes. For example, the HDL assigns “my_signal” to L5 with OPENDRAIN set to ON. Later, OPENDRAIN is changed to OFF in Spreadsheet View. The pin assignment remains at L5, and the OPENDRAIN setting of OFF is honored.

See “Conflicting IOBUF Constraints” on page 396

Redundant UGROUP Declarations In the following example, two group preferences with the same name contain different members:

Figure 59:

```
UGROUP "Group_0"
    BLKNAME reg0
    BLKNAME reg1;
UGROUP "Group_0"
    BLKNAME reg2
    BLKNAME reg3;
```

When the design is mapped, the first occurrence of Group_0, with members reg0 and reg1, is ignored. Warnings will appear in the output log and in the map report.

The following example contains two group preferences with different names that contain the same members.

Figure 60:

```
UGROUP "Group_1"
    BLKNAME reg6
    BLKNAME reg7;
UGROUP "Group_2"
    BLKNAME reg6
    BLKNAME reg7;
```

When the design is mapped, Group_1 is ignored because its members conflict with the membership declared in Group_2 that appears second. Warnings will appear in the output log and in the map report.

Conflict between UGROUP and LOCATE COMP The following example contains a combination of group and location preferences that conflict:

Figure 61:

```
UGROUP "Group_0" BBOX 9 9
  BLKNAME I1
  BLKNAME I2;
LOCATE UGROUP "Group_0" SITE "EBR_R36C6" ;
LOCATE COMP "I1/pdp_ram_0" SITE "EBR_R36C22" ;
```

The Group_0 contains two blocks of the design. One element of block I1, an embedded block RAM (EBR) named pdp_ram_0, is placed at a specific EBR device site (EBR_R3C22) using the LOCATE preference.

Because LOCATE is more specific than a UGROUP preference, when the place and route program encounters this condition, it honors the LOCATE preference. It does not necessarily place pdp_ram_0 in proximity to the other members of Group_0. No warnings or errors are generated.

The following example contains a member (ip_ram_dq_0_1_0) that has a LOCATE preference. This results in the removal of this member from the UGROUP during placement. The LOCATE preference for this member will not influence the placement of the other members of the UGROUP, because this member has been removed from the UGROUP.

Figure 62:

```
UGROUP "grp1"
        BLKNAME ip_ram_dq_0_0_1
        BLKNAME ip_ram_dq_0_1_0;
LOCATE UGROUP "grp1" REGION "region_1" ;
LOCATE COMP "ip_ram_dq_0_1_0" SITE "EBR_R29C8" ;
```

The UGROUP “grp1” will continue to be put in “region_1”, but grp_1 now only has the single member: ip_ram_dq_0_0_1. The element ip_ram_dq_0_1_0 will be placed at site “EBR_R29C8”.

Redundant DEFINE GROUP Declarations Resolution of conflicting DEFINE GROUP preferences, such as port groups, is not handled consistently across all programs. The style of declaration shown in the following example should be avoided. It contains port groups that have the same name but contain different members.

Figure 63:

```
DEFINE PORT GROUP "Group_0"
"d0(0)"
"d0(1)" ;
DEFINE PORT GROUP "Group_0"
"d0(2)"
"d0(3)" ;
INPUT_SETUP GROUP "Group_0"INPUT_DELAY 5.000000 ns HOLD
3.000000 ns CLKPORT "CLK" ;
```

The first occurrence of Group_0 with members d0(0) and d0(1) is ignored by the preference views, however, the second occurrence of Group_0 with member d0(2) and d0(3) is ignored by the TRACE (trce) and PAR programs. Both groups are passed into the physical preference file by map. Ignored groups are not reported by the system in this example.

See Also ▶“The Logical Preference File” on page 373

▶ “The Physical Preference File” on page 403

Changes to Net Names Between Preferences and Reports

If you define certain preferences, such as a net name, and you re-run synthesis, the name of that net may be changed. If you have an opportunity to refer to a port versus a net, you should always use the port, because the name will be more constant from run to run.

If must specify a net, it's possible that the net name can change, so you must manage them.

One way specify net names is to specify those constraints through SDC. If a net constraint is specified in SDC, that constraint will get updated automatically by synthesis, because synthesis will write the logical preference file (.lpf) for each run. Refer to "Using SDC Constraints" on page 362.

In some instances, constrained net names in the logical preference file (.lpf) differ from those in the physical preference (.prf) file because optimization takes place during the mapping process. In most instances, the mapper honors the preference, althought it may change the net names in the .prf.

A message will be written to the output log when this happens to show each net name as it appears in the .lpf file and the conversion to the new name as it appears in the .prf file.

Net Names in the .lpf File For example, the following timing preferences appear in the .lpf file:

Figure 64:

```
MULTICYCLE FROM CLKNET "clk1_bn" TO CLKNET "clk2_dn" 6.000000
ns ;
INPUT_SETUP ALLPORTS 8.000000 ns CLKNET "clk1_cn" ;
INPUT_SETUP ALLPORTS 9.000000 ns CLKNET "clk2_dn" ;
CLOCK_TO_OUT ALLPORTS 10.000000 ns CLKNET "clk1_dn" ;
CLOCK_TO_OUT ALLPORTS 11.000000 ns CLKNET "clk2_bn" ;
```

Equivalent Net Names in the .prf File During the mapping process, nets get merged or optimized, and their equivalent nets are found and converted to the original preference. The preferences and equivalent nets then appear in the .prf file. For example:

Figure 65:

```
MULTICYCLE FROM CLKNET "clk1_in_c" TO CLKNET "clk2_in_c"
6.000000 ns ;
INPUT_SETUP ALLPORTS 8.000000 ns CLKNET "clk1_in_c" ;
INPUT_SETUP ALLPORTS 9.000000 ns CLKNET "clk2_in_c" ;
CLOCK_TO_OUT ALLPORTS 10.000000 ns CLKNET "clk1_in_c" ;
CLOCK_TO_OUT ALLPORTS 11.000000 ns CLKNET "clk2_in_c" ;
```

Net Names Matched in the Output Log To match up the net names shown in the .prf with those shown in the .lpf, open the **Output** log and scroll down to the “Optimizing” section. This section shows the net name that has been “clipped” for each preference and the new name that the preference has been moved to. For example:

Figure 66:

```
Optimizing...
Net clk1_bn is clipped. Preference MULTICYCLE on "clk1_bn" is moved to "clk1_in_c".
Net clk2_dn is clipped. Preference MULTICYCLE on "clk2_dn" is moved to "clk2_in_c".
Net clk2_dn is clipped. Preference INPUT_SETUP on "clk2_dn" is moved to "clk2_in_c".
Net clk2_dn is clipped. Preference USE SECONDARY on "clk2_dn" is moved to "clk2_in_c".
Net clk2_bn is clipped. Preference CLOCK_TO_OUT on "clk2_bn" is moved to "clk2_in_c".
Net clk1_dn is clipped. Preference CLOCK_TO_OUT on "clk1_dn" is moved to "clk1_in_c".
Net clk1_cn is clipped. Preference INPUT_SETUP on "clk1_cn" is moved to "clk1_in_c".
Net clk1_cn is clipped. Preference USE PRIMARY on "clk1_cn" is moved to "clk1_in_c".
```

Whenever the mapper does not find the equivalent net, it does not write a message to the Output file. Instead, it issues a warning in the Map Report file (.mrp). For example:

Figure 67:

```
WARNING: Net "net_a" is clipped. Preference INPUT_SETUP on
"net_a" is ignored.
```

The Physical Preference File

The physical preference file (.prf) is an ASCII output of the Map Design process. Preferences saved in the logical preference file (.lpf) are written to the native circuit description (.ncd) and to the .prf file during the map process. The map process rewrites the physical preference file each time it is executed. The .prf file is used as an input file to placement and routing and TRACE.

Note

A physical preference file should never be saved as an .lpf file, because a .prf file is quite different. A .prf file saved as an .lpf file will not perform as expected.

In the Diamond flow, the .prf file is considered a background file and is not visible in the File List. Though the .prf file can be opened from the project directory, its use for modifying preferences is no longer necessary and not recommended in most cases. You can use a Timing Preference File (.tpf), available from Timing Analysis View, to experiment with timing preferences and view the analysis without having to remap the design. But if you edit physical preferences in the .prf file, they will be inconsistent with logical ones in the .lpf, and they will be obsolete when mapping is rerun. It is better to define preferences in the logical preference file (.lpf) through the Diamond

preference views or with a text editor. This ensures that preference assignments in both the logical and physical domains stay in sync when the design is remapped.

Preferences from the .lpf file that have been modified or validated by map are listed inside the SCHEMATIC START and SHEMATIC END section, and they will be removed or replaced the next time the Map Design process is run. Preferences with syntax errors are preserved when the .prf file is read. Tools that write out preference files—for example, the Map Design process (map)—will automatically write the preserved preferences. Such a file, when read back in, will again produce syntax errors unless the erroneous preferences are corrected.

The .prf file can contain any number of preferences, both logical and physical, and any number of comments in any order. A comment consists of either a pound sign (#) or double slashes (//) followed by any number of other characters up to a new line. The program automatically comments out illegal preferences.

- "Setting Preferences" on page 457

Using Diamond's Preference Views

Diamond provides six views for editing design constraints known as preferences. These preference-editing views, which are available from the Diamond toolbar and Tools menu, include "Spreadsheet View" on page 406, "Package View" on page 424, "Device View" on page 429, "Netlist View" on page 430, "NCD View" on page 430, and "Floorplan View" on page 431.

Additionally, two read-only preference views are provided after placement and routing: "Physical View" on page 443, which enables you to view a more detailed layout of the design; and "Logic Block View" on page 445, which provides details of a selected block in schematic or tabular format.

Diamond's preference views enable you to develop constraints that will shorten turn-around time and achieve a design that conforms to critical circuit performance requirements. They enable you to perform the following tasks:

- Define timing constraints based on design signals and logic elements
- Define sysIO Buffer properties based on design signals
- Constrain clock signals to particular routing spines
- View, assign, and validate design signals and package pins
- Assign voltage reference pins
- Inspect the programming of design elements
- Group components and set REGIONs to help meet timing goals
- Cross-probe elements between physical and logical domains

- Perform DRC tests to ensure legal pin assignments or to detect incomplete or illegal conditions within the physical design database
- Generate simultaneous switching output (SSO) reports
- Back annotate post-route pin assignments to a logical preference file

See Also "Using the Zoom and Pan Tools" on page 452

Preference-Editing Views and Memory

Diamond provides six views for preference editing: Spreadsheet View, Device View, Package View, Netlist View, NCD View, and Floorplan View. Each of these views operates on preference access data that is stored in memory and shared across all six views. As soon as you create or modify a preference in one preference view, it is reflected immediately in all open preference views and in the status bar. When there are preference changes in memory, the tab of each open preference view is marked with an asterisk, and the status bar displays "Preferences Modified" on the bottom right.

Because of the shared memory between all preference-editing views, closing one or even all views does not delete the unsaved changes from memory, and you will not be prompted to save when you close a view. Diamond's status bar will always display "Preferences Modified" when you have unsaved preference changes, even when all preference views are closed.

Saving In-Memory Preference Changes You can save in-memory preference changes from any of the preference-editing views, with the exception of NCD View. When you issue the "Save" command, Diamond writes all of the preference changes stored in memory to the logical preference file, regardless of the preference views that were used for editing. The asterisks and the "Preferences Modified" indicators disappear as soon as you save the changes.

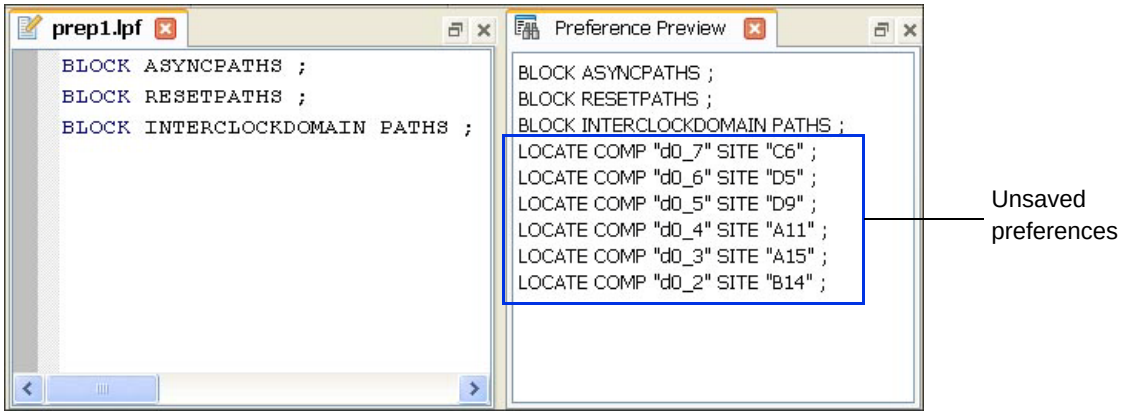
Diamond will prompt you to save in-memory preference changes each time you run a process, close the project, clear the tool memory, or exit Diamond.

Keeping Track of Unsaved Preferences Preference Preview is useful for keeping track of unsaved preference changes. Preference Preview lists all preferences that are already saved in the .lpf file, followed by the preferences that are in memory only. You can open the .lpf file, as well as Preference Preview, to do a side-by-side comparison.

See Also "Discarding In-Memory Preference Changes" on page 547

- "The Logical Preference File" on page 373
- "Previewing Preferences Before Saving" on page 545
- "Saving Preferences" on page 544

Figure 68:



Note

Preference Preview does not show unsaved changes that have been made manually to the .lpf file.

Spreadsheet View

Spreadsheet View provides a tabular format for viewing and assigning logical preferences. It displays all preferences, including those that have been assigned from other preference-editing views. It also displays timing constraints that have been set in the synthesis tool.

As soon as you have specified the target device, you can use Spreadsheet View to set global preferences. After synthesis and translation, you can use all of the following preference sheets to create and modify constraints:

Port Assignments The Port Assignments sheet provides a signal list of the design and shows any pin assignments that have been made. All ports assigned in the Logical Preference File (.lpf) and in the Native Generic Description (.ngd) file are displayed.

By default, the ports are grouped by direction—Input, Output, and Bidirectional—plus an "Others" category that includes user-defined port groups. This allows you to quickly focus, for example, on Output ports by closing the display of Input ports or vice versa. If you prefer to display the port rows in a single un-grouped alphabetical list, clear the "Show Group Row(s)" selection from the View > Display Group Row(s) menu.

The Port Assignments sheet enables you to assign or edit pin locations and other attributes by entering them directly on the spreadsheet. It also allows you to assign multiple signals, by right-clicking the selected signals and opening the Assign Pins dialog box. Any assignment problems are indicated

with a warning icon ⚠ in the signal Name column. The warning icon will appear for any invalid I/O assignment or combination.

Note

The default I/O type is LVCMOS25. Make sure this setting matches the IO in your design.

Pin Assignments The Pin Assignments sheet provides a pin list of the device and shows the signal assignments that have been made. In the Dual Function column, pins that can be used for I/O assignments or for another function, such as Vref, are identified.

By default, the rows of pins are grouped by bank number. You can also view the differential pin pair groupings within each bank by selecting "Show Differential Group Row(s)" from the View > Display Group Row(s) menu. To view the group of non-assignable pins, select "Show Non-user Assignable Pin Row(s)." If you prefer to display the rows of pins in a single un-grouped alphabetical list, clear the "Show Group Row(s)" selection from the View > Display Group Row(s) menu.

The Pin Assignments sheet enables you to edit signal assignments or assign new signals by right-clicking selected pins and opening the Assign Signals dialog box.

Clock Resource The Clock Resource sheet enables you to apply a clock domain to the device's primary or secondary clock or prohibit the use of primary and secondary clock resources to route the net. For LatticeECP2 devices, it enables you to use edge clock resources. For LatticeECP3 devices, it enables you to assign a secondary clock to a clock REGION that has been defined.

Route Priority The Route Priority sheet enables you to set the PRIORITIZE preference, which assigns a weighted importance to a net or bus. To set this preference, drag the desired nets from Netlist View to the Route Priority sheet. You can then select a priority value for each net. Values range from 0 to 100.

Cell Mapping The Cell Mapping sheet enables you to set the USE DIN and USE DOUT cell preferences for flip-flops in your design. The PIO Register column allows you to set the register to True or False. The True setting moves registers into the I/Os. The False setting moves registers out of the I/Os. To set these preferences, drag the desired registers from Netlist View to the Cell Mapping sheet.

Global Preferences The Global Preferences sheet enables you to set preferences that affect the entire design, such as junction temperature and voltage; BLOCK preferences applied to all paths of a particular type; and USERCODE. Also included in the Global sheet are sysCONFIG preferences for FPGA devices that support the sysCONFIG configuration port.

Timing Preferences The Timing Preferences sheet displays all timing preferences that have been set in the design, including BLOCK preferences

for specific nets, FREQUENCY, PERIOD, INPUT_SETUP, CLOCK_TO_OUT, MULTICYCLE, and MAXDELAY. It displays, in green font, the timing constraints that have been set in the synthesis tool and allows you to modify them and save the modified constraints to the .lpf file as preferences. You can create a new timing preference by double-clicking the preference name, which opens the dialog box. To modify an existing timing preference, double-click the preference name, edit the information in the dialog box, and click the Update button.

Group The Group sheet displays any groups that have been created and enables you to define a new cell, port, or ASIC group or create a new universal group (UGROUP). Double-click the group type to open the dialog box and create a new group preference. To modify an existing group preference, double-click the group name, edit the information in the group dialog box, and click the Update button.

Misc Preferences The Miscellaneous sheet enables you to define REGIONs, assign Vref locations, and reserve resources by setting a PROHIBIT preference. To set a new miscellaneous preference, double-click the preference type to open the dialog box. To modify an existing miscellaneous preference, double-click the preference name, edit the information in the dialog box, and click the Update button.

How Constraints are Recorded in Spreadsheet View

Spreadsheet View presents the union of constraints that originate from the HDL or schematic source or from the logical preference file (.lpf). Each cell of the preference sheet is color-coded to reflect the origin or status.

If any default, referenced, or HDL-based source constraint is modified, Diamond will add a preference to the .lpf file to record the change. Since preferences in the .lpf file have precedence over other constraint sources, the design mapper will ignore any conflicting constraints when the design is implemented. Diamond does not overwrite the original HDL or schematic constraint declaration. To restore the original constraint, you must delete the preference in the .lpf file.

Many preferences have one or more parameters. It is possible, therefore, to assign one parameter in the HDL or schematic source and another parameter

for the same preference in Spreadsheet View. Except for IOBUF attributes, Diamond will write the union of all parameters to the .lpf file. For IOBUF attributes that exist in the .lpf file and in the HDL for the same port or port group, those in the .lpf file will completely override those in the HDL. The exception to this rue is IO_TYPE and the placement constraint LOC, which will not get overriden.

For example, the IOBUF preference includes the parameter PULLMODE for an I/O port. Given a schematic-based IO_TYPE=LVCMOS12 attribute for the I/O port, if the PULLMODE parameter is modified within Spreadsheet View to PULLMODE=NONE, the following preference will appear in the .lpf file:

```
IOBUF PORT "my_signal" IO_TYPE=LVCMOS12 PULLMODE=NONE;
```

This IOBUF preference combines the IO_TYPE attribute from the source file with the new PULLMODE parameter that was made in Spreadsheet View.

See Also ▶"Conflicting HDL Attributes, Constraints, and Preferences" on page 399

- "Conflicting IOBUF Constraints" on page 396

Color Coding of Cell Values

The original font colors of cell values in Spreadsheet View are blue, gray, black, orange, green, and maroon. These colors, which can be changed in the Options dialog box, are based on the status of the cell values: default value, read-only value, modified (normal) value, referenced value, source value, or schematic value. The following descriptions explain the original color coding of these values.

- Blue font – Blue represents the default value of a preference. For example, the NONE value of PULLMODE for an HSTL I/O type is displayed in blue. Default values can be modified but not deleted.

  Blue also represents a value that is automatically assigned by the place & route process and written to the .ncd file. These values are displayed inside parentheses to distinguish them from default values.

- Gray font – Gray represents a read-only value, one that cannot immediately be changed. For example, the N/A value in the Vref column is displayed in gray when no Vref pin has yet been set or when Vref is not available for the selected I/O type. Gray also distinguishes pins that cannot be used as general-purpose I/Os.

- Black font – Black is the normal font color for a new or edited preference and represents a modified value, which can be a value that has been saved to the logical preference file (.lpf). For example, pin assignments made in the Port Assignments sheet and Block preferences made in the Global Preferences sheet are displayed in black. Modified values can be changed to the default value and font color, or to no value, by pressing the Delete key.

- Orange font – Orange represents a value for an element that is referenced by another preference. For example:

- If a port is a member of an IOBUF GROUP that has a Vref assignment, the port's Vref cell value will be displayed in orange unless it has been individually modified.
- If the Allports I/O Type is modified, the I/O type for all ports that have not been individually modified will be displayed in orange.

Referenced values can be modified but not deleted.

- Green font – Green represents the value from the design source. For Spreadsheet View, the source is the native generic database file (.ngd), which includes preferences from the HDL source code or EDIF file. The .ngd file also includes default configuration preferences, which appear in the Global Preferences sheet; and I/O types, which appear in the Port Assignments sheet. All of these source values from the .ngd file are displayed in green. Source values can be modified but not deleted.
- Maroon font – Maroon represents a value from a schematic source file. Schematic values can be modified but not deleted.
- Green font – Green represents a value from a timing constraint that was set in the synthesis tool. These SDC constraints are output to a synthesis .lpf file when the design is synthesized, and they are displayed in the Timing Preferences sheet when the strategy option "Use LPF Created from SDC in Project" has been enabled. By default, this option is set to True. Synthesis constraint values can be modified and saved as preferences, but not deleted. When you modify a synthesis constraint value and save it, the constraint is converted to a timing preference and saved to the active .lpf file.

Display of Incompatible Pins If you have selected a different device of the same family and package for possible pin migration, the rows of any incompatible pins will be dimmed on the Pin Assignments sheet.

Working with Preference Sheets

Spreadsheet View provides nine spreadsheets for setting and editing preferences. Preference values in spreadsheets are displayed in font colors based on their origin or status, and invalid values are highlighted in red.

The following techniques are useful for editing and viewing preferences in Spreadsheet View.

Enter data into table cells You can enter data into the table cells of Spreadsheet View in several ways:

- Double-click the cell that you want to edit.

  The cell changes to a drop-down menu or a text box, or it opens a dialog box, depending on the type of preference you are changing. You can then select from the menu, type a text entry, or select options and settings in the dialog box.

- Right-click the cell that you want to edit and choose from the pop-up menu. For a text entry, such as USERCODE, choose **Edit Cell** and type the string.

- To edit multiple cells at once, select the cells, right-click, and choose from the pop-up menu.

Cross-probe a signal assignment After a signal is assigned to a specific pin, you can cross-probe to Package View, Device View, Netlist View, or Floorplan View. After placement and routing, you can also cross-probe to NCD View.

To cross-probe a signal assignment:

- In the Port Assignments or Pin Assignments sheet, right-click the desired pin name or signal and choose the desired view from the **Show in** menu.

  The selected view is activated, and the pin is highlighted on the layout or design tree.

Sort a preference list You can sort a list on a preference sheet by a single column or more than one column.

By default, the ports on the Port Assignments sheet are sorted alphabetically within each group: input pins, output pins, bi-directional pins, and user-defined groups. Also by default, the pins on the Pin Assignments sheet are sorted alphabetically within each bank group. If you prefer to sort the rows based on a single un-grouped alphabetical list, clear the "Show Group Row(s)" selection from the View > Display Group Row(s) menu.

To sort a list by a single column:

- Select the desired preference sheet, and then click the heading of the column you want to sort.

  An up arrow is displayed in the heading, indicating that the list has been sorted by the column in ascending order. Click the heading again to sort the list in descending order.

To sort a list by more than one column:

1. In Spreadsheet View, select the desired preference sheet.
2. Choose **View >** **Sort**.
3. In the Sort dialog box, select the first column to sort by from the "Sort by" drop-down menu. Click **Ascending** or **Descending** to control the order of the sorted list.

4. Use the "Then by" boxes to select additional columns, as well as the **Ascending/Descending** option for each column. Click **More** to add more "Then by" menus if needed.

   The list will be sorted first by the column specified in the "Sort by" box and then by the additional columns in the "Then by" boxes in sequence.

5. Click **OK**.

Display an error or warning description Errors and warnings are highlighted with a triangular icon inside a cell.

To display the error or warning description:

- Hold your mouse pointer over the cell that contains the icon.

  A description of the error is displayed in a tool tip.

Change the font of cell values You can change the font style and size of information that is displayed in the spreadsheet cells.

To change the font of spreadsheet cells:

1. Choose **Tools > Options**.
2. In the Options dialog box, select **Spreadsheet View**, and then select **Font**.
3. Click the **Sheet Font** button, which shows the current font and size.
4. In the Select Font dialog box, select the desired font, style, and size and click **OK**.
5. Click **OK** to close the Options dialog box.

Adjust the font color of cell values The font colors of values in preference cells are based on their status: default value, read-only value, modified (normal) value, referenced value, source value, or schematic value. Refer to "Color Coding of Cell Values" on page 409 for default colors and detailed explanations of these values.

To change the font color of cell values:

1. Choose **Tools > Options**.
2. In the Options dialog box, select **Spreadsheet View**, and then select **Color**.
3. Click the color box for the type of value you would like to change.
4. Choose the desired color from the Select Color dialog box and click **OK**.
5. Click **OK** to close the Options dialog box.

Adjust columns You can adjust column widths manually or choose the right-click command to fit the column to the text.

To adjust the column width manually:

- Drag the vertical border on the right of a column heading.

When you fit the column width to the text, all the text in the column is displayed.

To fit a column to the text, do one of the following:

- Double-click the vertical border on the right of a column heading.
- Right-click the desired column heading and choose **Fit Column**.

To fit all columns to the text:

- Choose **View > Column > Fit All Columns** or press the **F5** function key.

Rearrange the positions of columns You can move the position of any editable column on the Port Assignments Sheet or Pin Assignments sheet.

To rearrange the position of an editable column:

1. On the Port Assignments or Pin Assignments sheet, hold down the column's heading with your mouse pointer.
2. Drag the heading to the left or right to the desired position, and then release the mouse button.

Hide and re-display columns You can hide a single column or select several columns that you want displayed or hidden.

To hide a single column:

- Right-click the desired column heading and choose **Hide Column**.

To hide several columns:

1. Choose **View > Column > Visible Columns** or press **Shift+F5** to open the Visible Columns dialog box.
2. Do one of the following:
   - In the "Show these Columns list," select the columns that you want to hide, and then click the single-arrow button to move them to the "Hide these Columns" list.
   - Click the double-arrow button to move all columns to the "Hide these Columns" list, and then select those you want displayed by selecting them and moving them to the "Show these Columns" list.
3. Click **Ok**.

To re-display some of the hidden columns:

- Press **Shift+F5**, and move the hidden columns back to the "Shows these Columns list."

To re-display all columns:

- Choose **View > Column > Fit All Columns** or press the **F5** function key.

Auto complete When you type an entry into a cell in the I/O Types column, the cell presents a list of matching values. You can then:

- Choose the first (or only) matching value by pressing **Enter**.
- Choose an alternate matching value by using the up/down arrow keys and then pressing **Enter**.
- Continue typing the rest of the value. If no matching value is found, nothing will be entered.

Edit a sequence of cells in a column Spreadsheet View enables you edit the cells in a column sequentially without moving your mouse. It does this by automatically moving the focus to the next cell.

To edit a sequence of cells:

1. Enter the data in a cell and press **Enter**.

   The cell below the edited one is activated.

2. Proceed to edit the data in the active cell, press **Enter**, and continue to the next cell until you have finished editing the cells in the column.

   You can also pass to the next cell without editing the current one by pressing **Enter**.

Delete cell contents You can clear cells of their new or edited contents in the Port Assignments, Pin Assignments, Clock Resource and Global Preferences sheets. When you do this, Diamond empties the cells of their contents or redisplays the default or referenced values.

To delete the edited values from one or more cells:

- Select the cells that you want to clear and do one of the following:
  - Press the Delete key.
  - Right-click the selected cell and choose **Clear** from the pop-up menu.
  - Choose **Edit > Clear**.

  Diamond empties the cells of any values or re-displays the default or referenced values.

Delete row contents You can delete the assignments from one or more selected rows on the Port Assignments sheet. For each cell in the selected rows, Diamond empties the contents, or it re-displays the default, source, or referenced value.

To delete the assignments in one or more rows:

- Select the rows that you want to clear, right-click, and choose **Clear Selected Row(s)**. Alternatively, choose **Edit > Clear Selected Row(s)**.

Across the columns of the selected rows, Diamond empties some cells. For others, it reverts to a referenced, source, or default value, as follows:

- a referenced value defined in a port group or in All Ports
- a source value defined in the .ngd file
- a default value defined in the legal combination table

Cut, copy, and paste cell contents You can cut or copy cell contents and paste them into other cells in the same column of a Port Assignments, Cell Mapping, Clock Resource, or Route Priority sheet.

To copy or cut and paste cell contents:

1. Select the cells that you want to cut or copy.
2. Choose **Edit > Copy** or **Edit Cut** or use the **Ctrl+C** or **Ctrl+X** shortcut.
3. Select the first cell in the column where you want to begin pasting the cell contents.
4. Choose **Edit > Paste** or use the **Ctrl+V** shortcut.

Use fill down/fill up editing Fill Down/Fill Up editing is supported in Port Assignments, Cell Mapping, Clock Resource, and Route Priority sheets. In these preference sheets, you can fill a range of cells within the same column by dragging down across cells or by using the Fill Down command.

To fill a range of cells by dragging:

1. Highlight the source cell which contains a valid value, and then move your mouse to the lower-right corner of the cell. The cursor changes to a cross symbol.
2. Drag the cross down over the range you want to fill.

   The destination cells are filled with the same value as in the source cell.

   Or

   If you are working with the Pin Location column, you can drag down to increment the pin numbers in the destination cells.

To fill a range of cells by using the Fill Down command:

1. Highlight the source cell together with the range of destination cells below it. The source cell must be at the top of the selected range and contain a valid value.
2. Choose **Edit > Fill Down** or press **Ctrl+D**.

   The destination cells are filled with the same value as in the source cell.

   Or

   If you are working with the Pin Location column, the destination cells will be filled with incremental pin numbers following the number specified in the source cell.

See Also ▶"Changing the Grouped Display of Ports and Pins" on page 416

- "Filtering the Display of Ports and Pins" on page 417
- "Adding Custom Columns" on page 418

Changing the Grouped Display of Ports and Pins

By default, the rows of ports and pins in Spreadsheet View are grouped by category. This grouped display allows you to easily view one category by closing others. For example, you can focus on Bidirectional ports by closing the Input and Output categories. Simply click the arrow in front of a displayed category to open or close it. When you sort one or more columns, the ports and pins are sorted alphabetically within each group.

On the Port Assignments sheet, all ports that are defined in the native generic description file (.ngd) and the logical preference fie (.lpf) are displayed. The rows are grouped by Input, Output, Bidirectional, and by "Other," a category that includes user-defined PIO groups and "Nonexistent" ports. Nonexistent ports are ports that do not exist in the .ngd file, even though they are defined in the logical preference file. You can delete a row for a port that exists only in the.lpf file by right-clicking and choosing "Delete Selected Row(s)." You also have the option of viewing differential pair groups for all LVDS ports that have been defined in the source file.

On the Pin Assignments sheet, the rows are grouped by Bank number, and you have the option of viewing differential pin pair groups within each bank. You can also view all non-assignable pins as a single group. Because the pins are grouped by bank, the BANK column does not appear on the Pin Assignments sheet when the grouped display is turned on. But you can view the BANK column by turning off the grouped display.

To view differential pair groups:

- On the Port Assignments sheet or Pin Assignments sheet, choose **View > Display Group Row(s) > Show Differential Group Row(s)**.

  Any LVDS ports that have been defined in the source are now displayed in differential groups on the Port Assignments sheet, and the rows displayed on the Pin Assignments sheet are organized by differential pin-pair groups within each bank.

To view the group of non-assignable pins:

- On the Pin Assignments sheet, choose **View > Display Group Row(s) > Show Non User-Assignable Pin Rows**.

  The Non User-Assignable category is added to the bottom of the sheet and includes rows for all pins that are not user-assignable.

You can also turn off the grouped display of ports and pins at any time in order to view each list as a single un-grouped alphabetized list.

To turn off the grouped display of ports and pins:

- On the Port Assignments sheet or Pin Assignments sheet, choose **View > Display Group Row(s) > Show Group Row(s)**.

All ports and pins are now listed in a single un-grouped alphabetized list.

Each of the View > Display Group Row(s) commands acts as a toggle key to turn the grouped display on or off. When the display is turned on, the menu item shows a check mark in front of it.

See Also "Filtering the Display of Ports and Pins" on page 417

"Adding Custom Columns" on page 418

Filtering the Display of Ports and Pins

Both the Port Assignments sheet and the Pin Assignments sheet enable you to filter each column so that only the row contents that you specify are displayed.

To filter the display of ports and pins:

1. On the Port Assignments or Pin Assignments sheet, right-click any column heading and choose **Filter > Enable Filter**.

   Each column heading now appears with a downward-pointing arrow on the right.

2. Click the arrow for the column that you want to filter.

   The filter dialog box opens and displays a list of the items that appear in the row contents for that column. By default, all items are selected.

3. Do one of the following to filter the list:

   - Clear the individual items that you do not want to appear on the spreadsheet.
   - Clear the Select All selection at the top, and then select the types of items that you want to appear on the spreadsheet.

4. Click **OK**.

5. Repeat Steps 2-4 for other columns that you want to filter.

   When you have finished, the spreadsheet displays the filtered contents. The row numbers are displayed in blue font, and a filter button  appears in the heading of each filtered column.

To edit a column's filtered list:

- Click the filter button and modify the selections in the filter dialog box.

To disable the filtering for a single column:

- Click the filter button and choose  **Clear Filter From** <column name>.

To disable the filtering for all columns:

- Right-click any column heading and choose **Filter > Disable Filter**.

See Also "Changing the Grouped Display of Ports and Pins" on page 416

▶ "Adding Custom Columns" on page 418

Adding Custom Columns

Spreadsheet View allows you to create custom columns on the Port Assignments sheet and the Pin Assignments sheet. Custom columns enable you to add your own information, such as notes for specific signals or pins or design data for third-party tools. You can create an unlimited number of custom columns, and you can include the column when you export to a Lattice CSV file or a Pin Layout File.

Custom columns can be added and edited at any stage of the design flow. Since custom columns are excluded from the generation of preferences, they do not cause a mapped implementation to get initialized back to pre-map status. The information is not added to the active logical preference file (.lpf) but is automatically saved with your project and made available for all implementations.

To add a custom column:

1. In Spreadsheet View, select the Port Assignments or Pin Assignments tab.
2. Right-click the column heading of any editable column and choose **Insert Custom Column**.
3. In the Custom Column dialog box, type a name for the column. The name must be unique to the selected preference sheet and must not conflict with a column heading that is built in to the Port Assignments sheet or the Pin Assignments sheets.

   Note

   Because the Port Assignments and Pin Assignments sheets act independently of one another, it is possible to use the same name for a custom column on each of these sheets. When you later export a pin layout file, Diamond will append "_port" or "_pin" to distinguish each custom column.

4. Click **OK**.

   The custom column appears on the spreadsheet. The column heading name is displayed in italic font to distinguish it as a custom column.
5. Enter the desired information into the cells of the custom column as desired.

   The custom column information is automatically saved with the project and is available for each implementation.

Editing a Custom Column You can edit or delete cell contents of a custom column, rename the heading, or remove the entire column.

To edit or delete a cell's contents:

▶ Double-click a cell, and then type a new value or press the Delete key.

To edit a custom column heading:

1. Right-click the custom column heading and choose **Edit Custom Column**.
2. Type a new name in the dialog box and click **OK**.

To remove a custom column:

- Right-click the custom column heading and choose **Remove Custom Column**.

See Also "Working with Preference Sheets" on page 410

"Exporting a Pin Layout File" on page 562

Searching Preference Sheets

Spreadsheet View provides Find dialog boxes for the Port Assignments, Pin Assignments, Clock Resource, Route Priority, and Cell Mapping preference sheets. Except for Pin Assignments, each of these preference sheets enables you to replace the contents of located preference cells.

Searching Port or Pin Assignment Sheets The Port Assignments and Pin Assignments sheets enable you to locate any string, including a preference, a pin assignment, and any built-in value such as a pad name. The dialog box for the Port Assignments sheet includes options for both finding and replacing.

To search for a string on the Port or Pin Assignments sheet:

1. Select the Port Assignments or Pin Assignments tab, and then do one of the following:
   - Click a cell that contains the cell value you want to find, and then choose **Edit > Find** or press **Ctrl+F**.

     The Find dialog box is populated with the cell value.
   - Click an empty cell and choose **Edit > Find** or press **Ctrl+F** to open the Find dialog box, and then type the name of the signal, pin, keyword, or other string you want to locate. Type the first few characters of the name to locate multiple items.
2. Select the "Match case" or "Match whole word" options as desired.
3. Click **Find Next**.

   Afterwards, you can continue to click the Find Next button or press the Enter key to locate each instance.
4. To search back toward the top, select Search Up and click **Find Next** or press **Enter**.
5. If you are using the Port Assignments sheet and the items you are locating are user preferences or keywords that you want to replace, do the following:

a. Click the **Replace** button at the top of the dialog box, and then enter the desired replacement preference or keyword in the "Replace with" text box.

b. Click the **Replace** button at the bottom of the dialog box to replace the next found item. To replace all found instances, click **Replace All**.

Searching Clock Resource, Route Priority, and Cell Mapping Sheets
Use the Find dialog boxes to locate a clock preference keyword, a priority number for prioritized nets, or keywords for registers used as flip-flops.

To find a cell value without replacing it:

- Choose **Edit > Find** or press **Ctrl+F**.

To find and replace a cell value:

1. Do one of the following:
   - Select the cell that contains the value you want to find and choose **Edit > Replace** or press **Ctrl+H**.

     The value appears in the "Find what" text box of the dialog box.
   - Choose **Edit > Replace** or press **Ctrl+H** and type the cell value that you want to find.
2. In the "Replace with" text box, type the value that you want to use as replacement, and then do one of the following:
   - To replace all cells that contain the "Find what" value, click **Replace All**.
   - To replace some but not all cells that contain the "Find what" value, click **Find Next** until the cell is highlighted that you want replaced, and then click **Replace**. Repeat for each cell that you want replaced.

Displaying I/O Placement Assignments in Spreadsheet View

After placement and routing, you have the option of viewing or hiding all the assignments that have been written to the native circuit description (.ncd) file. This includes automatic assignments made by Place & Route (PAR) and assignments that originated from the HDL source or the logical preference file (.lpf). By default, the display of I/O Placement assignments from the .ncd is turned on in Spreadsheet View.

To display or hide .ncd assignments:

- Choose **View > Display IO Placement** or click the Display IO Placement button  on the toolbar.

  This command acts as a toggle key and turns the display of I/O placement assignments on or off.

When "Display IO Placement" is turned on, NCD assignments are displayed differently, depending on whether they originated from a source or constraint file or were assigned by the placement and routing process.

Placement Assignments Originating from a Source or Constraint File Placement assignments from the .lpf file appear in black, or in the color designated for "Normal Value" in the Options dialog box. Those from the HDL source appear in green or in the color designated for "Source Value" in the Options dialog box. But unlike the display of these values before placement and routing, each assignment is now displayed twice: once normally and once in parentheses. The value in parentheses represents the value written to the native circuit description file (.ncd). When you change a post-PAR value, the new value, followed by the .ncd value in parentheses, is displayed. When you save the change, all values in parentheses are cleared.

Placement Assignments Made by PAR Placement assignments made by the Place & Route process (PAR) are displayed in blue font or in the color designated for "Default Value" in the Options dialog box. Pin and bank assignments are displayed in parentheses and appear only once. All other assignments are displayed twice: once normally and once in parentheses. When you edit the value for one of these assignments, the font color is changed to black, or the "Normal Value" color. The value you assigned then appears without parentheses, followed by the PAR-assigned value in parentheses.

When you edit preferences after placement and routing and save them, the PAR-generated assignments are cleared from Spreadsheet View and only the assignments from the source or .lpf file are displayed. The "Display IO Placement" command is then unavailable until you rerun Place & Route.

Hiding Default Values

You have the option of hiding the default values shown on the Port Assignments, Pin Assignments, and Global Preferences sheets. Hiding the default values narrows the display to preference, source, and read-only values. When turned on, default values are displayed in blue font, or in the font color that you have designated for "Default Values" in the Options dialog box. You can hide them and display them again at any time.

To hide or display default values:

- Choose **View > Show Default Value**

  This command acts as a toggle key and turns the display of default values on or off. A check mark indicates that they are to be displayed.

After placement and routing, if "Display IO Placement" is enabled, all assignments written to the .ncd file by Place & Route (PAR) are displayed in the default font color on the Port Assignments and Pin Assignments sheets. Each PAR-assigned value is displayed inside parentheses to distinguish it from a default value.

Adding Preferences from the Toolbar

You can quickly add timing preferences, a grouping assignment, or a Vref location by clicking the appropriate preference button on the toolbar. After you add the new preference, it is displayed in the appropriate preference sheet.

To add a new preference using the Spreadsheet View Toolbar:

1. Click the preference toolbar button for the preference you want to add:

    adds a BLOCK preference.

    adds a PERIOD or FREQUENCY preference.

    adds an INPUT_SETUP or CLOCK_TO_OUT preference.

    adds a MULTICYCLE preference.

    adds a MAXDELAY preference.

    adds a DEFINE GROUP preference for a cell, port, or ASIC group.

    adds a LOCATE VREF preference.

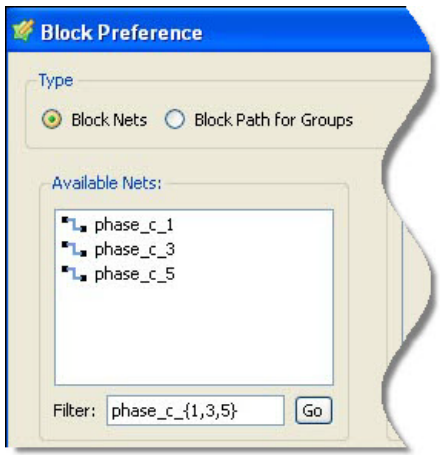
2. In the preference dialog box, specify the parameters and click **Add** or **OK**.

   The new preference is displayed in the Timing, Group, or Misc preference sheet.

Using Filters and Wildcards

The preference dialog boxes of Spreadsheet View provide a quick way to locate and filter design elements such as PORT, NET, ASIC PIN, and CELL objects. Many of the filters in these dialog boxes enable you to use wildcards to specify multiple elements that you want included in a single preference. Wildcards can be especially useful in large designs, because they reduce the number of preferences and conserve memory.

In the following example, the expression `phase_c_{1,3,5}` is typed in the Block Preference filter. When the Go button is clicked, only the three nets in the Available Nets list is displayed.



Clicking OK adds the preference with the wildcard expression as a single item to the existing BLOCK Preference list. It will be added as a single preference to the logical preference file with the Save command.

Note

Wildcard notation is not available with all preference parameters. See the individual preference descriptions in the "Constraints Reference Guide" on page 1194 for wildcard support.

Filter and Wildcard Support in Spreadsheet View Filters and wildcard expressions are supported in the following preference dialog boxes:

- Block
- Group Assignment
- INPUT_SETUP/CLOCK_TO_OUT
- MAXDELAY
- MULTICYCLE
- PERIOD/FREQUENCY

Wildcard Expressions The following basic wildcard expressions can be used with filters:

***** Match any (zero or more) characters.

? Match any single character.

?+ Match one or more characters.

{...} Match the enclosed list or range. The range can include a string of characters separated by commas, a lexical range separated by a dash (-), or an integer range separated by a colon (:).

{...}+ Match one or more occurrences of any character from the preceding list.

For more detailed information about wildcard expressions and syntax, see "Using Wildcard Expressions in Preferences" on page 531.

Package View

Package View shows the pin layout of the device and displays the assignments of signals to device pins. Package View interacts with Netlist View for assigning pins, enabling you to drag selected signals to the desired locations on the pin layout to establish LOCATE preferences. Each pin that is assigned with a LOCATE preference is color-coded to indicate the port direction of the related signal port. Package View allows you to edit these assignments, and it allows you to reserve sites on the layout that you want to exclude from placement and routing.

Banks and pin types are differentiated by color on the layout. You can use the Color Legend dialog box, available from the Package View toolbar, to view and change the default color coding. You can also use the Pin Display Selection dialog box to filter the display so that only certain banks and pin types are shown.

As you move your mouse pointer slowly over the layout, pin descriptions and locations are displayed in tool tips and in the status bar. The "View > Show Differential Pairs" command displays fly wires between differential pin pairs and identifies the positive differential pins with a magenta-colored + indicator.

Package View is available as soon as the target device has been specified.

- "Assigning Signals Using Package and Netlist Views" on page 469
- "Modifying Signal Assignments in Package View" on page 470
- "Migrating Pin Assignments" on page 482
- "Selecting a Device for Possible Pin Migration" on page 483
- "Displaying Incompatible Pins" on page 426
- "Using the Zoom and Pan Tools" on page 452

Using the "Show" Commands

The View menu in Package View provides two groups of "Show" commands. The first group consists of commands that are mutually exclusive; when one command is activated, the others become inactive. The second group consists of commands that are not mutually exclusive; they can be activated at the same time that another "Show" command is active.

In addition to the View menu, the "Show" commands are available from the pop-up menu when you right-click a blank space on the Package View layout.

Mutually Exclusive Commands When one of the following commands is activated, the other three are made inactive:

- Show Bank IO

- Show Port Groups
- Show DQS Groups
- Show SSO View

Non-mutually Exclusive Commands The following commands can be activated while another "Show" command is active:

- Show Pin Display Selection Dialog
- Show Differential Pairs
- Show Incompatible Pins
- Show Placement

Displaying Bank I/O Assignments

By default, Package View displays any assigned I/Os within each color-coded bank. The bank I/O display is turned off, though, when the display for Port groups or DQS groups is turned on.

To display bank I/Os:

- In Package View, choose **View > Show Bank IO**

  The I/O assignments are displayed within each bank. Port groups, DQS groups, and SSO View are hidden.

See Also "Displaying Incompatible Pins" on page 426

Displaying Port Groups

Package View enables you to view the placement of assigned port groups on the pin layout. Each port group is color-highlighted with the same distinctive color that is displayed in the Group sheet of Spreadsheet View.

To display port groups:

- In Package View, choose **View > Show Port Groups**.

  The color-coded port groups are displayed. Bank I/O assignments, DQS groups, and SSO View are hidden.

Displaying DQS Groups

You can view the placement of DQS groups in color-coded format on Package View's pin layout by turning on the "Show DQS Groups" command.

To display DQS Groups:

- In Package View, choose **View > Show DQS Groups**.

The color background of each DQS group is displayed. Bank I/O assignments, port groups, and SSO View are hidden.

Displaying SSO View

The "Show SSO View" command, available from Package View, displays the output pins that have been selected for SSO analysis. Tool tips for each pin provide SSO details. Output pins that passed SSO analysis are color-coded green; those that failed are color-coded red. This command also opens the SSO report in the Output window.

To display the SSO View:

- In Package View, choose **View > Show SSO View**.

  The SSO analysis output pins are displayed, color-coded according to pass or fail status. Bank I/O assignments, port groups, and DQS groups are hidden. The tool tip for each SSO pin includes information from the SSO Analysis Report.

Displaying Differential Pin Pairs

Package View's "Show Differential Pairs" command enables you to identify all the differential pin pairs on the layout. When this command is activated, fly wires are displayed that connect the differential pin pairs. Each unplaced positive differential pin displays a small magenta-colored cross in the upper right corner. By default, these indicators are hidden.

To display differential pin pairs:

- In Package View, choose **View > Show Differential Pairs**.

  The layout displays the fly wires connecting differential pins and the cross indicator for each positive differential pin.

  The "Show Differential Pairs" command acts as a toggle key and displays a check mark when the differential pair fly wires are displayed. To turn off the display, select the command again to remove the check mark.

Displaying Incompatible Pins

The "Show Incompatible Pins" command opens a dialog box that enables you to select one or more devices of the same family and package and then view the pins on the layout that would not be available or would have a different function were you to switch devices.

To display incompatible pins on the pin layout:

- In Package View, choose **View > Show Incompatible Pin**, and in the dialog box, select one or more devices and click **OK**.

  Package View displays each incompatible pin with a dark circle behind the pin square.

See Also "Migrating Pin Assignments" on page 482

- "Selecting a Device for Possible Pin Migration" on page 483

Displaying I/O Placement Assignments in Package View

After placement and routing, Package View enables you to examine all pin assignments that have been written to the native circuit description file (.ncd), including those made by Place & Route (PAR). A rotated square in the background of each placed pin serves as a placement indicator when the "Display IO Placement" command is turned on. The pin assignments that originated from the logical preference file (.lpf) are displayed with a color fill to distinguish them from PAR-assigned pins.

To display I/O Placement assignments in Package View:

- In Package View, choose **View > Display IO Placement** or click the Display IO Placement button  on the toolbar.

  A rotated square appears in the background of each placed pin. PAR-assigned pins are displayed with no color fill.

  Pin assignments that originated from the .lpf file are displayed with a color fill.

The "Display IO Placement" command acts as a toggle key and displays a check mark when the assignments are displayed. To turn off the display, select the command again to remove the check mark.

When you edit pin assignments after placement and routing and save them, the placement indicators are cleared from Package View. The "Display IO Placement" command is then unavailable until you rerun Place & Route.

Changing the Default Color Coding

The color coding in Package View is used to differentiate each bank and each type of pin. You can easily view the significance of each color by opening the Color Legend, which is available on the Package View toolbar. The Color Legend dialog box also enables you to change the default color coding for banks and pin types.

To change the default color coding for banks and pins:

1. Click the Color Legend button  on the Package View toolbar.
2. In the dialog box, select the Banks or Pins tab.
3. Click the color box in front of the desired bank or pin type that you want to change.
4. In the Select Color dialog box, select a different color and click **OK**.
5. If you want to change more than one color, click **Apply** in the Color Legend dialog box, and then repeat Steps 3 and 4. To revert to the default colors, click **Restore Defaults**.
6. When you have finished color editing, click **Close**.

Filtering the Display of Banks and Pin Types

When you open Package View, it shows all banks and pin types by default. You can use the Pin Display Selection dialog box to filter the banks and pin types so that only selected banks and pin types are displayed.

To filter the display of banks and pin types in Package View:

1. In Package View, choose **View > Show Pin Display Selection Dialog** or click the Pin Display Selection button  on the toolbar.
2. Do one of the following:
   - To eliminate the display of a few items, clear the check mark in front of each item that you do not want displayed.
   - To filter the display so that just a few items are displayed, click **Clear All**, and then select the banks and pin types that you want to see displayed. At least one bank must be selected.

     For example, to display only the dual function pins that are available in Bank 5, you would click **Clear All**, and then you would select **Bank 5** in the Visible Banks section and **Dual Function** in the General Purpose section.
3. Click **Close**.

   Package View displays only the items that you selected.

To re-display all banks and pin types:

- Reopen the Pin Display Selection dialog box, click **Select All**, and then click **Close**.

Package View displays all items.

When you close Package View and re-open it, it automatically reverts to the default view and displays all banks and pin types.

See Also ▶"Using the "Show" Commands" on page 424

Reversing the Pin Layout View

You can reverse the view of Package View 's device pin layout from a bottom to a top perspective or vice versa.

To reverse the pin layout view:

- In Package View, choose **View > Top View** or **View > Bottom View**.

  The View command acts as a toggle key and changes to its opposite, depending on the current view.

Device View

Device View provides an alphabetized index of device resources based on the target device. Statistics in Device View include:

- DCS blocks
- Assignable PIO cells, categorized by bank
- IOLOGIC sites
- PFF and PFU slices
- DQS blocks
- PCS blocks
- sysDSP blocks
- sysMEM blocks
- PLL and DLL blocks
- DDR support with bonded DQS, categorized by bank
- Other embedded ASIC blocks.

The right-click menu of Device View enables you to assign PROHIBIT preferences for sites that you want to exclude from placement and routing. From Device View, you can cross-probe selected resources to their sites in Package View, Floorplan View, and Physical View.

Device View is available as soon as the target device has been specified.

See Also ▶"Reserving Sites" on page 522

Netlist View

Netlist View displays the design elements of the post-synthesis native generic database (NGD) netlist. The NGD is a binary speed-optimized data structure that is used by the system to browse the logical netlist. Netlist View organizes the netlist by ports, instances, and nets, and it provides a toolbar button and design tree view for each of these categories. Each design tree view is equipped with utilities for filtering the list and searching for elements. Netlist View enables you to set location, timing, and group preferences.

Ports design tree

Right-click selected signals to assign pin locations, create port groups, or assign INPUT_SETUP and CLOCK_O_OUT preferences.

Drag selected signals to Package View to assign them on the pin layout.

Instances design tree

Right-click selected instances to create UGROUPs. Right-click selected registers to create cell groups or UGROUPs.

Drag registers to the Cell Mapping sheet of Spreadsheet View to specify registers for flip-flops.

Nets design tree

Right-click a selected clock net to set a PERIOD or FREQUENCY preference. Right-click a selected net to set a BLOCK preference.

Drag selected nets to Spreadsheet View's Route Priority sheet to prioritize them.

Netlist View is available after synthesis and translation.

See Also ▶"Modifying Pin Assignments Using Netlist View" on page 468

- "Assigning Signals Using Package and Netlist Views" on page 469
- "Creating UGROUPs" on page 507
- "Setting Timing Preferences in Netlist View" on page 501
- "Setting LOCATE Preferences in Floorplan View" on page 486

NCD View

NCD View, available after a successful run of Place & Route, provides a categorized index of synthesized design resources and consumption based on the target device and the in-memory native circuit description (NCD) database. Statistics cover System PIOs, User PIOs, PFUs, PFFs, sysDSP blocks, sysMEM blocks, IOLOGIC, PLL/DLLs, and other embedded ASIC blocks.

NCD View is organized by nets and instances and provides a toolbar button and design tree view for each of these categories. Each design tree view is equipped with utilities for filtering the list and searching for elements.

 Instances design tree

Right-click selected instances to create a new UGROUP or to view logic details in Logic Block View.

Cross-probe selected instances to Netlist View, Floorplan View, or Physical View; and cross-probe PIO instances to Package View.

 Nets design tree

Right-click a selected net to view the connection in Floorplan View or the complete physical path in Physical View

See Also ▶"Viewing Logic Details of Components" on page 446

- "Creating UGROUPs" on page 507

Floorplan View

Floorplan View provides a large-component layout of your design. It displays user constraints from the logical preference file (.lpf) and placement and routing information. All connections are displayed as fly-lines. Floorplan View allows you to create REGIONs and bounding boxes for UGROUPs and specify the types of components and connections to be displayed. As you move your mouse pointer slowly over the floorplan layout, details are displayed in tool tips: the number of resources for each UGROUP and REGION; the number of utilized slices for each PLC component; and the name and location of each component, port, net, and site.

If your design contains partitions, for the incremental design flow, you can display and edit the partitions in Floorplan View. See "Floorplan View and Physical View Partition Support" on page 671 for details.

Floorplan View is available as soon as the target device has been specified.

See Also ▶"Creating UGROUPs" on page 507

- "Creating a REGION" on page 517
- "Setting LOCATE Preferences in Floorplan View" on page 486
- "Viewing Logic Details of Components" on page 446
- "Using Incremental Design Flow" on page 649
- "Using the Zoom and Pan Tools" on page 452

Displaying Assignments and Connections

The Floorplan View toolbar allows you to select the types of elements that will be displayed on the layout, including REGIONs, UGROUPs, placed components, and component connections. These commands are also available from the View menu.

 Display Placement – displays all placed components, including assignments originating from the logical preference file (.lpf) and those made

by Place & Route. The Display Placement button controls the Display Placement Group button, the Display Congestion button, and the three Display Connection buttons below it. It must be active in order for group member components, routing congestion, and component connections to be displayed.

Display Placement Groups – highlights the placed UGROUP component sites with the designated color fill.

Display Congestion – Displays a representation of the amount of routing congestion for a PLC component or site. When Display Congestion is turned on, a highlighted rectangle overlays the site. The thickness of the rectangle represents the percentage of congestion for the row and column location. The tool tip for the location shows the precise percentage of congestion.

Display Connections To/From Selection(s) – This command controls the two Display Connections buttons below it. When active, it enables you to activate one or both of these buttons to view the connections between selected components, outside of selected components, or both:

- Display Connections Between Selection(s) – shows the connections between selected components.
- Display Connections Outside of Selection(s) – shows the connections that extend outside of the selected components.

Display Placement Preferences – shows placement assignments that originated from the .lpf file. When this button is active, placed components assigned with a LOCATE preference are distinguished with a cross-hatch pattern.

Note

The Display Placement Preferences button must be active in order to access the editing commands for creating or editing a UGROUP or REGION, prohibiting a site, or setting a LOCATE preference.

The Display Placement Preferences button also controls the three buttons below it. These buttons enable you to view REGIONs and UGROUPs and the logical connections between them.

- Display REGIONs – shows the bounding boxes of REGIONs that exist in memory or in the logical preference file.
- Display UGROUPs – shows the bounding boxes of UGROUPs that exist in memory or in the logical preference file.
- Display Logical Connections – shows the logical connections between UGROUPs, including those assigned to REGIONs, and between

UGROUPs and assigned PIO sites. The connections are based on the logical instances within each UGROUP.

Note

Connections in Floorplan View are displayed at a high level of abstraction and do not reflect the complete physical path. When you cross-probe a delay path from Timing Analysis View, Floorplan View displays the delay path connection, but it does not enable you to cross-probe the path to other views. To examine the physical path, cross-probe from Timing Analysis View to Physical View instead of Floorplan View.

 Displays partitions that are included in an incremental design flow.

- "Using the Zoom and Pan Tools" on page 452
- "How Assignments are Displayed in Floorplan View" on page 433
- "Display of FPGA Elements" on page 438
- "Using Incremental Design Flow" on page 649

How Assignments are Displayed in Floorplan View

Floorplan View displays assignments from the logical preference file (.lpf) at any stage of the design flow. These can include assigned sites, UGROUPs, REGIONs, and reserved resources. After routing, it displays all placements assigned by the Place & Route process, as well as assignments originating from the .lpf file.

The "Display" commands on the toolbar or the View menu control the display of assignments. The types of assignments displayed will depend on whether the commands "Display Placement," "Display Placement Preferences," or both are activated.

Assigned Sites After placement and routing, a site to which a component has been assigned appears on the layout with a solid fill.

Figure 69:

If the assignment originated from the logical preference file or the HDL source, the site will be filled and overlaid with a cross-hatch pattern when both "Display Placement" and "Display Placement Preferences" are activated.

Figure 70:

When only "Display Placement Preferences" is activated, an assignment originating from the logical preference file or HDL source is displayed with the cross-hatch pattern but without the fill.

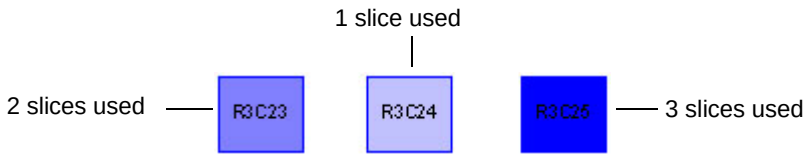
Figure 71:

Reserved Sites Sites reserved with the PROHIBIT preference are displayed with a gray pattern.

Figure 72:

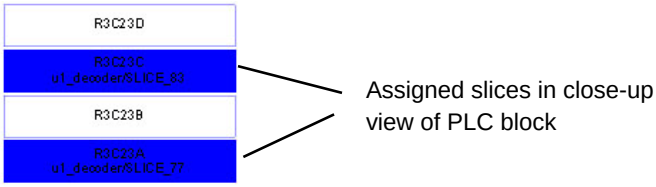
PLC Blocks (PFU and PFF) After placement and routing, a programmable logic cell (PLC) in which one or more logical components have been placed will appear on the layout with a solid fill until you zoom in. The color fill will be darker or lighter in shade, depending on how many sites are used.

Figure 73:



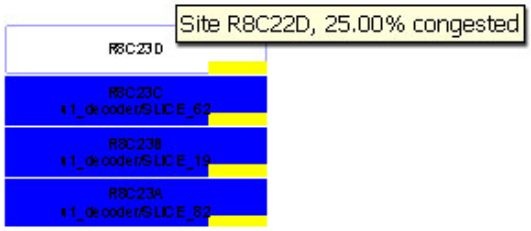
As you zoom in so that individual slices are visible, only the slices that contain placed logical components are displayed with a color fill.

Figure 74:



When Display Congestion is turned on, a highlighted rectangle is displayed that represents the amount of congestion for the row and column location. The tool tip shows the precise percentage of congestion.

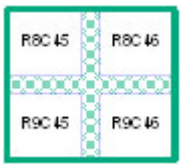
Figure 75:



UGROUPs Anchored UGROUPs are displayed when both the "Display Placement Preferences" and "Display UGROUPs" commands are activated. An anchored unbounded UGROUP is indicated with a small square icon at the upper left of the assigned anchor location. The icon becomes visible as you zoom in.

A bounded UGROUP is displayed with a solid border, corresponding to the assigned width and height, and a dotted pattern between blocks. UGROUPs are distinguished from one another by their designated colors. After placement, the sites that contain the member elements of the UGROUP are filled with the designated color when the "Display Placement Groups" command is activated.

Figure 76:



Bounded UGROUP

Placed UGROUP members

Note

To quickly view the color legend for all UGROUPs or REGIONS in the design, click the color legend button on the toolbar, and then select the UGROUPs or REGIONs tab.

REGIONs REGIONs are displayed when both the "Display Placement Preferences" and "Display REGIONs" commands are activated. A REGION bounding box is shown with a solid border and a solid fill between blocks. It is distinguished from other REGIONs by its designated color. When a REGION is reserved with the Prohibit command, it is overlaid with a gray dotted pattern.

Viewing and Changing the Color Coding

The Color Legend dialog box in Floorplan View provides a color map of items such as sites and connections, plus all UGROUPs and REGIONs that are in the design. It enables you to quickly edit the color of each of these items. You can also change the color of a UGROUP or REGION by using the pop-up menu on the floorplan layout.

To view and edit the color coding:

1. Click the Color Legend button on the toolbar.

   The Floorplan View Color Legend shows three tabs: Item Types, which displays the colors of connections, selected items, and types of sites; UGROUPs, which shows the color coding of each UGROUP preference in the design; and REGIONs, which shows the color coding of each REGION preference in the design.

2. Select the tab for the category that you want to view or change.
3. Click the color box in front of the UGROUP, REGION, or item type that you want to change.
4. Select a color from the Select Color dialog box and click **OK**.
5. If you want to change more than one color, click **Apply** in the Color Legend dialog box, and then repeat Steps 3and 4. To revert to the default colors for sites or connections, click **Restore Defaults**.
6. When you have finished color editing, click **Close**.

To change the color of a UGROUP or REGION from the pop-up menu:

1. On the floorplan layout, select the UGROUP or REGION that you want to change.
2. Right-click the selection and choose **Edit Color**. Select a color from the Select Color dialog box and click **OK**.

Going to a Specific Site

Floorplan View provides a "Go To Location" dialog box for quick navigation to a specific column and row on the layout.

To go to a specific site:

1. In Floorplan View, right-click an empty space on the layout and choose **Go to Location**.
2. In the dialog box, enter the desired Row and Column.
3. Click **OK**.

   Floorplan View zooms in to the location you specified.

Display of FPGA Elements

The following table describes the graphical representations of FPGA component blocks and ports that are visible on the floorplan layout. These elements can be cross-probed between Device View's categorized list and Floorplan View. For complete information about FPGA logic design primitives, see the "FPGA Libraries Reference Guide" on page 1664.

Note

FPGA elements that are specific to certain devices are so noted below the description.

Table 23: FPGA Elements

Object	Assignable	Description	Location syntax
ALU	Yes	Arithmetic Logic Unit, configurable as a 24-bit or 54-bit ternary adder/subtractor. *ECP5, LatticeECP3, LIFMD*	R<row> C<column>
AMBOOT	Yes	Automatic multiple boot that enables the LatticeECP3 device to reconfigure itself upon SED failure. *LatticeECP3*	AMBOOT
CIBTEST	No	Common interface block test. CIBTEST blocks are used for internal hardware testing only. CIBTESTs are positioned around the chip and in rows near special blocks such as EBRs, MULTs, and MACs.	
CLKDIV	Yes	Clock divider block. *ECP5, LatticeECP2/3, LatticeSC/M, LatticeXP2, LIFMD, MachXO2, MachXO3D, MachXO3L, Platform Manager 2*	LatticeECP2/3 R<row> C<column> LatticeSC/M CLKDIV1A, CLKDIV1B, CLKDIV1C, CLKDIV1D MachXO2 TCLKDIV0, TCLKDIV1 BCLKDIV0, BCLKDIV1
CLKDIVTEST	No	Clock divider block test. Used for internal hardware testing only.	
CLKFBBUF	Yes	Clock feedback buffer that provides a dummy feedback delay between PLL clk output and PLL fb port. Two are provided per device (1k and above) *MachXO2, MachXO3D, MachXO3L, Platform Manager 2*	CLKFBBUF0 CLKFBBUF1
DCC	No	Dynamic Quadrant Clock Enable/Disable. For internal use only. *ECP5, LatticeECP3, LIFMD, MachXO2, MachXO3D, MachXO3L, Platform Manager 2*	

Table 23: FPGA Elements

Object	Assignable	Description	Location syntax
DCM	Yes	Dynamic clock MUX incorporating a multiplexer function, for primary clock tree bank 6 and 7. *MachXO2, MachXO3D, MachXO3L, Platform Manager 2*	DCM6, DCM7
DCS	Yes	Dynamic clock select, a global clock buffer incorporating a smart multiplexer function. The DCS takes two independent input clock sources and avoids glitches or runt pulses on the output clock regardless of when the enable signal is turned on. *ECP5, LatticeEC, LatticeECP/2/M, LatticeECP3, LatticeSC/M, LatticeXP/2, LIFMD*	For most devices: ULDC0, ULDC1 URDCS0, URDCS1 LLDCS0, LLDCS1 LRDCS0, LRDCS1 Example: "M_DCS" SITE "LLDCS1" where: UL is upper left UR is upper right LL is lower left LR is lower right For LatticeSC and LatticeSCM devices: DCSTA, DCSTB DCSLA, DCSLB DCSRA, DCSRB DCSBA, DCSBB Example: "U_DCS" SITE "DCSTA" where: DCST is top DCSL is left DCSR is right DCSB is bottom
DLL	Yes	Delay-locked loop, a digital circuit used to perform clock management functions on and off the chip.	R<row> C<column> For LatticeSC and LatticeSCM devices: DLL_[UL][UR][LL][LR]C[CDEF] Example: DLL_LLCC where: UL is upper left, UR is upper right, LL is lower left, LR is lower right C is component

Table 23: FPGA Elements

Object	Assignable	Description	Location syntax
DLLDEL	Yes	Slave delay line for generating the desired delay in DDR/SPI4 applications. *ECP5, LatticeECP2/M, LatticeECP3, LIFMD, MachXO2, MachXO3D, MachXO3L, Platform Manager 2*	R<row> C<column>
DQS	Yes	Data strobe signal block that provides the required clock alignment for DDR memory interfaces. *Not available for LatticeSC/M*	LDQS<row> RDQS<row> TDQS<column> BDQS<column> where: L is left, R is right T is top, B is bottom.
DQSDLL	Yes	Delay-locked loop block for the data strobe signal. The DLL generates a 90-degree phase shift required for the DQS signal in DDR memory interfaces. *LatticeECP2/3, LatticeXP2, MachXO2, MachXO3D, MachXO3L, Platform Manager 2*	LDQSDLL, RDQSDLL where: L is left, R is right
DQSDLLTEST	No	Delay-locked loop for data strobe signal test. Used for internal hardware testing only.	
EBR	Yes	Embedded Block RAM, a large dedicated fast memory block that can be configured as ROM or RAM.	EBR_R<row> C<column> Example: EBR_R27C56
ECLKBRIDGECS	Yes	Edge clock bridge clock select, a high-speed clock bridge that takes the high-speed edge clock sources from the top and bottom. *ECP5, MachXO2, MachXO3D, MachXO3L, Platform Manager 2*	ECLKBRIDGECS0, ECLKBRIDGECS1
ECLKSYNC	Yes	Edge clock synchronization block for DDR memory. *ECP5, LatticeECP3, LIFMD, MachXO2, MachXO3D, MachXO3L, Platform Manager 2*	LECLKSYNC1, LECLKSYNC2, TECLKSYNC1, TECLKSYNC2, RECLKSYNC1, RECLKSYNC2, BECLKSYNC1, BECLKSYNC2 WHERE: L is left, R is right, T is top, B is bottom
EFB	Yes	Embedded function block for a hard IP. For the MachXO2 device, it contains a SPI, two I2Cs, and a timer/counter peripheral. The block is connected to a WISHBONE bus in slave mode. *MachXO2, MachXO3D, MachXO3L, Platform Manager 2*	EFB

Table 23: FPGA Elements

Object	Assignable	Description	Location syntax
FSLICE	Yes	One of four interconnected slices in a programmable fast functional unit (PFF). Each FSLICE is capable of logic, ripple, and ROM modes of operation but not RAM. FSLICE sites are displayed in white by default.	R<row> C<column>
IOL or IOLOGIC	Yes	Input and output logic blocks.	L<row>A|B R<row> A|B T<column> A|B B<column> A|B where: L is left, R is right, T is top, B is bottom
JTAG	N/A	Joint Test Action Group Controller. It provides the control and interconnect circuit used by the boundary scan function	JTAG
M[3:0]	Yes	Non-JTAG dedicated configuration mode select pads. *LatticeSC/M*	The configuration mode pads can be assigned as user input by pin name. Example: LOCATE COMP "USERINPUT1" SITE "K23";
MAC	Yes	Multiply-accumulate block. *LatticeECP/2/3, LatticeECP2M, LatticeSC/M*	R<row> C<column>
MACO	Yes	Mask array for cost optimization block, an ASIC block for implementing various functions. *LatticeSCM*	MACO blocks must be located as shown in the logical preference file provided for each Lattice MACO IP. Example: LOCATE COMP "spi4_256ch/s4dp/s4dp_hc" SITE "LLMACO0" ;
MULT	Yes	Multiplier digital signal processing block that implements a multiply with no addition or accumulator nodes. *ECP5, LatticeEC, LatticeECP/2/3*	MULT9|MULT18|MULT36 R<row> C<column>
PCNTR	Yes	Power Controller block. *MachXO2, MachXO3D, MachXO3L, Platform Manager 2*	PCNTR

Table 23: FPGA Elements

Object	Assignable	Description	Location syntax
PCS	Yes, when not connecting to a system bus	Physical coding sublayer. When connected to a system bus, the interconnect to the system bus determines the location. *ECP5, LatticeSC/M, LatticeECP3*	If not connecting to a system bus, the PCS should be assigned as described in the PCS application note. Example: LOCATE COMP "pcs_instance_name_in_hierarchy" SITE "PCS36000";
PERREG	Yes	Persistent User Register. Stores information from 16-bit registers and keeps the data intact during reconfiguration. *LatticeECP3*	PERREG
PICTEST	No	Programmable interface cell test, used for internal hardware testing only.	
PIO (P)	Yes	Programmable input-output block, often accompanied by an IOL or IOLOGIC block, that provide high-speed I/O registers and buffering to support a variety of signal interface standards. Two PIOs connected to sysIO buffers are the physical blocks of programmable interface cells (PICs).	L<row>A|B|C|D R<row> A|B|C|D T<column> A|B|C|D B<column> A|B|C|D where: L is left, R is right, T is top, B is bottom **Note**: Generally, PIOs should be located by their external pin names. For example, AK47
PLL	Yes	Phase-locked loop, a block with a voltage- or current-driven oscillator that is constantly adjusted to match in phase and therefore lock on the frequency of an input signal.	R<row> C<column> For LatticeSC and LatticeSCM devices: PLL_[UL][UR][LL][LR]C[AB] Example: PLL_LLCA where: UL is upper left, UR is upper right, LL is lower left, LR is lower right C is component
PLLREFCS	Yes	PLL reference clock select, which supports dynamic reference clock switching. *ECP5, LIFMF, MachXO2, MachXO3D, MachXO3L, Platform Manager 2*	LPLLREFCS (for 1k and above) RPLLREFCS (for 4k and above)
PRADD	Yes	Pre Adder for DSP block *ECP5*	R<row> C<column>

Table 23: FPGA Elements

Object	Assignable	Description	Location syntax
RESETN	Yes	Non-JTAG dedicated configuration res et input pad. RESETN is assigned to the specific input shown in the device's data sheet. *LatticeSC/M*	Example: LOCATE COMP "USERINPUTRESETBAR" SITE "H5";
SED	Yes	Soft error detect, an IP that checks for changes in the state of a configuration SRAM bit due to colliding alpha or neutron particles. The soft error detect IP can be set to automatically reconfigure the device on error. *ECP5, LatticeECP2/3, LatticeXP2, MachXO2, MachXO3D, MachXO3L, Platform Manager 2*	SED
SLICE	Yes	One of four interconnected slices in a programmable functional unit (PFU). Each SLICE is capable of logic, ripple, ROM, and RAM modes of operation. By default, SLICE sites are displayed in lavender.	R<row>C<column> A|B|C|D
SPLL	Yes	Simple phase-locked loop.	R<row>C<column>
STF	Yes	Store to flash block for user flash module (UFM) operations. *LatticeXP2*	STF
TSALL	Yes	Tri-state all, an element that puts all programmable input cells on the device in a tri-state condition. *MachXO, MachXO2,, MachXO3D, MachXO3L, Platform Manager, Platform Manager 2*	TSALL

Physical View

Physical View provides a read-only detailed layout of your design that includes switch boxes and physical wire connections. Routed connections are displayed as Manhattan-style lines, and unrouted connections are displayed as flylines. As you move your mouse slowly over the layout, the name and location of each REGION, group, component, port, net, and site are displayed as tool tips.

Displaying Components and Connections The Physical View toolbar allows you to select the types of elements that will be displayed on the layout.

 Displays local wires, those that expand across several blocks.

 Displays long wires, those that expand over a large area of the chip.

 Displays pin wires, short wires that are used to connect two or more net pins.

 Displays switch boxes, switching matrix resources located at the junctions of horizontal and vertical local lines.

 Displays switches, contact points employed for signal switching between resources on the chip.

 Displays sites, unused or vacant blocks to which logic can be assigned.

 Displays components, blocks that have assigned logic.

 Displays routes, physical connections between resources on the chip after the design has been routed.

 Displays unrouted nets, those that PAR failed to route or those that could not be routed because a site associated with a net was unlocked by the user.

 Displays the latest timing path selected in Timing Analysis View.

Displaying UGROUPs and REGIONs The Physical View toolbar also enables you to display or hide UGROUPs and REGIONs that exist in memory or that have been saved to the logical preference file.

 Display REGIONs – shows the bounding boxes of REGIONs.

 Display UGROUPs – shows the bounding boxes of UGROUPs.

Highlighting Elements Use the View menu's Highlight/Unhighlight commands to highlight selected nets or sites or to remove the highlighting.

Viewing Highlighted Items, Prohibited Sites, and Labels Use the View menu's Layer commands to display highlighted items, prohibited sites, and the textual labels of sites and components.

Note

When the text display has been turned on, a label will sometimes overlap the edge of the symbol or even appear aligned with the symbol below it. However, when you hold the mouse pointer over the symbol, the correct label will appear in the tool tip.

Displaying Partitions If your design includes partitions for the incremental design flow, you can display them in Physical View. See "Floorplan View and Physical View Partition Support" on page 671 for details.

See Also ▶"Viewing Logic Details of Components" on page 446

- "Auto Cross-probing Between Floorplan, Physical, and Logic Block Views" on page 451
- "Using Incremental Design Flow" on page 649
- "Using the Zoom and Pan Tools" on page 452

Logic Block View

Logic Block View enables you to examine logic details of one or more placed and routed components. It provides either a schematic or tabular view, depending on the type of component selected.

Schematic views of PIO and PFU/PFF components can be accessed from NCD View, Floorplan View, and Physical View. Tabular views of PLL, EBR, and DSP blocks can be accessed from Floorplan View and Physical View.

See Also
- "Viewing Logic Details of Components" on page 446
- "Auto Cross-probing Between Floorplan, Physical, and Logic Block Views" on page 451
- "Using the Zoom and Pan Tools" on page 452

Opening Logic Block View

You can open a schematic Logic Block View from Floorplan View, Physical View, or NCD View. Schematic views are available for PFU/PFF slice components or PIO components. For tabular views of EBR, PLL, and DSP components, you must use either Floorplan View or Physical View.

To open a Logic Block View from Physical View or Floorplan View:

1. Using the zoom tool, enlarge the area that contains the components you want to examine; or cross-probe to a single component from Netlist View or NCD View.
2. Select one or more components, right-click, and choose **Logic Block View** from the pop-up menu. Alternatively, double-click a single component to open it in Logic Block View.

To open a schematic Logic Block View from NCD View:

1. Select the Instances folder in NCD View.
2. From the Instances design tree, select one or more instances that you want to examine.
3. Right-click the selected instances and choose **Logic Block View**.

The Logic Block View opens in the main window. If you selected multiple components, the multiple views will be arranged in tabs at the top of the main window.

See Also
- "Changing the Maximum Number of Logic Block Views" on page 446
- "Exporting an Image of a Schematic Logic Block View" on page 447

Changing the Maximum Number of Logic Block Views

You can use the Options dialog box to change the number of Logic Block Views that can be open at the same time. The default maximum number is 15, but you can change it to a lower number or increase it up to 25.

To change the number of Logic Block Views that can be open at the same time:

1. Choose **Tools > Options**.
2. In the Options dialog box, select **Physical View**, and then select **General**.
3. In the right pane, enter the desired number in the text box for "Maximum number of Logic Block Views can be opened (1-25)," and click **OK**.

Viewing Logic Details of Components

Logic Block View provides either a schematic or a tabular view, depending on the type of component selected.

Viewing Schematic Details of I/Os and PFUs The schematic Logic Block View displays color-coded details for device elements IOB, IOL, and PFU/PFF.

To view more details of a schematic Logic Block View:

- Use the zoom buttons to enlarge the display.
- Double-click a LUT to view a list of look-up table equations. Alternatively, select a LUT and click the EQU button on the vertical toolbar.
- Hold the mouse pointer over schematic symbols to view information in tool tips.

Viewing Tabular Details of PLL, EBR, and DSP Blocks The Logic Block View presents a tabular version of details for sysCLOCK PLL, sysMEM EBR, and sysDSP blocks and illustrates the device element programming. It lists the properties and shows the features that are enabled and the values for each. It also lists all physical site pins associated with the DSP block and includes port names.

For more detailed information on the types of blocks displayed in the tabular Logic Block View, see the following references:

Exporting an Image of a Schematic Logic Block View

The Export command for Logic Block View enables you to capture a bitmap image of an open schematic view.

To export a schematic Logic Block View image:

1. Open the Logic Block View that you want to save as a bitmap image.
2. Choose **File > Export** or click the Export button on the vertical toolbar.
3. In the Export Image File dialog box, select the location for the image, and then type a name for the image in the File name text box.
4. Click **Save**.

   A bitmap image of the schematic view is saved in the directory you specified.

Cross-Probing Between Views

Diamond's preference-editing views allow you to select an element in one view and quickly display the corresponding logical or physical element in a different view. For example, you can cross-probe a component in Floorplan View to view the logical elements in Netlist View; or you can cross-probe a signal in Spreadsheet View to examine its placement on the pin layout of Package View.

To cross-probe an element from one view to another:

1. Right-click an element in any view.
2. Choose **Show in**, and then choose the desired view from the pop-up menu.

The following tables show the cross-probing availability for each preference view.

Table 24: Cross-probing from Spreadsheet View

See Also ▶"Auto Cross-probing Between Floorplan, Physical, and Logic Block Views" on page 451

Auto Cross-probing Between Floorplan, Physical, and Logic Block Views

When both Floorplan View and Physical View are open, an item that you select in one of these views is automatically selected in the other. This auto cross-probing is especially useful for immediately examining connections in both views. Additionally, when you open the Logic Block View for a selected component, the component is selected in both Floorplan View and Physical View.

The auto cross-probing tool does not zoom in to selected items or change the focus of the targeted view, and it does not open the targeted view if it is not already open. But when both Floorplan View and Physical View are open, auto cross-probing enables you to immediately examine objects in the context of each type of layout.

For example:

- Select a component in Floorplan View. Switch to Physical View and click the Zoom To button to view the selected component.
- Select a net in Physical View. Switch to Floorplan View to examine the net in the larger component layout.
- Double-click a component in Floorplan View to open Logic Block View.
  - Select a net in Logic Block View.
  - Switch to Floorplan View to view the highlighted net in the larger component layout.
  - Switch to Physical View to view the highlighted net in the more detailed layout.

See Also "Cross-Probing Between Views" on page 448

Using the Zoom and Pan Tools

The Diamond toolbar provides zoom tools for the layout views: Package View, Floorplan View, Physical View, and Logic Block View. In addition, the vertical toolbar included with Package View and Floorplan View provides commands that work together with the zoom tools to help you navigate to different objects and areas of the layout. Also, both Physical View and Logic Block View provide an area zoom that is controlled through the left mouse button. All of the layout views enable you to zoom in and out using the mouse wheel and function key combinations, and to pan using the arrow keys.

Diamond Toolbar Zoom Commands The following commands are available on the Diamond toolbar and in the View menu for each layout view.

Zoom In – enlarges the view of the entire layout.

Zoom Out – reduces the view of the entire layout.

Zoom Fit – reduces or enlarges the entire layout so that it fits inside the window.

Zoom To – enlarges the size of one or more selected sites, components, or connections on the layout and fills the window with the selection. The Zoom To command is available for all layout views except Logic Block View.

Area Zoom with the Mouse in Physical and Logic Block Views In Physical View and Logic Block View, you can enlarge an area of the layout by holding the left mouse button and dragging to the right and downward. Afterwards, you can zoom out of the area by dragging your mouse upward and to the left.

Vertical Toolbar Commands for Package View and Floorplan View The Select, Pan, and Zoom Area commands are available from the vertical toolbar in Package View and Floorplan View. They are also available from the "Mouse Tools" section of the View menu. These commands are mutually exclusive,

meaning that only one of them can be active at a time. Each allows you, however, to continue using the Diamond toolbar zoom commands.

Select – enables you to select objects on the layout by clicking an individual object or by dragging around an area to select multiple objects. It also enables you to move an assignment to a different location by dragging it. After selecting objects, you can zoom in with the Zoom To command. The Select command is activated by default. When Select is active, the Pan and Zoom Area commands are disabled.

Pan – enables you to use the mouse pointer to drag the layout in any direction. This command is useful for viewing a hidden area on the layout after zooming in. When Pan is active, the Select and Zoom Area commands are disabled.

Zoom Area – enables you to immediately enlarge an area of the layout by dragging to the right and downward with your mouse. When Zoom Area is active, the Select and Pan commands are disabled.

Panning with the Mouse in Physical and Logic Block Views After zooming in to a section of the layout, in Physical View or Logic Block View, you can press and hold the mouse wheel to drag the layout in any direction.

Zooming with Function Key Shortcuts The following key combinations, available for all the layout views, enable you to instantly zoom in or out from your keyboard:

- Zoom In – Ctrl++
- Zoom Out – Ctrl+-

Zooming with the Mouse Wheel The mouse wheel gives you finer zoom control, enabling you to zoom in or out in small increments. While pressing the **Ctrl** key, move the mouse wheel forward to zoom in and backward to zoom out. The mouse wheel zoom is available for all the layout views.

Panning with the Arrow Keys After enlarging the layout with the zoom tools, you can use the keyboard arrow keys to pan horizontally or vertically to different areas of the layout. Panning with the arrow keys is available for all the layout views.

Searching for Design Elements

Diamond's preference views enable you to search for design elements—either through a Find dialog box or through Find and Filter text boxes within the view.

Device View, Netlist View, and NCD View each provide Find and Filter text boxes at the top of the window. Diamond highlights the found objects and enables you to navigate through them and cross-probe to other views.

Spreadsheet View, Floorplan View, and Physical View each provide a Find dialog box. See the topic "Working with Preference Sheets" on page 410 for

information about searching in Spreadsheet View. The Find dialog box in Floorplan View and Physical View enables you to search for components, nets, and sites.

To search for design elements in Device View, Netlist View, or NCD View:

1. Open the desired view.
2. The Find and Filter text boxes appear at the top of the window.
3. To narrow the scope of the search, use wildcards in the Filter text box.
   - Use the asterisk to match one or more characters.
   - Use the question mark to match any single character.

   The view displays only those items that contain the characters you entered.
4. To locate a single design element from the list, type the name in the Find text box and press **Enter**.

   The found element is brought to the top of the view and highlighted.
5. To navigate through a list of elements that contain the same characters, use wildcards in the Find text box, and then press **Enter**.

   The first element containing the characters you entered is brought to the top of the view and highlighted. Press Enter again to go to the next element in the list.

To search for components, nets, or sites in Floorplan View or Physical View:

1. Open Floorplan View or Physical View, and then choose **Edit > Find** or press **Ctrl+F**.
2. In the Find dialog box, type the name of the component, net, or site that you want to find. Use the asterisk and question mark characters to perform wildcard searches.
3. Select the type from the Find Type drop-down menu.
4. Select Match Whole Word and Match Case as desired, to narrow your search to a complete name or to match upper and lower case letters.
5. Click **Find Next** or **Select All**.

   The item or items are highlighted on the layout.

   Use the Find Next and Find Previous buttons to navigate from one found item to another. Each will be highlighted on the layout.

See Also ▶"Going to a Specific Site" on page 437

Using Drag-and-Drop to Make Assignments

Diamond's preference-editing views provide a convenient drag-and-drop feature for making assignments or editing them. This feature is available between Netlist View and Spreadsheet View, between Netlist View and Package View, and between Netlist View and Floorplan View. The drag-and-drop feature is also available within Package View and within Floorplan View. This feature allows you to perform the following actions:

- Drag signals from Netlist View to Package View to assign them to pin locations.
- Drag assigned signals within Package View to reassign them to other locations.
- Drag nets from Netlist View to the Route Priority sheet of Spreadsheet View to set routing priority.
- Drag registers from Netlist View to the Cell Mapping sheet of Spreadsheet View to specify them as input or output flip-flops.
- Drag EBR, DSP, PCS, PLL, and ASIC block instances from Netlist View to Floorplan View to set LOCATE preferences.
- Drag non-SLICE logical components within Floorplan View to reassign them to other locations.
- Drag UGROUPs and REGIONS within Floorplan View to reassign them to other locations.

Undoing and Redoing Assignments

Diamond's Undo and Redo commands allow you to reverse preference changes that were made in a selected preference view. You can make multiple assignments, undo them all, and then redo them as desired. When all of your manual assignments have been undone or redone, the Undo or Redo command becomes dim. When you save your preference changes, the undo and redo commands are disabled.

Note

The Undo command will not remove the in-memory preference change indicators: the asterisk from a preference view tab or the "Preferences Modified" from the status bar. To remove these indicators after all assignments have been undone, use the Save command.

The commands are available from the Edit menu and from the Undo  and Redo  buttons on the Diamond toolbar.

The standard Windows keyword shortcuts are also available:

- Press **Ctrl+Z** to undo an assignment.
- Press **Ctry+Y** to redo an assignment.

Spreadsheet View Undo and Redo commands are available after design translation to reverse a preference change that was made in Spreadsheet View or pin assignments made in Netlist View. The commands are also available after Place & Route to reverse changes made in NCD View.

Package View Undo and Redo commands are available after design translation to reverse the following actions that were performed in Package View: signal re-assignments, unlocking of pin assignments, and prohibiting of pin sites.

Device View Undo and Redo commands are available after design translation to reverse any PROHIBIT preferences that were made in Device View.

Netlist View Undo and Redo commands are available after design translation to reverse any unlocking of assigned pins that was done in Netlist View.

Floorplan View Undo and Redo commands are available after design translation to reverse component, group, or REGION assignments and PROHIBIT preferences that were made in Floorplan View.

See Also ▶"Previewing Preferences Before Saving" on page 545

Printing a Preference View

You can print any preference sheet or any layout view. Diamond provides a preview for each view, enabling you to select options before printing.

Printing a Preference Sheet Any of the preference sheets can be printed. Categories, such as sysCONFIG, or groups are automatically expanded for the purpose of printing.

To print a preference sheet:

1. In Spreadsheet View, select the preference sheet that you want to print.
2. Choose **File > Print Preview**.
3. Select from the toolbar options at the bottom, and then click **Print**.

Printing a Layout View You can print a copy of the layout from Floorplan View, Package View, Physical View, or Logic Block View.

To print a layout:

1. Select the layout view that you want to print.
2. Choose **File > Print Preview**.
3. Select from the toolbar options at the top, and then click the **Print** button.

Setting Preferences

Preferences can be defined in the logical preference file (.lpf) at any stage of the design flow, but they are typically defined after synthesis and translation. You can use Diamond's preference-editing views or a text editor. Afterwards, the mapping process adds the changes to the physical preference (.prf) file and updates the native circuit description (.ncd).

Note

If you have a large design in the 100K LUT range and the logical preference file contains a large number of preferences (approximately five thousand), you might encounter the "out of memory" system error. See "Using Wildcard Expressions in Preferences" on page 531 to see how to reduce the number of preferences.

Diamond's preference-editing views allow you to specify many FPGA preferences, saving you the time it normally takes to write out logical preference syntax manually. These views include Spreadsheet View, Package View, Device View, Netlist View, NCD View, and Floorplan View.

Diamond implements simple error checking to ensure that the user assignments are applicable to the selected FPGA device and that there are no conflicting assignments. If the user preferences conflict with the selected device, the software will display these preferences in red. For example, if you change the device type after specifying some pin assignments, the non-applicable pin assignments will be displayed in red. You can delete these preferences within Diamond's preference views or within the .lpf file.

The validity of all the nets and ports are also checked against the logical native generic database (.ngd) file. If the .lpf file contains any of the physical naming in a net or a cell, it will result in an error condition. Physical names cannot be validated in the pre-map stage.

After the Translate Design process, you can view and edit any preferences that were passed from the HDL as attributes. When you edit these preferences or add new ones, you are writing changes in the form of logical preferences directly into the .lpf file. These preferences will be written to the physical preference file (.prf) by the mapping process.

Adding a Logical Preference File to a Project

When you create a new project in Diamond, a logical preference file (.lpf) is automatically generated and assigned the same name as the FPGA project. All changes that you make to logical constraints will be saved to this file until you create a new logical preference file or add an existing one.

Adding a new or existing .lpf file allows you to experiment with a different set of preferences for each implementation.

To add an existing .lpf file:

1. Choose **File > Add > Existing File**. Optionally, right-click the active implementation and choose **Add > Existing File**.
2. In the Add Existing File dialog box, do the following:
   a. Choose **Constraint Files (*.lpf)** from the "Files of type" drop-down menu.
   b. If you want to add the file to the implementation directory, select the option **Copy file to Implementation's Source directory**.
   c. Navigate to the .lpf file that you want to use and click **Add**.

   The selected .lpf file is added to the Constraint Files folder. If the file came from a directory outside your current project and you did not select the option to copy the file to the implementation directory, the relative path will be shown.

To create a new .lpf file and add it to the project:

1. Choose **File > New > File** or use the keyboard shortcut **Ctrl+N**. Optionally, right-click the active implementation and choose **Add > New File**.
2. In the New File dialog box, under Categories, select **Source Files**.
3. In the Source Files pane, select **Preference Files**.
4. In the Name box, type a new file name and select the **lpf** extension from the Ext drop-down list.
5. Accept the current directory for the new .lpf file or use the Browse button to select a different directory.
6. Select the **Add to Implementation** option to add the new file to the active implementation. Selecting this option also adds the file to the LPF Constraint Files folder in the File List view.
7. Click **New**.

   The new .lpf file opens in the Source Editor window. The file name appears in the Constraints Files list for your current implementation.

   Note

   If you did not select the Add to Implementation option, the file will not appear in the Constraint Files folder. To add it, use the procedure for adding an existing preference file.

See Also ▶"Activating a Preference File" on page 459

- "Saving Preferences to a Different .lpf File" on page 545
- "Integrated Synthesis" on page 581

Activating a Preference File

When your project's Constraint Files folder contains more than one .lpf file, you can select one of them to serve as the active preference file for the current implementation.

To activate a preference file:

1. Select the .lpf file in the Constraint Files folder.
2. Right-click the selected file and choose **Set as Active Preference File**.

   If there are modified preferences or file changes in memory for your currently open project, the "Save Modified Files" dialog box will appear. If this happens, either click OK to save all files or clear the check marks in front of any files that you do not want to save and click OK.

The newly activated .lpf file now appears in bold type and will be used in processing the current implementation. All open preference views are refreshed and display any preferences contained in the newly activated file.

Setting Global Preferences

The Global sheet of Spreadsheet View enables you to set constraints that affect the entire design, such as voltage, temperature, global BLOCK preferences, and configuration preferences. The list of these preferences varies by device family.

To set global preferences:

1. In Spreadsheet View, select the **Global Preferences** tab.
2. To edit the value for a global or sysCONFIG preference, do one of the following:
   - Double-click the value and enter a new one.

     The table cell changes format. If the cell changes to a text box, type the new value. If it changes to a box with a drop-down menu, choose the value from the list.
   - Right-click the preference value cell and select the desired value from the pop-up menu. For a text entry, choose **Edit Cell**, and then type the new value.
3. To return to the default value, highlight the value and press the **Delete** key or right-click the value and choose **Clear**.

For ECP5, MachXO2, MachXO3D, MachXO3L, and Platform Manager 2 devices, the Global Preferences sheet allows you to specify the VCCIO voltage setting for each bank. The VCCIO setting will then appear in the read-only BANK_VCC column of the Port Assignments sheet for any signal or bank assignments. It will also appear in the BANK_VCC column of the Pin Assignments sheet. For other devices, the BANK_VCC preference can be set manually in the logical preference file (.lpf).

For LatticeSC/M devices, the Global Preferences sheet allows you to specify voltage derating preferences for VCC, VCC12P, VCCAUX, and VCCIO. For other devices, voltage derating preferences can be set manually in the .lpf file.

Setting Temperature and Voltage Derating

The following tables show the min-max junction temperature range and the supported voltages for derating for each Lattice device family. The nominal values are specified where applicable. Lattice Diamond will use these values for DRC checks. Except for LatticeSC/M devices, voltage derating preferences are set manually in the .lpf file. They include VCC_DERATE, VCC1P2_DERATE, VCCAUX_DERATE, VCCIO_DERATE, and VREF_DERATE.

Note

The data ranges listed in the tables are derived from data collected during test conditions that might not match your unique operating conditions. You should compare your own data to ensure reliability. Also refer to relevant data sheets or application notes on the Lattice web site for updated information. Contact technical support for more information.

Setting a Global Set/Reset Net Preference

The GSR_NET Preference dialog box allows you to specify a net as the input to the global set/reset (GSR) buffer inferred by the design mapper.

To set a Global Set/Reset Net preference:

1. In Spreadsheet View, select the Global tab.
2. Double-click **Global Set/Reset Net** to open the New GSR_NET Preference dialog box.

   Alternatively, right-click and choose **New GSR_NET**.
3. In the dialog box, select one or more nets from the Available Logical Nets list and click the **>** button to move the selection to the Selected Logical Nets list.

   You can use wildcards in the Filter text box to narrow the list of nets. To move all available nets to the Selected Logical Nets list, click the **>>** button.
4. Click **Add**.

Your selection of one or more nets is displayed on the Global preference sheet under “Global Set/Reset Net.” When you save the preference, each net is added to the .lpf file as a separate GSR_NET preference.

Assigning Signals

Diamond’s Spreadsheet View and Netlist View enable you to assign signals to pin locations. You can also assign signals by dragging them from Netlist View to pin locations on the Package View layout. Signals can be assigned or reassigned at any stage of the design flow.

Assigning Signals in Spreadsheet View

Spreadsheet View provides two methods for assigning signals to pin locations:

- Use the Port Assignments sheet to assign pins to listed signals. The Port Assignments sheet displays signals by port type and signal names.
- Use the Pin Assignments sheet to assign signals to listed pins. The Pin Assignments sheet lists pins by pin, pad name, bank, dual function, and polarity.

Both views enable you to make single or multiple assignments. Saved pin assignments are written to the logical preference file as LOCATE preferences.

Assigning Pins Using the Port Assignments Sheet For a single pin assignment, you can simply double-click the pin cell for a given signal and type the desired pin name. For multiple pin assignments, use the Assign Pins dialog box, as explained below.

To assign pin locations:

1. Select the pin cells, in the Pin column, for the signals that you want to assign.

   Note

   PCS-related signals for ECP5, LatticeECP2M, LatticeSC, and LatticeECP3 designs, are displayed in a dim font, indicating that they are read-only. For more information, refer to TN1261, *ECP5 SERDES/PCS Usage Guide*, TN1124, *LatticeECP2M SERDES/PCS Usage Guide*; TN1145, *LatticeSC flexiPCS/ SERDES Design Guide*; and TN1176, *LatticeECP3 SERDES/PCS Usage Guide*.

   To select multiple pin cells, do one of the following:

   - Drag down the pin column or use the Ctrl+click or Shift+click combination.
   - For a bus, open Netlist View and detach it. Select the bus from the Ports list of Netlist View and drag it to the Port Assignments Sheet of Spreadsheet View. All the rows for the bus signal names become highlighted.

2. Right-click the selected cells in the Pin column and choose **Assign Pins**.

   In the Assign Pins dialog box, the signals you selected are displayed in boldface in the left pane. In the pin list next to it, the same number of pins are displayed in bold at the top of the list. The software automatically interprets the design files and displays the pin filters that should be enabled by default. For example, if you selected an LVDS25 type of port in Spreadsheet View, the polarity section on the right will show the True P-side filter as enabled. If you selected a BLVDS type of port, it will show the Emulated P-side filter as enabled.

3. Clear or select the desired options under Pin Types to narrow or expand the list of available pins, and then select **Auto Sort** or **Manual Sort**.

   - If Auto Sort is selected, select the desired sorting option under "Sort by," and then select **Ascending** or **Descending** order.
   - If Manual Sort is selected, use one of the following methods to drag pins and place them in the desired order:
     - Click one pin to select it, and then drag it to the desired location.
     - Use the Shift key to select several adjacent pins at once and release the mouse button. Afterwards, drag the highlighted pins to the desired position.

4. From the pin list, select the pin location where you would like the assignment to begin.

   The dialog box highlights the selected pin and displays in bold type the sequence of pins following it—one for each signal.

   Note

   If you have used the "Incompatible Pins" dialog box to select a device for possible pin migration, the incompatible pins will be displayed in a dim font on the pin list. If you have disabled the incompatible pins, Diamond will assign the next available pin for each pin that has been disabled.

5. From the Assign Pin drop-down menu at the bottom left, select the desired Assign Pin option: every, every second, every third, or every fourth pin.

6. To check the validity of the selected pin assignments, click **Check Pins**.

   A message box appears that lists any assignment errors. If errors are reported, repeat Steps 4–6 until the pin check is free of errors.

7. Click **Assign Pins**.

Assigning Signals Using the Pin Assignments Sheet For a single assignment, you can simply double-click the Signal Name cell for a selected pin to open the Assign Signals dialog box. For multiple assignments, right-click the selected cells.

To assign signals:

1. In the Signal Name column, select one or more cells for the signals that you want to assign. You can drag down the column to select multiple signal cells or use the Ctrl+click or Shift+click combination.

   Note

   If you have used the “Incompatible Pins” dialog box to select a device for possible pin migration, the incompatible pins will be displayed in a dim font. If you have disabled the incompatible pins, Diamond will assign the next available pin for each pin that has been disabled.

2. Right-click the selected cells in the Signal Name column and choose **Assign Signals**.

   In the Assign Signals dialog box, the pins you selected are displayed in boldface in the left pane. In the signal list next to it, the same number of signals are displayed in bold at the top of the list.

3. Clear or select the desired options under Signal Types to narrow or expand the list of available signals, and then select **Auto Sort** or **Manual Sort**.
   - If Auto Sort is selected, select the desired sorting option under “Sort by.”
   - If Manual Sort is selected, use one of the following methods to drag signals and place them in the desired order:
     - Click one signal to select it, and then drag it to the desired location.
     - Use the Shift key to select several adjacent signals and release the mouse button. Afterwards, drag the highlighted signals to the desired position.
4. Select **Ascending** or **Descending** order.
5. From the signal list, select the signal where you would like the assignment to begin.

   The dialog box highlights the selected signal and displays in bold type the sequence of signals following it—one for each pin.

6. To check the validity of the signal assignments, click **Check Signals**.

   A message box appears that lists any assignment errors. If errors are reported, repeat Steps 6 and 7 until the signal check is free of errors.

7. Click **Assign Signals**.

Modifying Assignments in Spreadsheet View

You can modify pin assignments in Spreadsheet View before or after placement and routing. After routing, you can also modify assignments that were made automatically by the Place & Route Process.

To modify assignments:

1. From the Port Assignments sheet or Pin Assignments sheet, select the assignments that you want to modify, right-click, and choose **Assign Pins** or **Assign Signals**.
2. Follow the same procedure for assigning pins or signals in Spreadsheet View.

To modify assignments made automatically by Place & Route:

1. Choose **View > Display IO Placement**.

   All the placed and routed assignments are displayed in parentheses, including user assignments. User assignments appear twice—once without parentheses and once in parentheses—and they are displayed in black font or the font color that has been designated for “Normal” in the options dialog box. Assignments that were made automatically by Place & Route appear only once. They are displayed in parentheses and are distinguished by blue font or the font color designated for “Default Values.”
2. Select the assignments made by Place & Route that you want to modify, right-click, and choose **Assign Pins** or **Assign Signals**.
3. Follow the same procedure for assigning pins or signals in Spreadsheet View.

   The assignments are now displayed in black font. Those that were assigned by Place & Route now appear in parentheses, preceded by the new assignments.

To remove assignments:

- Select the assigned pins or signals that you want to delete, and then press the **Delete** key. Optionally, right-click the selected assignments and choose **Clear**.

  Note

  Only user assignments can be deleted. Assignments made automatically by Place & Route can be modified but not deleted.

Assigning Pins Using Netlist View

Netlist View enables you to select the signals from the design tree that you want to assign.

To assign pins:

1. From the Netlist View design tree, expand the category of signals that you want to assign.
2. Select the signals that you want to assign, right-click, and choose **Assign Pins**.
3. Follow the procedure for assigning pins using the Port Assignments sheet.

See Also ▶"Assigning Signals Using Package and Netlist Views" on page 469

- "Back Annotating Assignments" on page 489

Modifying Pin Assignments Using Netlist View

Netlist View enables you to select the assigned signals from the design tree that you want to reassign.

To modify pin assignments:

1. Select the assigned signals that you want to modify, right-click, and choose **Assign Pins**.
2. Follow the procedure for assigning pins using the Port Assignments sheet.

   Note

   You can also modify one or more pin assignments by dragging from Netlist View to a different location in Package View.

To remove pin assignments:

- Select the assigned signals that you want to remove, right-click, and choose **Unlock**.

Assigning Signals Using Package and Netlist Views

You can drag signals from Netlist View onto the Package View pin layout to assign them or reassign them.

To assign signals using Netlist and Package views:

1. Choose **Tools > Package View**.
2. Click the Show Pin Display Selection button on the toolbar.

   The Pin Display Selection dialog box, by default, shows that all pin types and banks are selected.
3. In the dialog box, clear the types of pins and banks that you do not want to appear on the layout.
4. Click **Close**.
5. To display the fly wires for differential pins, choose **View > Show Differential Pairs**.

   Note

   For IO_TYPEs that require differential pins, Diamond automatically prohibits you from assigning the complement of a differential pin that is already assigned.
6. Choose **Tools > Netlist View**. The Ports design tree should be displayed. If it is not, click the Ports button on the toolbar.
7. Do one of the following:

   - Click the Detach Tool button at the top right to open Netlist View in a separate window, and then position Netlist View alongside Package View.
   - Click the Split Tab Group button on the toolbar to separate Netlist View into a tab group, and then select Package View in the main tab group. Both views now appear side-by-side.
8. From the Netlist View window, expand the list of ports and select the desired signals or bus.

   Note

   PCS-related signals for ECP5, LatticeECP2M, LatticeSC, and LatticeECP3 designs, are displayed in a dim font, indicating that they are read-only. For more information, refer to TN1261, *ECP5 SERDES/PCS Usage Guide*, TN1124, *LatticeECP2M SERDES/PCS Usage Guide*; TN1145, *LatticeSC flexiPCS/ SERDES Design Guide*; and TN1176, *LatticeECP3 SERDES/PCS Usage Guide*.
9. Drag your selection to the desired location on the Package View layout and release the mouse button.

   Package View fills the specified pin locations with color and assigns multiple signals in the order they were selected. The assignments are also shown in Netlist View and in the Port Assignments sheet of Spreadsheet View. When you save the assignments, each is written to the .lpf file as a LOCATE preference.

Click the “Integrate All Tools” button  to integrate the detached Netlist View with the main window.

Click the “Merge Tab Group” button  to merge the split tab into the main tab group.

See Also ▶“Back Annotating Assignments” on page 489

Modifying Signal Assignments in Package View

Package View enables you to use drag-and-drop to move one or more signal assignments to unlocked pins. It also allows you to move a single signal assignment to a pin that is already locked and swap the two assignments.

To modify one or more assignments in Package View:

1. Select the device pins on the layout that contain the assignments you want to modify.

   To select only one pin, click it once so that it is highlighted. Use the Ctrl key or the Shift key to select more than one pin, or drag your mouse around multiple pins to select them.

2. Slowly move the mouse toward the desired unlocked pin location.

   As you begin to drag, the cursor displays a crossed-out circle symbol. The cursor changes to an arrow as you move it over valid pins. Keep dragging until you have reached the targeted location.

3. When the cursor displays the arrow symbol over the targeted location, release the mouse button.

   Note

   If you are modifying a single assignment, make sure that the pin is highlighted before you try to drag it. If you try to drag a pin before it is highlighted, you will activate the multiple selection tool.

To swap two assignments:

1. Select the single device pin that contains the assignment you want to swap.
2. Drag the selected signal to the desired locked pin location and release the mouse button.
3. In the dialog box click **Swap assignments**.

To remove assignments in Package View:

1. Select the pins that contain the assignments you want to remove.
2. Right-click the selected pins and choose **Unlock**.

- "Viewing Incompatible Pins" on page 484

Modifying Signal Assignments in Floorplan View

In Floorplan View, you can modify a signal assignment by dragging it from one PIO to another. You can modify an assignment that originated from the logical preference file (.lpf) or one that was made automatically by Place & Route (PAR).

To modify a signal assignment in Floorplan View:

1. Make sure that the "Display Placement" button  is turned on if you will be modifying a PAR-assigned I/O. If you will be modifying an I/O assignment from the .lpf file, make sure that the "Display Placement Preferences" button  is turned on.
2. In Floorplan view, zoom in so that you can easily view the placed PIO component that you want to reassign and the targeted location.

   PIO components that were assigned automatically by PAR are displayed with a solid color fill. PIO components whose assignments originated from the .lpf file are displayed with a color fill and a cross-hatch overlay.
3. Drag from the assigned site to the targeted location and release the mouse button.

   The previous location is now displayed with a fill and no cross-hatch, and the targeted location is displayed with the cross-hatch and no fill. The targeted location will appear in the .lpf as a LOCATE preference when you save the change.

Setting Vref Locations

Lattice FPGA devices commonly provide two input pins per bank that can serve as on-chip voltage references (Vref) for the I/O types that require them. Spreadsheet View enables you to name and assign the specific voltage reference pins for these I/O types. If you do not assign Vrefs for I/O types that require them, the software will automatically create them for you. However, automatically generated Vrefs will not be added to the .lpf file if you decide to back annotate assignments.

After you have specified a Vref location, you can associate the Vref pin with a port group or with single signals. All Vrefs that you define are written to the logical preference file as LOCATE preferences.

Note

The Vref preference is not available for MachXO and Platform Manager devices.

To set Vref locations:

1. In Spreadsheet View, click the Vref Locations button on the toolbar to open the Create New VREF dialog box.

   Alternatively, select the Misc Preferences sheet and double-click **VREF LOCATE** in the Preference Name column.
2. In the dialog box, under VREF Name, type a new VREF string.
3. If available, select a voltage rail from the Rail drop-down list.

   Note

   The Rail option is available and required for LatticeSC/M devices only.
4. Under SITE, select the desired pin location.
5. Click **Add**.

   The Misc Preferences sheet opens, displaying the list of Vrefs in the VREF LOCATE list.
6. To add more Vrefs, repeat steps 1-5.

When you save the design, Vref assignments appear in the .lpf file as LOCATE preferences.

To modify a Vref location:

1. Open the Misc Preferences sheet.
2. Expand VREF LOCATE and double-click the Vref that you want to modify.

   Alternatively, right-click the Vref and choose **Modify**.
3. In the Edit VREF Property dialog box, select the desired site and click **Update**.

To delete a Vref:

1. In the Misc Preferences sheet, select the Vref you want to remove.
2. Press the Delete key or right-click and choose **Delete**.

For more details on Vref usage, refer to the sysIO Usage Guide for your targeted device family:

- "IO_TYPE" on page 1309

Setting Port, Net, and Cell Attributes

Spreadsheet View's Port Assignments Sheet, Clock Resource sheet, Route Priority sheet, Cell Mapping sheet, and Global Preferences sheet enable you to set attributes for ports, nets, and cells. They allow you to set I/O port attributes, assign net priorities, specify registers for flip-flops, and set junction temperature and voltage.

Defining I/O Defaults

Diamond allows you to set values for all ports in your design at once. There are two ways to do this: use the ALLPORTS preference, which is available in Spreadsheet View, or manually create a DEFINE PORT GROUP preference in the .lpf file to create a group that includes all ports. Each of these methods allows you set default values while at the same time retaining values for individual ports or port groups that are set with other preferences.

For example, in a MachXO2 design, you might want to change the default I/O type to LVCMOS33, which would allow you to select a drive strength of 24 for individual output ports. But you might want to maintain the Vref settings for a port group with I/O type SSTL18_I. When you change the default to LVCMOS33 for all of the ports, Diamond changes the I/O type to LVCMOS33 for ports that use the default; but it maintains the SSTL18_I I/O type for the port group that uses the Vref assignment.

For example, in a LatticeSC design, you might want to change the default I/O type to HSTL15_1, which would allow you to select an impedance setting of 50 for individual output ports. But you might want to maintain the impedance setting of 100 that you have already set for a port with I/O type LVCMOS25. When you change the default to HSTL15_1 for all of the ports, the software changes the I/O type to HSTL15_1 for ports that use the default; but it

maintains the LVCMOS25 I/O type and impedance of 100 for the output port that you have already set.

You should use care when defining I/O defaults, especially if your design includes I/O settings in the HDL. Any existing IOBUF attributes in the HDL will get overridden by the Map process when an ALLPORTS preference or an all-ports PORT GROUP is used in the .lpf file. Before you define I/O defaults, make sure that you move any existing HDL IOBUF assignments to the .lpf file.

Defining I/O Defaults Using ALLPORTS The ALLPORTS row in Spreadsheet View's Port Assignments sheet enables you to quickly define a default setting for I/O attributes. It can be especially useful for setting the I/O type default.

To define default settings Using ALLPORTS:

1. In Spreadsheet View, select the Port Assignments tab.
2. Double-click the desired attribute cell in the ALLPORTS row and select a value from the drop-down list. Optionally, right-click the cell and select a value from the pop-up list.

   The newly selected value is displayed in orange, or the font color designated for “Reference Value,” for all of the ports that do not have other values already assigned.

   Note

   The range of attribute values available with the ALLPORTS row reflect the intersection of valid values across all port types. To access all available values, use individual ports or port groups.

   You can return to the original default setting by selecting the attribute cell and pressing the **Delete** key.

   The following is an example of an ALLPORTS preference.

```
IOBUF ALLPORTS IO_TYPE=LVCMOS33 PULLMODE=UP;
```

Defining I/O Defaults Using DEFINE PORT GROUP The DEFINE PORT GROUP preference enables you to use a wildcard to include all ports in one group. Afterwards, you can use Spreadsheet View to set IOBUF values for the entire group.

To define I/O defaults using a port group:

1. In the logical preference file, create the port group using the following syntax with the “*” wildcard:

```
DEFINE PORT GROUP "<group_name>" "*" ;
```

After you have created the port group and saved it in the .lpf file, the group appears at the bottom of Spreadsheet View's Port Assignments sheet. When there are other port groups in the .lpf file, Diamond issues a warning for each port that exists in one of these other groups.

2. In Spreadsheet View's Port Assignments sheet, scroll down to the port group row and select the desired IOBUF values from the appropriate columns.

The following is an example of an all-ports group, with IOBUF settings:

```
DEFINE PORT GROUP "all_ports" "*" ;
IOBUF GROUP "all_ports" IO_TYPE=LVCMOS18 PULLMODE=DOWN ;
```

See Also ▶"IO_TYPE" on page 1309

▶ "Conflicting IOBUF Constraints" on page 396

Defining IOBUF Preferences

Spreadsheet View's Port Assignments sheet enables you to define IOBUF preferences for individual ports and port groups. IOBUF attributes include BANK, IO_TYPE, PULLMODE, SLEWRATE, and many others. The available attributes will vary, depending on the selected Lattice device. These modified attributes will be written as IOBUF preferences in the logical preference file (.lpf).

The IOBUF preference does not support the use of wildcards. But you can use wildcards with the DEFINE GROUP preference to create a port group. Afterwards, you can assign IOBUF preferences to the entire group of ports at once. Port groups are shown at the bottom of the Port Assignments sheet. See also "Defining I/O Defaults" on page 473.

To define IOBUF preferences:

1. In Spreadsheet View, select the Port Assignments sheet.
2. Double-click the cell in the attribute column that you want to modify for a given signal or port group and choose a value from the drop-down menu. Optionally, right-click the cell and choose a value from the pop-up menu.

   Note

   For some designs, the OPENDRAIN attribute cannot be set to ON in Spreadsheet View but must be set in the HDL. Refer to the sysIO Usage Guide for the device family.

3. Press **Enter**.

   The modified value now appears in black font in the preference sheet or in the font color designated for "Normal Value."

IOBUF Attributes

The following table describes the available attributes in the Port Assignments sheet for defining IOBUF preferences.

The options that you can select for these attributes will depend on the combinations that are legal for each device type. See the references below the table under See Also.

Table 40:

Attribute	Supported Devices	Description
BANK VCCIO	All	Sets the VCCIO voltage level of the IO bank.
CLAMP	ECP5, MachXO2, MachXO3D, MachXO3L, Platform Manager 2	Turns on the non-PCI-compliant clamp for smaller MachXO2 and MachXO3L devices. For 1200, 2k, 4k, 7k, and 10k devices, provides the option of setting the PCI-compliant clamp in the bottom bank.
DIFFCURRENT	LatticeSC/M	Sets the output current level for differential signals. Settings include 2, 3P5, 4, 6.
DIFFDRIVE	ECP5, LatticeECP3, MachXO2, MachXO3D, MachXO3L, Platform Manager 2	Sets the differential current drive strength for the MINILVDS output standard. Differential outputs with different DIFFDRIVE settings cannot be placed in the same IO bank. Settings include 1.6, 1.65, 1.7, 1.75, 1.81, 1.87, 1.93, 2.0. **Note**: The DIFFDRIVE value must be enclosed in quotation marks in the logical preference file.
DIFFRESISTOR	ECP5, LatticeSC/M, LatticeECP3	Provides differential termination for differential I/O types. Settings include OFF, 100, 150, 200. OFF is the default.

Table 40:

Attribute	Supported Devices	Description
DRIVE	All	Specifies the drive strength for bidirectional and output buffers.
EQ_CAL	LatticeECP3	Provides equalization filtering for single-ended inputs on both true and complementary I/Os and for differential inputs on true I/Os. **Note**: Only the default 0 value is valid for EQ_CAL.
HYSTERESIS	ECP5, MachXO2, MachXO3D, MachXO3L, Platform Manager 2	Sets the amount of hysteresis for the PCI, LVTTL and LVCMOS input and bidirectional I/O standards.
IMPEDANCE	LatticeSC/M	Sets the on-chip programmable output impedance. Depending on the I/O type and other selected attributes, settings can include OFF, 25, 33, 50, 100. OFF is the default.
IO_TYPE	All	Sets the I/O standard for the signal or port group.
MULTDRIVE	LatticeECP3	Sets the drive strength for individual output buffers for the MINILVDS output standard. Differential outputs with different MULTDRIVE settings can be placed in the same IO bank. Settings include 1X, 2X, 3X, 4X. **Note**: The MULTDRIVE value must be enclosed in quotation marks in the logical preference file.
OPENDRAIN	All	ON - specifies open-drain for an output or bidirectional buffer. OFF is the default. **Note**: For some designs, the OPENDRAIN attribute cannot be set to ON in Spreadsheet View but must be set in the HDL. Refer to the sysIO Usage Guide for the device family.
PCICLAMP	LatticeECP/EC, LatticeECP2, LatticeECP3, LatticeXP, LatticeSC/M, MachXO 1200/2280	ON - turns on the programmable PCI clamp diode. OFF is the default.
PULLMODE	All	Specifies the pull mode option: UP - pull-up (default) DOWN - pull-down NONE - pull off KEEPER - bus keeper
PWRSAVE	LatticeSC/M	Reduces power dissipation on comparator types of input pins. ON - Turns on the power save capability. OFF is the default.

Table 40:

Attribute	Supported Devices	Description
REFCIRCUIT	LatticeSC/M	Specifies a reference circuit for an output or bidirectional buffer. Settings include OFF, INTERNAL, EXTERNAL. OFF is the default.
SLEWRATE	All	Sets the slew rate for output and bidirectional buffers. Options are SLOW or FAST. SLOW is the default except for LatticeECP3 devices.
TERMINATEGND	LatticeSC/M	Sets the on-chip parallel input and output termination to ground. Depending on the I/O type and other selected attributes, settings can include OFF, 50, 100, 120. OFF is the default.
TERMINATEVCCIO	LatticeSC/M	Sets the on-chip parallel input and output termination to VCCIO. Depending on the I/O type and other selected attributes, settings can include OFF, 50, 100, 120. OFF is the default.
TERMINATEVTT	LatticeSC/M, LatticeECP3	Sets the on-chip input parallel termination to VTT. Depending on the I/O type and other selected attributes, settings can include OFF, 60 , 75, 120, 150, 210. OFF is the default.
TERMINATION	ECP5	Sets the on-chip input parallel termination to VCCIO/2. This parallel termination is achieved using a programmable Thevenin termination scheme of 50/75/150 ohms to VCCIO/2. OFF is the default.
VCMT	LatticeSC/M	Establishes a common mode voltage for input buffer elements. Depending on the I/O type and other selected attributes, settings can include OFF, VCMT, VTT, DDR_II. OFF is the default.
VREF	All except MachXO and Platform Manager	Assigns a defined voltage reference for the signal or port group.

Setting Clock Preferences

The Clock Resource sheet enables you to apply a clock domain to the device's primary or secondary clock or prohibit the use of primary and secondary clock resources in routing the net. For LatticeECP2 and LatticeXP2, it allows you to use edge clock resources to minimize the delay from the clock sources to I/O registers. For LatticeECP3 devices, it also enables you to specify a defined clock REGION, instead of a quadrant, for a secondary clock.

For clock enable (CE) or local set reset (LSR) signals, a secondary clock can be assigned or prohibited. Clocks for a clock net can be prohibited with the Prohibit Both command. This command writes a PROHIBIT PRIMARY and a PROHIBIT SECONDARY preference to the logical preference file (.lpf).

For a primary clock, you can also specify DCS or PURE for routing the clock spine. DCS will route the clock spine using the dynamic clock resource; PURE will route the clock spine without using the DCS routing resource.

The settings that you specify are written to the logical preference file (.lpf) as USE PRIMARY, USE SECONDARY, PROHIBIT PRIMARY, PROHIBIT SECONDARY, USE EDGE, and PROHIBIT EDGE preferences.

To set clock preferences:

1. In Spreadsheet View, select the Clock Resource sheet.
2. In the Selection, Quadrant, and DCS/PURE columns, double-click the cell for a given signal and choose the desired setting from the drop-down list. Optionally, right-click the cell and choose the setting from the pop-up menu.

Note

When a clock REGION is specified for a secondary clock, the REGION <region_name> <region_clock_space> preference must precede the USE SECONDARY preference that references it in the logical preference file.

Setting Output Load

The OUTPUT LOAD preference enables you to modify loading on output buffers from the default 0 pFs for timing analysis. You can specify the output load in the Port Assignments sheet of Spreadsheet View.

To set output load:

1. In Spreadsheet View, select the Port Assignments tab.
2. Double-click the cell in the Outload column that you want to modify for a given output signal and type the desired output load value.

Setting Maximum Skew

The MAXSKEW preference sets a maximum signal skew between a driver and loads on a specific clock signal.

To set the maximum skew:

1. In Spreadsheet View, select the Port Assignments tab.
2. Double-click the cell in the MaxSkew column that you want to modify for a given signal, and type the desired maximum skew value.
3. To specify the maximum skew for clock load only, double-click the Clock Load Only cell and choose **True**.

Assigning Route Priorities

The PRIORITIZE preference enables you to assign a priority to a selected net. Values range from 0 (lowest priority) to 100 (highest). This preference is used by the placement and routing (PAR) process, which assigns long lines by net priority and routes higher-priority nets before routing lower-priority nets.

To assign route priorities:

1. In Spreadsheet View, select the **Route Priority** tab.

   The Route Priority sheet contains three column headings: Type, Name, and Prioritize.
2. Choose **Tools > Netlist View** and click the nets button from the Netlist View toolbar.
3. Do one the following:

   - Click the Detach Tool button at the top right to open Netlist View in a separate window, and then position Netlist View alongside Spreadsheet View.
   - Click the Split Tab Group button on the toolbar to separate Netlist View into a tab group, and then select Spreadsheet View in the main tab group. Both views now appear side-by-side.
4. In Netlist View, expand the Nets list in the design tree.
5. Use Ctrl+click or Shift+click to select the nets that you want to prioritize.
6. Drag the selected nets to the Route Priority preference sheet and release the mouse button.

   Each net is given the default priority of 3.

7. To change the net priority of a selected net, double-click the Prioritize cell, and either type the desired value or select the value from the up and down arrows.
8. To return any nets to the default value, right-click the Prioritize cells for the selected nets and choose **Clear** or press the Delete key.

Click the “Integrate All Tools” button  to integrate the detached Netlist View with the main window.

Click the “Merge Tab Group” button  to merge the split tab into the main tab group.

To remove nets from the Route Priority sheet:

- Select the entire rows of the nets you want to remove, right-click, and choose **Delete Selected Rows**.

Specifying Registers for Flip-Flops

The USE DIN CELL and USE DOUT CELL preferences enable you to specify registers in your design that are to be used as input or output flip-flops. For each of these preferences, the True setting moves registers into the I/Os, and the False setting moves registers out of the I/Os.

To specify registers for flip-flops:

1. In Spreadsheet View, select the **Cell Mapping** tab.
2. Choose **Tools > Netlist View** and click the instances button  from the Netlist View toolbar.
3. Do one the following:
   - Click the Detach Tool button  at the top right to open Netlist View in a separate window, and then position Netlist View alongside Spreadsheet View.
   - Click the Split Tab Group button  on the toolbar to separate Netlist View into a tab group, and then select Spreadsheet View in the main tab group. Both views now appear side-by-side.
4. To add registers to the Cell Mapping sheet, expand the Registers folder in the design tree of Netlist View, and then select the registers that you want to specify as flip-flops.
5. Drag the selected registers to the Cell Mapping preference sheet and release the mouse button.
4. In the Din/Dout column for the selected flip-flop, choose **DIN** or **DOUT** and press **Enter**.

   The PIO Register cell is automatically changed to TRUE.
5. To change the PIO Register value, double-click the PIO Register cell and choose **FALSE**.

6. To undo the any of the values you have assigned, right-click the selected Prioritize cells and choose **Clear** or press the Delete key.

Click the “Integrate All Tools” button  to integrate the detached Netlist View with the main window.

Click the “Merge Tab Group” button  to merge the split tab into the main tab group.

To remove registers from the Cell Mapping sheet:

- Select the entire rows of the registers you want to remove, right-click, and choose **Delete Selected Rows**.

Specifying Voltage and Temperature

The Global preference sheet enables you to define the device core voltage and core temperature for any Lattice device. For LatticeSC/M devices, it also allows you to set other voltages for derating.

To specify voltage and temperature settings:

1. In Spreadsheet View, select the Global Preferences tab.
2. In the Preference Value column, double-click the cell for Junction Temperature and type a new value. Do the same for Voltage.
3. For LatticeSC/M devices, double-click the Preference Value cell for Derating and choose the desired value from the drop-down list.

Migrating Pin Assignments

Diamond provides pin compatibility information that helps you migrate pin assignments to a different device of the same family and package as the currently targeted device. This information enables you to save your current pinout while you explore other devices. It shows you which pins in your current device will be unavailable or have different functions when you switch devices, and it allows you to export the pin migration information to a pin layout file.

You use the “Incompatible Pins” dialog box to select one or more devices that are of the same family and package as your current device. Afterwards, you can view all incompatible pins in Spreadsheet View and Package View. The rows for incompatible pins are dimmed on the Pin Assignments sheet of Spreadsheet View. In Package View, a dark gray circle appears behind each incompatible pin square.

Pin compatibility information is available after the Translate Design process. It is available for all device families except Platform Manager.

Note

Pin migration is not available for LatticeSC/M devices.

See Also ▶"Selecting a Device for Possible Pin Migration" on page 483

- "Viewing Incompatible Pins" on page 484
- "Exporting Pin Migration Information" on page 486
- "Exporting a Pin Layout File" on page 562
- "Color Coding of Cell Values" on page 409

Selecting a Device for Possible Pin Migration

The Incompatible Pins dialog box allows you to select one or more devices for possible pin migration. Afterwards you can view the incompatible pins—those that would not be available or that would have a different function if you were to switch from the current device.

To select one or more devices for pin migration:

1. Open Spreadsheet View or Package View.
2. Choose **View > Show Incompatible Pin** or click the  button on the toolbar.

   The Incompatible Pins dialog box lists all the devices that are of the same device family and package as the current device.
3. Select one or more of the devices from the Compatible Devices list, or select **All Devices**.

   If you select one device from the list, the incompatible pins will include those between the current device and the selected device.

   If you select more than one device or All Devices, the incompatible pins will include those between the current device and the combination of all selected devices.

   Note

   The LFE3-17EA, in a 484 package, may have a DQS grouping migration issue that requires design changes if DQS-DQ associations are used in the design. Refer to the ECP3 Data Sheet and the ECP3 pinout files for the specific devices to check for DQS grouping mismatches.
4. In the Check Areas section, select the types of incompatibility that you want included for the selected devices: pins whose type, configuration, LVDS/high speed, and bank numbers differ between the current device and the selected devices.
5. Optionally, select **Disable Incompatible Pins Assignment** to unlock any previously assigned pins that would now be incompatible.

6. Click **OK**.

   If you did not select the “Disable Incompatible Pin Assignments” option, all of the pins that are incompatible will be displayed in a dim font on the Pin Assignments sheet and with a dark gray circle in Package View.

   If you selected the “Disable Incompatible Pin Assignments” option and your design includes pin assignments that are incompatible with the selected devices, a dialog box will warn you that all assignments to incompatible pins will be released. Do one of the following:

   - Click **Yes** to continue.

     This releases the pin assignments that are now incompatible but retains all other pin assignments. All incompatible pins will be displayed in a dim font on the Pin Assignments sheet and with a dark circle in Package View. Names of previously assigned signals whose pins are now incompatible will not be displayed.

     There is no Undo for this operation. If the design has already been mapped, it will be initialized back to pre-map status when you save the change.

   - Click **No** if you decide that you do not want to release the previously assigned pins.

     This maintains all of your current assignments but displays none of the pins as incompatible. To display incompatible pins while maintaining the assignments, you must re-open the Incompatible Pins dialog box and select other devices.

- “Color Coding of Cell Values” on page 409

Viewing Incompatible Pins

An incompatible pin is one that would not be available or would have a different function if you were to switch your design from the current device to a different device. After selecting one or more devices of the same family and

package for possible pin migration, you can view the incompatible pins in Spreadsheet View and Package View. In Package View, you can also view the tool tip that explains why a device pin is incompatible.

Note

None of the pin sites that are marked as incompatible can be assigned. If you need to use any of these sites for your design, you must return to the "Incompatible Pins" dialog box and adjust your device selections.

To view incompatible pins in Spreadsheet View:

- Select the Pin Assignments sheet and scroll through the list of pins.

  The rows for pins that are incompatible are dimmed.

  Note

  When you use the Assign Pins dialog box from the Port Assignments sheet, all incompatible pins in the dialog box are dimmed.

To view incompatible pins in Package View:

- In Package View, maximize the view or choose **View > Zoom Fit**.

  On the Package View layout, each incompatible pin is displayed with a dark gray circle behind the pin square.

- Hold your mouse pointer over an incompatible pin to view the tool tip.

  The explanation of why the pin is incompatible is listed at the end of the tool tip and will include one of the following:

  "[TYPE] is not compatible"

  "[HIGHSPEED] is not compatible"

  "[CFG] is not compatible"

  "[Bank Number] is not compatible"

See Also "Spreadsheet View" on page 406

- "Package View" on page 424
- Migrating Pin Assignments
- "Exporting Pin Migration Information" on page 486
- "Exporting a Pin Layout File" on page 562

Prohibiting Incompatible Pins

Both Spreadsheet View and Package View enable you to create a PROHIBIT preference for selected incompatible pins or all incompatible pins. Prohibiting incompatible pins will prevent you from assigning signals to them. It will also prevent the Map and Place & Route processes from using these incompatible pins. When you prohibit incompatible pins, none of the pins that have already been assigned will become unlocked.

To prohibit all incompatible pins:

1. In Spreadsheet View or Package View, select the devices for possible pin migration.
2. Click the **Prohibit Incompatible Pins** button  on the toolbar.

   On the Pin Assignments sheet of Spreadsheet View, “Prohibit” appears in the signal name column for all prohibited incompatible pins.

   In Package View, all prohibited incompatible pins are highlighted in red.

To release all prohibited incompatible pins:

- Click the **Release Incompatible Pins** button  on the toolbar.

To prohibit one or several incompatible pins:

- On the Pin Assignment sheet of Spreadsheet View or in Package View, select the incompatible pins that you want to prohibit. Right-click, and choose **Prohibit**.

To release one or several incompatible pins:

- On the Pin Assignment sheet of Spreadsheet View or in Package View, select the prohibited pins that you want to release. Right-click and choose **Release**.

See Also “Viewing Incompatible Pins” on page 484

- “Selecting a Device for Possible Pin Migration” on page 483

Exporting Pin Migration Information

Diamond allows you to include pin migration information in an exported pin layout file of your design. The exported pin layout file uses a delimiter-separator format, such as comma-separator value (.csv), which allows you to view the report in an external spreadsheet application. In addition to pin migration information, the pin layout file provides a report of available device pins, pin assignments, and IOBUF attributes. You can include pin migration information in the report by selecting the **Pin Migration** option in the Export Pin Layout File dialog box.

See “Exporting a Pin Layout File” on page 562

Setting LOCATE Preferences in Floorplan View

You can set LOCATE preferences in Floorplan View for I/O, EBR, PLL, DLL, and DSP components. There are three ways to make these assignments:

- Drag and drop selected elements from Netlist View to Floorplan View

- Use the “Set LOCATE Preference” command for placed components in Floorplan View.
- Drag an assigned component to a new location in Floorplan View.

When you save the change, Diamond saves each assignment with a LOCATE COMP preference in the logical preference file (.lpf).

Dragging Elements from Netlist View to Floorplan View You can drag and drop I/O, EBR, PLL, DLL, and DSP elements from Netlist View to Floorplan View at any stage of the design flow after design translation.

To set LOCATE preferences using Netlist View and Floorplan View:

1. Open both Netlist View and Floorplan View, and then position each view next to each other by doing one the following:
   - Select Netlist View and click the Detach Tool button at the top right to open it as a separate window. Do the same for Floorplan View, if desired, and then position both views next to each other.
   - Click the Split Tab Group button on the toolbar to separate Netlist View into a tab group, and then select Floorplan View in the main tab group. Both views now appear side-by-side.
2. In Floorplan View, zoom in as needed to the area where you want to make the assignment.
3. In Netlist View, do one of the following:
   - Click the Ports button , and select one or more ports for I/O assignments.
   - Click the Instances button and expand the appropriate folder. Select one or more instances for EBR, PLL, DLL, or DSP assignments.
4. Using the left mouse button, drag the selection to the desired sites on the Floorplan View layout, and release the mouse button.

   If you make an error, choose **Edit > Undo**.

   Netlist View displays the newly assigned locations, and each site is filled with color in Floorplan View. When you save the change, each assignment is written to the .lpf file as a LOCATE COMP preference. The placement will be retained in the next Place & Route process.

Click the “Integrate All Tools” button to integrate the detached Netlist View with the main window.

Click the “Merge Tab Group” button to merge the split tab into the main tab group.

Using the “Set LOCATE Preference” Command in Floorplan View After placement and routing, you can set LOCATE preferences directly on the Floorplan View layout. You can do this for one or more I/O, EBR, PLL, DLL, or DSP components that you want placed in the same location that was

assigned by Place & Route. This will ensures that the placement will be retained when you rerun PAR. When you save the changes, Diamond saves each instance with a LOCATE COMP preference in the logical preference file (.lpf).

To assign LOCATE preferences using Floorplan View:

1. In Floorplan View, use the zoom tools to enlarge the area that contains the instances that you want to reassign.
2. Select the assigned components, using one of the following methods:
   - Click a single component.
   - Use Ctrl+click to select more than one component.
   - Click a component in a row or column, and then hold the Shift key while you select a different component in the same column or row. Diamond highlights all components and sites within range of the two selected components.
   - Drag the mouse pointer around the area that contains the desired components. All components and sites within the area become highlighted.
3. To keep the locations assigned by Place & Route, right-click the selected components and choose **Set LOCATE Preference**.

   The components are now displayed with a cross-hatch overlaying the solid color fill.
4. Choose **File > Save**.

   Diamond saves each assignment as a LOCATE COMP preference in the .lpf file. The placement will be retained in the next Place & Route process.

Dragging an Assigned Component to a New Location in Floorplan View You can drag an assigned component to a new location in Floorplan View. You can do this for components that have already been assigned with a LOCATE preference or for those that were automatically assigned by Place & Route.

1. In Floorplan View, use the zoom tools to enlarge the area that contains the assigned components that you want to reassign.
2. Select one or more I/O, EBR, PLL, DLL, or DSP components, using one of the following methods:
   - Click a single component.
   - Use the Ctrl key to select more than one component.
   - Click a component in a row or column, and then hold the Shift key while you select a different component in the same column or row. Diamond highlights all components and sites within range of the two selected components.

- Drag the mouse pointer around the area that contains the desired components. All components and sites within the area become highlighted.

Note

DSP components can be dragged and dropped only after Place & Route.

3. Using the left mouse button, drag the selected components to the desired sites, and then release the mouse button.

   The targeted sites are now displayed with a cross-hatch overlay. The previously assigned locations are still displayed with a solid color fill. The components will be moved to the new location when you rerun Place & Route.

Back Annotating Assignments

To ensure that subsequent Place & Route (PAR) processes produce the same results, Diamond enables you to back annotate placement and configuration assignments to the logical preference file (.lpf), where they can be modified as needed. The back annotation process gathers the assignments produced by PAR from the physical design (.ncd) file, and it places them in memory. They can then be viewed in the Preference Preview before saving. When you save the assignments, Diamond writes the placement assignments to the .lpf file as LOCATE preferences, and it writes the configuration assignments as IOBUF preferences. The design is then returned to the pre-map stage.

To back annotate assignments:

1. Run the **Place & Route Design** process to obtain a physical design (.ncd) file for the design.
2. Open Package View, Spreadsheet View, or Floorplan View.
3. Choose **Design > Back Annotate Assignments**.
4. In the dialog box, select the types of assignments that you want to back annotate and click **OK**.

   Diamond gathers the assignments from the .ncd file and places them in memory.
5. To view the assignments before saving, choose **View >  Preference Preview**.
6. To write the assignments to the .lpf file, return to Package View, Spreadsheet View, or Floorplan View, and then choose **File > Save <file_name>.lpf**.

   Diamond back annotates the assignments to the active .lpf file and re-initializes the design to the pre-map stage.
7. Modify preferences as needed, and then rerun **Place & Route Design**.

See Also ▶"Setting LOCATE Preferences in Floorplan View" on page 486

- "Displaying I/O Placement Assignments in Spreadsheet View" on page 420
- "Displaying I/O Placement Assignments in Package View" on page 427
- "How Assignments are Displayed in Floorplan View" on page 433

Setting Timing Preferences

The first five buttons on Spreadsheet View's toolbar gives you quick access to timing preference dialog boxes. You can also access the dialog boxes from the Timing Preferences spreadsheet and from Spreadsheet View's Edit > Preference menu.

 adds a BLOCK preference.

 adds a PERIOD or FREQUENCY preference.

 adds an INPUT_SETUP or CLOCK_TO_OUT preference.

 adds a MULTICYCLE preference.

 adds a MAXDELAY preference.

Auto Generating Timing Preferences

If you do not define any timing preferences for your FPGA design, the software will automatically generate a few timing preferences when you run the Map TRACE process. It generates FREQUENCY preferences to set your fMAX for each clock network and writes these preferences to the physical preference file (.prf). This estimated maximum frequency drives the PAR process to provide better performance results. You can either accept these preferences or use them as the starting point to set your own timing preferences.

By default, the Auto Timing option is turned on in the Strategy dialog box for the Map Trace process and the Place & Route Trace process. To prevent the auto generation of timing preferences, change the Auto Timing setting to False for each of these processes.

Note

If you have specified even a single timing preference, the auto-generation will not happen.

When the Auto Timing option is turned on, the software checks the project's physical preference file (.prf) during the Map Design process to see if it contains any timing preference. If no timing preferences are found, the software will automatically generate fMAX preferences for each clock network and write them to the .prf file. These timing preferences represent the estimation of fMAX, which can drive the Place & Route process to get better performance.

The following example shows auto-generated preferences that have been added to the .prf file:

Figure 78:

```
// Section Autogen
BLOCK RESETPATHS ;
BLOCK ASYNCPATHS ;
FREQUENCY PORT "CLK" 346.741 MHz ;
FREQUENCY NET "CLK_int" 346.741 MHz ;
// End Section Autogen
```

When auto-generating timing preferences, the software identifies all clock sources at input ports and internal nets, which drive the clock pin of any internal register/RAM/DSP or I/O register in a given design. The fMAX preference is generated for each clock source input port or net. There is no preference generated for any multi-domain path crossing over different clock source input ports. For a gated clock such as a clock from an AND gate, both input ports to 2-input of an AND gate will be identified as clock source with Fmax preference based on MAP-module-delay result.

The auto-generated timing preferences are written to the .prf file. The logical preference file (.lpf) does not contain them. When you rerun the Map Design process, the software regenerates the .prf file from the preferences defined in the .lpf file and design source files, which means that the auto-generated preferences in the previous .prf file will be lost. If you want to retain these preferences, copy them into your .lpf file before you remap your design.

To get auto-generated timing preferences and adjust them based on your actual requirement, run the Map process without setting any timing preferences. The software will auto generate timing preferences and write them to the .prf file in the project directory. You can then open the .prf file in a text editor as a reference and edit the .lpf file accordingly. Otherwise, you can copy the timing preferences from the .prf file to the .lpf file and open Spreadsheet View to edit them. When you remap the design, the previous .prf file with auto-generated preferences will be overwritten.

Setting BLOCK Preferences

A BLOCK preference is useful for excluding specific nets or paths from timing analysis that are not relevant to the synchronous timing of your design. The Block Preference dialog box enables you to block one or more nets or buses and all paths through them or block a path to and from specified groups or objects. The BLOCK preferences are displayed in the Timing Preferences sheet of Spreadsheet View.

You can also set global preferences to block all paths of a certain type from timing analysis. See “Global Preferences” on page 382.

To block a path that goes through a specified pin of a named component, you can set a BLOCK COMP PIN preference in the .lpf file, using a text editor. See “Setting Preferences in a Text Editor” on page 525.

To open the BLOCK preference dialog box:

- In Spreadsheet View, click the Block Preference button on the toolbar.

  Alternatively, open the Timing Preferences sheet and double-click **BLOCK** in the Preference Name column.

To block a net: 1.In the Block Preference dialog box under Type, select the **Block Nets** option.

All the nets in your design appear in the Available Nets list. You can use the Filter box and wildcards to narrow the list of displayed nets or to create a single BLOCK preference for multiple nets.

2. Do one of the following:
   - Select the net that you want to block
   - Using wildcards, type a string (case-sensitive) in the Filter box to create a single BLOCK preference for multiple nets.
3. Click **OK**.

   The new preference is added to the BLOCK Preference list on the Timing Preference sheet.

To block a bus: 1.In the Block Preference dialog box under Type, select the **Block Buses** option.

All the buses in your design appear in the Available Buses list. You can use the Filter box and wildcards to narrow the list of displayed buses or to create a single BLOCK preference for multiple buses.

2. Do one of the following:
   - Select the bus that you want to block.
   - Using wildcards, type a string (case-sensitive) in the Filter box to create a single BLOCK preference for multiple buses.
3. Click **OK**.

   The new preference is added to the BLOCK Preference list on the Timing Preference sheet.

To block the path from one group to another: 1.In the Block Preference dialog box under Type, select the **Block Path for** option, and then select **Group** from the drop-down menu.

All the port, cell, and ASIC groups that have been defined in your design are displayed in the two lists. You can use the Filter box and wildcards to limit the number of groups displayed in each list. You cannot, however, create a single BLOCK preference from multiple groups.

2. In the “From User Groups” list, select the source group.
3. In the “To User Groups” list, select the destination group.
4. Click **OK**.

   The new preference is added to the BLOCK Preference list on the Timing Preferences sheet.

To block the path from one clock net, port, cell, or ASIC to another:

1. In the Block Preference dialog box under Type, select the **Block Path for** option, and then select the desired object type from the drop-down menu.

   Depending on your selection, all the clock nets, ports, cells, or ASICs in your design are displayed in the appropriate “From” and “To” lists. You can use the Filter box and wildcards to limit the number of objects displayed in each list. You cannot, however, create a single BLOCK preference from multiple objects.

2. In the “From” list, select a clock net, port, cell, or ASIC path source.
3. In the “To” list, select a clock net, port, cell, or ASIC path destination. For ASICs, also select an ASIC pin from the “From Pins” list and the “To Pins” list.
4. Clock **OK**.

   The new preference is added to the BLOCK Preference list on the Timing Preferences sheet.

Setting PERIOD and FREQUENCY Preferences

The PERIOD preference allows you to verify sequential data paths internal to the design. It identifies a clock period for all sequential output to sequential input pins clocked by the specified net. If no net name is given, the specific clock period will apply to all sequential input pins that do not have a specific clock period.

The FREQUENCY preference identifies the minimum operating frequency for all sequential output to sequential input pins clocked by the specified net. If no net name is given, the preference applies to all clock nets in the design that do not have a specific clock frequency. FREQUENCY works in the same way as PERIOD, except that time is specified in Hz instead of seconds.

You can set PERIOD and FREQUENCY preferences using the PERIOD/FREQUENCY Preference dialog box. These preferences are then displayed in the Timing Preferences sheet of Spreadsheet View.

To set a PERIOD preference: 1.In Spreadsheet View, do one of the following:

- Click the Period/Frequency button  on the toolbar to open the dialog box, and then select **PERIOD**.
- Open the Timing Preferences sheet and double-click **PERIOD** in the Preference Name column. When the dialog box opens, the PERIOD preference type will already be selected.

2. Under Second Type, do one of the following:

   - Select **None** if you want to specify a clock period that applies to all sequential input pins that do not have a specific clock period.
   - Select **Clock Net** if you want to specify a clock period for all sequential output to sequential input pins clocked by a specified net.

- Select **Clock Port** if you want to assign a clock period to the specified top-level clock signal port.

3. If you have chosen **Clock Net** or **Clock Port** in step 2, select one or more objects in the Available Clock Nets or Available Clock Ports list.

   For nets, you can use the Available Clock Nets list Filter and wildcard notation to create a single PERIOD preference for multiple clock nets. Using wildcard notation, type a string (case-sensitive) to limit the list to the clock nets you want to include, and then click Go.

   See "Using Filters and Wildcards" on page 422.

   For ports, you can use the filter to limit the list of ports displayed. You must then select a clock port from the list.

4. Enter a value in nanoseconds for Time, and do the same for Hold Margin.
5. In the PAR_ADJ box, type the desired value. The PAR_ADJ option is available when **Clock Net** or **Clock Port** is selected under Second Type.

   Note

   PAR_ADJ allows you to loosen requirements for place-and-route results while tightening up the requirements reported by the TRACE static timing analysis tool. The variance in required timing values on PAR and TRACE enables you to experiment more efficiently with the strategy of purposely over-constraining your design to determine your best constraint settings. For example, if FREQUENCY is set to 250MHz and you set PAR_ADJ to 20, the software will use the simple addition formula of 250 + 20 = 270MHz to direct PAR while running TRACE on 250MHz.

6. In the CLOCK_JITTER (p-p) box, which is available for a clock port only, type a value in nanoseconds for peak-to-peak jitter on the incoming clock.

   Trace will use half of this peak-to-peak jitter value for all analysis.

7. Click **OK**.

   The Timing Preferences sheet displays the new preference in the PERIOD list.

To Set a FREQUENCY Preference 1.In Spreadsheet View, do one of the following:

- Click the Period/Frequency button  on the toolbar to open the dialog box, and then select **FREQUENCY**.
- Open the Timing Preferences sheet and double-click **FREQUENCY** in the Preference Name column. When the dialog box opens, the FREQUENCY preference type will already be selected.

2. Under Second Type, do one of the following:

   - Select **None** if you want to specify a clock frequency that applies to all sequential input pins that do not have a specific clock period/ frequency.
   - Select **Clock Net** if you want to specify a clock frequency for all sequential output to sequential input pins clocked by a specified net.

- Select **Clock Port** if you want to assign a clock frequency to the specified top-level clock signal port.

3. If you have chosen **Clock Net** or **Clock Port** in step 2, select one or more objects in the Available Nets/Clock Ports list.

   For nets, you can use the Available Clock list Filter and wildcard notation to create a single FREQUENCY preference for multiple clock nets. Using wildcard notation, type a string (case-sensitive) to limit the list to the clock nets you want to include, and then click Go.

   See "Using Filters and Wildcards" on page 422.

   For ports, you can use the filter to limit the list of ports displayed. You must then select a clock port from the list.

4. Type a value in MHz for frequency, and a value in nanoseconds for Hold Margin.

5. In the PAR_ADJ box, type the desired value. The PAR_ADJ option is available when **Clock Net** or **Clock Port** is selected under Second Type.

   Note

   PAR_ADJ allows you to loosen requirements for place-and-route results while tightening up the requirements reported by the TRACE static timing analysis tool. The variance in required timing values on PAR and TRACE enables you to experiment more efficiently with the strategy of purposely over-constraining your design to determine your best constraint settings. For example, if FREQUENCY is set to 250MHz and you set PAR_ADJ to 20, the software will use the simple addition formula of 250 + 20 = 270MHz to direct PAR while running TRACE on 250MHz.

6. In the CLOCK_JITTER (p-p) box, which is available for a clock port only, type a value in nanoseconds for peak-to-peak jitter on the incoming clock.

   Trace will use half of this peak-to-peak jitter value for all analysis.

7. Click **OK**.

   The Timing Preferences sheet is activated and displays the new preference in the FREQUENCY list.

Setting INPUT_SETUP and CLOCK_TO_OUT Preferences

INPUT_SETUP specifies a setup time requirement for input ports relative to a clock net. CLOCK_TO_OUT specifies a maximum allowable output delay relative to a clock. These preferences are displayed in the Timing Preferences sheet of Spreadsheet View.

To set INPUT_SETUP preferences: 1.In Spreadsheet View, do one of the following:

- Click the Input_setup/Clock_to_out button  on the toolbar to open the dialog box, and then select **INPUT_SETUP**.

- Open the Timing Preferences sheet and double-click **INPUT_SETUP** in the Preference Name column. When the dialog box opens, the INPUT_SETUP preference type will already be selected.

2. Under Second Type, select one of the following:
   - **All Ports** to specify the time delay from all input ports to the specified clock port/net.
   - **Individual Ports** to specify the time delay from one or more specified input ports to the specified clock port/net.
   - **Group** to specify the time delay from one or more specified input groups to the specified clock port/net.
3. If you have chosen Individual Ports or Group in step 2, select one or more ports in the Available Input Ports list or one or more groups in the Available Input Groups list.

   For ports, you can use wildcard notation in the Available Input Ports filter to create a single INPUT_SETUP preference for multiple ports. Type a string (case-sensitive) to limit the list to the input ports you want to include, and then click **Go**.

   See "Using Filters and Wildcards" on page 422.

   For groups, you can use the filter to limit the list of groups displayed. You must then select one or more groups from the list.
4. Under Available Clock Ports/Nets, select the destination port/net.

   You can use the Clock Ports/Nets filter to limit the list. You must then select a clock port or net from the list.
5. In the Time box, enter a delay value in nanoseconds.
6. If you also want to specify hold, enter a value in the Hold Time box.
7. To specify a multiple of the clock period for adjusting the timing analysis, type a value in the Clock Offset text box.
8. Optionally select the following:
   - **Input Delay** to specify Time as an INPUT_DELAY value
   - **PLL Phase Back** to reverse the offset direction of the phase delay programmed into a PLL
   - **SS** to indicate that the data input and clock input are source-synchronous. This will allow input jitter specified on the clock to be ignored for setup and hold timing analysis.
9. Click **OK**.

   The Timing Preferences sheet displays the new preference in the INPUT_SETUP list.

To set CLOCK_TO_OUT preferences: 1.In Spreadsheet View, do one of the following:

- Click the Input_setup/Clock_to_out button  on the toolbar to open the dialog box, and then select **CLOCK_TO_OUT**.

- Open the Timing Preferences sheet and double-click **CLOCK_TO_OUT** in the Preference Name column. When the dialog box opens, the CLOCK_TO_OUT preference type will already be selected.

2. Under Second Type, select one of the following:
   - **All Ports** to specify the time delay from all output ports to the specified clock port/net.
   - **Individual Ports** to specify the time delay from the specified output ports to the specified clock port/net.
   - **Group** to specify the time delay from the specified output group to the specified clock port/net.
3. If you have chosen **Individual Port** or **Group** in step 2, select one or more ports in the Available Output Ports list or one or more groups in the Available Output Groups list.

   For ports, you can use wildcard notation in the Available Output Ports filter to create a single CLOCK_TO_OUT preference for multiple ports. Type a string (case-sensitive) to limit the list to the output ports you want to include, and then click **Go**.

   See "Using Filters and Wildcards" on page 422.

   For groups, you can use the filter to limit the list of groups displayed. You must then select one or more groups from the filtered list.
4. Under Clock Ports/Nets, select the destination port/net.

   You can use the Clock Ports/Nets filter to limit the list of clocks displayed. You must then select a clock port or net from the list.
5. If you want to specify the output clock port with respect to which output delay needs to be measured, make your selection under Clock Out Ports.

   You can use the Clock Out Ports filter to limit the list of ports displayed. You must then select a port from the list.
6. In the Time box, enter a time delay value in nanoseconds.
7. If you also want to specify hold time, enter a value in the Min Time box.
8. To specify a multiple of the clock period for adjusting the timing analysis, type a value in the Clock Offset text box.
9. To specify a register as the starting point for the maximum delay, click the **From Cell** button. In the From Cell dialog box, you can use the filter to narrow the list. You must then select a cell from the list and click **OK**.
10. Optionally, select the following:
    - **Output Delay** to specify this as an OUTPUT_DELAY value
    - **PLL Phase Back** to reverse the offset direction of the phase delay programmed into a PLL
11. Click **OK**.

    The Timing Preferences sheet displays the new preference in the CLOCK_TO_OUT list.

Setting MULTICYCLE Preferences

MULTICYCLE allows for relaxation of previously defined PERIOD/ FREQUENCY preferences on a path. MULTICYCLE is considered in conjunction with the FREQUENCY and PERIOD preferences specified and will relax ONLY those paths that are constrained by FREQUENCY and PERIOD. These preferences are displayed in the Timing Preferences sheet of Spreadsheet View.

To set MULTICYCLE preferences:

1. In Spreadsheet View, click the Multicycle Preference button  on the toolbar.

   Alternatively, open the Timing Preferences sheet and double-click **MULTICYCLE** in the Preference Name column.

2. In the dialog box, under Type, do one of the following:

   - Select **General** if you want to relax the PERIOD or FREQUENCY preferences on a specified general path.
   - Select **Clock Net to Clock Net** if you want to relax the PERIOD or FREQUENCY preferences on a path starting from one clock net to another.
   - Select **Slow/Fast Path Exception** if you want to relax the PERIOD or FREQUENCY preferences on a path starting from one user group to another.

3. In the “From” area, do one or both of the following:

   - Click **<path_elem>** to specify the start point component for the MULTICYCLE path.
   - Click **CLKNET <Snet>** to specify the source clock net/port for the MULTICYCLE path.

   For ports and cells, you can use wildcard notation in the dialog box filters to create a single MULTICYCLE preference for multiple elements. Type a string (case-sensitive) to limit the list to the ports or cells you want to include, and then click **Go**.

   See “Using Filters and Wildcards” on page 422.

   For other elements, you can use the filter to limit the list of elements displayed. You must then select an element from the list.

4. In the “To” area, do one or both of the following:

   - Click **<path_elem>** to specify the end point component for the MULTICYCLE path.
   - Click **CLKNET <Dnet>** to specify the destination clock net/port for the MULTICYCLE path.

   If desired, use the dialog box filters, as explained in Step 3.

5. Do one of the following:

   - Select **Time** and type a delay value in nanoseconds.

- Select **X** and type a value to specify a multiple of the clock period for the clock driving the start and end point components. Select X, X_Source, or X_Dest from the drop-down list.

6. Optionally, choose a path type from the drop-down list:
   - Select READPATHS to define the multicycle paths at memory-block read-side.
   - Select SAMECLKEN to define the multicycle paths at the source/destination register controlled by the same clock-enable signal.
   - Select CLKEN_NET to define the multicycle paths at the source/destination register controlled by a given <net_name>.

     If you choose CLKEN_NET, specify the net name in the ClkEnNet text box.
7. Click **Add**.

   The Timing Preferences sheet displays the new preference in the MULTICYCLE list.

See Also "Modifying Timing Preferences" on page 503

- "Using Wildcard Expressions in Preferences" on page 531.

Setting MAXDELAY Preferences

MAXDELAY identifies a maximum total delay for a net, bus, or path in the design. Maximum delay preferences are displayed in the Timing Preferences sheet of Spreadsheet View.

To set a MAXDELAY preference:

1. In Spreadsheet View, click the MaxDelay Preference button  on the toolbar.

   Alternatively, open the Timing Preferences sheet and double-click **MAXDELAY** in the Preference Name column; or right-click MAXDELAY and choose **New MAXDELAY FROM TO** from the pop-up menu.
2. In the "From" area, click **<path_elem>** to specify the start point component for the MAXDELAY path.

   For ports and cells, you can use wildcard notation in the dialog box filters to create a single MAXDELAY preference for multiple elements. Type a string (case-sensitive) to limit the list to the ports or cells you want to include, and then click **Go**.

   See "Using Filters and Wildcards" on page 422.

   For other elements, you can use the filter to limit the list of elements displayed. You must then select an element from the list.
3. In the "To" area, click **<path_elem>** to specify the end point component for the MAXDELAY path.

If desired, use the dialog box filter, as explained in Step 2.

Note

It is recommended that you always specify both the start point and end point of the path. If you do not select a component for both FROM and TO, the default for the unspecified path element will include all I/O ports and registers, which is similar to the preference FREQUENCY. If the BLOCK ASYNCPATH preference is set to ON, all input-pad-to-register paths will be removed for the unspecified start point or end point, in the same way as the preference FREQUENCY.

4. In the Time text box, type a delay value in nanoseconds.
5. Click **Add**.

   The Timing Preferences sheet is activated and displays the new preference in the MAXDELAY list.

See Also ▶"Modifying Timing Preferences" on page 503

- "Using Wildcard Expressions in Preferences" on page 531
- "Setting a MAXDELAY Preference for a Net" on page 500

Setting a MAXDELAY Preference for a Net

The MAXDELAY_NET dialog box enables you to set a MAXDELAY preference for a specific net instead of a path. When you use Net, the maximum delay constraint applies to all driver-to-load connections on the net.

To set a MAXDELAY preference for a specific net:

1. In Spreadsheet View, select the Timing Preferences sheet.
2. Right-click **MAXDELAY** and choose **New MAXDELAY NET** from the pop-up menu..
3. In the dialog box, type the full name of the desired net in the name text box.
4. To include only data path delay information, choose **ON** from the dataPath Only drop-down menu.
5. In the delay text box, type a delay value in nanoseconds.
6. Click **Add**.

   The new MAXDELAY_NET preference is added to the Timing Preferences sheet under MAXDELAY.

See Also ▶"Modifying Timing Preferences" on page 503

Setting a CLKSKEWDIFF Preference

The CLKSKEWDIFF preference specifies an input skew between two top-level input clock ports.

To set a CLKSKEWDIFF preference:

1. In Spreadsheet View, select the Timing Preferences sheet.
2. Double-click **CLKSKEWDIFF** to open the dialog box.
3. Select a clock from the Available Clock Ports 1 list and one from the Available Clock Ports 2 list.

   You can use the Filter box and wildcards to narrow each of these list. Type a string (case-sensitive), and then click **Go**.
4. In the Value text box, type a value for the maximum skew between the selected top-level ports.
5. Optionally, type a value for the minimum clock skew in the Min Value text box.
6. Click **OK**.

   The new CLKSKEWDIFF preference is added to the Timing Preferences sheet.

See Also ▶"Modifying Timing Preferences" on page 503

▶ "Using Filters and Wildcards" on page 422

Setting Timing Preferences in Netlist View

Netlist View enables you to set timing preferences for selected ports and nets. The preferences are added to the Timing Preferences sheet of Spreadsheet View.

To add timing preferences for selected ports:

1. In Netlist View, click the Ports button  to open the ports tree.
2. Select the desired port, right-click, and choose a timing preference from the pop-up menu.
3. Follow the instructions for setting PERIOD and FREQUENCY, INPUT_SETUP and CLOCK_TO_OUT, MULTILCYCLE, or MAXDELAY preferences.

To add a PERIOD or FREQUENCY preference for a selected clock net:

1. In Netlist View, click the Nets button  to open the nets tree, and then expand the Clock folder.
2. Select the desired clock net, right-click, and choose **Set Clock Preference**.
3. Follow the instructions for setting PERIOD and FREQUENCY preferences.

To add BLOCK preferences for selected nets:

1. In Netlist View, click the Nets button  to open the nets tree.
2. Select the desired net, right-click, and choose **Set BLOCK Preference**.

3. Follow the instructions for setting BLOCK preferences.

The timing preferences are added to the Timing Preferences sheet of Spreadsheet View.

Setting PLL and DLL Attributes

If your design contains PLL or DLL modules, Spreadsheet View will include them on the Timing Preferences sheet, which enables you to set both PLL and DLL attributes.

To set PLL or DLL Attributes:

1. In Spreadsheet View, click the Timing Preferences tab.

   The Timing Preferences sheet shows the type, name, and attributes of your PLL/DLL module. For LatticeECP/EC, LatticeECP2, and LatticeXP designs, you can only edit the FDEL attribute. LatticeSC/M designs have more PLL and DLL attributes available for editing.

2. Double-click the Preference Value cell for the PLL or DLL preference you want to edit, and then type a new value.

The attribute values you specify in Spreadsheet View take precedence over those defined during module generation. You can also edit PLL/DLL attributes directly in the ASCII logical preference file (.lpf) using a text editor.

See "How to Design with sysCLOCK PLLs and DLLs" on page 1168 for more information, including application notes that are available from the Lattice Semiconductor web site.

Modifying Timing Preferences

Use the Timing Preferences sheet to modify or delete a timing preference.

To modify a timing preference:

1. Open the Timing Preferences sheet and double-click the preference that you want to modify. Alternatively, right-click the preference and choose **Modify** from the pop-up menu.
2. In the dialog box, modify the preference as desired and click **Update**.

Note

You can also modify values for timing preferences directly on the Timing Preferences sheet. Double-click or right-click the Preference Value cell and type a new value.

To delete a timing preference:

- On the Timing Preferences sheet, select the preference that you want to remove and press the Delete key. Alternatively, right-click the preference and choose **Delete** from the pop-up menu.

Using Timing Preference Files (.tpf)

A timing preference file (.tpf) is an editable version of your timing preferences that you can modify for the purpose of timing analysis. It is available from Timing Analysis View after placement and routing. Timing preference files enable you to experiment with different sets of timing preferences and obtain quick analysis without having to rerun Map, Place & Route.

Timing Analysis View provides a "Spreadsheet View – TPF" that displays global, timing, and group preferences. When you first open the TPF Spreadsheet View, it displays any timing preferences from the HDL source files and the active logical preference file (.lpf). You can modify these preferences in the TPF Spreadsheet View or create new ones. When you save the changes, Diamond writes them to a .tpf file that you name, and it adds the .tpf file to the Analysis Files folder.

When you are ready, you can transfer timing preferences to Spreadsheet View from the TPF Spreadsheet. You can then add them to the logical preference file with the Save command.

See "Using Timing Analysis View" on page 729 for complete information.

See Also "Analyzing Static Timing" on page 691

Grouping Logical Components

Diamond enables you to establish groups of ports, cells, or ASIC blocks and create universal groups (UGROUPs) of logical elements to guide placement and routing.

Defining groups and regions should be done in the pre-mapped stage of the design flow, whenever possible. The topics that follow explain how to define logical groups using Diamond's preference-editing views.

Defining Port, Cell, and ASIC Groups

Cell, port, and ASIC groups enable you to place identical timing constraints on grouped elements. For port groups that use certain SSTL or HSTL I/O types, the defined group allows you to associate a voltage reference (Vref) for all the signals in the group.

The Group Assignment dialog box allows you to define each type of group and create multiple groups in one session. It is available from the Spreadsheet View toolbar, the Group preference sheet, and Spreadsheet View's Edit > Preference menu. It is also available from Netlist View for selected ports or registers. The groups are written to the logical preference file as DEFINE GROUP preferences.

To define a port group:

1. In Spreadsheet View, click the **Grouping Assignment button** on the toolbar.

   Alternatively, open the Group preference sheet and double-click **Define Port Group**.

2. In Group Name box at the top, type a name for the new group.
3. Under Type, select **Port**.

   All the ports in your design are displayed in the Available Ports list.

   To narrow the list of ports, select a port type from the **By** drop-down list under Group Name. The Available Ports list will be updated to include only the selected type of ports.

4. In the Available Ports list, do one of the following:

   - Select one or more ports, and then click **>** to add the instances to the Selected Ports list.
   - Use the Filter edit box to narrow the list, and click **Go**. Click click **>>** to add the entire filtered list to the Selected Ports list or select from one or more ports from the list and click **>**.
   - Use wildcard notation in the Filter edit box to create a single-line DEFINE GROUP preference that includes the wildcard expression. Type a string (case-sensitive) to limit the list, and then click **=>** to add the filtered list as a wildcard expression to the Selected Ports list.

5. To customize the color for the port group, click the **Color** button in the top right and select a color from the Select Color dialog box.

The color for the port group will persist when you run Place & Route, enabling you to identify each group within Package View when you use the View > Show Port Groups command.

6. Click **Add**.

   The Port Group appears at the bottom of the Port Assignments sheet, enabling you to set attributes for the entire group at once.

   The Group preference sheet also displays the new preference in the Define Port Group list.

To define a cell instance group: 1.In Spreadsheet View, click the Grouping Assignment button  on the toolbar.

Alternatively, open the Group preference sheet and double-click **Define Cell Group**.

2. In the Group Name box at the top, type a name for the new group.
3. Under Type, select **Cell**. All the cell instances in your design are displayed in the Available Instances list.

   To narrow the list, select **By Clock**, **By Clock Enable**, **By Sync Reset**, or **By Async Reset** in the “By” drop-down list under the Group Name, and then select one item from the list that opens on the left. The Available Instances list in the middle will be updated to include only the instances connected with the selected clock, clock enable, sync reset, or async reset.

4. In the Available Instances list, do one of the following:

   - Select one or more instances, and then click **>** to add the instances to the Selected Instances list.
   - Use the Filter edit box to narrow the list, and click **Go**. Click click **>>** to add the entire filtered list to the Selected Instances or select from one or more instances from the list and click **>**.
   - Use wildcard notation in the Filter edit box to create a single-line DEFINE GROUP preference that includes the wildcard expression. Type a string (case-sensitive) to limit the list, and then click **=>** to add the filtered list as a wildcard expression to the Selected Instances list.

5. Click **Add**.

   The Group preference sheet displays the new preference in the Define Cell Group list.

To define an ASIC block group: 1.In Spreadsheet View, click the Grouping Assignment button  on the toolbar.

Alternatively, open the Group preference sheet and double-click **Define ASIC Group**.

2. In the Group Name box at the top, type a name for the new group.
3. Under Type, select **ASIC**. All the ASIC instances in your design are displayed in the Available ASIC Instances list.

4. In the Available ASIC Instances list, select one instance. You can use the filter text box to narrow the list before making your selection. All pins for the selected instance are displayed in the Available Pins list.
5. In the Available Pins list, do one of the following:
   - Select one or more ASIC pins, and then click **>** to add them to the Selected ASIC-Pin Pairs list.
   - Use the Filter edit box to narrow the list, and click **Go**. Click click **>>** to add the entire filtered list to the Selected ASIC-Pin Pairs list or select from one or more pins from the list and click **>**.
   - Use wildcard notation in the Filter edit box to create a single-line DEFINE GROUP preference that includes the wildcard expression. Type a string (case-sensitive) to limit the list, and then click **=>** to add the filtered list as a wildcard expression to the Selected ASIC-Pin Pairs list.
6. Click **Add**.

   The Group preference sheet displays the new preference in the Define ASIC Group list.

To define a group from selected ports or registers 1.In Netlist View, do one of the following:

- Click the Ports  button on the toolbar to define a port group.
- Click the Instances  button on the toolbar to define a cell group.

2. Select the ports or registers that you want included in the group.
3. Right-click the selected ports or registers and choose **Define GROUP Name** from the pop-up menu.

   The Type is automatically selected in the Group Assignment dialog box. The ports or registers you selected are displayed in the Selected Ports or Selected Instances list.
4. Type a name for the group in the Group Name box.
5. Use the **>** and **<** buttons to add or delete items from the Selected Ports or Selected Instances list.
6. Click **Add**.

   The Group preference sheet displays the new preference in the Define Port Group or Define Cell Group list.

Setting Preferences for Port Groups

After you have defined port groups for your design, you can set preferences for them in Spreadsheet View.

The Map Design process will turn each port group into a PGROUP. For example, if your LPF file has the following:

Your PRF file will have:

```
DEFINE PORT GROUP "grp1" "d1" "d2";
IOBUF GROUP "grp1" IO_TYPE=LVCMOS33 BANK=3;

PGROUP "grp1" COMP "d1" COMP "d2";
LOCATE PGROUP "grp1" BANK 3;
```

To set preferences for port groups:

1. In Spreadsheet View select the Port Assignments sheet and scroll down to the bottom.

   Port groups are displayed at the bottom of the Port Assignments sheet in the Other > Groups folder.

2. For each preference that you want to assign, double-click the cell in the appropriate column and select the value from the drop-down menu.

See Also ▶"Setting Vref Locations" on page 471

- "IO_TYPE" on page 1309
- "LOCATE" on page 1227

Creating UGROUPs

The Universal Group (UGROUP) preference consists of logical components that are to be packed close together. UGROUPs can include PFU, PFF, EBR, and DSP blocks. You can create UGROUPs in Spreadsheet View, Netlist View, NCD View, and Floorplan View. UGROUPs are listed on the Group preference sheet of Spreadsheet View. After placement and routing, Floorplan View displays the group member elements with the UGROUP color fill.

Note

A UGROUP must be anchored if it includes a DSP block. If such a UGROUP is not anchored, Diamond will issue a warning and ignore the DSP block.

Creating UGROUPs in Spreadsheet View Spreadsheet View's Group preference sheet provides immediate access to the Create New UGROUP dialog box, which allows you to select components for a UGROUP and define the anchor location and bounding box.

To create a UGROUP in Spreadsheet View:

1. Select the **Group** preference sheet and double-click **UGROUP**.
2. In the Create New UGROUP dialog box, specify a name for the group and select a color.
3. To anchor the group, select **Anchor**, and then select either **Region** or **Site**.
   - If you have selected Region, select a REGION from the drop-down list. Regions must already be defined in order to appear on the list.

When Region is selected, the group will float inside the selected REGION.

- If you have selected Site, specify the column and row for the anchor. The allowable range is shown in parentheses above each box.

  When Site is selected, the specified site will serve as the northwest corner anchor location.

4. To define the size of the group's bounding box, select **BBox**, and then specify the number of columns and rows that the UGROUP's bounding box should cover. The allowable range for height and width is shown in parentheses above each box.

   The group's resource coverage is now displayed at the top under UGROUP Name: the number of LUTs, registers, and EBRs.

5. From the list of Available Instances, select those that you want included in the UGROUP.

   - Use a string and wildcards (asterisk or question mark) in the Filter text box to narrow the list.
   - Use the Ctrl key or the Shift key to select multiple instances from the full or filtered list.

6. Click the **>** button to move the selected instances to the Selected Instances list. Click the **>>** button to move all instances to the Selected instances list.

   You can further modify the group membership by moving elements between the Available Instances and Selected Instances lists.

7. Click **Add**.

   The new UGROUP is added to the Group preference sheet.

   Make sure that the UGROUP's bounding box does not overlap the bounding box of another UGROUP or REGION. Compare the dimensions on the Group sheet and the Misc sheet and modify the UGROUP if necessary.

Creating UGROUPs in Netlist View Netlist View enables you to create a UGROUP from selected instances in the netlist.

To create a UGROUP in Netlist View:

1. In Netlist View, select the Instance button  on the toolbar, and then expand the Instances folder.
2. Select the instances that you want to place in a UGROUP.

   - Use a string and wildcards in the Filter box at the top to narrow the list of instances.
   - Use the Ctrl key or the Shift key to select multiple instances from the full or filtered list.

3. Right-click the selected instances and select **Set UGROUP Preference**.

   The Create New UGROUP dialog box opens. The instances you selected are displayed in the Selected Instances list on the lower right.

4. In the boxes at the top of the dialog box, specify a name for the UGROUP and select a color.
5. To anchor the group, select **Anchor**, and then select either **Region** or **Site**.
   - If you have selected Region, select a REGION from the drop-down list. Regions must already be defined in order to appear on the list.

     When Region is selected, the group will float inside the selected REGION.
   - If you have selected Site, specify the column and row for the anchor. The allowable range is shown in parentheses above each box.

     When Site is selected, the specified site will serve as the northwest corner anchor location.
6. To define the size of the group's bounding box, select **BBox**, and then specify the number of columns and rows that the UGROUP's bounding box should cover. The allowable range for height and width is shown in parentheses above each box.

   The group's resource coverage is now displayed at the top under UGROUP Name: the number of LUTs, registers, and EBRs.
7. If desired, modify the group's membership by using the **<** and **>** buttons to move elements between the Available Instances and Selected Instances lists.
8. Click **Add**.

   The new UGROUP is added to the Group preference sheet.

   Make sure that the UGROUP's bounding box does not overlap the bounding box of another UGROUP or REGION. Compare the dimensions on the Group sheet and the Misc sheet and modify the UGROUP if necessary.

Creating UGROUPs in Floorplan View In Floorplan View, you can draw a bounding box for a new UGROUP, and then select the instances to be included. For routed designs, you can create a UGROUP from selected components displayed on the layout.

To create a UGROUP bounding box and add instances:

1. Choose **Tools > Floorplan View**.
2. Zoom in, as needed, to the desired area on the floorplan layout.
3. Right-click and choose **Create UGROUP BBox**.

   The mouse pointer changes from an arrow to a cross symbol.

4. Draw a rectangle around the sites where you want to place the UGROUP. Make sure that the bounding box does not overlap the bounding box of another UGROUP or REGION.

   Note

   For certain MachXO2 devices, the first EBR site on the left is positioned at column 1 and cannot be included in an anchored group or region that contains SLICEs. The column 1 EBR site is not aligned with SLICEs, which begin at column 2. Affected devices include LCMXO2-1200/4000/7000/10000.

   When you release the mouse button, the Create New UGROUP dialog box opens. In the Anchor and BBox sections, it shows the anchor site location and the bounding box size, based on the rectangle you drew on the floorplan. At the top, under UGROUP Name, it shows the resources covered by the bounding box: LUTs, registers, and EBRs.

   Note

   A UGROUP must be anchored in order to be displayed in Floorplan View.

5. In the boxes at the top of the dialog box, specify a name for the UGROUP and select a color.
6. From the list of Available Instances, select those that you want included in the UGROUP.
   - Use a string and wildcards (asterisk or question mark) in the Filter text box to narrow the list.
   - Use the Ctrl key or the Shift key to select multiple instances from the full or filtered list.
7. Click the **>** button to move the selected instances to the Selected Instances list. Click the **>>** button to add all instances to the Selected Instances list.

   You can further modify the group membership by moving elements between the Available Instances and Selected Instances lists.
8. Click **Add**.

   The new UGROUP is displayed in Floorplan View with a bounding box in the color you selected. The new UGROUP is added to the Group preference sheet in Spreadsheet View.

To create a UGROUP from selected placed components in Floorplan View:

1. In Floorplan View, zoom in to the desired area as needed.
2. Select the placed components that you want to include in the UGROUP. These can include PFU or PFF slices, EBR blocks, or DSP blocks.

   Note

   To view the precise logical identifiers for a PFU or PFF slice, select it on the layout and cross-probe to Netlist View.

3. Right-click the selected components and choose **Create UGROUP**.

   The Create New UGROUP dialog box opens. In the Selected Instances list, it shows the placed components from the blocks you selected in Floorplan View.

4. In the boxes at the top of the dialog box, specify a name for the UGROUP and select a color.

5. To select a different anchor location, select either **Region** or **Site**.

   - If you have selected Region, select a REGION from the drop-down list. Regions must already be defined in order for them to appear on the list.

     When Region is selected, the group will float inside the selected REGION.

   - If you have selected Site, specify the column and row for the anchor. The allowable range is shown in parentheses above each box.

     When Site is selected, the specified site will serve as the northwest corner anchor location.

6. To define a different size for the group's bounding box, specify the number of columns and rows that the UGROUP's bounding box should cover. The allowable range for height and width is shown in parentheses above each box. Make sure that the bounding box does not overlap the bounding box of another UGROUP or REGION.

   The group's revised resource coverage is now displayed at the top under UGROUP Name: the number of LUTs, registers, and EBRs.

7. Click **Add**.

   The new UGROUP is displayed in Floorplan View with a bounding box in the color you selected, and it is added to the Group preference sheet in Spreadsheet View.

Creating UGROUPs in NCD View After placement and routing, you can create a UGROUP from selected instances in NCD View.

To create a new UGROUP in NCD View:

1. Select NCD View, and then expand the Instances folder.
2. Select the instances that you want to place in a UGROUP:

   - Use a string and wildcards in the Filter box at the top to narrow the list of instances.
   - Use the Ctrl key or the Shift key to select more than one instance from the full or filtered list.

   Note

   To view the precise logical identifiers for a PFU or PFF slice, select it and cross-probe to Netlist View.

3. Right-click the selected instances and select **Set UGROUP Preference**.

The Create New UGROUP dialog box opens. In the Selected Instances frame, it lists the logical components of the instances you selected.

4. In the boxes at the top of the dialog box, specify a name for the UGROUP and select a color.
5. To anchor the group, select **Anchor**, and then select either **Region** or **Site**:
   - If you have selected Region, select a REGION from the drop-down list. Regions must already be defined in order to appear on the list.

     When Region is selected, the group will float inside the selected REGION.
   - If you have selected Site, specify the row and column for the anchor. The allowable range is shown in parentheses above each box.

     When Site is selected, the specified site will serve as the northwest corner anchor location.
6. To define the size of the group's bounding box, select **BBox**, and then specify the number of columns and rows that the UGROUP's bounding box should cover. The allowable range for height and width is shown in parentheses above each box.

   The group's resource coverage is now displayed at the top under UGROUP Name: the number of LUTs, registers, and EBRs.
7. If desired, modify the group's membership by using the **<** and **>** buttons to move elements between the Available Instances and Selected Instances lists.
8. Click **Add**.

   The new UGROUP is added to the Group preference sheet.

   Make sure that the UGROUP's bounding box does not overlap the bounding box of another UGROUP or REGION. Compare the dimensions on the Group sheet and the Misc sheet and modify the UGROUP if necessary.

Grouping Components Along a Net

Both Netlist View and NCD View enable you to create a UGROUP from selected nets. The selected nets must be connected to NGD components that are appropriate for UGROUPs. These types of components include PFU, PFF, EBR, and DSP blocks. A selected net in NCD View, after placement and routing, can be used to identify a set of NCD components into which UGROUP-appropriate NGD components are packed.

To group components along a net in Netlist View or NCD View:

1. Open Netlist View or NCD View, and then select the Nets view.
2. Select one or more nets, right-click, and choose **Set UGROUP Preference**.

In the Create UGROUP dialog box, the Selected Instances list displays any appropriate components that are connected to the selected nets.

Note

If no appropriate instances for a UGROUP are connected to the selected nets, the Selected Instances list will be empty.

3. In the boxes at the top of the dialog box, specify a name for the UGROUP and select a color.
4. To anchor the group, select **Anchor**, and then select either **Region** or **Site**:
   - If you have selected Region, select a REGION from the drop-down list. Regions must already be defined in order to appear on the list.

     When Region is selected, the group will float inside the selected REGION.
   - If you have selected Site, specify the row and column for the anchor. The allowable range is shown in parentheses above each box.

     When Site is selected, the specified site will serve as the northwest corner anchor location.
5. To define the size of the group's bounding box, select **BBox**, and then specify the number of columns and rows that the UGROUP's bounding box should cover. The allowable range for height and width is shown in parentheses above each box.

   The group's resource coverage is now displayed at the top under UGROUP Name: the number of LUTs, registers, and EBRs.
6. If desired, modify the group's membership by using the **<** and **>** buttons to move elements between the Available Instances and Selected Instances lists.
7. Click **Add**.

   The new UGROUP is added to the Group preference sheet.

See Also "Grouping Components Along an Individual Signal" on page 513

Grouping Components Along an Individual Signal

In Floorplan View, you can group components along an individual signal of a timing path. You can do this by cross-probing a signal from Timing Analysis View to Floorplan View. From Floorplan View, you can then select the components along the displayed connection to create a new UGROUP.

To group components along an individual signal:

1. After placement and routing, choose **Tools > Timing Analysis View**.
2. In the timing preference list in the lower left pane, expand Analysis Results, and then select the desired timing preference.

   The path table opens in the upper right pane.

3. Select a signal from the path table, right-click, and choose **Show in > Floorplan View**.

   The connection is highlighted in Floorplan View.

4. While holding the **Ctrl** key, click each component related to the net.
5. Right-click the selected components and choose **Create > UGROUP**.

   The Create New UGROUP dialog box displays the anchor location and bounding box size of the components you selected, and it lists the instances in the Selected Instances pane.

6. In the top part of the dialog box, assign a name to the UGROUP. Click the color box to assign a different color.
7. Click **Add**.

   The new UGROUP is displayed in Floorplan View with a bounding box in the color you selected. The new UGROUP is added to the Group preference sheet in Spreadsheet View.

See Also ▶"Using Timing Analysis View" on page 729

Modifying UGROUPs

Use the Edit UGROUP Property dialog box to quickly modify the name, color, and membership of a group preference. You can access the dialog box from the Group preference sheet and from Floorplan View. You can also use Floorplan View to delete a UGROUP, or you can use the Group preference sheet to delete a UGROUP or UGROUP elements.

To modify a group preference:

1. To access the Edit UGROUP Property dialog box, do one of the following:
   - In the Group sheet of Spreadsheet View, double-click the group you want to modify or right-click the group and choose **Modify**.
   - In Floorplan View, zoom in to the UGROUP and click the border or an empty space inside so that the group's border is highlighted. Right-click and choose **Edit UGROUP**.
2. In the dialog box, make the desired changes and click **Update**.

To remove elements from a group on the Group preference sheet:

1. Select the Group preference sheet and expand the desired UGROUP.
2. Select the group elements you want to remove, right-click, and choose **Remove UGroup Elements**.

To delete a group preference on the Group sheet:

- Right-click the group you want to delete and choose **Delete**, or press the Delete key.

To delete a UGROUP using Floorplan View:

1. Zoom in to the UGROUP and click the border or an empty space inside so that the group's border is highlighted.
2. Right-click and choose **Remove UGROUP**.

Note

A UGROUP that originated in the HDL source does not get removed from the logical preference file (.lpf) when you simply reverse any modifications that were made in Diamond. To restore the UGROUP to its HDL settings, you must remove the UGROUP from the .lpf file. To remove the UGROUP completely, you must delete it from both the .lpf file and the HDL source.

See Also ▶"Creating UGROUPs" on page 507

- "Assigning a UGROUP to a REGION" on page 518
- "Removing a REGION Assignment from a UGROUP" on page 519

Resizing or Moving a UGROUP in Floorplan View

You can use your mouse to resize a UGROUP in Floorplan View or change its anchor location.

To resize a UGROUP using Floorplan View:

1. In Floorplan View, zoom in to the UGROUP and select it by clicking the border or an empty space inside. The border should be highlighted. You should be able to see the small circles on the UGROUP's border—one in each corner and one on each side.

   Note

   By default, UGROUPs are displayed in Floorplan View. If they do not appear on the layout, click the  button on the vertical toolbar.

2. Position your mouse pointer over one of the corner or side circles.

   The cursor symbol changes to a double-headed arrow.

3. Drag the border outward or inward until the bounding box contains the sites you want to include.

   Floorplan View displays the new bounding box dimensions. The Group sheet in Spreadsheet View shows the updated dimensions.

To change the UGROUP's anchor location:

1. Zoom out until you can easily view the current location on the layout and the targeted location.
2. Click the UGROUP's border or an empty space inside it so that the border is highlighted.

   The crossed arrows symbol should immediately appear. If it does not, move your mouse pointer very slightly until it does appear.

3. Hold down the left mouse button, drag the UGROUP box to the targeted location, and then release the mouse button.

   Floorplan View displays the UGROUP in its new location. The Group sheet in Spreadsheet View shows the updated location.

See Also ▶"Creating UGROUPs" on page 507

- "Assigning a UGROUP to a REGION" on page 518

Setting Miscellaneous Preferences

Spreadsheet View's Misc Preferences sheet enables you to assign Vref locations and define REGIONs. Double-click the preference type that you want to create to open the dialog box. Or double-click a listed Vref or REGION preference to open the Edit dialog box. A list of current preferences is displayed under each preference type.

The Misc Preference sheet also lists modules and any sites that have been reserved with the PROHIBIT preference. A site reserved with the PROHIBIT preference will not be used in placement and routing. The PROHIBIT SITE preference can be set using Floorplan View, Device View, Package View, or the Pin Assignments sheet of Spreadsheet View.

See Also ▶"Reserving Resources" on page 522

- "Setting Vref Locations" on page 471
- "Defining REGIONs" on page 516

Defining REGIONs

A REGION preference sets aside a fixed area of the device for the placement of UGROUPs or for reserving resources. A REGION that is set aside for the placement of UGROUPs instructs the placer to place the groups within the area specified by the REGION's bounding box. A reserved REGION instructs the placer to avoid all resources within the REGION's bounding box.

When you create a REGION, you identify a northwest corner as the anchor location and specify the width and height of the bounding box. Since a REGION always defines a physical rectangle inside the device (DEVSIZE), its bounding box will be measured by contiguous rows and columns regardless of the types of components they contain. This means that it can include such components as PFUs, PFFs, EBRs, and DSP blocks.

Note

For certain MachXO2 devices, the first EBR site on the left is positioned at column 1 and cannot be included in an anchored group or region that contains SLICEs. The column 1 EBR site is not aligned with SLICEs, which begin at column 2. Affected devices include LCMXO2-1200/4000/7000/10000.

You can create a new REGION using Spreadsheet View's Misc Preferences sheet, or you can use your mouse to draw a REGION in Floorplan View. REGIONs are displayed with solid colored borders on the layout.

Note

Unless a REGION is reserved or contains one or more UGROUPs, it will be ignored by the Place & Route process.

For more information about REGIONs and other physical preferences, refer to the "Preferences" on page 1195 section of the Constraints Reference Guide.

See Also "Creating a REGION" on page 517

- "Assigning a UGROUP to a REGION" on page 518
- "Reserving REGIONs" on page 523
- "Using Incremental Design Flow" on page 649

Creating a REGION

The Create New REGION dialog box is available from the Misc Preferences sheet of Spreadsheet View and from Floorplan View. It enables you to create a REGION preference for the placement of UGROUPs or a reserved REGION that will be not be used in the next placement process. For LatticeECP3 devices, the dialog box also allows you to create clock REGIONs for assigning secondary clocks.

To create a new REGION:

1. Do one of the following to open the Create New REGION dialog box:
   - In Spreadsheet View, select the **Misc Preferences** sheet, and then double-click **REGION**. Alternatively, right-click and choose **New Region**.
   - In Floorplan View, right-click an empty area of the floorplan layout and choose **Create > REGION**. Draw a rectangle around the area of the layout that you want to include in the REGION, and then release the mouse button.
2. At the top of the Create New REGION dialog box, give the REGION a descriptive name and select a color to identify the border.
3. To reserve the REGION and prevent its resources from being used, select the **Prohibit** option.

   Note

   You can also reserve the REGION later by right-clicking it on the Floorplan View layout and choosing **Prohibit**. When you reserve a REGION, it will not be available for groups.

4. If you used Spreadsheet View, type the row and column that will identify the northwest corner of the bounding box. This information is required.

Make sure that the values you type are within the available range displayed.

If you used Floorplan View, the Anchor text boxes will already be populated.

5. If you used Spreadsheet View, type the width and height for the bounding box in the BBox text boxes. This information is also required. Make sure that the values are no greater than the maximum values displayed by default.

   If you used Floorplan View to draw a REGION, the BBox text boxes will already be populated.

   After the anchor and bounding box are defined, the dialog box displays the area's resource coverage near the top, including LUTs, registers, and EBRs.

   Note

   DEVSIZE, which is automatically selected, means that all contiguous rows and columns are counted for the bounding box regardless of the types of resources they contain. Since a REGION's bounding box is always considered DEVSIZE, this check box cannot be cleared.

6. Click **Add**.

   The Misc Preferences spreadsheet displays the new REGION. Floorplan View displays the REGION with a solid border. If the REGION is reserved, the sites will be marked with a cross-hatch pattern.

   Examine the Misc sheet and the Group sheet to make sure that the new REGION does not overlap the bounding box of any other REGION or UGROUP.

   Note

   By default, REGIONs are displayed in Floorplan View. If they do not appear on the layout, click the Display Regions button  on the Floorplan View toolbar.

See Also ▶"Assigning a UGROUP to a REGION" on page 518

Assigning a UGROUP to a REGION

After you have created a REGION, you can anchor a new or existing UGROUP to it. The UGROUP will be placed in the designated REGION during placement and routing.

To assign an existing UGROUP to a REGION:

1. Do one of the following to open the Edit UGROUP Property dialog box:
   - In Spreadsheet View, select the Group preference sheet and double-click the UGROUP you want to assign. Alternatively, right-click and choose **Modify**.
   - In Floorplan View, zoom in to the UGROUP you want to assign, right-click it, and choose **Edit UGROUP**.

2. In the dialog box, select **Anchor**, and then select **Region**.

   When you select the Region option, the row and column become unavailable. If the UGROUP was originally anchored to a site, the anchor location will be removed.

3. Select the desired REGION from the drop-down list.

4. Click **Update**.

   The REGION assignment for the UGROUP is displayed on the Group preference sheet.

   After placement and routing, when “Display Placement Groups” is turned on, Floorplan View will display the group member elements within the REGION. Zoom in to view the individual slices, EBRs, or DSP blocks that contain the group elements. These blocks will be displayed with the UGROUP color fill.

See Also ▶“Creating UGROUPs” on page 507

▶ “Displaying Assignments and Connections” on page 431

Removing a REGION Assignment from a UGROUP

Use the Edit UGROUP Property dialog box to remove a REGION assignment from a UGROUP.

To remove a REGION assignment from a UGROUP:

1. In the Group sheet of Spreadsheet View, double-click the UGROUP you want to edit. Optionally, right-click the UGROUP and choose **Modify**.

2. Do one of the following:

   - To remove the REGION assignment and make the UGROUP a floating group, clear the Anchor selection.
   - To remove the REGION assignment and anchor the UGROUP to a specific site, select **Site** instead of Region and specify the row and column for the anchor location.

3. Click **Update**.

   The Group preference sheet shows the modified attributes of the UGROUP.

Defining a Clock REGION

Clock REGIONs enable you to geographically control the distribution of control signals to secondary routing and to ensure that the logic that uses these control signals is placed in the same geographic area. Devices such as the LatticeECP3 are divided into specific clock REGIONs. You can specify these REGIONs, instead of quadrants, for secondary routing. Diamond enables you define a clock REGION from Spreadsheet View or from Floorplan View. After you have defined the clock REGION, you can select it from the Quadrant column of Spreadsheet View for a secondary clock.

To define a new clock REGION:

1. Do one of the following:
   - In the Misc Preferences sheet of Spreadsheet View, right-click **REGION** and select **New Clock Region**.
   - In Floorplan View, right-click an empty area of the layout and choose **Create > CLOCK REGION**.
2. In the Create New Clock Region dialog box, specify the REGION name, anchor location and bounding box in the text boxes provided.
3. Use the Color box to change the border color for the new clock REGION
4. Click **Add**.

   The new clock REGION is added to the preference sheet. It is also displayed in Floorplan View with the color you assigned it.

To select the clock REGION for secondary routing:

- In the Clock Resource sheet of Spreadsheet View, select **Secondary** in the Selection Column for the desired clock, and then select the newly defined clock REGION from the Quadrant column.

Note

The clock REGION <clock_region_name> <region_clock_space> preference must precede the USE SECONDARY preference that references it in the logical preference file (.lpf).

See Also "Setting Clock Preferences" on page 479

Editing a REGION Preference

Use the Edit Region Property dialog box to change the name, color, anchor position or bounding box of a REGION or clock REGION. You can access the dialog box from Spreadsheet or from Floorplan View. You can also edit the bounding box directly in Floorplan View.

To edit a REGION preference:

1. Do one of the following to open the Edit Region Property dialog box or the Edit Clock Region Property dialog box:
   - In Spreadsheet View, select the Misc Preferences sheet and double-click the REGION you want to edit. Optionally, right-click the REGION and choose **Modify**.
   - In Floorplan View, select the REGION you want to edit by clicking the outer border or an empty space inside the REGION. The border should be highlighted. Right-click and choose **Edit REGION** or **Edit CLOCK REGION**.
2. Modify the properties as desired and click **Update**.

   The Misc Preferences sheet shows the REGION's modified attributes.

To edit a REGION bounding box in Floorplan View:

1. Zoom in sufficiently so that you can see the small circles on the REGION's border—one in each corner and one on each side.
2. Hold your mouse above one of the circles until the double-headed arrow symbol appears.
3. Drag the sides or corners of the REGION to resize it to the desired dimensions.

See Also ▶"Assigning a UGROUP to a REGION" on page 518

- "Removing a REGION Assignment from a UGROUP" on page 519
- "Moving a REGION in Floorplan View" on page 521

Moving a REGION in Floorplan View

You can change the physical location of a REGION in Floorplan View by dragging it to a different location on the layout.

To move a REGION:

1. In Floorplan View, use the zoom tools as needed so that both the REGION you want to move and the desired new location are clearly visible.

   Note

   By default, REGIONs are displayed in Floorplan View. If they do not appear on the layout, click the Display Regions button on the Floorplan View toolbar.

2. Click the REGION's border or an empty space inside it to select it.

   The border of the REGION becomes highlighted.
3. Hold the pointer above an empty space inside the REGION until the crossed arrows symbol appears.
4. Press the left mouse button and drag the REGION to the desired location.
5. Release the mouse button.

See Also ▶"Editing a REGION Preference" on page 520

- "Assigning a UGROUP to a REGION" on page 518
- "Removing a REGION Assignment from a UGROUP" on page 519

Removing a REGION

You can use the Misc Preferences sheet in Spreadsheet View to quickly remove a REGION from your design. Alternatively, you can remove a REGION using Floorplan View.

To remove a REGION using Spreadsheet View:

1. In Spreadsheet View, select the **Misc Preferences** sheet.
2. Right-click the REGION you want to remove, and choose **Delete**. Alternatively, select the REGION and press the Delete key.

   The REGION is removed from the preference sheet and will no longer be displayed in Floorplan View.

To remove a REGION using Floorplan View:

1. Click the border of the REGION or an empty space inside it so that the border is highlighted.

   Note

   By default, REGIONs are displayed in Floorplan View. If they do not appear on the layout, click the Display Regions button  on the Floorplan View toolbar.

2. Right-click and choose **Remove REGION**.

   The REGION is removed from the floorplan layout and from the Misc Preferences sheet of Spreadsheet View.

See Also ▶"Removing a REGION Assignment from a UGROUP" on page 519

Reserving Resources

The Prohibit command enables you to specify device resources that you do not want the placer and router to use. You can reserve specific pins or sites using Package View, Device View, or Floorplan View. You can also reserve an entire area of the chip that you do not want used. When you use the prohibit command, these resources are avoided in the next Place & Route process.

See Also ▶"PROHIBIT" on page 1242

▶ "Defining REGIONs" on page 516

Reserving Sites

You can use Spreadsheet View, Package View, Device View, or Floorplan View to specify sites that you do not want to be used in the next Place & Route process. All reserved sites are listed in the PROHIBIT SITE section of Spreadsheet View's Misc Preference sheet.

To reserve sites in Spreadsheet View:

1. Select the Pin Assignments sheet, and then select the pins that you do not want to be used in placement and routing.
2. Right-click the selected pins and choose **Prohibit Pin(s)**.

Each reserved pin is tagged with the “Prohibit” label on the Pin Assignments sheet.

To reserve sites in Package View:

1. In the device pin layout of Package View, select the pins that you do not want to be used in placement and routing.
2. Right-click the selected pins and choose **Prohibit**.

   Each reserved pin is highlighted with the Prohibit color to indicate that it will not be used.

To reserve sites in Device View:

1. Expand the folder that contains the desired resources.
2. Select the sites that you want to reserve, right-click, and choose **Prohibit**.

   Each reserved site is tagged with the “Prohibited” label.

To reserve sites in Floorplan View:

1. Zoom in to the area that contains the sites that you want to reserve. The borders should be clearly visible. For PFF or PFU blocks, zoom in so that the individual slices are visible.
2. Select the sites that you want to reserve, right-click, and choose **PROHIBIT Site**.

   Each reserved site is displayed with a gray pattern.

When you save the changes, each reserved site is added as a PROHIBIT SITE preference in the .lpf file and will be avoided in the next Place & Route process.

See Also ▶“PROHIBIT” on page 1242

▶ “Reserving REGIONs” on page 523

Reserving REGIONs

The Reserve REGION option is very useful for partitioning large designs or for setting aside areas that are not to be used in the Placement and Routing process.

There are two ways to reserve a REGION: use the Prohibit option in the New REGION or Edit REGION dialog box or use the Prohibit command for an existing REGION in Floorplan View.

Note

A prohibited REGION cannot contain UGROUPs. Before reserving the REGION, make sure that no UGROUPs have been assigned to it.

To reserve a REGION using the dialog box:

1. Do one of the following:
   - Create a new REGION in Spreadsheet View or in Floorplan View to open the New REGION dialog box.
   - Double-click an existing REGION in Spreadsheet's Misc Preferences to open the Edit Region Property dialog box. Optionally, right-click the REGION and choose **Modify**.
   - In Floorplan View, right-click the selected REGION and choose **Edit REGION** to open the Edit Region Property dialog box.
2. In the dialog box, select the **Prohibit** option.
3. Click **Add** for a new REGION or **Update** for an existing REGION.

To reserve an existing REGION in Floorplan View

- Right-click the REGION on the floorplan layout and choose **PROHIBIT REGION**.

In Floorplan View, the reserved REGION is displayed with a gray pattern overlay. In Spreadsheet View, the REGION is tagged with the Prohibit label on the Misc Preferences sheet. When you save the changes, each reserved REGION is added as a PROHIBIT REGION preference in the .lpf file and will be avoided in the next Place & Route process.

See Also "PROHIBIT" on page 1242

Releasing Reserved Resources

After reserving sites or REGIONs, you can easily free them up to be used for placement and routing.

To release reserved sites in Spreadsheet View, do one of the following:

- On the Pin Assignments sheet, select the prohibited sites that you want to release. Right-click and choose **Clear** or press the Delete key.
- On the Misc Preferences sheet, select the sites from the PROHIBIT SITE list that you want to release. Right-click and choose **Delete** or press the Delete key.

To release reserved sites in Package View or Device View:

- Select the reserved sites that you want to release, right-click, and choose **Release**.

To release reserved sites in Floorplan View:

1. Zoom in so that the sites are clearly visible on the layout.
2. Select the reserved sites that you want to release, right-click, and clear the **PROHIBIT Site** command from the pop-up menu.

To release a reserved REGION using Floorplan View:

- Select the reserved REGION that you want to release, right-click and clear the **PROHIBIT REGION** command from the pop-up menu.

To release a reserved REGION using Spreadsheet View:

1. On the Misc Preferences sheet, select the Preference Value cell for the REGION that you want to release.
2. Right-click and choose **Clear Prohibit**.

Setting Preferences in a Text Editor

You can create and edit preferences manually in the logical preference file using a text editor. When setting preferences manually, adhere to the guidelines outlined in "Preference Syntax Guidelines and Conventions" on page 525.

To set preferences in a text editor:

1. In Diamond, select the File tab on the left.
2. Select the desired implementation. If the selected implementation is not the active one, right-click and choose **Set as Active Implementation**.
3. Expand the Constraints Files folder inside the implementation directory, and then do one of the following:
   - Double-click the name of the .lpf file to open it in the Diamond Source Editor or the default editor.

     The logical preference file opens in Source Editor on the right.
   - Right-click the name of the .lpf file and choose **Open With**. Select the desired external editor and click **OK**.

     The logical preference file opens in the external editor.
4. Modify the preferences or add new ones as desired, and then choose **File > Save**.

See Also "Preference Flow" on page 374

- "Preferences" on page 1195

Preference Syntax Guidelines and Conventions

The following guidelines explain basic syntax rules for editing preferences directly in the logical preference file and shows the conventions for character and units usage. The specific syntax for each preference is provided in the "Preferences" on page 1195 section of the Constraints Reference Guide.

- Preferences are not case sensitive. They can be typed in upper or lower case characters.

- Comment strings begin with either # or //, and continue to the end of the line.
- All statements are terminated with a semicolon, and can span multiple lines.
- User-supplied identifiers may optionally be enclosed in double quotes.
- Identifiers that start with a number must be enclosed in double quotes.
- Any identifier that is the same as a logical preference keyword must be enclosed in double quotes.
- Wildcard patterns cannot begin with a number.
- The keyword CELL refers to hierarchical instance names from the netlist. The hierarchy delimiter is a forward slash (/).
- The keyword PORT refers to top-level I/O signal names.
- The keyword PIN refers to hierarchical instance pin names.
- The keyword NET refers to hierarchical net names.
- A time value may be entered as 0–1,000,000,000 nanoseconds (entered as **NS**), 0–1,000,000 microseconds (entered as **US**), or 0–1,000 milliseconds (entered as **MS**).
- A frequency value may be entered as 0–1,000 MHz or 0– 1,000,000 KHz.
- Names of sites, nets, buses, and other design elements are case sensitive.
- If an object name in the design is a keyword in a preference, or if the name begins with anything other than a valid character, you must use quotes around the word. Valid start characters are:

  A-Z, a-z, [,], _

  For example, if the site name is 11R7, you must use quotes around the word in the preference statement: LOCATE COMP xxx SITE “11R7”
- Names may not start with a plus '+' or a minus '-' sign. If you have a name that must begin with either a plus or minus sign character, you can still do so by enclosing the name in quotes. For example, the following preference would now result in a syntax error because +any_name begins with a plus sign.

  `LOCATE COMP +any_name SITE R3C2;` (results in syntax error)

  `LOCATE COMP “+any_name” SITE R3C2;` (acceptable)
- Multiple preferences applying to the same design element that occur in the same or multiple input .prf files are subject to the rules of preference conflict resolution. See “Preference Conflict Resolution” on page 393. This generally means that preferences that are input last take precedence, overriding previously specified like preferences completely.

Conventions The following conventions are used in the preference syntax:

- Keywords are **boldfaced**.
- ( ) parentheses are for grouping

- [ ] square brackets enclose optional constructs.
- | pipe lines indicate “or”.
- + plus sign means the preceding construct is repeated one or more times.
- < > angle brackets enclose non-terminal symbols and identifiers.
- All other characters and punctuation are literal.

Units ▶Time: ms, us, ns, ps, fs

- Temperature: C, F, K
- Voltage: v
- Capacitance: F, mF, uF, nF, pF, fF

See Also ▶“The Physical Preference File” on page 403

- “Preference Keywords” on page 527

Preference Keywords

Any object name or identifier that is the same as a preference keyword must be enclosed in double quotation marks. Otherwise, the design will fail with syntax errors when you map the design. If you use any of the following preference keywords as identifiers, make sure that you enclose the name in double quotation marks.

Using Wildcard Expressions in Preferences

Wildcards are useful in designs where bus and net names are very similar. They can be especially beneficial for large designs, because they significantly reduce the number of preferences and conserve memory. This topic describes preference wildcard support and the usage and syntax of wildcard characters and integer ranges.

Preferences that Support Wildcards The following table shows the preferences that support wildcard expressions and the elements that are supported for each preference. For many of these preferences, the applicable

dialog boxes provide filters that allow wildcard notation. These dialog boxes are available from Spreadsheet View. For more information, see "Using Filters and Wildcards" on page 422.

Table 41:

Preference	Wildcard Support
BLOCK	Nets, buses, ports, cells
CLOCK_TO_OUT	Ports
DEFINE GROUP	Ports, cells, ASIC pins
FREQUENCY	Nets
INPUT_SETUP	Ports
IOBUF	Groups
MAXDELAY	Ports, cells
MULTICYCLE	Ports, cells
OUTPUT LOAD	Ports
PERIOD	Nets, ports
SSO	Ports
USE SECONDARY	Nets

Wildcard Characters The logical preference language allows the following set of wildcard characters to be used in the specification of cell, port, and pin names:

***** Match any (zero or more) characters.

? Match any single character.

?+ Match one or more characters.

{ . . . } Match any single character in the enclosed list or range. A list is a string of characters separated by commas. A lexical range is two characters separated by a dash (-), and includes all the ASCII characters in between. An integer range is two integers separated by a colon (:) and includes all integers between the two.

{ . . . }+ Match one or more occurrences of any character from the preceding list.

Range Expansion The logical preference language syntax allows the specification of integer ranges. This feature, used in conjunction with wildcard expansion, is a powerful tool that can simplify the task of writing a preference file.

General syntax is as follows:

```
<bus_range> := {<range_list>}
```

```
<range_list> := <range_spec> | <range_list>,<range_spec>
<range_spec> := <upper>:<lower> | <bit_position>
<upper> := integer
<lower> := integer
<bit_position> := integer
```

Examples of Wildcard and Range Expansion The following examples demonstrate some of the most common uses of wildcards. These examples refer to logical preferences.

Wildcards for Timing-Related I/Os

```
INPUT_SETUP PORT "*_in*" 4 ns
CLKPORT "clk" ;
CLOCK_TO_OUT PORT "*at*" 7 ns CLKPORT "clk" ;
CLOCK_TO_OUT PORT "data_io_{2:4}" 4.5 ns CLKNET "clk_c";
```

Wildcards to Define a Group

```
DEFINE PORT GROUP "data_io_group"
"*io* ;
IOBUF GROUP "data_io_group" IO_TYPE=HSTL15_I ;
```

Wildcards for Timing Preferences In the following example, CELL refers to a register.

```
BLOCK PATH FROM CELL "r2datb*" ;
MULTICYCLE TO CELL "data_out*" 2 X;
MULTICYCLE FROM CELL "r2dat*" TO CELL "equal_out*" 4 X ;
```

Wildcards can also be used with MAXDELAY, although such use is not very common:

```
MAXDELAY NET "*sqmuxaZ*" 1.0 ns ;
```

Wildcards for Clock Nets The following examples show wildcard use for clock nets.

```
BLOCK PATH FROM CLKNET "clk1*" TO CLKNET "clk2*" ;
```

Note

The wildcard expression for clock nets in the BLOCK PATH preference should be specific enough to cover only the paths to be blocked. If "`clk*`" is used, as in:

```
BLOCK PATH FROM CLKNET "clk*" TO CLKNET "clk*"
```

the preference will block all the paths from clk1 to clk1 as well as from clk1 to clk2.

```
MULTICYCLE FROM CLKNET "clki*" TO CLKNET "clkt*" 3 ns;
FREQUENCY NET "clk*" 20 MHz;
USE SECONDARY NET "clk*";
```

Note

PRIMARY NET "CLK*" is not supported.

Although SECONDARY NET "*" can be used, it might produce warning messages.

Other Examples The following examples further illustrate range expansion:

```
// define a group for a 16 bit data bus
```

```
define port group data_out dataout({15:0});
// define a group for the upper/lower 4 bits of the bus
define port group upper_lower dataout({15:12,3:0});
// define a group consisting of only the odd bit positions
define port group odd_bits dataout({15,13,11,9,7,5,3,1}) ;
```

This bus range syntax can be used anywhere a wildcard is legal, not only in the define group command. It also can be applied to wildcard instance names, if you have a “bus” style instance naming convention, where your instance names have a common string prefix and a numeric suffix.

Be careful not to confuse lexical character range specification ({<*from_char*>-<*to_char*>}) with integer range specification ({<*start*>:<*end*>}). The following two examples are NOT equivalent:

`{0-15}` expands to the characters ’0’, ’1’, and ’5’.
`{0:15}` expands to the integers 0 through 15.

See Also ▶“Using Filters and Wildcards” on page 422

- “Preference Syntax Guidelines and Conventions” on page 525
- “Preferences” on page 1195

Using Preference Scripts

Preference scripts enable you to set preferences conditionally and maintain multiple sets of preferences for different device families. A script enables you to define symbols and set specific values using constant expressions for such things as temperatures and frequencies. It also allows you to use arithmetical expressions.

The script commands in the .lpf file are interpreted at map time, and only the appropriate commands are used by map and written into the .prf file. To see how the tools are interpreting the script, examine the .prf file.

When you use a preference script, most editing should be done with a text editor instead of the Diamond preference views. The preference views should be used mainly to examine the design.

Defining Symbols Defined symbols enable you to determine which preferences are to be used in the preference file.

Note

Symbol names are case-sensitive.

Use the @define keyword and a variable name.

Figure 79:

```
@define $<variable_name>;
```

The dollar sign character must prefix the variable name. The variable name can start with any of the following characters:

Figure 80:

```
A-Z a-z $ _ * [ ] / . \ : { } ( ) ?
```

The remaining part of the variable name can contain any of the following characters:

Figure 81:

```
0-9 A-Z a-z , $ _ * [ ] / . \ : { } + - ? ^ ( )
```

Testing for Defined Symbols Use the defined symbols and the @ifdef keyword to determine which preferences are to be used in the preference file:

Figure 82:

```
@ifdef $<variable_name> ;
  <preferences>
@endif ;
```

If the symbol has been defined earlier in the preference file, all preferences between @ifdef and @endif will be considered valid. If the symbol has not been defined, the preferences will be ignored.

Use the @ifndef keyword to test for the nonexistence of a symbol:

Figure 83:

```
@ifndef $<variable_name> ;
  <preferences>
@endif ;
```

This works in the same way as @ifdef, except that the condition is true if the symbol has *not* been defined earlier in the preference file.

Another keyword, @else, can be used after @ifdef or @ifndef to specify an alternate set of preferences when the first condition is not met:

Figure 84:

```
@ifdef $<variable_name> ;
  <preferences>
@else ;
  <alternate_preferences>
@endif ;
```

Tests using @ifdef and @ifndef can be nested to any level.

Examples Using Defined Symbols In the following example, the symbol DEBUG is defined, and it is followed by the @ifdef keyword and a LOCATE preference. Because DEBUG has been defined, the LOCATE preference is used.

Figure 85:

```
@define $DEBUG ;
@ifdef $DEBUG ;
  LOCATE COMP “in” SITE R29C4B ;
@endif ;
```

In this next example, the LOCATE preference is not used, because the DEBUG symbol is not defined:

Figure 86:

```
@ifdef $DEBUG ;
  LOCATE COMP “in” SITE R29C4B;
@endif ;
```

In the following example, the symbol DEBUG is defined. However, the LOCATE preference will not be used, because the test is for DEBUG *not* being defined.

Figure 87:

```
@define $DEBUG;

@ifndef $DEBUG ;
  LOCATE COMP “in” SITE R29C4B ;
@endif ;
```

In the following example, the symbol DEBUG is defined. As as result, the second LOCATE preference after the @else keyword is used, because the @ifndef DEBUG fails.

Figure 88:

```
@define $DEBUG ;

@ifndef $DEBUG ;
  LOCATE COMP “in” SITE R29C4B ;
@else ;
  LOCATE COMP “in” SITE R30C10B ;
@endif ;
```

Example Using Nested Preferences The following example includes a nested FREQUENCY preference. Because both DEBUG and HIGHSPEED are defined, the frequency of the net “clk” will be set to 500.0000 MHz.

Figure 89:

```
@define $DEBUG ;
@define $HIGHSPEED ;

@ifdef $DEBUG ;
    @ifdef $HIGHSPEED ;
        FREQUENCY net “clk” 500.0000 MHz ;
    @else ;
        FREQUENCY NET “clk” 250.0000 MHz ;
    @endif ;
@else ;
    FREQUENCY NET “clk” 250.0000 MHz ;
@endif ;
```

Using Constant Expressions Constant expressions enable you to set a specific value for a defined symbol. You can then test the value using conditional expressions. The same @define keyword is used, but it is associated with a constant value.

Figure 90:

```
@define $<variable_name> <constant_value> ;
```

The constant value can be any integer or floating point number that is within the range supported for numeric values. The value can also be a string that is within the preference naming limitations. The variable can have a string or numeric value, but not both. See “Preference Syntax Guidelines and Conventions” on page 525.

Testing for Constant Expressions You can test a symbol for its value as well as its definition by using the @ifdef and @ifndef keywords:

Figure 91:

```
@ifdef $<constant_compare_expression> ;
  <preferences>
@else ;
  <alternate_preferences>
@endif ;

@ifndef <constant_compare_expression> ;
  <preferences>
@else ;
  <alternate_preferences>
@endif ;
```

The constant compare expression supports a variety of tests:

Figure 92:

```
<constant_compare_expression> :=
  <variable_name> > | >= | = | == | < | <= <constant_value>
```

After defining a symbol with a constant expression, you can use the defined constant in place of a numerical value in the preference by prefixing '$' to the variable name.

Examples Using Constant Expressions In the following example, the symbol MAX_FREQ is defined as 1. The script tests whether MAX_FREQ is equal to 1. Because the test passes, the first FREQUENCY PORT preference is used.

Figure 93:

```
@define $MAX_FREQ 1 ;

@if $MAX_FREQ = 1 ;
  FREQUENCY PORT clk1 200 MHz ;
@else ;
  FREQUENCY PORT clk1 100 MHz ;
@endif ;
```

Variables can also be used to substitute for parameters in preferences. In the following example, the symbols `temp` and `freq` are defined.

Figure 94:

```
@define $temp 100.000000 ;
@define $freq 150.000000 ;
TEMPERATURE $temp C ;
FREQUENCY NET "clk_c" $freq MHz ;
```

After mapping, the .prf file will contain the following preferences:

Figure 95:

```
TEMPERATURE 100.000000 C ;
FREQUENCY NET "clk_c" 150.000000 MHz ;
```

In this next example, BITPATTERN is defined as a string value.

Note

Currently, USERCODE is the only preference that can use a variable defined as a string.

Figure 96:

```
@define $BITPATTERN ""01010011011001010110110101101001" ;
USERCODE BIN $BITPATTERN ;
```

Using Arithmetical Expressions You can use arithmetical expressions with @define, @ifdef, and @ifndef. The usual precedence of operations, from highest to lowest, is supported:

- expressions in parentheses

  Note

  A space must be placed inside each parenthesis.

- multiplication and division (* and /)
- addition and subtraction (+ and -)
- comparison operations (>, <, >=, <=, =)

  The == symbol can also be used with @ifdef and @ifndef to test for equality.

Examples Using Arithmetical Expressions In the following example, A is defined as 10 and B is defined as 4. The @ifdef statement tests whether A plus 4 is greater than 10. Since this is true, the CLOCK_TO_OUT preference is used.

Figure 97:

```
@define $A 10.000000;
@define $B 4.000000;

# TRUE: 14 > 10
@ifdef $A + 4.000000 > 10.000000;
CLOCK_TO_OUT PORT "speaker" 100.000000 ns MIN 100.000000 ns
CLKNET "clk_c" CLKOUT PORT "speaker" ;
@endif;
```

In the following example, the @ifdef statement tests whether A plus B is less than 10. Since this is false, the CLOCK_TO_OUT preference is not used.

Figure 98:

```
@define $A 10.000000;
@define $B 4.000000;

# FALSE: 14 < 10
@ifdef $A + $B < 10.000000;
CLOCK_TO_OUT PORT "speaker" 900.000000 ns MIN 100.000000 ns
CLKNET "clk_c" CLKOUT PORT "speaker" ;
@endif;
```

In this next example, the comparison in the @ifdef statement utilizes parentheses that change the precedence so that 2 plus 4 is calculated first. Notice that a space is placed inside each parenthesis so that the expression will be parsed correctly. In the end, the expression is true, so the CLOCK_TO_OUT preference is used.

Figure 99:

```
@define $A 10.000000;
@define $B 4.000000;

# TRUE: ( ( 6.000000 ) * 10.000000) / 2 > 25, 30 > 25
@ifdef ( ( 2.000000 + $B ) * $A ) / 2.000000 > 25.000000;
CLOCK_TO_OUT PORT "speaker" 3000.000000 ns MIN 100.000000 ns
CLKNET "clk_c" CLKOUT PORT "speaker" ;
@endif;
```

The following example adds two new variables, G and H. The G variable is used in a comparison with 20, which is true, so the CLOCK_TO_OUT preference is used.

Figure 100:

```
@define $A 10.000000;
@define $B 4.000000;
@define $G $A + 10;
@define $H $G - $B;

@ifdef $G == 20;
   CLOCK_TO_OUT PORT "speaker" 900.000000 ns MIN 100.000000 ns
CLKNET "clk_c" CLKOUT PORT "speaker" ;
@endif;
```

In this next example, H, which computes to 16, is used in a comparison with 20. Since H is less than 20, the CLOCK_TO_OUT preference is not used.

Figure 101:

```
@define $A 10.000000;
@define $B 4.000000;
@define $G $A + 10;
@define $H $G - $B;

@ifdef $H > 20;
   CLOCK_TO_OUT PORT "speaker" 1000.000000 ns MIN 100.000000 ns
CLKNET "clk_c" CLKOUT PORT "speaker" ;
@endif;
```

See Also ▶"Preferences" on page 1195

Generating Preferences from Synthesis Tools

Diamond enables you to add preferences generated from SDC or FDC synthesis tools to the logical preference file (.lpf) for the design. With the Output Preference File strategy option turned on, a synthesis .lpf file gets generated when you run Translate Design or when you run Synthesize Design for LSE. You can then add these preferences to the design's .lpf file and modify them as desired.

To generate the synthesis preference file:

1. In the File List view, select the strategy you want to use and make it the active strategy.
2. Choose **Project > Active Strategy > <synthesis tool> Settings**
3. Scroll down to the **Output Preference File** and double-click the cell in the Value column.
4. Select **True** from the drop-down menu and click **OK**.
5. In the Process view, do one of the following:
   - Double-click **Translate Design** if your synthesis tool is Synplify Pro or Precision.
   - Double-click **Synthesize Design** if your synthesis tool is LSE.

   Diamond synthesizes the design and outputs the preferences to the synthesis .lpf file.

The synthesis .lpf file is located in the <project_name><project_name> folder. The .lpf file name includes the project name, followed by the name of the synthesis tool; for example, attributes_attributes_synplify.lpf.

The following is an example of an .lpf file generated by Synplify:

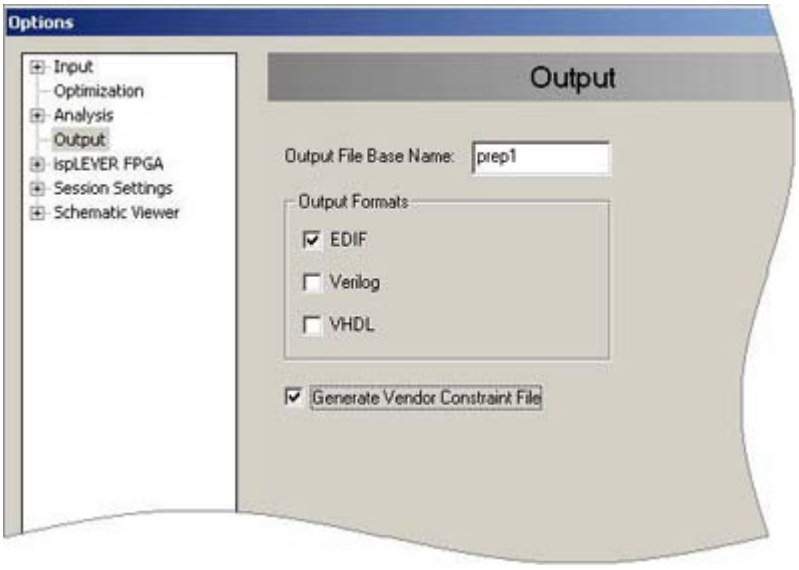
```
#
# Logical Preferences generated for Lattice by Synplify 9.0.0,
Build 260R.
#
# Period Constraints
FREQUENCY PORT "CLK" 200.0 MHz;
# Output Constraints
CLOCK_TO_OUT "Q_0" 5 NS CLKPORT = "CLK";
CLOCK_TO_OUT "Q_1" 5 NS CLKPORT = "CLK";
CLOCK_TO_OUT "Q_2" 5 NS CLKPORT = "CLK";
CLOCK_TO_OUT "Q_3" 5 NS CLKPORT = "CLK";
CLOCK_TO_OUT "Q_4" 5 NS CLKPORT = "CLK";
CLOCK_TO_OUT "Q_5" 5 NS CLKPORT = "CLK";
CLOCK_TO_OUT "Q_6" 5 NS CLKPORT = "CLK";
CLOCK_TO_OUT "Q_7" 5 NS CLKPORT = "CLK";
# Input Constraints
INPUT_SETUP "S_L" 5 NS CLKPORT = "CLK";
INPUT_SETUP "S1" 5 NS CLKPORT = "CLK";
INPUT_SETUP "S0" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d0_0" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d0_1" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d0_2" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d0_3" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d0_4" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d0_5" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d0_6" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d0_7" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d1_0" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d1_1" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d1_2" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d1_3" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d1_4" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d1_5" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d1_6" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d1_7" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d2_0" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d2_1" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d2_2" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d2_3" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d2_4" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d2_5" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d2_6" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d2_7" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d3_0" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d3_1" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d3_2" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d3_3" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d3_4" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d3_5" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d3_6" 5 NS CLKPORT = "CLK";
INPUT_SETUP "d3_7" 5 NS CLKPORT = "CLK";
BLOCK ASYNCPATHS;
# End of generated Logical Preferences.
```

How to Turn on Preference Output for Precision The Mentor Graphics Precision synthesis tool provides an option that outputs a constraint file for Diamond. When you select this option, some of the synthesis constraints will be written to the design's .prf file. You can then copy these preferences to the logical preference file (.lpf).

To turn on Generate Constraint File in Precision:

1. Open your <*project_name*>.psp file in Precision.
2. Choose **Tools > Set Options**.
3. In the left pane of the dialog box, select **Output**.

Figure 102:



4. In the Output pane, select **Generate Vendor Constraint File** and click **OK**.
5. In Diamond, select the target device, and then double-click **Translate Design**.

   Diamond synthesizes the design and outputs the Precision preferences to the .prf file.

To write the synthesis preferences to the active .lpf file:

1. Using a text editor, open the generated synthesis .lpf file and also the desired .lpf file for the design.
2. Copy the preferences from the synthesis .lpf file, paste them into the .lpf file for the design, and then close the synthesis .lpf file.
3. In the .lpf file for the design, choose **File > Save**.

   When the modified .lpf file is set as the active one, Diamond will use these added preferences in processing the design.

See Also ▶"Integrated Synthesis" on page 581

Saving Preferences

Each time you issue a process command, such as Map or Place & Route, Diamond prompts you to save any new modifications to your project files, including the logical preference file (.lpf) for the current implementation. Diamond also prompts you to save new or modified preferences when you close the project or exit the software.

You will not be prompted, however, to save changes each time you close a preference-editing view. Your preference modifications are kept in memory as long as Diamond is running. An asterisk on the tab of any preference view indicates unsaved preference changes, and so does the "Preferences Modified" indicator on the status bar. The "Preferences Modified" statement remains on the status bar as long as there are preference changes in memory, even when all preference views are closed.

You can save preference changes to the .lpf file at any time from a preference-editing view. Click one of the available Save buttons on the toolbar or use any of the available Save commands from the File menu.

Note

When you use any of the Save commands after running Place & Route, the design gets initialized back to pre-map status.

Save <file_name>.lpf Saves preference changes to the .lpf file for the active implementation. The Save command is available from any preference view and saves all preference changes—not just those that were made from the active preference view.

Save <file_name>.lpf as Saves preference changes to a different .lpf file name or to a different directory that you specify. When you use the "Save as" command and give the .lpf file a new name, the new .lpf file is automatically added to the Constraints Files folder and set as the active constraint file for the current implementation.

Save All Saves preference changes to the currently active .lpf file, as well as changes that were made using other tools. For example, if changes are made using Spreadsheet View and Power Calculator, it will save the Spreadsheet View changes to the .lpf file, and it will save the Power Calculator changes to the .pcf file. At least one of the preference-editing views must be open in order to save preference changes with the Save All command.

See Also ▶"Preference-Editing Views and Memory" on page 405

Previewing Preferences Before Saving

You can quickly preview all preferences in a read-only file to ensure that preference changes are correct before you save them. The Preference Preview lists the preferences from the Logical Preference File (.lpf), plus all preference changes that exist in memory only.

Preference Preview is also useful for copying in-memory preferences and pasting them into a different .lpf file. This allows you to save the in-memory changes without changing the currently active preference file.

To preview all preferences:

- Choose **View >** **Preference Preview**.

  A read-only preference file opens in a separate view.

  Note

  The Preference Preview does not list unsaved changes that were made manually to the .lpf file.

See Also "Preference-Editing Views and Memory" on page 405

Saving Preferences to the Currently Active .lpf File

You can immediately save preference changes to the currently active .lpf file from any preference-editing view.

To save preference changes to the currently active .lpf file:

- From a preference-editing view, choose **File >** **Save <file_name>.lpf**.

  Diamond saves your changes to the active logical preference file and project directory. The design is initialized back to pre-map status.

See Also "Preference-Editing Views and Memory" on page 405

Saving Preferences to a Different .lpf File

The "Save as" feature is useful for creating a set of modified preferences to use with an existing implementation or a new one. When you use the "Save as" command, Diamond adds the new .lpf file to the Constraint Files folder and sets it as the active constraint file for the current implementation. If you have already placed and routed the design, the "Save as" command will initialize the design back to pre-map status.

To save preferences to a new .lpf file:

1. Activate Spreadsheet View, Package View, Device View, or Floorplan View; or double-click the .lpf file to open it in the Text Editor window.
2. Choose **File > Save <file_name>.lpf as**.
3. In the dialog box, type the desired name for the .lpf file in the Name text box, navigate to the desired directory, and click **Save**.

   The new .lpf file is added to the Constraint Files folder and is set as the active one for the current implementation. The design is initialized back to pre-map status.

To revert to the previous .lpf file for the current implementation:

- In the Constraint Files folder, right-click the previous .lpf file and choose **Set as Active Preference File**.

See Also "Preference-Editing Views and Memory" on page 405

Saving Preferences and Other Changes

The Save All command saves all modifications made to your project files. It saves preference changes to the .lpf source file, and it saves changes made with other tools to source files or analysis files.

To save all changes:

1. Make sure that at least one preference-editing view is open in Diamond.
2. From any view, choose **File > Save All**.

Applying External Preference Changes

While using the preference views, you may sometimes need to modify preferences externally. For example, you might want to open the logical preference file (.lpf) in an external text editor to quickly modify a UGROUP or REGION. You can afterwards view the changes in Diamond before processing the design.

Before applying external preference changes, make sure that there are no preference changes in memory. If there are unsaved preference changes in Diamond, save them to a different .lpf file or close and reopen Diamond without saving the changes.

Caution

When there are preference changes in memory, using the Save command in a preference view will cause you to lose the external preference changes.

External changes made to the .lpf file will be reflected in the preference views when you reopen them. If a preference view is already open when the

changes are made externally, the changes might not be displayed. To display the external changes, close and reopen any preference view.

Rerun the Map Design process to apply the changes.

Discarding In-Memory Preference Changes

There are two ways to delete all modified preferences that are in memory.

Discard In-Memory Preference Changes Only The “Discard Modified Preferences” command clears all unsaved preferences from memory and displays only those that are in the logical preference file.

To discard in-memory preferences:

1. Choose **File > Discard Modified Preferences**.
2. In the warning dialog box, click **Yes** to continue.

   The unsaved preferences are cleared from all open preference views. Diamond removes the asterisks from the preference view tabs and the “Preferences Modified” indicator from the status bar.

Discard All In-Memory Design Changes The “Clear Tool Memory” command discards all in-memory design changes, including preferences, and closes the open tools. Before the memory is cleared, a Confirm dialog box enables you to save the changes to the appropriate source file. When you select “Deselect All,” Diamond discards all changes.

To clear tool memory:

1. Choose **Tools > Clear Tool Memory**.

   The Confirm dialog box opens and lists in the upper section the tools that have unsaved changes. The lower section lists the affected files, including the .lpf file.
2. In the Confirm dialog box, clear the check mark in front of the .lpf file or click **Deselect All**, and then click **OK**.

   Diamond closes the open tools and removes the changes from memory.

Checking Design Rules

Diamond provides PIO design rule checking (DRC), which enables you to validate I/O placement, logic, and routing.

During load time and initialization, Diamond’s preference views interpret the database and preference files in a similar manner as the Map and Place & Route processes. Syntax or semantic violations within the logical preference file are also treated in a manner similar to the Map and Place & Route

processes. Illegal preferences are ignored but retained in the logical preference file and the physical preference file. Diamond loads and applies the legal subset it detects and displays error and warning messages.

After the project is loaded, Diamond provides access to on-demand and real-time PIO DRC Check. All DRC reports are presented in the Output window for the current session.

For LatticeSC, LatticeECP3, and MachXO2 devices, a PIO DRC report is placed in the Tool Reports folder when you run on-demand PIO DRC. Any errors or warnings appear in the top part of the Summary section of the report, and each error or warning is hyper-linked to the appropriate DRC rule in the Details section. See "PIO DRC Rules" on page 550.

See Also ▶"PIO DRC" on page 548

PIO DRC

PIO design rule check can catch many common errors and prevent wrong pin usage at the early stage of the design process. It helps you ensure that design I/Os are assigned correctly before the design is mapped, placed, and routed. This can dramatically reduce design errors, help you meet timing requirements, optimize for both the FPGA and printed circuit design, and reduce the number of design iterations.

PIO DRC performs logical and physical tests to validate I/O placement such as signal standard and VCCIO combinations bank by bank, true and emulated LVDS combinations, VREF requirements, and potential conflicts with user assignments made to multi-function pins like those of the sysCONFIG interface. It is available as real-time and on-demand DRC.

Real-time PIO DRC Real-time PIO DRC, when enabled, runs automatically in real time for items that have been modified. For example, when you import constraints from an external source, real-time PIO DRC runs automatically. Real-time PIO DRC also runs automatically when you set I/O preferences through one of the preference-editing views such as Spreadsheet View.

You can enable or disable real-time PIO DRC in Spreadsheet View. The second button on the toolbar acts as a toggle key that turns real-time PIO DRC on or off. By default, it is turned on.

On-demand PIO DRC On-demand PIO DRC means that you can run it manually at any time for the whole design. For example, when you have modified preferences in Spreadsheet View, you can use the Preference PIO DRC Check command to find out if any PIO design rules have been violated in the entire design as a result of the modifications. On-demand PIO DRC is available in Spreadsheet View, Package View, Device View, and Floorplan View.

See Also ▶"Performing On-Demand PIO Design Rule Check" on page 549

Performing On-Demand PIO Design Rule Check

The PIO DRC feature validates pin assignments to banks based on legal combinations of signal standards, including true and emulated LVDS combinations. Diamond performs immediate real-time PIO DRC on any preference changes. But you can run PIO DRC on the entire design, after modifying preferences, by running on-demand PIO DRC.

To perform PIO design rule checking:

1. From Diamond's Tools menu, select one of the following views:
   - Spreadsheet View
   - Package View
   - Device View
   - Floorplan View
2. Choose **Design >**  **Preference PIO DRC**.

   Diamond checks the I/Os . A message box reports whether errors or warnings were encountered. A log of errors and warnings appears in the Output window.

   If your design's target device is LatticeSC, LatticeECP3, or MachXO2, a DRC report will appear in the Tool Reports folder. Any DRC errors or warnings are listed at the top of the Summary section. Click the hyperlinks to jump to the design rule description in the Details section.

See Also "PIO DRC" on page 548

"PIO DRC Rules" on page 550

Post-Map DRC Check

In the post-map stage, DRC performs logical and physical tests: Block, Net, Pad, Clock Buffer, Name, and Primitive Pin. Reported errors from DRC check indicate conditions where routing or component logic will not operate correctly. Warnings indicate conditions where routing or logic is incomplete or the condition is incorrect but not serious. Some conditions considered warnings might be reported as errors when DRC is performed by the Generate Bitstream Data (bitgen) process.

Post-Map DRC Check is available in the post-map or post-PAR stage in Spreadsheet View, Package View, Device View, and Floorplan View.

See Also "Performing On-Demand PIO Design Rule Check" on page 549

PIO DRC Rules

The following tables describe the PIO design rules for LatticeSC, LatticeECP3, and MachXO2 device families. The tables are organized by the category of elements affected by the PIO design rules: port, pin, bank, device, Vref, IOBUF, and programmable interface cells (PIC). Example messages are provided, as well as suggestions for resolving errors and warnings.

Table 42: Port-Related Rules

Rule Name and Description	Severity	Affected Devices	Message Example	Suggestion
NSidePortAssignmentCheck N-side port assignment check	error	LatticeSC LatticeECP3 MachXO2	The n-side port [PORT_NAME] assignment is not supported.	Use p-side port to make the assignment.
PortBusDirectionConsistency Bus direction consistency check	warning	LatticeSC LatticeECP3 MachXO2	The bus [BUS_NAME] has members with different port direction.	Use the same direction for the bus.
PortBusIoTypeConsistency Bus IO Type consistency check	warning	LatticeSC LatticeECP3 MachXO2	The bus [BUS_NAME] has members with different IO types [IO_TYPE, IO_TYPE,…].	Use a consistent IO Type for all the members in the bus.
PortClockAssignment[1] Clock port assignment check	warning	LatticeSC LatticeECP3 MachXO2	The clock port [PORT_NAME] is assigned to a non-clock-dedicated pin [PIN_NAME]	Use dedicated clock resources for the port.
PortConnection Port connection check	error	LatticeSC LatticeECP3 MachXO2	The port [PORT_NAME] doesn't have a load.	Connect or remove the port.
PortDifferentialIoType Differential port IO Type check	error	LatticeSC LatticeECP3 MachXO2	Non-differential IO type [IO_TYPE] is assigned to the differential port [PORT_NAME].	Use a differential IO type for the port.
PortDifferentialPSideExistence Differential port positive side existence check	error	LatticeSC LatticeECP3 MachXO2	The port [PORT_NAME] doesn't have a complementary positive side port defined.	Check port definition.
PortExistence Port existence check	error	LatticeSC LatticeECP3 MachXO2	The port [PORT_NAME] doesn't exist in the design.	Remove the port.
PortFloatingNumber Floating port number check	error	LatticeSC LatticeECP3 MachXO2	The number of unassigned ports ([NUMBER]) exceeds the number of available pins [NUMBER] left based on the current assignment.	▶ Rearrange pin assignments. ▶ Change to a large device with more pins.

Table 42: Port-Related Rules (Continued)

Rule Name and Description	Severity	Affected Devices	Message Example	Suggestion
PortGlobalClkNumber Global clock total number check	warning	LatticeSC LatticeECP3 MachXO2	The number of clocks [NUMBER] exceeds the available number of global clock dedicated pins [NUMBER].	Warning: non-clock-dedicated pins will be used for some clock ports.
PortGroupExistence Port group existence check	error	LatticeSC LatticeECP3 MachXO2	The port group [GROUP_NAME] is not defined.	Remove the port group.
PortGroupUniqueness Port group uniqueness check	error	LatticeSC LatticeECP3 MachXO2	The port [PORT_NAME….] defined in group [GROUP_NAME] has been included in multiple port groups.	Change group definitions and make sure that the port is included in only one port group.
PortInGroupExistence Port defined in PORT GROUP existence check	error	LatticeSC LatticeECP3 MachXO2	The port [PORT_NAME] defined in port group [PORT GROUP] does not exist in the design.	Remove the port.
PortPllAssignment[2] PLL ports assignment check	error	LatticeSC LatticeECP3 MachXO2	The port [PORT_NAME] connects to a PLL but is not assigned to a PLL dedicated pin.	Assign the port to a PLL dedicated pin.
PortTotalDifferentialPairNumber Differential port total number check	error	LatticeSC LatticeECP3 MachXO2	The total number of differential ports ([NUMBER]) exceeds the total differential pin pairs available [NUMBER] in the target device [DEVICE_NAME].	▶ Change to a device with more differential pin pairs. ▶ Migrate to a large device with more differential pin pairs.
PortTotalIoTypeNumber IO type number check	error	LatticeSC LatticeECP3 LatticeECP4 MachXO2	The number of VCCIO or banks required exceeds the total number of banks ([NUMBER]) available based on the current assignment.	▶ Reduce the number of IO Types. ▶ Use compatible IO types. ▶ Change to a large device with more banks.
PortTotalNumber Port total number check	error	LatticeSC LatticeECP3 MachXO2	The total number of ports ([NUMBER]) exceeds the total assignable pins available ([NUMBER]) in the target device [DEVICE_NAME].	Change to a device with more available pins.
PortVrefAssignment Port assigned to a vref which is in different bank	error	LatticeSC LatticeECP3 MachXO2	The port [PORT NAME] assigned to bank [BANK#] is also assigned to VREF [VREF name], which is in different bank [BANK#].	Assign the port to the same bank [BANK#] of the VREF [VREF NAME].
PortVrefSupport Port Vref support check	error	LatticeSC LatticeECP3 MachXO2	The Port [PORT_NAME] does not support Vref.	Change IOBUF setting to enable VREF.

Notes

[1] The PortClockAssignment rule checks a “CLOCK Input” type of port (a clock port) and ensures that it is assigned to a PCLK or PLL pin. In order to achieve optimized performance for some cases, it is suggested that the CLOCK input be connected to a dedicated PCLK pin or PLL pin. The PIO DRC will issue a Warning if the clock is not connected to one of these pins. For high speed designs, it is recommend that a PCLK pin be used for going directly to the Primary or Edge clock tree and a PLL pin be used if the clock is going to a PLL. If speed is not a requirement for the design, these Warning messages can be ignored.

[2] The PortPllAssignment rule checks a port that connects to a PLL (a PLL port) and ensures that it connects to a PCLK pin or PLL pin. In some cases, such as the DDR edge aligned interface where the high speed clock is going directly to a PLL, the CLOCK port must connect to a PLL pin. In this case, if the port is assigned to a PCLK pin, PIO DRC will not issue a warning. When this is the case, make sure that the PLL port is assigned to a PLL pin.

Table 43: Pin-Related Rules

Rule Name and Description	Severity	Affected Devices	Message Example	Suggestion
PinDDRSite DDR site assignment check	error	LatticeECP3	Cannot place PIO comp [COMP NAME] on the PIO site [SITE VALUE] because the types of their IOLOGICs are incompatible.	Assign it to a supported site which is on the left or right hand side.
PinDdrUsageCheck Pin DDR usage pattern check	error	LatticeECP3	The following IDDRX(s) [port_names] and ODDRX(s) [port_names] can not be placed in the same DQS group.	Check these ports' DDR usage, and follow the DDR usage model.
PinDifferentialCapability Pin differential capability check	error	LatticeSC LatticeECP3 MachXO2	The differential port [PORT_NAME] is assigned to a non differential pin [PIN_NAME] (or illegal differential pair [NAME]).	Reassign the port to a valid differential pin.
PinDifferentialPairComplementary Differential pin pair usage check	error	LatticeECP3	The differential port [port_name] is assigned to the pin [pin_name], but this pin's complementary pin [pin_name] is taken by the port [port_name].	Assign the port to a different differential pin pair, or release the complementary pin.
PinDifferentialPairTrue Differential pin pair positive pin check	error	LatticeECP3	The differential port [port_name] must be placed on a positive pin of a differential pin pair.	Assign the port to a positive pin of a differential pin pair.
PinDifferentialPSideExistence Differential pin pair positive pin existence check	error	LatticeSC LatticeECP3 MachXO2	The differential port [PORT_NAME] cannot be assigned to the pin [PIN_NAME] because this pin doesn't have a complementary positive pin.	Assign the port to a valid differential pin pair.
PinDirection Directional pin assignment check	error	LatticeSC LatticeECP3	The [input/output] port [PORT_NAME] is assigned to an [output/input] dedicated pin [PIN_NAME].	Reassign the port to a valid pin.

Table 43: Pin-Related Rules (Continued)

Rule Name and Description	Severity	Affected Devices	Message Example	Suggestion
PinExistence Pin existence check	error	LatticeSC LatticeECP3 MachXO2	The port [PORT_NAME] is assigned to a nonexistent pin [PIN_NAME].	Reassign the port to a valid pin.
PinFeatureSupport Pin-supported features check	error	LatticeSC	The port [port_name] with [MODE_NAME] mode uses [VCCIO3.3|LVDS|RSDS|HYPT that is not supported by the pin [pin_name].	Assign the port to a pin that supports the VCCIO/LVDS/RSDS/HYPT feature.
PinInputOnly Pin input only check	error	MachXO2	The [output|BIDI] port [port_name] is placed on an input-only pin [pin_name].	Assign the port to a different pin that supports output mode.
PinIoTypeCapability Pin IO Type capability check	error	LatticeSC LatticeECP3 MachXO2	The port [PORT_NAME] has IO Type [IO_TYPE] assigned, but the IO Type is not supported by the assigned pin [PIN_NAME].	Use a pin that supports the IO Type.
PinStateValue Pin state value check	error	LatticeSC LatticeECP3 MachXO2	The pin [PIN_NUMBER] is [reserved/assigned to [PORT_NAME]] and cannot be assigned to the port [PORT_NAME].	Change the pin's assignment.
PinSysConfig SysConfig pin assignment check	error	LatticeSC LatticeECP3 MachXO2	The state of the assigned pin [PIN_NAME] conflicts with the config mode and cannot be assigned to the port [PORT_NAME].	▶ Change pin assignment ▶ Change SysConfig setting.
PinTypeValue Pin type value check	error	LatticeSC LatticeECP3 MachXO2	The type value [PIN_TYPE] of pin [PIN_NAME] is invalid and cannot be assigned to the port [PORT_NAME].	Change the pin's assignment.
PinVrefAvailability VREF pin availability check	error	LatticeSC LatticeECP3 MachXO2	VREF is required in bank [BANK#] but there is no VREF pin available in the bank.	Release a [VREF pin (LatticeSC/LatticeECP3) / pin for VREF(MachXO2)] in bank [BANK#].
PinVrefGroup Pin Vref group check	error	LatticeSC LatticeECP3 MachXO2	Pins in the VREF group [GROUP_NAME] require different VREF values.	Make sure that all the pins in the same VREF group require the same VREF value.

Table 44: Bank-Related Rules

Rule Name and Description	Severity	Affected Devices	Message Example	Suggestion
BankDifferentialLimit Bank differential output limitation check	error	LatticeSC	HYPT buffer is used together with LVDS/RSDS in the same bank. The port [port_name] is in conflict with other ports in the bank [bank_value] (refer to port [port_name]).	Assign the port t o a different bank.
BankDiffPairCapacity Bank differential pin pair capacity check	error	LatticeSC LatticeECP3 MachXO2	The number of differential ports ([NUMBER]) assigned to the bank [BANK_NAME] exceeds the number of differential pin pairs ([NUMBER]) available in the bank.	Use multiple banks.
BankExistence Bank existence check	error	LatticeSC LatticeECP3 MachXO2	Bank [BANK] is not available in the target device [DEVICE_NAME].	Use valid bank number.
BankIoTypeCapability Bank IO Type capability check	error	LatticeSC LatticeECP3 MachXO2	The port [PORT_NAME] has IO Type [IO_TYPE] assigned, but the IO Type is not available in the assigned bank [BANK_NAME].	Use a bank that supports the IO Type.
BankIoTypeCompatability Bank IO Type compatibility check	error	LatticeSC LatticeECP3 MachXO2	Ports [PORT_NAME, PORT_NAME...] with incompatible IO types [IO_TYPE, IO_TYPE,…] are assigned to the same bank [BANK_NAME].	Use multiple banks.
BankPinCapacity Bank pin capacity check	error	LatticeSC LatticeECP3 MachXO2	The number of ports ([NUMBER]) assigned to the bank [BANK_NAME] exceeds the number ([NUMBER]) of pins available in the bank.	Use multiple banks.
BankUniqueINRD BANK unique INRD check	error	MachXO2	In the bank [bank_number], more than one INRD signals [signal_name, signal_name,…] are found for the ports [port_name, port_name, ...]	Assign the port to a bank with the same INRD signal.
BankUniqueLVDS BANK unique LVDS check	error	MachXO2	In the bank [bank_number],, more than one LVDS signals [signal_name, signal_name,…] are found for the ports [port_name, port_name, ...]	Assign the port to a bank with the same LVDS signal.

Table 44: Bank-Related Rules (Continued)

Rule Name and Description	Severity	Affected Devices	Message Example	Suggestion
BankUniquePG BANK unique PG check	error	MachXO2	In the bank [bank_number],more than one PG signals [signal_name, signal_name,…] are found for the ports [port_name, port_name, ...]	Assign the port to a bank with same PG signal
BankVccioValueConsistency Bank VCCIO value consistency check	error	LatticeECP3 MachXO2	In the bank [bank_value], VCCIO for [port_name] is [VCCIO_value] and is incompatible with other ports that use VCCIO [VCCIO_value] (refer to port [port_name])	Assign the port to a compatible bank.
BankVcmtConsistency Bank VCMT usage and IO_TYPE consistency check	error	LatticeSC	The ports [port_name] and [port_name] in the bank [bank_value] use VCMTs but their IO_TYPEs [IO_TYPE_value] and [IO_TYPE_value] are different.	Assign the port to a different bank, or modify IO_TYPE for one of the ports.
BankVrefCapacity Bank VREF capacity check	error	LatticeSC LatticeECP3 MachXO2	The number of VREF required ([NUMBER]) exceeds the number of VREF capacity ([NUMBER]) supported by the bank/device [BANK_NAME/ DEVICE_NAME].	Reduce the number of different VREF required for [{BANK/DEVICE}] [{BANK_NAME}/ {DEVICE_NAME}].
BankVrefLoad1DriverMatch Bank VREF1 load driver consistency check	error	LatticeSC	The port [port_name] in the bank [bank_value] uses VREF1_LOAD, but there is no VREF1_DRIVER in that bank.	Add VREF1_DRIVER to the bank.
BankVrefLoad2DriverMatch Bank VREF2 load driver consistency check	error	LatticeSC	The port [port_name] in the bank [bank_value] uses VREF2_LOAD, but there is no VREF2_DRIVER in that bank.	Assign the port to a different bank.
BankVrefLoadConsistency Bank VREF load IO_TYPE consistency check	error	LatticeSC	In the bank [bank_value], VREF for [port_name] is different from the other two VREFs for ports [port_name] and [port_name]	Assign the port to a compatible bank.
BankVttDdrIIVcmtExclusive VTT/DDR_II and VCMT exclusive check	error	LatticeSC	VCMT buffer is used together with VTT/DDR_II in the same bank. The port [port_name] is in conflict with other ports in bank [bank_value] (refer to port [port_name]).	Assign the port t o a different bank.

Table 44: Bank-Related Rules (Continued)

Rule Name and Description	Severity	Affected Devices	Message Example	Suggestion
BankVttValueConsistency Bank VTT value consistency check	error	LatticeSC LatticeECP3	In the bank [bank_value], VTT for [bank_port] is [VTT_value] and is incompatible with other ports that use VTT [VTT_value] (refer to port [port_name])	Assign the port to a compatible bank.
ConfigBankIOVoltageMismatch PERSISTENT Config Bank I/O voltage check	error	LatticeSC LatticeECP3 MachXO2	Cannot assign [PORT NAME] to [IO_TYPE] in bank [BANK#] because PERSISTENT is turned ON and CONFIG_IOVOLTAGE do not match the I/O voltage of the [PORT NAME] in bank [BANK#] .	Either set PERSISTENT to OFF or match CONFIG_IOVOLTAGE to an acceptable [IO_TYPE] for the port [PORT NAME].

Table 45: Device-Related Rules

Rule Name and Description	Severity	Affected Devices	Message Example	Suggestion
DeviceVccioCapacity Device VCCIO capacity check	error	LatticeSC LatticeECP3 MachXO2	The number of VCCIO or banks required exceeds the total number of banks available ([NUMBER]) based on the current assignment.	Use large devices.
DeviceVrefCapacity Device VREF capacity check	error	LatticeSC LatticeECP3 LatticeECP4 MachXO2	The number of VREF required ([NUMBER]) exceeds the number of VREF capacity ([NUMBER]) supported by the device [DEVICE_NAME].	Use large devices with more VREF pins.

Table 46: Vref Group-Related Rules

Rule Name and Description	Severity	Affected Devices	Message Example	Suggestion
VrefGroupExistence Vref group existency check	error	LatticeSC LatticeECP3 MachXO2	VREFGROUP [GROUP NAME] assigned to the port [PORT NAME] is not defined	Define the Vref Group.

Table 47: IOBUF-Related Rules

Rule Name and Description	Severity	Affected Devices	Message Example	Suggestion
IOBUFAttributeNameValidation IOBUF attribute name validation	error	LatticeSC LatticeECP3 MachXO2	The port [PORT_NAME] has invalid IOBUF attribute name [KEY_NAME].	Check the string [KEY_NAME] for typos, or use a valid attribute name.
IOBUFAttributeValueValidation IOBUF attribute value validation	error	LatticeSC LatticeECP3 MachXO2	The port [PORT_NAME] has some invalid IOBUF attribute values: [KEY: VALUE], [KEY:VALUE] ….	Check the assignments for those attribute and use valid values.
IOBUFLegalCombinationTableValidation IOBUF legal combination table validation	error	LatticeSC LatticeECP3 MachXO2	The port [PORT_NAME] has invalid combination of the IOBUF settings according to the device I/O specifications.	Check the IOBUF setting and correct the errors.

Table 48: PIC-Related Rules

Rule Name and Description	Severity	Affected Devices	Message Example	Suggestion
PicCompatibleOutput PIC IOLOGIC output and SHX4/DDR4 compatible check	error	LatticeSC	The port [port_name] at pad [A|B|C|D] cannot be used as output (or input) when the [port_name] at pad [A|B|C|D] is in SHX4/DDRX4 mode (or using AIL).	Assign the port to a different PIC (A group of PIO pins consists of adjacent A/B/C/D pads).
PicCompatibleX24AilTri PIC IOLOGIC x2/x4/Ail/Tri-State compatible check	error	LatticeSC	The port [port_name] at pad [A|B|C|D] and the port [port_name] at pad [A|B|C|D] are competing for DDR resources (x2,x4,AIL or tri-state), they cannot be shared in one PIC.	Assign the port to a different PIC (A group of PIO pins consists of adjacent A/B/C/D pads).

Analyzing SSO

For many FPGA devices, Diamond enables you to run an analysis of simultaneous switching outputs (SSO). SSO analysis describes the noise on signals caused by a large number of out drivers that are switching at the same time. When multiple output drivers change state at the same time, the changing current in the power system induces a voltage that results in power supply disturbances. These disturbances, or noise, can cause undesired transient behavior among output drivers, input receivers, or internal logic. Analysis of simultaneous switching outputs helps ensure that your I/O plan meets the I/O standards and power integrity requirements of the PCB design.

SSO Calculator The SSO calculator estimates Simultaneous Switching Noise (SSN) affecting a victim pin according to the switching characteristics of aggressor pins. It does this either on a victim-pin-by-victim-pin basis (Pin

Analysis) or on the basis of the worst-case victim pin placement in each bank (Bank Analysis). In many cases, adjusting the location of aggressor pins relative to victims can help mitigate noisy conditions. Noise is characterized by the calculator as ground bounce or voltage drop depending on the type of analysis run. The calculator will produce worst-case bank-based ground bounce results for those banks that have partial signal assignments, and it will produce a more accurate pin-based ground bounce and voltage drop results if all signals of a bank are assigned.

The following calculation is made for a victim pin (in Bank-based Analysis, the worst case victim is used for each bank):

Pass/Fail status: Fails if (Total Noise) > (Pass/Fail criteria) * ALLOWANCE

where:

Total Noise (mV) = Board Noise + Device Noise

Board PCB Noise can be on the ground plane, for ground bounce calculations; or it can be on the power plane, for Vcc drop calculations. PCB estimated ground plane noise is entered as +X mV. PCB estimated power plane noise is entered as -X mV.

Device noise is the maximum noise imposed on a victim pin by each of the aggressor pin groups. Aggressor groups are specified by using SwitchingID assignments. Reports show which aggressor group is causing the most noise on a victim.

The Pass/Fail criteria is based on the IO_TYPE of the victim. SSO allowance is a user override that adjusts the pass/fail criteria, where default is no change to the pass/fail criteria (100%)

SSN Accuracy SSO calculator estimations are based off of hardware data collected during characterization. The measurements were taken using Lattice test PC boards with signal loading on individual banks. Because the total SSN is a function of PCB ground and board inductance, care must be given to apply accurate SSO preferences based on the parasitic inductances of your system environment.

About Pin-Based Analysis Reports Pin-based analysis produces estimates for ground bounce and voltage drop SSN per pin. Pin-based analysis is performed after design signals have been assigned to pins. These pin assignments can be made by setting preferences or by placing and routing the design. The analysis calculates the noise that each pin, as a victim, experiences. It reports the pass/fail status of each pin and where the noise originates—the aggressor group identified by SwitchingID.

About Bank-Based Analysis Reports Bank-based analysis produces ground bounce SSN per bank. When at least one signal is assigned only to a bank and not to a pin, bank-based calculation is performed. Compared to pin-based analysis, bank-based analysis assumes worst case placement in the bank for the victim and set of aggressors. Any placement information that does exist is ignored, and worst-case placement is used.

For both Pin-based and Bank-based analysis, pins or banks programmed for signal standards (IO_TYPE) other than those that the calculator supports are ignored.

Addressing SSN Problems The SSO calculator is a good tool for confirming the quality of an I/O plan. After legal signal assignments have been verified and placed using the I/O Assistant strategy, use the SSO calculator to adjust relative placement where SSN margins are exceeded.

The following adjustments to your I/O plan can help avoid SSN problems:

- Spread aggressors away from victim pins. Use the “Assign Pin” feature of the Assign Pins dialog box in Spreadsheet View to stagger package pin assignments.
- Use slow slew outputs.
- Use lower drive strengths

See Also ▶“Running SSO Analysis” on page 559

- “Viewing SSO Analysis Results” on page 560
- “Exporting an SSO Report in CSV Format” on page 561

Running SSO Analysis

For bank-based SSO analysis, the SSO calculator requires a SwitchingID that indicates the output drivers that will be switching in parallel, and the banks to which the drivers will be assigned. For pin-based analysis, the SSO calculator also requires detailed signal-to-pin placement. You can specify these parameters in the Port Assignments sheet of Spreadsheet View at any stage of the design flow. The more complete your assignments, the more accurate the analysis results will be.

Because the SSO calculator uses the in-memory state of preferences, you are not required to save the SSO parameters in order to run an analysis. This enables you to experiment with placement and other parameters before committing a change to the logical preference file (.lpf).

To run SSO analysis:

1. In Spreadsheet View, select the Port Assignments tab.
2. Assign pin locations or just the bank locations to the output or bidirectional signals that you wish to analyze.
3. Select from the following attributes for each signal to be analyzed:
   - an appropriate I/O buffer from the IO_TYPE column
   - a drive strength for the output buffers from the DRIVE column
   - a slew rate from the SLEWRATE column
4. Type a capacitive output load (pF) value in the Outload column.

5. Specify settings in the following SSO columns for each signal to be analyzed:
   - SwitchingID – Type an alphanumeric value to identify the aggressor output drivers that can switch at the same time.

     If you do not specify a Switching ID, the Default_ID will be assigned to all output pins.
   - Ground plane PCB noise – Type a floating point value to specify the millivolt units of estimated board noise for bounce.
   - Power plane PCB noise – Type a floating point negative value to specify the estimated board noise for drop.
   - SSO Allowance – Specify an allowable percentage of SSO per bank.

   If any of the settings are estimated to be the same for all output signals, you can use the Allports row to quickly set the values for all outputs.
6. Choose **Design >**  **Preference SSO Analysis**.

   The SSO calculator runs the analysis, based on the parameters, and displays the results in Package View.

   Any pins that failed the analysis are highlighted in red.

To view the full I/O SSO Analysis Report, select the Reports tab.

If some of the pin or bank assignments failed the analysis, adjust the assignments or parameters to try to reduce the SSO noise. Afterwards, rerun the SSO analysis.

See Also ▶"Viewing SSO Analysis Results" on page 560

- "Analyzing SSO" on page 557
- "Exporting an SSO Report in CSV Format" on page 561
- "Running I/O SSO Analysis from the Command Line" on page 2546

Viewing SSO Analysis Results

After running SSO analysis, you can immediately open the I/O SSO Analysis Report, or you can export the results to a spreadsheet format file. You can also view the status of SSO pins in Package View. You do not have to save the SSO preferences in order to view or export the analysis.

To view the SSO Analysis Report:

- In the Report window, expand the Tool Reports folder and select **I/O SSO Analysis**.

The SSO Analysis Report is organized by "Bank SSO Results" and "Pin SSO Results." Each of these sections is further organized according to the type of change in current—ground bounce or drop—that is caused by the switching aggressor pins.

Bounce – When the aggressor pins switch from high to low, the power supply needs to sink current. If a large amount of current needs to be sunk, the ground level will start to rise. This rise in current is the ground bounce.

Drop – When the aggressor pins switch from low to high, the power supply needs to source current. If too much current is required, the VCC level will start to drop temporarily as the charge is supplied. This initial drop is the VCC drop. As the charge is supplied, the VCC level starts to go back up to the proper VCC level.

The “Pin SSO Results” section also contains hyperlinks to details organized by pin and bank.

To navigate to bank and pin details in the SSO Analysis Report:

- Click the desired bank number in the “Worst Bounce SSO of each Bank” section or the “Worst Drop SSO of each Bank” section to jump to the appropriate table in “SSO Information of Pins of each Bank”.
- Click a signal name in one of the tables of “SSO Information of Pins of each Bank” to jump to the detailed SSO Report by pin.

To view the SSO information for each output pin in Package View:

1. In Package View, choose **View > Show SSO View** or click the **SSO** button on the toolbar.

   On the pin layout, the SSO pins are highlighted with the status color. Those that failed the analysis are highlighted in red.

2. Hold your mouse pointer over an SSO pin to view the tool tip.

   The tool tip for each pin includes information from the SSO Analysis Report.

See Also ▶“Analyzing SSO” on page 557

- “Running SSO Analysis” on page 559
- “Running I/O SSO Analysis from the Command Line” on page 2546
- “Exporting an SSO Report in CSV Format” on page 561

Exporting an SSO Report in CSV Format

After placement and routing, you can use Package View to export an SSO report as a comma-separated value file (.csv).

To export an SSO report in CSV format:

1. In Package View, choose **File > Export > SSO Report CSV File**.
2. In the dialog box, browse to the desired directory for the report.
3. Type a name in the file name box and click **Save**.

The SSO report is saved as a .csv file in the location you specified. You can view the report using a spreadsheet program that supports the CSV file format.

See Also ▶"Running SSO Analysis" on page 559

Exporting/Importing Pin Files and Preference Sheets

Diamond's Spreadsheet View supports delimiter-separated text formats, such as comma-separated value (CSV), to ease the viewing and editing of assignments and attributes. It also supports the exportation of a text version of all Spreadsheet View preferences. The following options are provided for exporting the contents of preference sheets:

Pin Layout File A pin layout file is a customizable report of pin information for your design. You can open the file in an external spreadsheet application for editing, and then import the edited pin layout file back into Spreadsheet View.

Lattice CSV File A Lattice CSV file is an exported preference sheet in CSV format. Preference sheets that can be exported include Port Assignments, Pin Assignments, Clock Resource, Route Priority, and Cell Mapping. You can edit the exported Lattice CSV file in an external spreadsheet program, and then import it back into Spreadsheet View.

Pinout File A pinout file is a comprehensive report, in CSV format, of all available and unbonded pins in the device.

LPF File of All Spreadsheet View Preferences This LPF file is a text file of all Spreadsheet View preferences, including default preferences.

See Also ▶AN8087, *Using Lattice Diamond Pin Layout Files and Pinout Files*

▶ "Exporting an SSO Report in CSV Format" on page 561

Exporting a Pin Layout File

A pin layout file is a customizable report of pin information for your design. Depending on the stage of the design flow, the pin layout file can be as simple as a list of available pins, pad names, functions, and banks. Or it might be a more detailed report that includes differential polarity, type, user assignments, default attributes, and custom column information. Finally, it can be a comprehensive report that also includes PAR assignments. You select the types of information you want included in the file, specify the order of presentation, and select the delimiter to be used as the value separator.

You can obtain a pin layout file from Spreadsheet View at any stage of the design flow. When you later import a pin layout file back into Spreadsheet View, all the information that was saved in the file is displayed.

To export a pin layout file:

1. In Spreadsheet View, save any assignments that are still in memory, and then choose **File > Export Pin Layout File**.

   The Export Pin Layout File dialog box opens and displays a list of all items that can be included in the report. Any custom columns that have been created are listed last, and you might need to scroll down to view them. You can also include pin migration information, if you have selected the Show Incompatible Pins option in Spreadsheet View or Package View. See “Migrating Pin Assignments” on page 482.

2. Select the items from the list that you want to appear as column headings in the file. Clear those that you do not want included.

   Note

   Pin_Number, Pad_Name, Function, and IO_Bank_Number cannot be cleared. These items will always be included in the pin layout file.

   If you select Pin Migration, a Migration column for each device that you selected in the Incompatible Pins dialog box will be included in the report. In each of these columns, a Y or N will indicate which pins are compatible or incompatible. Any Check Areas that were selected in the Incompatible Pins dialog box will not affect the report’s contents.

3. Use the **Up** and **Down** buttons for selected items, as desired, to rearrange the order in which the column headings will appear in the report.

4. Select a value separator that will be used to separate the data into columns: comma, semicolon, space, or tab.

5. If you want the default values to be included for the user-assigned signals in the report, select the **Export Default Value** option. If you do not want the default values included, clear this option.

   Note

   If your design has already been placed and routed, the Export Default Value option will be dimmed.

6. Do one of the following:

   - To export the pin layout file to your current project directory, type a a name in the File Name box. If you are using the comma as the delimiter, include the .csv extension.
   - To export the pin layout file to a different directory, click **Browse**, navigate to the desired directory, and type a name in the File name box. If you are using a delimiter other than the comma, choose **All Files** from the “Save as type” drop-down menu; other wise, keep the default .csv extension. Click **Save**.

7. Click **OK**.

The pin layout file is saved to your project directory or to the directory you specified. When you open the pin layout file in a spreadsheet program, the columns will appear in the order you selected, including any custom columns. You can edit the cell contents of the columns as desired and import the file back into Spreadsheet View.

See Also ▶AN8087, *Using Lattice Diamond Pin Layout Files and Pinout Files*

- "Exporting a Pinout File in CSV Format" on page 566
- "Importing a Pin Layout File" on page 564

- "Migrating Pin Assignments" on page 482
- "Adding Custom Columns" on page 418

Importing a Pin Layout File

A pin layout file can be imported into Spreadsheet View after the Translate Design process.

To import a pin layout file:

1. In Spreadsheet View, choose **File > Import Pin Layout File**.
2. In the dialog box, select the same value separator that was used in the pin layout file when it was exported.
3. Click the **Browse** button to open the dialog box and navigate to the pin layout file. If the file is not a comma-separated-value (.csv) file, select **All Files** from the "Files of type" drop-down menu.
4. Select the file and click **Open**.
5. Click **OK**.

   If the pin layout file contains custom columns, the Import Custom Columns dialog box will appear. If you do not want to import custom columns, click **Skip**.

   To import custom columns, do the following:

   a. Select the custom columns that you want to import.

   b. For each custom column, select Port Tab or Pin Tab from the Dest. Tab list.

   c. If desired, change the name of one or more of the selected custom columns.

   d. Click **OK**.

Spreadsheet View displays the pin assignments and attributes from the imported pin layout file.

Note

If you selected a value separator that is not in the pin layout file, you will receive an error message that the file cannot be imported. If this happens, verify the correct value separator and begin the procedure again.

See Also ▶"Exporting a Pin Layout File" on page 562

- "Exporting a Pinout File in CSV Format" on page 566

Exporting and Importing Preference Sheets

Diamond enables you to export the contents of an active preference sheet as a Lattice comma-separated value (CSV) file, edit the preferences in a preferred spreadsheet program, and then import the edited file back into Spreadsheet View. Preference sheets that can be exported in CSV format include Port Assignments, Pin Assignments, Clock Resource, Route Priority, and Cell Mapping.

To export a preference sheet as a Lattice CSV file:

1. In Spreadsheet View, make sure that the preference sheet you want to export is active. If not, click the tab at the bottom of the Preference Sheet pane to display the desired sheet.
2. Choose **File > Export > Lattice CSV File**.
3. In the "Export Sheet in CSV format" dialog box, specify the file name and desired location, and then click **Save**.

   The contents in the active preference sheet is saved as a .csv file with the name and location you specified. You can edit it with another spreadsheet program that supports the CSV file format.

   Note

   When you export a Lattice CSV file of the Port Assignments sheet, the CSV file will contain an extra column, "I/O Direction." This column will not be displayed when you import the CSV file back into Spreadsheet View.

After you have exported a preference sheet as a comma-separated value file (.csv), you can import it back into Spreadsheet View and edit the contents.

To import a Lattice CSV preference sheet:

1. In Spreadsheet View, choose **File > Import > Lattice CSV File**.
2. In the "Import Sheet in CSV format" dialog box, browse for the existing .csv file that you want to import and click **Open**.

The imported file is displayed, replacing the original contents of the related preference sheet.

See Also ▶"Exporting a Pin Layout File" on page 562

▶ "Exporting a Pinout File in CSV Format" on page 566

Exporting a Pinout File in CSV Format

The pinout file is a report of all device pins in the targeted device. It includes information such as pin/ball function, pin number, type, bank, dual function usage, and differential type. Information is included for all available pins and unbonded pins. The file is exported in comma-separated value (.csv) format, which enables you to examine it in an external spreadsheet application. You can export a pinout file from Spreadsheet View at any stage of the design flow.

To export a pinout file:

1. In Spreadsheet View, choose **File > Export > Pinout File**.
2. In the "Export Pinout File" dialog box, specify the file name and location that you want, and then click **Save**.

   The information is saved as a .csv file with the name and location you specified. You can view the file using a spreadsheet program that supports the CSV file format.

   Note

   The pinout file cannot be imported into Spreadsheet View.

See Also ▶"Exporting a Pin Layout File" on page 562

▶ AN8087, *Using Lattice Diamond Pin Layout Files and Pinout Files*

Exporting All Spreadsheet View Preferences

Diamond enables you to export all Spreadsheet View preferences to a single .lpf file. The new .lpf file will include all preferences that are still in memory, those from the HDL, and those that you have saved to the currently active .lpf file. It will also include default values for all preferences that you have not set for the design. Unlike the exportation of a pin layout file, exporting all Spreadsheet View preferences does not require that you save in-memory preferences before you export.

This is a quick way to save all of the preference settings so that they can be easily be modified and used in the current design or reused in another design. To use the new .lpf file, add it to your project and activate it for an implementation.

To export all Spreadsheet View preferences to an .lpf file:

1. In Spreadsheet View choose **File > Export > All SSV Preferences to LPF**.
2. In the dialog box, type a file name for the .lpf file.

   The file name must be different than the name of the active .lpf file in your project. If you try to save it using the same name as the active .lpf file, you will get an error message, even if you use a different directory.
3. Click **Save**.

   Diamond gathers all user assignments, plus default values for preferences that have not been set, and places them in the new file.

See Also ▶"Managing Constraint Files" on page 40

▶ "Exporting and Importing Preference Sheets" on page 565

Adding FPGA Attributes to HDL

HDL attributes that you specify in the source code are passed through logic synthesis into the EDIF netlist. The Translate Design process passes them to the native generic database (.ngd), and they are finally extracted or interpreted by the Map Design process (design mapper). Most attributes are extracted by the mapper and are written into the SCHEMATIC START/END section of the project's physical preference file (.prf). These are then used by PAR to update the native circuit description (.ncd). Some attributes, such as IO_TYPE, are interpreted directly by the mapper and are applied as part of the physical design file (.ncd) output.

To pass FPGA attributes to your EDIF netlist, use a synthesis tool. When edif2ngd reads the EDIF file, the attributes become part of the FPGA database.

The examples that follow show how the HDL code appears with an attached attribute and how the FPGA attributes appear in an EDIF netlist.

Note

Editing the EDIF file directly is not recommended in most cases, because the attributes should be present in the original HDL design in order to maintain design integrity. If you edit the EDIF file, it will no longer match the HDL. Consequently, design adjustments that you make later in the design flow will be compromised. When you re-synthesize your design, the edited EDIF files are overwritten. For test purposes, you might want to edit the EDIF file and run it through the flow. An example is provided here that shows where attributes occur in the resulting EDIF output.

Figure 103: Example 1 - Verilog Using Synplify

```
IB I_0 (.I(I[0]), .O(X[0])) /* synthesis IO_TYPE="LVDS" */ /*
synthesis PULLMODE="NONE" */ ;
```

The input buffer (IB) element is instantiated with an IO_TYPE attribute with a value of “LVDS,” which specifies the buffer type. The attributes are specified at the instance line before the semicolon.

Figure 104: Example 2 - Verilog Using Precision

```
  IB I_0 (.I(I[0]), .O(X[0]));
  ...

  // pragma begin
  // pragma attribute IO_TYPE LVDS
  // pragma attribute I_0 PULLMODE NONE
  // pragma end
endmodule
```

The attributes for all the instantiations are specified at the end just before endmodule.

Figure 105: Example 3 - VHDL Output

```
attribute IO_TYPE : string;
attribute PULLMODE : string;
attribute IO_TYPE of I_0 : label is "LVDS";
attribute PULLMODE of I_0 : label is "NONE";
...
I_0 : IB
  port map (I => I(0),
            O => X(0));
```

The attributes are defined and specified in the architecture declaration section. The VHDL syntax is the same for Synplify and Precision.

Figure 106: Example 4 - EDIF Netlist

```
(instance IZ0Z_0 (viewRef verilog (cellRef IB))
(property IO_TYPE (string "LVDS"))
(property PULLMODE (string "NONE"))
```

The input buffer (IB) element in Example 2 shows how it would appear in an EDIF netlist. Notice that the attribute appears enclosed in parentheses in the following format below the instance line:

(property <*attribute*> (string “<*parameter*>”))

Achieving Timing Closure

Setting meaningful constraints is one of the most important strategies for meeting timing goals. Attributes and preferences work together with synthesis, mapping, placement and routing to favorably impact final design timing.

The following steps address the tools and related information available for each stage of the design flow.

1. Generate meaningful and efficient HDL code for the specific architecture to guide the synthesis tools. Though many popular synthesis tools have significantly improved FPGA optimization algorithms, front-end design entry coding still plays an important role in utilizing FPGA resources.
2. Use synthesis tool options to improve the EDIF file. In some designs, this is essential for meeting the desired target.
3. Use FPGA preferences to specify the design timing goals that you want targeted during the Place & Route Design process. Along with a good functional design, a good set of timing preferences is crucial for meeting timing goals and for proper device operation on the system board. Preferences can be entered and modified at multiple points of the Diamond process flow.
4. Leverage Place & Route Design process properties, such as increased placement effort level and multiple routing passes. While the default settings address most designs in the most time-efficient manner, timing-critical designs may require the extra effort that such options provide.
5. If you cannot meet the performance goals of your design with timing preferences and additional effort levels of the Place & Route Design process, you can still improve performance by directing the physical layout of the circuit in the FPGA. This step, often referred to as floorplanning, is done by specifying FPGA location preferences.
6. Use location preferences to keep certain key logic together (UGROUP/HGROUP) and, optionally, to keep them in a particular area of the device (REGION/LOCATE). This is especially useful in creating an effective data flow direction in a datapath-intensive design. Your goal is to create an optimized placement starting point for the timing-critical portion of the design. The remaining logic will be placed by the tools to meet timing goals.
7. Use Diamond's preference views and integrated timing analysis to find the root cause of long timing paths. After problem areas are identified, your goal is to guide placement by refining LOCATE, REGION, and UGROUP preferences or by developing additional ones.
8. Use the ECO Editor, to customize your design implementation. The ECO Editor provides intimate access to routing control and the PFU/PFF array of the chip design. At this point a Lattice factory representative is usually involved to help you meet your objectives.

Chapter 7

Implementing the Design

Design implementation includes the processes of synthesizing and translating the design to build the internal database, mapping the design to device-specific components, assigning the mapped components to specific locations, and establishing physical connections that will join the components in an electrical network. The Diamond environment enables you to set options for each of these processes to help optimize results. Such options might include mapping, map register retiming, placement effort level, and placement and routing, among others. These options are available in the active strategy for the design. For descriptions of all design implementation process options, see the "Strategy Reference Guide" on page 1113.

Defining a device pinout is also an important part of design implementation. The I/O Assistant strategy enables you to produce a valid device pinout, based on board layout requirements, before the design is complete. The output of the I/O Assistant flow can then be back annotated to the logical preference file. See "Validating an I/O Plan" on page 571 for more information about the I/O Assistant flow. When you run an implementation process, the Diamond software automatically generates a report of the results and makes it available in the Reports window. Diamond will also generate timing reports, including Map Trace, Place & Route Trace, and I/O Timing Analysis when you have selected these options in the Process view.

- "Mapping" on page 588
- "Place and Route" on page 600
- "Applying Design Constraints" on page 358
- "Command Line Reference Guide" on page 2432

Validating an I/O Plan

Defining a device pinout can be a complicated process because of constraints in the PC board layout and the FPGA architecture, and it is typically done long before the entire FPGA design is complete. The I/O Assistant, a special predefined strategy within Diamond, assists you with this task, enabling you to produce an FPGA-verified pinout early on based upon PC board layout requirements.

The I/O Assistant strategy helps you select a legal device pinout and produce LOCATE and IOBUF preferences for optimal I/O placement. It helps you accomplish this without completing the entire design. In fact, the only design content required to validate an I/O plan is an HDL model of the I/O ports. Details of the internal logic can be treated as a black box. The primary output of the I/O Assistant flow is a validated placement of I/O signals that can be back annotated to the logical preference file.

I/O Assistant Design Flow

The following sequential steps are typical for the I/O Assistant design flow:

1. Create a top-level module in HDL that describes all of the ports in the design. You can do so manually or use the I/O modules generated by IPexpress.
2. In Diamon, make the I/O Assistant strategy the active one for your project. From the Strategies folder in the File list pane, right-click **I/O Assistant** and choose **Set as Active Strategy**.

   The I/O Assistant strategy is a read-only predefined set of properties for the design flow.

   Note

   The I/O Assistant flow does not include exporting a JEDEC or bistream file. If you attempt to use the Export JEDEC File or Export Bitstream File process while using the I/O Assistant strategy, the process will fail.

3. Synthesize your HDL as you would normally.
   - If you are using Synplify Pro, Diamond will automatically pass the required attributes and header files for I/O Assistant flow when you run theTranslate Design process.
   - If you are running synthesis in stand-alone mode, you will need to include these attributes and header library files in the source code before synthesis.
4. Constrain your design to add banking location preferences, I/O types, I/O ordering, and minor customizations. You can set these preferences using Diamond's Spreadsheet View or you can do this manually.
   - To set the preferences in Spreadsheet View, choose **Tools > Spreadsheet View** and edit the I/Os.

     See "Assigning Signals" on page 464 and "Setting Port, Net, and Cell Attributes" on page 473.

- To set I/O preferences manually, double-click the name of the project's logical preference file (.lpf) from the LPF Constraint Files folder in the File List pane.

5. Run the **Place & Route Design** process.

   The process maps and places the I/Os based on the preferences, the I/O Assistant strategy, and the architectural resources. The output is a pad report (.pad) to guide future placement and a placed and routed native circuit description (.ncd) that contains only I/Os.

6. Examine the I/O Placement results by doing one or more of the following:

   - From the Process Reports folder in the Reports view, select **Signal/ Pad** to open the PAD Specification File and examine the pinout.
   - Choose **Tools > Package View**, and then choose **View > Display IO Placement** to view the pin assignments on the layout to cite areas for minor customization.
   - To view the results of timing constraints:
     - Run the **Place & Route Trace** process and open the Place & Route Trace report from the Reports window.
     - Run the **I/O Timing Analysis** process and open the I/O Timing Report from the Reports window.

7. Make any needed adjustments to the I/O preferences, as you did in Step 4.
8. Rerun **Place & Route Design**.
9. Repeat steps 5 through 7as necessary to achieve your I/O placement objectives.
10. From Package View, Spreadsheet View, or Floorplan View, choose **Design > Back Annotate Assignments** to copy the I/O preferences to the logical preference file, and then choose **File > Save**.

    I/O placement preferences are written to the end of the .lpf file and will take precedence over any existing preferences that may conflict with them.

11. In Diamond, create a new strategy or add an existing one. Set the strategy as the active one, and take your design through the regular flow.

See Also "I/O Assistant Design Entry" on page 572

I/O Assistant Design Entry

The I/O Assistant flow begins with an HDL model of the I/O plan. Create your HDL template files and assemble your HDL into a full chip-level HDL design. IPexpress can provide HDL templates of specialty interfaces required for DDR memories. In IPexpress, produce a module HDL template, perform instantiation of any necessary clocking structure, and any further customization.

The HDL design does not need to be complete. Input nets can be left hanging. The design tools will not optimize away dangling nets or outputs that are not driven.

The HDL model may contain I/Os only. Synthesis directives are applied to force I/O buffers to be inferred and prevent the incomplete model from being optimized away.

syn_force_pads Attribute If you are using Synplify Pro in the Diamond environment or in stand-alone mode, you must include the syn_force_pads attribute in the top level of your HDL source. This attribute prevents Synplify from optimizing away user-instantiated pads. It also causes Synplify to insert pads on unconnected ports, insert bidirectional pads on ports declared as inouts, and insert output pads on unconnected outputs as opposed to tristate pads.

If you are running Synplify in stand-alone mode, you will also need to include the following attributes and header library files in the source code.

syn_noprune Attribute This attribute ensures that the unconnected I/O buffers in a partial design are not optimized away.

The following Synplify code examples illustrate the synthesis attributes that enable the I/O Assistant flow to run a partial design through the Diamond software. The module cannot be empty. At least some logic or dummy equation must be present; otherwise, Synplify interprets the architecture as a black box model.

Figure 107: Verilog Example

```
module ioa1(rxclk, rxd,
            txclk, txd) /* synthesis syn_force_pads=1
syn_noprune=1*/;
input rxclk;
input  [15:0]  rxd;
output  txclk;
output [15:0]  txd;
wire xy;
assign xy = 1'b0;  //dummy equation
endmodule
```

Running I/O Assistant Flow from the Command Line

To run your design through an I/O Assistant design flow using the command line, proceed initially as you would for a regular command-line flow. In Map and PAR, however, use the special switches described in Steps 5 and 6 that will allow the pinout to be selected early in the design process without having a complete design.

1. Complete the top-level design module and synthesize the design.

   See “I/O Assistant Design Entry” on page 572.

Figure 108: VHDL Example

```
library ieee;
use ieee.std_logic_1164.all;
entity ioa1 is port (
  rxclk : in std_logic;
  rxd : in std_logic_vector(15 downto 0);
  txclk : out std_logic;
  txd : out std_logic_vector(15 downto 0)
);

end ioa1;
architecture rtl of ioa1 is
attribute syn_force_pads : boolean;
attribute syn_force_pads of rtl : architecture is true;
attribute syn_noprune : boolean;
attribute syn_noprune of rtl : architecture is true;
signal dummy : std_logic;
begin
dummy <= rxd(0);
end rtl;
```

2. Run **edif2ngd** on your top-level EDIF file from the command line. This command outputs an .ngo file for input into **ngdbuild**. For example:

   ```
   edif2ngd -l or5s00 toplevel.edn
   ```

3. Run **ngdbuild** on your top-level native generic database (.ngd) file from the command line. This process uses the input .ngo file to output the .ngd file. For example:

   ```
   ngdbuild -a or5s00 toplevel.ngo
   ```

   Syntax:

   edif2ngd -l <*library_name*> <*source*>.edn

   ngdbuild -a <*arch_name*> <*input*>.ngo -mc

   where:

   -l switch indicates the library for a specific architecture.

   -a switch indicates the architecture name follows.

4. Set preferences for the types of I/Os and relative locations on the device package, using the Diamond's Spreadsheet View or a text editor, and save them to the logical preference file (.lpf).

   See "Assigning Signals" on page 464 and "Setting Port, Net, and Cell Attributes" on page 473.

5. Run **map** on your .ngd and .lpf files, using the -u switch, to produce a physical native circuit description (.ncd) file.

   The –u switch indicates to the map program to leave unconnected logic in the design. This allows a design to consist solely of the I/Os without

internal logic. This allows the pinout to be selected early in the design process without having a complete design. For example:

```
map -a or5s00 -p or5s25 -u toplevel.ngd -o toplevel.ncd
toplevel.lpf
```

The map program creates a physical database, .ncd, which is passed onto the par program to assign the pinout.

6. Run **par** on your physical design (.ncd) file from the command line, using the -io switch.

   The –io switch indicates to the par program to only route connections to the I/O logic and I/O buffers in the design. This is mainly to save run time of par. It might be necessary in some cases to not use the –io switch and let par route the entire design when selecting a pinout. This depends on how complete the design is and if the pinout needs to be verified when working in a complete design environment. For example:

   ```
   par -io toplevel.ncd toplevel_par.ncd toplevel.prf
   ```

   The par program creates a .pad file that contains the results of the I/O pinout.

7. Review the .pad file to see if the I/O pinout is suitable for the board design.
8. Repeat steps 4 through 7until you have a suitable pinout and are satisfied that the design is ready for final placement and routing.
9. Copy the preferences from the end of the .pad file and paste them into the logical preference file.
10. Run the design through final placement and routing, using the regular command-line flow.

Figure 109: Sample Command Line DOS Batch File

```
set design=top
set edif=top.edn
edif2ngd -l LatticeSC %edif% %design%
ngdbuild -a LatticeSC %design%.ngo %design%.ngd
map -a LatticeSC -p LFSC25E -u %design%.ngd -o %design%_map.ncd
%design%.prf -pr %design%_map.prf
par -w -io %design%_map.ncd %design%_par.ncd %design%_map.prf
```

Synthesizing the Design

Synthesis is the process of translating a register-transfer-level design into a process-specific, gate-level netlist that is optimized for Lattice Semiconductor FPGAs.

In different ways, Diamond can be used with almost any synthesis tool. Diamond comes with two tools fully integrated: Synopsys Synplify Pro for Lattice and Lattice Synthesis Engine (LSE). “Fully integrated” means that you can set options and run synthesis entirely from within Diamond. Diamond also supports Mentor Graphics Precision RTL Synthesis but does not include the tool itself. If you want to use Precision RTL Synthesis, you need to get the software on your own. If you prefer, you can use other synthesis tools by running them independently of Diamond.

Synthesis tools can be run three ways with Diamond:

- Integrated synthesis is the simplest way. You work entirely within Diamond. See “Integrated Synthesis” on page 581.
- Interactive synthesis provides much greater control of how synthesis is done. You set up a design project in Diamond, but set up and run synthesis directly in the synthesis tool. See “Interactive Synthesis” on page 583.
- Stand-alone synthesis allows use of other, non-supported synthesis tools. You set up and run synthesis directly in the synthesis tool and then Diamond imports the result. See “Stand-Alone Synthesis” on page 584.

LSE can only be run in integrated synthesis.

Whichever method you use, see “Pre-Synthesis Check List” on page 576 to make sure your project is ready to synthesize.

- Synplify and Synplify Pro for Lattice User Guide
- Synplify and Synplify Pro for Lattice Reference Manual

Pre-Synthesis Check List

Following is a list of tasks to be done before running synthesis. Most of these are normally done as parts of other tasks, such as setting up the project and design entry.

In all cases, in the source code, add or adjust the constraints, attributes, and directives used by the synthesis tool. See the synthesis tool’s user documentation. For LSE, see “Lattice Synthesis Engine (LSE) Constraints” on page 1338.

If using PMI modules:

- Add the PMI synthesis header file, pmi_def.v or pmi_def.vhd, to the project. See “PMI Synthesis Header Files” on page 201.
- If using PMI modules in VHDL code, compile the PMI component declaration file into your work library. See “VHDL Requirements” on page 201.

Integrated synthesis:

- Specify a synthesis tool. See “Selecting a Synthesis Tool” on page 88.
- Specify the top-level unit. See “Setting the Top-Level Unit for Your Project” on page 42. This is not always required but is a good practice. If not specified, you are relying on the defaults of the synthesis tool.

  Note

  In VHDL and mixed-language designs, LSE stops with an error if the top-level unit is not specified. LSE can find the top-level unit in pure Verilog designs.

- Specify a search path for files referenced by Verilog include directives. See “Specifying Search Path for Verilog Include Files” on page 89.
- Specify a VHDL library name. The default is “work.” See “Specifying VHDL Library Name” on page 89.
- Order the source files for synthesis. The synthesis tool processes the files in the order showing in the File List frame.
- Specify the strategy settings for the synthesis tool. See “Using Strategies” on page 47. If using LSE, also see “Optimizing LSE for Area and Speed” on page 579.

Interactive and stand-alone synthesis:

- Reference the Lattice synthesis header library in the source code. See “Lattice Synthesis Header Libraries” on page 577.
- If using guided mapping or guided place-and-route, set the synthesis tool to minimize changes to signal names, such as with an incremental flow.
- For interactive synthesis, if you want to use the Synplify Pro strategy settings instead of Synplify Pro’s own defaults, change the “Export Diamond Settings to Synplify Pro GUI” option to **Yes** or **Only on First Launch**. See “Export Diamond Settings to Synplify Pro GUI” on page 1121.

Lattice Synthesis Header Libraries

The synthesis header libraries define primitives from the FPGA Libraries. A separate library is available for each device family and in Verilog and VHDL versions. The header libraries support both Precision and Synplify synthesis tools. If the design has any primitives from the FPGA Libraries instantiated, the appropriate header library is required.

The integrated flow automatically includes the FPGA libraries, but if you are running synthesis outside of Diamond with interactive or stand-alone synthesis, you need to add a reference to the appropriate library manually. Look in Table 49 for the device family that you are using and add it to the source file list of your synthesis project. If your design is VHDL-based, add the .vhd file. If your design if Verilog-based, add the .v file.

The files are located at:

<*install_dir*>/cae_library/synthesis/verilog
<*install_dir*>/cae_library/synthesis/vhdl

If your design is in VHDL, also specify the library name for the header file.

Table 49: Synthesis Header Files

Device Family	Header Library File	Library Name

Optimizing LSE for Area and Speed

The following strategy settings for Lattice Synthesis Engine (LSE) can help reduce the amount of FPGA resources that your design requires or increase the speed with which it runs. (For other synthesis tools, see those tools' documentation.) Use these methods along with other, generic coding methods to optimize your design. Also, consider using the predefined Area or Timing strategies.

Minimizing area often produces larger delays, making it more difficult to meet timing requirements. Maximizing frequency often produces larger designs, making it more difficult to meet area requirements. Either goal, pushed to an extreme, may cause the place and route process to run longer or not complete routing.

To control the global performance of LSE, modify the strategy settings. Choose **Project > Active Strategy > LSE Settings**. In the Strategy dialog box, set the following options, which are found in Synthesize Design > LSE. See the following text for explanations and more details.

Table 50: LSE Strategy Settings for Area and Speed

Option	Area	Speed
FSM Encoding Style	Binary or Gray	One-Hot
Max Fanout Limit	<*maximum*>	<*minimum*>
Optimization Goal	Area	Timing
Remove Duplicate Registers	True	False
Resource Sharing	True	False

Table 50: LSE Strategy Settings for Area and Speed

Option	Area	Speed
Target Frequency	*<minimum>*	
Use IO Registers	Auto or True	Auto or False

FSM Encoding Style If your design includes large finite state machines, the Binary or Gray style may use fewer resources than One-Hot. Which one is best depends on the design. One-Hot is usually the fastest style. However, if the finite state machine is followed by a large output decoder, the Gray style may be faster.

Max Fanout Limit A larger fanout limit means less duplicated logic and fewer buffers. A lower fanout limit may reduce delays. The default is 1000, which is essentially unlimited fanout. Select a balanced fanout constraint. A large constraint creates nets with large fanouts, and a low fanout constraint results in replicated logic. You can use this in conjunction with the syn_replicate attribute. See “syn_replicate” on page 1382. To minimize area, don’t lower this value any more than needed to meet other requirements. To minimize speed, try much lower values, such as 50.

You can change the fanout limit for portions of the design by using the syn_maxfan attribute. See “syn_maxfan” on page 1371. Set Max Fanout Limit to meet your most demanding requirement. Then add syn_maxfan to help other requirements.

Optimization Goal If set to Area, LSE will choose smaller design forms over faster whenever possible.

If set to Timing, LSE will choose faster design forms over smaller whenever possible. If a create_clock constraint is available in an .ldc file, LSE ignores the Target Frequency setting and uses the value from the create_clock constraint instead.

If you are having trouble meeting one requirement (area or speed) while optimizing for the other, try setting this option to **Balanced**.

Note

The minimum pulse width associated with devices is not checked by the synthesis timing engine. The place and route timing engine checks if a given clock definition is within the minimum pulse width requirement of the devices that the clock drives.

Remove Duplicate Registers Removing duplicate registers reduces area, but keeping duplicate registers may reduce delays.

Resource Sharing If set to True, LSE will share arithmetic components such as adders, multipliers, and counters whenever possible.

If the critical path includes such resources, turning this option off may reduce delays. However, it may also increase delays elsewhere, possibly reducing the overall frequency.

Target Frequency A lower frequency target means LSE can focus more on area. A higher frequency target may force LSE to increase area. Try setting this value to about 10% higher than your minimum requirement. If Optimization Goal is set to Timing and a create_clock constraint is available in an .ldc file, LSE will use the value from the create_clock constraint instead.

Use IO Registers If set to True, LSE will pack all input and output registers into I/O pad cells. Register packing reduces area but adds delays.

Auto, the default setting, enables this register packing if Optimization Goal is set to Area. If Optimization Goal is Timing or Balanced, Auto disables register packing.

You can also control packing on individual registers. See “syn_useioff” on page 1397. Set Use IO Registers to meet your most demanding requirement. Then add syn_useioff to help other requirements.

- “LSE Options” on page 1130

Integrated Synthesis

In integrated synthesis, you create, synthesize, and implement a design completely within the Diamond environment. This is the simplest method, but it limits your control of synthesis to tools and features directly supported by Diamond.

Note for Lattice Synthesis Engine (LSE)

LSE does not produce the usual EDIF file. Instead, LSE takes the next step, translating the design into an .ngd file ready for mapping.

Also, LSE produces a Verilog netlist suitable for simulation. The file is placed in the design implementation’s folder and is named <*top_module*>_prim.v.

To synthesize your design in Diamond:

If you haven’t already, check the Pre-Synthesis Check List before running synthesis.

1. If desired, change the strategy settings. Choose **Project > Active Strategy >** <*Synthesis Tool*> **Settings**. See also “Using Strategies” on page 47.

   Note

   If you are switching from interactive synthesis to integrated, you need to reset all the options in Diamond. Options set directly in the synthesis tool have no effect in Diamond.

2. In the Process view, double-click **Synthesize Design** or any following stage. Double-clicking a following stage runs Synthesize Design, if necessary, and any other stages up to the one you clicked.

   Note for LSE

   If this is the first time running synthesis on the design or if you changed the .ldc file, double-click **Synthesize Design** only. You may need to adjust your .lpf file before running Map Design (see the final step below).

   If Synthesize Design has already been run and does not recognize any changes in the design, it won't run again. You can force Synthesize Design to run by right-clicking it and choosing **Rerun** from the pop-up menu.

3. When finished, check the icon next to Synthesize Design in the Process frame. A green check mark indicates success; a yellow triangle indicates success with warnings; a red X indicates failure.

4. For more information on how the synthesis ran, open the **Reports** view in the Tools area (choose **View > Reports**). Under Design Summary, choose **Process Reports >** <*Synthesis Tool*>. This report lists actions taken by the synthesis tool, warnings, and errors. The report also provides a list of FPGA resources used and a timing report based on estimated place-and-route data. See "Viewing Logs and Reports" on page 100.

   To quickly find warnings or errors, click the **Warning** or **Error** tab in the Logs area. The Output tab includes the same information that is in the detailed report.

   You can find a more detailed area report in the folder of the active implementation. The report is named with an.areasrr extension (for Synplify Pro) or with an .arearep extension (for LSE). The report includes the resources used by each module of the design. Similar information can also be found in the Hierarchy view.

   If you are using LSE, you can also find a more detailed timing report in the folder of the active implementation. The report is named <*top_module*>_lse.twr. It is similar to the report described in "TRACE Report File" on page 697.

5. If you are using LSE with an .ldc file and set Use LPF Created from SDC in Project to True in the strategy settings, the output includes an .lpf file that has preferences equivalent to those in the .ldc file. The .lpf file is placed in the design implementation's folder and is named <*top_module*>_lse.lpf. You can make these preferences available to later stages of the design implementation process by merging <*top_module*>_lse.lpf into your active .lpf file. See the following procedure.

To merge LSE's .lpf into the active .lpf:

1. Go to the File List view and open the folder for the active implementation. The folder uses this icon, , and the name is in bold text.

2. Under Constraint Files, double-click the active .lpf file.

   Source Editor opens with the .lpf file.

3. In the main window, choose **File > Open > File**.
4. In the Open File dialog box, in the “Files of type” drop-down menu at the bottom, choose **Preference Files**.
5. Browse to the implementation folder and select <*top_module*>_**lse.lpf**.
6. Click **Open**.

   Source Editor opens a second view with the .lpf file. This is the .lpf created by LSE. Besides the preferences based on the synthesis constraints, the .lpf file automatically includes two BLOCK preferences that are added automatically to .lpf files.
7. Choose **Window > Split Tab Group**.

   The tools area of the main window splits into two groups. You should have the active .lpf on one side and <*top_module*>_lse.lpf on the other side. If they are both on the same side, select the tab of one and drag it to the other side.
8. In <*top_module*>_lse.lpf, select everything from line 3 down. This is everything except the first two BLOCK preferences.
9. Press Ctrl-c to copy the selected preferences.
10. Go to the active .lpf and place the cursor at the bottom of the file, in a blank line beneath all the text.
11. Press Ctrl-v to paste in the new preferences.

    Note

    If the active .lpf file already has preferences from a previous run of LSE, paste the new preferences over the old version. Do not create multiple copies of the same preferences.
12. Save the active .lpf file and close both files.

Interactive Synthesis

In interactive synthesis, you set up a design project in Diamond, but set up and run synthesis directly in the synthesis tool. This gives you more complete control of synthesis than integrated synthesis and allows you to make full use of the synthesis tool’s features.

Note

If you decide to use interactive synthesis, remember to use it every time you make a design change. If you try to repeat the implementation process by simply double-clicking an item in the Process frame, Diamond will synthesize the design with integrated synthesis, which will probably give unexpected and inferior results.

LSE cannot be used in interactive synthesis.

To synthesize your design using interactive synthesis:

If you haven't already, check the "Pre-Synthesis Check List" on page 576 before running synthesis.

1. Open the synthesis tool from the **Tools** menu.

   The synthesis tool opens with the device and source files for your design.
2. Set options in the tool as desired.
3. If you choose to create a preference file, make sure it is not named <*project_name*>.lpf. That would overwrite the logical preference file created by Diamond.
4. To re-use the settings, save the synthesis tool's project file as <*project_name*>_**syn.prj** (Synplify) or <*project_name*>**.psp** (Precision) in the project folder.

   Make sure the Diamond strategy option, "Export Diamond Settings to Synplify Pro GUI" (under Synplify Pro in the Strategies dialog box) is set to **No** or **Only on First Launch**. See "Export Diamond Settings to Synplify Pro GUI" on page 1121.
5. Synthesize the design to create an EDIF file.
6. Analyze the results in the synthesis tool.
7. When you are satisfied with the synthesis, make sure the EDIF file is in your project directory and named <*project_name*>.edi. Synplify should do this automatically. With Precision you may need to move the file.

Stand-Alone Synthesis

In stand-alone synthesis, you can use a synthesis tool that is not directly supported by Diamond. In this flow you set up and run synthesis directly in the synthesis tool. Then create a design project in Diamond using the output of the synthesis tool as the source file.

Note

If you decide to use stand-alone synthesis, remember to use it every time you make a design change. If you try to repeat the implementation process by simply double-clicking an item in the Process frame, you probably will see nothing happen because the EDIF file has not changed.

LSE cannot be used in stand-alone synthesis.

If you haven't already, check the "Pre-Synthesis Check List" on page 576 before running synthesis.

To set up a project using a stand-alone tool:

1. Open the synthesis tool directly, without using Diamond.

2. Using your synthesis tool, create a project, including specifying a device, source files, and options.
3. Synthesize the design to create an EDIF file.
4. Analyze the results in the synthesis tool.
5. When you are satisfied with the synthesis, create a design project in Diamond.
6. Choose **File > Add > Existing File**.
7. In the Add Existing File dialog box, browse to the EDIF file and click **Open**.

To re-synthesize your design using the stand-alone tool:

This procedure assumes that you have already set up the project to use stand-alone synthesis.

1. Open the synthesis tool directly, without using Diamond.
2. In the synthesis tool, open the project.
3. If desired, change the options.
4. Synthesize the design to create an EDIF file.
5. Analyze the results in the synthesis tool.

Translating the Design Database

After you have created a project and imported the source files, the next step is to translate and build an internal database. The database is a logical network of device-independent components such as gates and flip-flops, and it is logically equivalent to your high-level source description. This step takes the hierarchy in the input netlist and translates and converts it into primitive terms that the Diamond system can understand and manipulate.

The input source file for this process is an EDIF file. The EDIF file can be generated from a stand-alone synthesis tool and imported into the Diamond environment as your design, or it can be created automatically from a Verilog or VHDL design using the integrated synthesis flow within the Diamond software.

When you run the translation and build processes (EDIF2NGD and NGDBUILD tools respectively), Diamond converts the EDIF file to a Native Generic Database (*.ngd) file. Both the translation and build processes are executed when you run the Translate Design process from the Process view in the Diamond environment.

If the design utilizes parameterized modules (PMI) or IP cores (Lattice modules and ispLeverCORE IP modules), or user firm macros, the cores are expanded in this process. The output .ngd file will be used later by the Map Design process to implement your design. The output of the translation and build processes is a logical Native Generic Database (.ngd) file.

About the Translate Design Process Given an HDL-based project file, the Translate Design process executes a logic synthesis phase using the synthesis tool you have configured to produce an EDIF file. It then performs the translations necessary on the EDIF to produce an .ngd file. If your project is EDIF-based, the build skips the logic synthesis phase and performs the EDIF-to-NGD translation only. The EDIF-to-NGD translation can be run from the command line using the edif2ngd and ngdbuild programs. For more information on HDL-based and EDIF-based projects, see “Managing Projects” on page 21.

The edif2ngd and ngdbuild processes of Translate Design perform netlist translation and netlist conversion. The netlist reader, edif2ngd, converts the netlist to an .ngo file. An .ngo file is a binary file that describes the design in terms of the components and hierarchy specified in the input design file. The ngdbuild program translates and merges one or more .ngo files, combining each component in the design to its equivalent Lattice FPGA primitives.

Setting Translate Design Options

When you run the Translate Design process in Diamond, the design is translated and the database built automatically, based on design options that are in the active strategy. You can use the Strategies dialog box to modify the Translate Design options before running a full or partial design flow.

To set Translate Design options in the Diamond environment:

1. Choose **Project > Active Strategy > Translate Design Settings** to open the Strategies dialog box.
2. For each option that you want to change, double-click a cell in the Value column. Select the desired value from the drop-down menu or click the browse button, as appropriate.
3. Click **OK**.

- "Running Translate Design" on page 588

Translate Design Input Files

The following files are input to the Translate Design process:

- EDIF Netlist (.ed*) – Given an EDIF-based project file, the build reads the input netlist and expands any related PMI modules or macro files (.nmc) as part of the EDIF-to-NGD process.
- Verilog HDL Source File (.v) – Given a Verilog HDL-based project file, the build reads the input source files, performs logic synthesis to produce EDIF, then expands any related PMI modules or macro files (.nmc) as part of the EDIF-to-NGD process.
- VHDL HDL Source File (.vhd) – Given a VHDL-based project file, the build reads the input source files, performs logic synthesis to produce EDIF, then expands any related PMI modules or macro files (.nmc) as part of the EDIF-to-NGD process.

Note

For more information on PMI modules, see the "Lattice Module Reference Guide" on page 1399. For more information on .nmc physical macro files, see the Physical Macros topic in the EPIC Device Editor online Help.

- "Translate Design Output Files" on page 588

Translate Design Output Files

The following files are created from the Translate Design process:

- Native Generic Database File (.ngd) – This is a generic database file that contains a logical description of the design in terms of Lattice library elements from structural models or inferred by logic synthesis. This converted file is the output of the ngdbuild process, which uses an .ngo input file that has been translated by a netlist reader (edif2ngd).
- Data Netlist Reader File (.ngo) – Output of the edif2ngd (netlist reader) subprocess, this data file contains a logical description of the design in terms of its original components and hierarchy. This translated file is the input to ngdbuild, which converts the file to describe it in terms of familiar system primitives.

See Also ▶"Translating the Design Database" on page 586

- "Translate Design Input Files" on page 587
- "Running Translate Design" on page 588

Running Translate Design

In the Diamond environment, the Translate Design process builds the design database automatically.

To run Translate Design in the Diamond environment:

- In the Process view, double-click **Translate Design**.
- Alternatively, right-click **Translate Design** and choose **Run** from the pop-up menu.

To build your design database using the command line, use the edif2ngd and ngdbuild programs in a two-step process.

See Also ▶"Setting Translate Design Options" on page 587

- "Running Processes" on page 69

Mapping

Mapping is the process of converting a design represented as a network of device-independent components, such as gates and flip-flops, into a network of device-specific components, such as PFUs and EBRs or configurable logic blocks.

You can use the Map Design process in the Diamond environment or the MAP program from the command line.

Using the logical Native Generic Database (.ngd) file created by the Translate Design process, the Map Design process generates physical descriptions of

the logical configuration within the programmable device elements. These device elements include programmable function units (PFU), programmable I/O cells (PIC), embedded block RAM (EBR). They also include special function blocks: internal oscillator, global set/reset (GSRN), start-up logic, phase locked loop (PLL), delay locked loop (DLL), and physical coding sublayer (PCS) logic.

Depending upon the attributes specified in the input netlist, mapping includes absolute placement, logical partitioning (hierarchical netlists), component group placement, and regional group placement information in the physical description. The resulting physical description is output to a physical native circuit description (.ncd) file, in terms of the components in the target architecture. This .ncd file can then be placed and routed using the Place & Route Design process.

Map and Preference Errors The Map process can be set up to stop whenever preference errors are encountered. This can be accomplished by setting the “Ignore Preference Errors” option to “False” in the Map Design section of the active strategy or by using the -pe option from the command line. This will cause the Map process to terminate and issue error messages when preference errors are found. By default, the Map process ignores preference errors.

Map and Trace In the Diamond Process view under Map Design, a Map Trace process is available that runs static timing analysis on the mapped .ncd file. This process reports any timing errors associated with preferences that have been set in the pre-map stage. You can view the Map Trace report in the Reports window by selecting it from the Analysis Reports folder. In addition, the processes Verilog Simulation File and VHDL Simulation File produce post-map source simulation files for functional simulation of primitive gate-level logic.

See Also ▶“Running MAP from the Command Line” on page 2463

- “Setting Map Design Options” on page 589
- “Mapping Input Files” on page 590
- “Mapping Output Files” on page 590

Setting Map Design Options

When you run the Map Design process in Diamond, the design is mapped based on design options that are in the active strategy. Mapping options can influence the performance and utilization of the design implementation, ease incremental design changes, cause the mapping process to stop when preference editors are encountered, or allow you to overmap in order to review how many resources are required for a particular implementation.

To set Map Design options:

1. Choose **Project > Active Strategy > Map Design Settings** to open the Strategies dialog.

2. For each option that you want to change, double-click a cell in the Value column. Select the desired value from the drop-down menu, enter text, or click the browse button, as appropriate.
3. Click **OK**.

See Also ▶"Map Design Options" on page 1140

- "Mapping" on page 588
- "Mapping Input Files" on page 590
- "Mapping Output Files" on page 590

Mapping Input Files

The following files are input to the Map Design process.

- Native Generic Database File (.ngd) – This file is a logic description of the design in terms of Lattice library elements from structural models or inferred by logic synthesis produced by the Translate Design process.
- Logical Preference File (.lpf) – This file is the source file for storing constraints called logical preference. You can directly edit the .lpf file in Diamond's preference-editing views, the Source Editor, or an external text editor. When preferences are modified in the active .lpf file, the Map Design must be rerun.

See Also ▶"Mapping" on page 588

- "Setting Map Design Options" on page 589
- "Mapping Output Files" on page 590
- "Using Diamond's Preference Views" on page 404
- "Setting Preferences" on page 457

Mapping Output Files

The following files are created from the Map Design process:

- Native Circuit Description File (.ncd) – The .ncd file is a physical description of the design in terms of the components in the target device.
- Physical Preference File (.prf) – The physical preference file is an ASCII output of the Map Design process. Preferences saved in the logical preference file (.lpf) are written to the .ncd file and to the .prf file during the map process. The map process rewrites the physical preference file each time it is executed. The .prf file is used as an input file to placement and routing and TRACE.
- MAP Report File (.mrp) — The map report file provides details about how the design was mapped to physical elements and reports any errors. Mapping details can include such things as how attributes were interpreted, logic that was removed or added, and how signals and

symbols in the logical design were mapped to components in the physical design.

See Also ▶"Mapping" on page 588

- "Setting Map Design Options" on page 589
- "Mapping Input Files" on page 590

Running Map Design

In the Diamond environment, the Map Design process automatically maps the design based on the active strategy settings and preferences in the active .lpf file.

To run Map Design in the Diamond environment:

- In the Process view, double-click **Map Design**.
- Alternatively, right-click Map Design and choose **Run** from the pop-up menu.

See Also ▶"Running MAP from the Command Line" on page 2463

- "Running Processes" on page 69

MAP Report File

The MAP Report (.mrp) file supplies statistics about component usage in the mapped design and shows the number and percentages of resources used out of the total resources in the device. The report is produced whether you have run Map in the Diamond environment or the command line.

To view the MAP Report file in Diamond:

- Click the **Reports** tab to activate the Report view and select **Map** in the Process Reports folder of the Design Summary pane.

  The Map report is displayed in the Reports window to the right.

  OR

- Using a text editor, open the .mrp ASCII file in your project directory.

Although detailed information varies depending on the device, the format of the .mrp file is the same. The report is divided into sections, which can include the following:

- Design Information – Shows the map command line, the LPF file path, the device/performance grade, and the time/date stamp of the run.

- Design Summary – Shows the number and percentage of resources used out of the total of the resources of the mapped device.

  Note

  The total resources reported represents the total resource count in the device and not the total accessible resources. Since the accessibility of resources can change, depending on the design and design revisions, there will sometimes be a gap between the number of resources that are available for use and the total number in the device.

  You will see a line showing the number of PFUs or Slices and whether they are implemented as logic/ROM/RAM or just logic/ROM. For older architectures that are PFU-based, you will see the number of PIO IDDR/ODDR, distributed RAM, ripple logic, shift registers, and many other items.

```
Design Summary
   Number of registers:    106 out of 13023 (1%)
      PFU registers:           85 out of 12420 (1%)
      PIO registers:           21 out of   603 (3%)
   Number of SLICEs:       125 out of  8280 (2%)
      SLICEs as Logic/ROM:    125 out of  8280 (2%)
      SLICEs as RAM:            0 out of  1485 (0%)
      SLICEs as Carry:          5 out of  8280 (0%)
   Number of LUT4s:        194 out of 16560 (1%)
      Number of logic LUTs:      184
      Number of distributed RAM:   0 (0 LUT4s)
      Number of ripple logic:      5 (10 LUT4s)
      Number of shift registers:   0
   Number of PIO sites used: 46 out of 201 (23%)
   Number of PIO FIXEDDELAY:    0
   Number of DQSDLLs:  0 out of 2 (0%)
   Number of PLLs:  2 out of 4 (50%)
   Number of block RAMs:  0 out of 15 (0%)
   Number of CLKDIVs:  0 out of 2 (0%)
   Number of GSRs:  1 out of 1 (100%)
   JTAG used :      No
   Readback used :  No
   Oscillator used :  No
   Startup used :   No
   Notes:-
      1. Total number of LUT4s = (Number of logic LUT4s) +
2*(Number of distributed RAMs) + 2*(Number of ripple logic)
      2. Number of logic LUT4s does not include count of
distributed RAM and ripple logic.
```

  The Number of registers in the sample report shows a total 106, derived from a total of 85 PFU registers and an additional 21 registers used in the IOLOGIC components in the Programmable I/O cell.

  The Number of SLICEs information in the Design Summary will vary in LatticeSC versus LatticeECP/EC and LatticeXP devices, which contain different types of slices. For LatticeECP2 and higher, Map has been enhanced to adjust its reporting to account for SLICEs of the PLC_Sr

variety, which are not usable for memory, so that the available resource capacity reporting is not misleading. A breakdown of LUT4 is given after this with a line that has the total number used in the design.

The number and percentage of PIO sites used, out of the total number, is given in the Design Summary. Sometimes this is further broken down into external and differential PIOs. The Number of external PIOs is based on the number of PIO pads programmed with a single-ended signal standard out of the total number of bonded pads on the chip die. The Number of differential PIOs counts those PIOs programmed with a differential signal standard.

- Design Errors/Warnings – Shows any warnings or errors encountered by the mapping process. For example, the section will report a pad that is not connected to any logic, or a bidirectional pad that has signals passing only in one direction.

  This section will also report excluded or disabled preferences. These are constraints from the logical preference file (.lpf) that were not implemented for some reason. The name of the .lpf file is given and the applicable components for the excluded preferences.

- IO (PIO) Attributes – Provides a table by input/output port of programmed direction, I/O type, and whether the PIO is registered. Shows any attributes (properties) specified on PIO logic elements.

- Removed Logic – Describes any logic that was removed from the input logical Native Generic Database (.ngd) file when the design was mapped. Logic may be removed for the following reasons:

  - A design uses only part of the logic in a library macro.
  - The design has been mapped even though it is not yet complete.
  - The mapping process has optimized the design logic.
  - Unused logic has been created in error during design entry.

  This section also indicates which nets were merged when a component separating them was removed.

  The Removed Logic section also enumerates how many blocks and signals were removed from the design, including the following kinds of removed logic:

  - Blocks clipped – A "clipped" block is removed because it is along a path that has no driver or no load. Clipping is recursive; that is, if Block A becomes unnecessary because logic to which it is connected has been clipped, then Block A is also clipped.
  - Blocks removed – A removed block is removed because it can be eliminated without changing the operation of the design. Removal is recursive; that is, if a Block A becomes unnecessary because logic to which it is connected has been removed, then Block A is also removed.
  - Blocks optimized – An "optimized" block is removed because its output remains constant regardless of the state of the inputs—for example, an AND gate with one input tied to ground. Logic generating an input to this optimized block (and to no other blocks) is also removed, and appears in this section.

- Signals removed – Signals were removed because they were attached only to removed blocks.
- Signals merged – Signals were combined because a component separating them was removed.

- Memory Usage – Lists all memory instances and all of the device resources that are used; for example, EBRs, RAM SLICEs, Logic SLICEs and PFU registers. Information on data width, type of element used, and attributes is also reported.
- ASIC Components – Lists any ASIC instances in the design by name and specifies the type used for each. These components mostly include processors or memory blocks such as ROM, RAM, and EEPROM.
- Added Logic – Describes any logic that the mapping process added to the design.
- Expanded Logic – Describes the mapping of logic that has been added to the physical design file (.ncd) to resolve blocks.
- Symbol Cross Reference – Shows where symbols in the logical design were mapped in the physical design. By default, Map will not report symbol cross references unless you specify the -xref_sym Map command line option or enable the Report Symbol Cross Reference property for the Map Design process in the Diamond environment.
- Signal Cross Reference – Shows where nets in the logical design were mapped in the physical design. By default, Map will not report symbol cross references unless you specify the -xref_sig Map command line option or enable the Report Signal Cross Reference property for the Map Design process in the Diamond environment.
- DRC Messages – Shows any warnings or errors generated as a result of the design rule tests performed at the beginning of the mapping process. These warnings and errors do not depend on the device to which you are mapping.
- Physical Design Errors and Warnings – Shows errors and warnings associated with problems in assigning components to sites. For example, an attribute on a component specifies that the component must be assigned to site AK, but there is no site AK on the part to which you are mapping. Another example would be a problem in fitting the design to the part where the design maps to 224 logic blocks, but the part only contains 192 logic block sites.
- Schematic Attributes – Shows any attributes (properties) embedded in the input EDIF produced by logic synthesis or a schematic editor. Attributes are translated into preferences in the physical preference file (.prf) that Map produces.

Note

The term “schematic attribute” does not imply that you captured your design in a schematic editor. In the context of mapping or place and route, it refers to those attributes embedded in the input EDIF 2 0 0 netlist as distinct from preferences produced in Diamond’s preference-editing views or the EPIC Device Editor.

- PIO Utilization Report – Provides an account of the exact number and percentage of the total available PIO resources used in the design and breaks down the number of PIOs between differential and non-differential (single ended) I/O component types. It also breaks down the number of DDR cells used, as shown in the following example.

```
Total number of PIOs: 91 out of 222 (41%)
      Number of single ended PIOs: 89 out of 222 (41%)
      Number of differential PIOs: 2 (represented using 1
PIO comps in NCD)
   Number of IDDR/ODDR/TDDR cells used: 26
      Number of IDDR cells:   8
      Number of ODDR cells:  16
      Number of TDDR cells:   2
   Number of PIO using at least one IDDR/ODDR/TDDR: 16 (1
differential)
      Number of PIO using IDDR only:        0 (0
differential)
      Number of PIO using ODDR only:        7 (0
differential)
      Number of PIO using TDDR only:        0 (0
differential)
      Number of PIO using IDDR/ODDR:        7 (0
differential)
      Number of PIO using IDDR/TDDR:        0 (0
differential)
      Number of PIO using ODDR/TDDR:        1 (1
differential)
      Number of PIO using IDDR/ODDR/TDDR:   1 (0
differential)
```

- PLL/DLL Summary – Provides instance name, type, clock frequency, pin/node values, and a listing of all settings for each PLL or DLL in the design.
- OSC Summary – Provides the oscillator's instance name, possible oscillator primitive type, output clock, and nominal frequency. This section is only included in the map report if the OSC primitive has been instantiated in the design. Below is an example of an OSC Summary in a PAR report:

```
OSC Summary
-----------

OSC 1:                                    Pin/Node Value
  OSC Instance Name:                              osc
  OSC Type:                                       OSCF
  OSC Output:                             NODE
reg_clk_2x
  OSC Nominal Frequency:                          130.0
```

- PGROUP Utilization – Reports any PGROUPs that exist in the design and the resources that they occupy in terms of SLICEs within PFUs. Also an account of the size of the bounded area in terms of PFUs are reported and whether the PGROUP is anchored or unbounded (floating).
- Run Time and Memory Usage – Lists total CPU time, real time, and peak memory usage related to the Map run.

PFU Logic Mapping with HGROUP/ UGROUP

When an HGROUP/UGROUP is defined in an EDIF netlist, Map will prevent logical elements of different HGROUPs/UGROUPs to be mapped into the same Programmable Function Unit (PFU). By doing so, a natural partitioning of the mapped design is achieved.

Map then groups all PFUs of the same HGROUP and writes out PGROUP preferences. The HULOC attribute translates to the LOCATE PGROUP preference. The LOC attribute translates to the relative location within a PGROUP preference.

See Also ▶"UGROUPs" on page 391

Packing of Duplicate Registers

Designers often duplicate registers in order to reduce fan-out and improve timing. Duplicated registers are registers with the same data and control paths. The software keeps duplicated registers from being mapped into the same PFU.

If the COMP= attribute is attached to duplicate registers, it will override duplicate register packing.

Map Register Retiming

Register retiming is a technique for improving timing. It involves moving registers across logic to shift path delay from one side of a register to the other side. This retiming technique has the same goal as clock boosting (or cycle stealing), which adjusts the timing by introducing predefined clock delays.

The map register retiming property moves registers across combinational logic to balance timing according to the constraints t_{SU} (INPUT_SETUP), t_{CO} (CLOCK_TO_OUT) and f_{MAX} (FREQUENCY). This is a typical logic optimization technique to balance combinational logic across register-pairs to allow you to maximize clock frequency. However, there is no guarantee that a better f_{MAX} can be achieved. The f_{MAX} constraint activates retiming around all registers. The t_{SU} and t_{CO} constraints may de-activate retiming on I/O registers depending on the balancing of t_{SU} versus f_{MAX} and t_{CO} versus f_{MAX}.

The retiming process stops when it estimates that the constraints have been met.

To enable register retiming in your design:

- Enable the **Register Retiming** Map option in the Strategies dialog box, as explained in “Setting Map Design Options” on page 589. This Map option will be available after an initial design run, not before. Values are True and False (default).

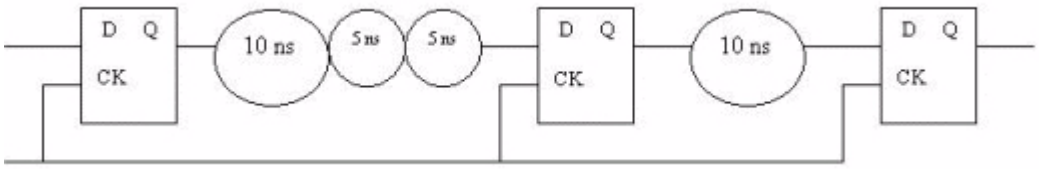
  See “Register Retiming” on page 1142 for details on option settings and default values. This feature can also be prevented for specific design elements with the NORETIME attribute.

- For command line usage, review the documentation on the -retime parameter in the “Running MAP from the Command Line” on page 2463 topic.

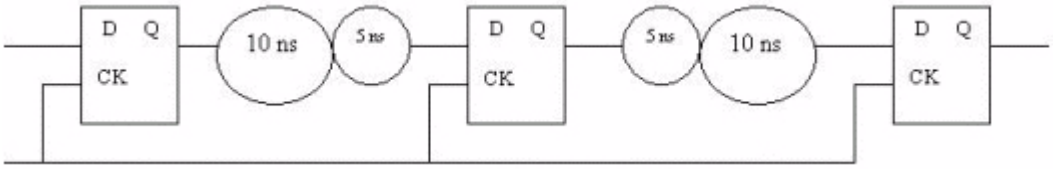
Register retiming can be either forward or backward. Forward retiming will move a set of registers that are the inputs of logic to a single register at its output. Backward retiming will move a register that is at the output of a logic to a set of registers at its input. Retiming works on data path, and has variable delay shift and variable area cost from design to design.

One big positive factor about register retiming is that it will allow for more delay shift. On the negative side, it changes your netlist, making debugging more difficult. It also has a minimum delay shift of one logic level: for example, a LUT.

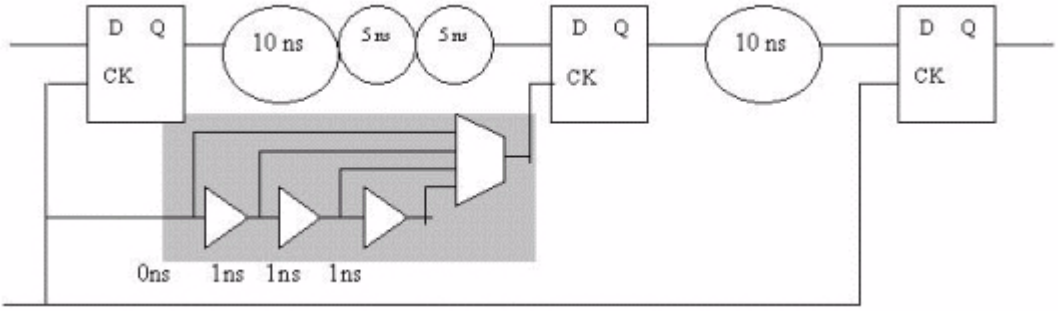
Example: the original network



retiming approach



Clock Boosting approach



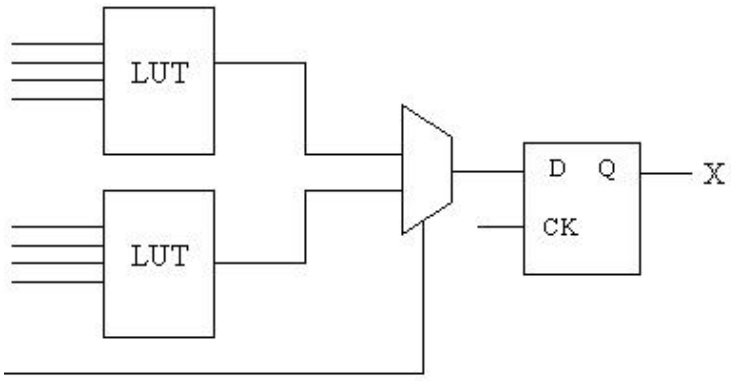
For comparison, clock boosting (only applicable to LatticeSC) works on clock paths and has fixed delay (e.g., 0 ns, 1 ns, 2 ns, or 3 ns) and a fixed area cost (on silicon). The delay shift is accurate after Place & Route (as fine as <= 1ns). Unfortunately, clock boosting requires the use of extra silicon area even if it is not used, and delay shift is limited to few choices up to about 3ns or more. So, please take these considerations into account when you are trying to optimize timing in your design using either of these features.

Note

Like clock boosting, register retiming, in most cases will improve your design's maximum frequency; however, improved timing is design-dependent and is not guaranteed in all cases. Circuits that have considerably unbalanced delay on two sides of a register will benefit the most from register retiming. Circuits that are already register-balanced may receive no benefit at all.

What Should You Retime?

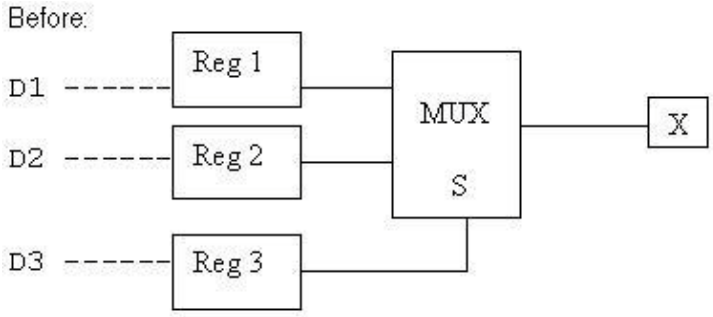
- In most cases, a register can be moved across a combinational logic component that has a known functionality, such as AND/OR gates, LUTs, etc.
- In most cases, registers are moved across one logic component at a time. Special architecture considerations will move registers across multiple levels of combinational logic components such as MUX5 (2 LUTs + 1 MUX2), carry chains, etc.



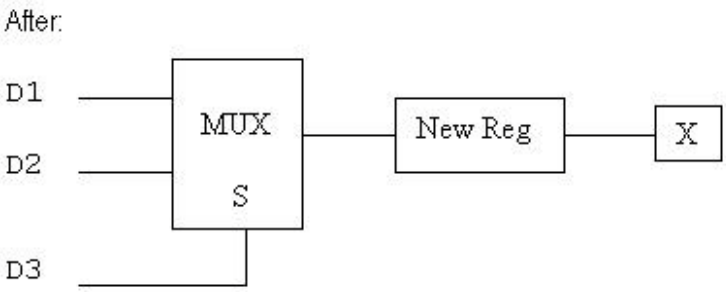
When Should You Retime? This depends upon timing constraints (i.e., f_{MAX}, t_{SU}, and t_{CO}). First compare the slack time on input (D) and output (Q) sides of the register and determine which direction to move.

When to move registers forward: when the output port of a register (Q) is much more critical than its input port (D) and the projected worst slack is better. Forward retiming generally saves area; that is, it reduces register counts.

Legal condition: all input registers must be “compatible”.



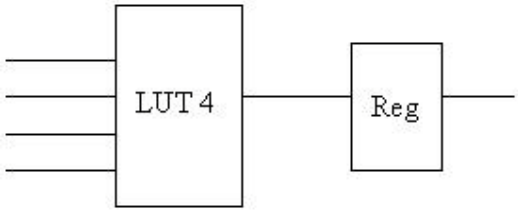
Reg1, 2, 3 must be compatible (i.e., have the same control signals).



When to move registers backward: when the input port of a register (D) is much more critical than its output port (Q) and the projected worst slack is better. The register needs to be replicated to all inputs of the combinational components it moves across.

What are the Costs? Area cost – The primary area cost is due to register replication in backward retiming.

Example: Four registers are replicated



Although forward retiming reduces the number of registers, more than 70 percent of retiming happens in backward retiming. So overall, it results in an area cost. Is this an issue? Statistically, most designs have more than double the amount of LUTs than FFs, because many FFs in used PFUs are left unused. They can be used for retiming purposes. In implementation, we have soft-constrained a certain percentage of device resources to allow for FF replication.

Run time cost – The main computation for retiming occurs in the timing engine. This will contribute to a longer run time in the flow.

NORETIME Attribute You can prevent retiming on an instance and its hierarchy with the NORETIME attribute. The NORETIME IO attribute will globally disallow retiming on I/O registers at the top level.

Preference Support Retiming supports six timing preferences. They are INPUT_SETUP, CLOCK_TO_OUT, FREQUENCY, MULTICYCLE, MAXDELAY, and PERIOD. Other preferences have no effect on retiming.

See Also ▶"Setting Map Design Options" on page 589

▶ "NORETIME" on page 1316 (HDL Attribute)

Place and Route

After a design has undergone the necessary translation to bring it into the physical design (.ncd) format during mapping, it is ready for placement and routing. Placement is the process of assigning the device-specific components produced by the mapping process to specific locations on the device floorplan. After placement is complete, the route phase establishes physical connections to join components in an electrical network. The place and route process takes a mapped physical design (.ncd) file and an optional preference (.prf) file, and places and routes the design. Placement and routing of a design can be cost-based or timing driven.

In most cases, your design will require timing-driven placement and routing, where the timing criteria you specify influences the implementation of the design. Static timing analysis results will show how constrained nets meet or do not meet your timing preferences.

In the Diamond Process view under Place & Route Design, a Place & Route Trace process is available that runs static timing analysis on the place and routed .ncd file. This process reports any timing errors associated with preferences and generates a report. The Place & Route Trace report can be accessed from the Analysis Reports folder of the Reports window.

The I/O Timing Analysis and I/O SSO Analysis processes also generate reports. View the I/O Timing Report to view data such as input and setup times on I/O in worst case scenarios and clock-to-output delay. Use the SSO analysis report to examine simultaneous switching outputs. These reports help ensure that your I/O plan meets the I/O standards and power integrity requirements of the PCB design.

Thermal Analysis Process (MachXO3L/LF 9400C/E devices only). This process must be run for MachXO3L/LF 9400C/E devices before running Bitstream File and JEDEC File processes. The Thermal Analysis process calculates the maximum safe ambient temperature for the user design implemented in MachXO3-9400C and mounted on three standard boards: JEDEC, Small, and Medium boards. This is to assist designers to determine if their design, implemented in MachXO3L/LF 9400C/E device, could safely be used in their application environment.

The thermal analysis software uses the clock specified in the TWR file. If the clock frequency is not set in the TWR file, the thermal analysis process errors out. The designer can either set the clock frequency in the strategy section or in the timing constraint file which will be reported in the TWR file after running Timing Analysis.

The Thermal Analysis report will include Device Operation Conditions, Operating Clock frequency, Percentage of LUT utilization; Percentage of I/O Utilization, and Activity Factor information.

The report contains Thermal Impedance and Maximum Ambient temperature based on three different Board Mounts, No Heat Sink, and No Air Flow.

By default, the Thermal Analysis process is checked. Uncheck this box if you do not wish to run this process.

- "Running Place & Route Design" on page 610
- "PAR Report File" on page 616

Setting Place & Route Design Options

Placement and routing options can influence the performance and utilization of the design implementation and ease incremental design changes. Some options, such as "Placement Sort Best Run," affect the way the results are reported. You can set Place & Route Design options in the Strategies dialog box in Diamond or use the par command-line program.

To set Place & Route Design options in the Diamond environment:

1. Choose **Project > Active Strategy > Place and Route Design Settings** to open the Strategies dialog.
2. For each option that you want to change, double-click a cell in the Value column.
3. Select the desired value from the drop-down menu, enter text, or click the browse button, as appropriate.

4. Click **OK**.

See Also ▶"Place & Route Design Options" on page 1145

- "Hold-Time Error Correction" on page 603
- "Running PAR from the Command Line" on page 2473
- "PAR Report File" on page 616

Options and Processes to Improve PAR Results

Experimenting with place and route settings in the Strategies dialog box can help improve your placement and routing results. Try changing certain strategy options to help meet your objectives, as in the following scenarios:

- Some number of connections are left unrouted.

  Increase the number of routing passes to help produce a fully routed design.

- Timing period/frequency objectives are not met.

  Try one or more of the following techniques:

  Increase the number of routing passes.

  Increase the effort level of the placer.

  Increase the number of times the placer runs.

- Efforts to meet setup and hold time requirements are increasing run time.

  Make sure that Auto Hold-Time Correction is set to **On**, which is the default setting. This will cause hold time correction to run automatically without increasing run time.

- A small amount of your logic design has changed and a rapid update is desired.

  Using the NCD Guide File option, select a previous version of your physical design (.ncd) file to guide the place and route process.

Other advanced options, such as clock boosting and re-entrant routing, are available from the command line. Clock boosting, (parcb), forces the router to insert extra wires to a Primary or Secondary route clock path to help compensate for hold time violations. Re-entrant routing, which uses the -kp option, instructs PAR to skip placement and leave the existing routing in place.

Hold-Time Error Correction

Hold-time error correction is a subtask in routing. In previous versions of Lattice Diamond (v3.1 and earlier), a post-step called “auto hold-time correction” (AHC) was carried out after a design was fully routed if there were any hold timing errors. This approach has the following issues:

1. A design could become unrouted after turning feature “AHC” on, especially for congested, hard-to-route designs.
2. Sometimes the performance on the setup could be decreased during the correction of hold timing errors.

A feature called “simultaneous setup/hold timing optimization” (SSH) was introduced in Lattice Diamond v3.2 onward. This feature considers both setup and hold timing at the same time in order to achieve better timing result and address routability. However, the feature “SSH” isn’t available for the routing method “CDR”, and it’s not supported for stand-alone hold timing correction. The table below shows the usage of SSH and AHC features at different settings.

Table 51: Usage of SSH and AHC Features at Different Settings

Command Line Option	Description	Routing Method			
		NBR (default)		CDR	
		SSH	AHC	SSH	AHC
Default	Turn on hold timing error correction only if there are no setup timing errors.	Auto	Off	Off	Auto
-exp parHold=0	Turn off hold timing error correction.	Off	Off	Off	Off
-exp parHold=1	Turn on hold timing error correction with default effort level.	On	Off	Off	On
-exp parHold=2	Turn on hold timing error correction with high effort level.	On	Off	Off	On
-exp parHoldOnly=1	Do hold timing error correction only.	Off	On	Off	On
-exp parHoldAgain=1	Do hold timing error correction again.	Off	On	Off	On

Simultaneous Setup/Hold Timing Optimization Simultaneous Setup/Hold Timing Optimization (SSH) was introduced in Lattice Diamond v3.2. This feature considers both setup/hold timing optimization during the entire routing process. Using the same routing engine and API functions, all the signals are routed under both setup/hold constraints.

For each signal connection, the timing slacks are calculated for both setup and hold constraints. By using slack allocation technology, a delay window is

created for each connection. If each connection can be routed within such delay window, the design will meet both setup/hold timing constraints. A patented routing technique is then called to do routing for the given specific delay window.

Compared to traditional “AHC” feature, the feature “SSH” can help the routing tool to achieve better results regarding hold timing error correction and routability improvement.

When the feature “SSH” is turned on, you should see the following message in par log file:

```
Start NBR section for setup/hold timing optimization with
effort level 3 at <time & date>
```

At the end of par log file, you should see the final timing info similar as following:

```
PAR_SUMMARY::Worst  slack<setup/<ns>> = 0.996
PAR_SUMMARY::Timing score<setup/<ns>> = 0.000
PAR_SUMMARY::Worst  slack<hold /<ns>> = 0.006
PAR_SUMMARY::Timing score<hold /<ns>> = 0.000
```

However, the timing models used in PAR runs may be different than the ones used in TRCE runs, so always use TRCE to verify the timing of your designs.

The feature “SSH” can be disabled by setting “-exp parUseSSH=0” at “Command Line Options” in the Place & Route Strategy window. Once the feature is disabled, the feature “AHC” will be used accordingly.

Auto Hold-Time Correction The Auto Hold-Time Correction (AHC) option causes Place & Route to process setup and hold time requirements in a single flow. The auto hold time correction is performed as soon as the setup timing score of 0 has been achieved. This option improves timing closure without increasing run time. It is supported for all FPGA device families and is set to **On** default.

- What Does Auto Hold-Time Correction Do?

  Auto Hold-Time Correction forces the router to automatically insert extra wires to compensate for hold time violations. The PAR process runs with the setup time target, and AHC begins as soon as a setup timing score of 0 is reached. If a hold time error is found, the hold time correction will kick off automatically. The router will try to resolve any hold time violations on registers that have preferences placed on them, including input I/O to register, register to register, and register to output I/O.

- What if a Setup Timing Score of 0 is not Achieved?

  If a setup timing score of 0 is not achieved, Auto Hold-Time Correction will be skipped during PAR unless AHC has been turned on through the command line.

  Failure to achieve a setup timing score of 0 can happen often, especially in the early design stage. When this happens, you will see a warning message.

```
Setup time error exists in the design, AHC (Auto Hold
Correction) optimization is skipped.
```

You can use the command line to force Auto Hold-Time Correction when setup timing is not achieved.

- From the command line, rerun Place & Route, using the following par option.

  ```
  -exp parHold=1
  ```

- Two Methods for Implementing Auto-Hold Time Correction
  - In the Diamond environment, this feature is implemented as a PAR switch setting for all implementation runs. Auto Hold-Time Correction runs automatically within the normal PAR flow. By default, the Auto Hold-Time Correction option is turned on in the active strategy.
  - You can also run through the flow with this setting turned off and then use the Standalone Auto Hold-Time Correction, which is available from the command line. The standalone program checks the input NCD for hold time violations and corrects any violations it finds.

To set Auto Hold-Time Correction in the Diamond environment:

1. Click **Project > Active Strategy > Place and Route Settings**.
2. In the Strategies dialog box, select **Auto Hold-Time Correction**.
3. Double-click the Value cell and choose **On** or **Off** from the drop-down menu.

To run Auto Hold-Time Correction from the command line:

- Specify the following command:

```
par mapped.ncd output.ncd design.prf
```

To force Auto Hold-Time Correction:

- Specify the following command:

```
par -exp parHold=1 mapped.ncd output.ncd design.prf
```

- To force AHC with extra effort to correct hold time errors, specify the following command:

```
par -exp parHold=2 mapped.ncd output.ncd design.prf
```

To run Stand-alone Hold-Time Correction:

- Specify one of the following example commands:

```
par -kp -w placed.ncd output.ncd design.prf -exp
parHold=1:parHoldOnly=1

par -kp -w placed.ncd output.ncd design.prf -exp
parHold=1:parHoldIter=5:parHoldLimit=500:
parHoldSpeedGrade=6:parHoldOnly=1
```

After the Auto-Hold Time Correction has been set from the command line, it will override the setting in the active strategy. It will force AHC to run if the setup timing score of 0 is not met.

See Also ▶"PAR Explorer Options" on page 2478

- "Running PAR from the Command Line" on page 2473
- PAR Explorer (-exp) Option – parHold
- "Changing Temperature and Voltage for Auto Hold-Time Correction" on page 606
- "Run Time Reduction" on page 607

Changing Temperature and Voltage for Auto Hold-Time Correction

When you enable Auto Hold-Time Correction and run a design flow, all timing is based on the same temperature and voltage settings that are defined in TEMPERATURE and VOLTAGE preferences.

Typically, the software will select the worst case scenarios for both setup and hold time analysis: the lowest voltage and highest temperatures for setup time (slowest time), and the highest voltage and lowest temperatures for hold time (fastest time). However, if you specify your own TEMPERATURE and VOLTAGE preferences, the software will assume that these settings are for setup analysis only.

To change your preferences so that hold time correction only is employed:

1. During your design flow in Diamond, run **Place & Route Design** with Auto Hold-Time Correction turned OFF.

   If you are using the command line, use the option **-exp parHold=0** in your command; for example:

   ```
   par mapped.ncd routed.ncd preference.prf -exp parHold=0
   ```

   This will optimize the maximum delay based on the current temperature/voltage settings defined in preferences, and it will skip hold timing correction.

2. Specify the desired TEMPERATURE and VOLTAGE preference settings in the .prf file.

3. Turn on the Auto Hold-Time Correction, and then rerun **Place & Route Design** to fix the hold timing problem. You define a different temperature/voltage only for hold timing.

   The following example shows how you would use the .ncd file from Step 1 to place and route the design.

```
par -kp routed_input.ncd routed_output.ncd preference.prf -
exp parHold=1:parHoldOnly=1
```

See Also ▶"Running PAR from the Command Line" on page 2473

- PAR Explorer (-exp) Option – parHold
- "Hold-Time Error Correction" on page 603

Run Time Reduction

Run Time Reduction is a multi-seed PAR option that uses checkpoints for comparing the result of the current placement seed with the results already obtained. A placement seed that is not producing better results will automatically be terminated. Beginning with Diamond 2.1, the Runtime Reduction option is ON by default.

As an example, let's say that you are doing a multi-seed run and you want to run Place & Route with ten seeds and save the NCD files for three of them. The PAR process will do the first three seeds as normal runs. But starting from the fourth seed, PAR will check the timing result in terms of the worst slack at different checkpoints and will compare it to the results already obtained. If the worst slack is worse, the remainder of the routing tasks for the fourth placement seed will be skipped, and PAR will continue to the next seed. Clearly, if the number of seeds to be saved is equal to the number of runs, there will be no run time reduction; and saving just one seed will produce the biggest run time reduction.

When a placement seed has been terminated, the following type of message will appear in the .par file for the 5_x placement seed:

```
************************************************************************
WARNING: The worst setup slack (-7.302ns) after initial routing exceeds the specified
threshold -5.164 ns. This par run will be terminated.
************************************************************************

!!!WARNING!!! Catch an exception in router NBR.
Reason : BASRT::Exceed the initial slack threshold -5.164ns.
Func   : RT_PFSTAR::routeUnifyPrepCongestion

!!!EXCEPTION!!! - BASRT::Exceed the initial slack threshold -5.164ns.
```

The PAR report file for the project, which you can access from the Reports tab in Diamond, will include a Worst Slack column in the Cost Table Summary, as shown in the following example:

```
Cost Table Summary
Level/      Number      Worst       Timing      Run         NCD
Cost [ncd]  Unrouted    Slack       Score       Time        Status
----------  --------    -----       --------    -----       ------
5_1   *     0           -3.038      485572      01:11       Complete
5_5   *     0           -3.238      476719      01:12       Complete
5_4         0           -4.446      564958      58          Complete
5_2         0           -5.164      729873      56          Complete
5_3         -           -           -           57          Skip

* : Design saved.
```

In the Cost Table Summary, the third column shows the worst slack (setup) after routing for the different seeds. Notice that seed 3 is skipped; therefore, there is no saved .ncd file or related timing information for seed 3.

By default, worst slack is used to compare the current seed to the best result obtained so far. However, you can change this so that the cost table is sorted based on timing score. In Diamond, choose **Project > Active Strategy > Place & Route Design Settings** and change the value for Placement Sort Best Run.

You can turn the Run Time Reduction feature off from the command line, with the following command:

```
-exp parASE=0
```

You can also turn this feature off in the Active Strategy user interface. In the Place & Route Design section, select the Command Line Options row and type **`-exp parASE=0`** in the Value cell.

- "PAR Report File" on page 616

Clock Skew Minimization

Clock Skew Minimization minimizes clock skew on selected non-global clock nets that warrant optimization. It provides pre-computed delay that is lower bound, which provides balanced routing.

This Clock Skew Minimization feature uses a program called CSM that will attempt to optimize the timing on nets you specify in the preference file before rerunning PAR. Details for using this feature are provided in application notes.

To turn on clock skew minimization in the Diamond environment:

1. Choose **Project > Active Strategy > Place & Route Design Settings**.
2. In the Strategies dialog box, select **Clock Skew Minimization**.
3. Double-click the Value cell and choose **1** or **2** from the drop-down menu.

   The “1” setting routes from driver pins to each clock load.

   The “2” setting routes a clock trunk first and then routes from the trunk to each clock load.
4. Click **OK**.

See the PAR -exp clockSkewMin Option for command-line instructions.

See Also ▶“Running PAR from the Command Line” on page 2473

Place & Route Input Files

PAR uses the following input files:

- Native Circuit Description File (.ncd) – This file is a physical description of the design in terms of the components in the target device.
- Physical Preference File (.prf) – This ASCII text file is an output of the Map Design process and includes preferences that were specified during design entry. It typically contains timing constraints that were specified in the logical preference file (.lpf). Preferences can indicate such things as clock speed for input signals, the external timing relationship between two or more signals, absolute maximum delay on a design path, or a general timing requirement for a class of pins.

  Editing the .prf file is not recommended. You should only edit constraints in the logical preference (.lpf) file or the HDL source to ensure the repeatability of the design flow through logical and physical domains. You can edit logical preferences using a text editor or Diamond’s preference-editing views.

See Also ▶“Place and Route” on page 600

- “Place & Route Output Files” on page 609
- “Setting Preferences” on page 457

Place & Route Output Files

The following files are the output files generated by the Place & Route Design process:

- Native Circuit Description File (.ncd) file — a placed and routed physical design file, which might contain placement and routing information in varying degrees of completion. One or more .ncd files will be produced depending on the options you choose. See “Multiple PAR Iterations” on page 610.

- PAR Report File (.par) — a PAR report including summary information of all placement and routing iterations.
- PAD Specification File (.pad) — a report file containing I/O pin assignments.
- Delay Report File (.dly) — an optional ASCII text file that includes a delay analysis of the 20 nets with the longest delay. PAR generates this file when the “Create Delay Statistic File” has been set to True in the Strategies dialog box or when the -y option is used in the command line.

  The option also appends a Delay Summary Report to the end of the Place & Route report. The first column of this summary gives the actual averages for the design. The figures in the second column, which are enclosed by parentheses, indicate a “worst case” scenario for the delay.

See Also “Place and Route” on page 600

- “Place & Route Input Files” on page 609

Running Place & Route Design

In the Diamond environment, the Place & Route Design process automatically assigns device-specific components to locations and connects them.

To run Place & Route Design in the Diamond environment:

- In the Process view, double-click **Place & Route Design**.
- Alternatively, right-click Place & Route Design and choose **Run** from the pop-up menu.

See Also “Setting Place & Route Design Options” on page 601

- “Running PAR from the Command Line” on page 2473
- “Running Processes” on page 69

Multiple PAR Iterations

The “Place Iterations” option for Place & Route Design sets the maximum number of placement/routing passes.

If you specify options that produce a single output design file, your output consists of a single .ncd file, .par file, and .pad file. The .par and .pad files all have the same root project name as the .ncd file. Optionally, you can output a Delay Statistics (.dly) file that will also, by default, assume the project name. See “Delay Statistics Report File” on page 628 for details.

If you run multiple placement and routing iterations, you produce a .ncd, .par, .dly, and .pad file for each iteration. After each iteration, the program saves the physical design (.ncd) file for every instance where the timing core has improved. This means that during long PAR runs, the current .ncd file with a minimal timing score is always available. This behavior prevents a few rare

cases where timing scores may have gone up rather than down when performing multiple PAR iterations. The timing score is determined as a weighted sum of several parameters including the number of unrouted nets, number of timing constraints not met, amount by which the timing constraints were not met, maximum delay on nets, and maximum delay on the ten highest nets.

As the par command is performed, PAR records one .par file (a summary of all placement and routing iterations) at the same level as the directory you specified. It also places within the directory an .ncd, .par, .dly and .pad file for each individual iteration.

The file names for the output files use the naming convention <*effort-level*>_<*cost-table-entry*>; for example, 1_1.ncd, 1_1.par, 1_1.dly, and 1_1.pad. In this example, the effort level and cost table entries start at 1 (the default effort level is 5).

Note

If you wish to further optimize your place-and-route results beyond multiple PAR iterations, a process which uses timing as the sole criteria for optimization, see "Using MPARTRCE to Optimize PAR Iterations" on page 611. In addition to timing score, the MPARTRCE tool's methodology uses a performance score when it determines the best design run for your purposes.

- "Run Time Reduction" on page 607

Using MPARTRCE to Optimize PAR Iterations

MPARTRCE is a multi-PAR program that uses a performance score for selecting the best iteration. It is available from the command line.

Multi-PAR When PAR processes design iterations using different placement seeds to produce the best possible placed-and-routed design, it does so by performing and evaluating each design on a timing score basis. See "Multiple PAR Iterations" on page 610.

The timing score is a useful measure for algorithms to perform optimal place-and-route on the design. However, timing score is not necessarily the best criteria to use to select the best iteration with respect to the user's preference. Furthermore, the timing score becomes zero if all the constraints are met, making the choice of the best implementation random because multiple implementations meet the timing constraints.

In multiple PAR scenarios, you are interested in the implementation that results in the best timing performance. For example, in a single clock design, where the setup and clock-to-out times are not critical, the best iteration is the one that results in the highest f_{MAX} in static timing analysis. When there are more timing preferences, the best result would be the one that scores best for each of the timing preferences.

MPARTRACE Multi-PAR The multiple PAR of MPARTRCE continues to use the timing score for PAR algorithms in multiple PAR iterations, but it also employs a measure called performance score for selecting the best iteration.

MPARTRCE attempts to do the following:

- Use the existing method for running multiple PAR iterations, each using a different placement seed and using “timing score” criteria for optimizing place and route processes.
- Automatically run static timing analysis (TRCE) on the implementation files (.ncd) after each PAR iteration.
- Establish a new selection criterion to pick the iteration that best satisfies user preferences and requirements.
- Provide options to specify special requirements, preferences, and criteria for selecting the best result.

Performance Score The MPARTRCE method for selection of the best design uses a performance score in its determination. The Performance Score (PS) is defined as the following:

PS = FS(i)

where "i" is the number of preferences used for PS computation and FSi is the Frequency Score for the ith preference. The Frequency Score (FS) is defined below:

If, (Achieved_time)i < (Required_time)i ,

FSi = (Required time - Achieved_time) * wi

else,

FSi = (Required time- Achieved_time) * pi

where wi is the weight factor for the ith preference and pi is the penalty factor for the ith preference. The weight factor is associated with positive slack (timing preference met) and penalty with negative slack (timing preference violated).

The performance score is calculated for each iteration’s implementation result (.ncd file), and the one with the highest (algebraic maximum) performance score is selected as the best result.

Preferences and achieved results that are in frequency domain will be converted to the corresponding time domain values and used in performance score equations.

MPARTRCE Process MPARTRCE executes the following operations:

1. Reads in the constraints from the physical preference file (.prf) and determines the weights and penalties based upon a specific .ini file and user overrides.

2. Runs PAR, TRCE and result selection algorithms multiple times. During result selection, it parses the TRACE report for the values of interest, determines the frequency and performance scores, and creates a report in .csv format.
3. After all the iterations, copies the implementation and report files corresponding to the best result from the results directory into the project directory and creates the log file.

If you break the process after any iteration N, the results and reports correspond to the best implementation to that point. The outputs would be equivalent to what you would have obtained if you had run multiple PAR to N iterations.

See Also ▶"Specifying Preferences for MPARTRCE" on page 613

- "Running MPARTRCE from the Command Line" on page 2490
- "Multiple PAR Iterations" on page 610

Specifying Preferences for MPARTRCE

To direct MPARTRCE to perform its intended function, you must accurately guide the tool by setting your timing preferences properly in the PAR physical preference (.prf) file. You can edit preferences in your text editor of choice.

If some of the preferences in the .prf file are not required for result selection or if you must change the values in the file for result selection, a different preference file can be specified for TRACE (trce) and result selection purposes.

In the MPARTRCE command line, this mpartrce.prf file can be named anything and supplied using the **-**tpr option. The mpartrce.prf file can contain any subset of the PAR preference file. If mpartrce.prf exists and is specified in the command line, then that file is used for trce and result selection purposes. Only the timing preferences and their values in the mpartrce.prf file will be used for performance score computation and result selection. In GUI mode, the preference file will have to be named "mpartrce.prf" and must reside in the project directory. The GUI option is not currently supported.

Overriding weights and penalties Performance score computation uses different penalty and weight factors for each timing preference. Default weights and penalties are defined for each preference group (f_{MAX}, t_{PD}, t_{SU} and t_{CO}) in the mpartrce program. It is possible for the advanced users to override these defaults by individually specifying relative weights and penalties for each timing preference line.

The weight and penalty values are specified as comments at the end of each preference line. A comment symbol (#) is placed at the end of the preference line and is followed by the lowercase letter w for weight and the value for weight. Similarly the penalty factor is entered by the lowercase letter p followed by the actual penalty factor value. The preferences that do not have overriding w or p value will use the default values.

The following sample preference lines and the corresponding weight/penalty override values illustrate the override mechanism.

```
FREQUENCY NET "clk_tx" 200.000000 MHz ; # w 20 p 400
  New weight for clk_tx = (default weight) * 20
  New penalty for clk_tx = (default penalty) * 400

FREQUENCY PORT "clk_rx" 150.000000 MHz ; # p 100
  New weight for clk_rx = (default weight)
  New penalty for clk_rx = (default penalty) * 100

INPUT_SETUP ALLPORTS 3.000000 ns CLKPORT "clk" ; # w 0.5 p 2
  New weight for Tsu for clk = (default weight) * 0.5
  New penalty for Tsu for clk = (default penalty) * 2

CLOCK_TO_OUT ALLPORTS 7.000000 ns CLKPORT "clk" ; # w 2
  New weight for clk_tx = (default weight) * 2
  New penalty for clk_tx = (default penalty)
```

The w/p overrides can be specified either in the PAR preference (.prf) file or the timing preference (.tpf) file. The additional preference values specified do not affect the PAR results as they are used only by trce and in the result selection processes. The weights and preference overrides in either preference files do not affect PAR or TRACE programs as they appear as comments for those programs.

Note

Any manual change to the PAR preference file will be lost when a MAP is re-run on the design.

Preference file and override options The following are the different options that can be used:

- Use only the PAR preference file (<proj_name>.prf) and specify no overrides. Here are some things to consider when using this option:
  - You do not need to create additional files or edit the .prf file.
  - You have to rely on over-constrained preference values.
  - You cannot remove an unneeded preference line.
  - You cannot override the default priorities for timing preferences.
- Use only the PAR preference file (<proj_name>.prf), but manually add w/p overrides. Here are some things to consider when using this option:
  - You do not need to create additional files.
  - You have to rely on over-constrained preference values.
  - You cannot remove an unnecessary preference line.
  - You can override the default priorities for timing preferences by specifying w and p. Indirectly, this can eliminate the effect of retaining unnecessary preferences on the performance score.

- The PAR preference file will get overwritten if you re-run map, and all the w/p overrides appearing as comments will be removed.

- Manually create a Timing preference (.tpf) file and specify no overrides. Here are some things to consider when using this option:
  - The Timing preference (.tpf) file can be easily created by copying the PAR preference file. Map can be re-run without affecting this preference file.
  - Over-constrained preference values can be replaced with reasonable values required for result selection.
  - Unwanted preferences can be removed.
  - You have to be content with default weight and penalty factors.
- Manually create a Timing preference (.tpf) file and add w/p overrides to the preferences in it. Here are some things to consider when using this option:
  - The Timing preference (.tpf) file can be easily created by copying the PAR preference file. MAP can be re-run without affecting this preference file or the w/p overrides.
  - Over-constrained preference values can be replaced with reasonable values required for result selection.
  - Unwanted preferences can be removed.
  - Weight and penalty values can be overridden as required to have complete control on the result selection method

- "Multiple PAR Iterations" on page 610

Place & Route Report Files

The Reports view in Diamond provides immediate access to reports produced by the Place & Route Design process, including the Place & Route report (.par) and the Pad Specification file (.pad). These reports open in the Report view in HTML format.

If you have enabled the Create Delay Statistics File option for the active strategy, a Delay Statistics Report File (.dly) will be included in your project directory. When you run multiple iterations of Place & Route, a .par file, .pad file, and .dly file will be included in your project directory for each run. You can open these files with a text editor.

See Also ▶"Multiple PAR Iterations" on page 610

- "Run Time Reduction" on page 607
- "PAR Report File" on page 616

PAR Report File

The PAR Report (.par) file contains execution information and shows the steps taken as the process converges on a placement and routing solution. To access this file in the Diamond environment, use the Report window.

To view the PAR Report file in Diamond:

- In the Design Summary pane of the Reports window, select **Place & Route**. Your report will appear in the pane to the right.
- Alternatively, use a text editor to open the .par ASCII file from your project directory.

Some of the sections included in a given .par file are described below, with links to a sample .par file. These sections will vary, depending on the FPGA architecture.

Cost Table Summary This section summaries the results of each placement seed and shows the worst slack and the timing score for both setup and hold. For a typical design, using five placement seeds with the best two runs saved, the cost table will resemble the following example:

```
Level/      Number    Worst   Timing  Worst       Timing      Run    NCD
Cost [ncd]  Unrouted  Slack   core    Slack(hold) Score(hold) Time   Status
----------  --------  -----   -----   ----------- ----------- -----  ------
5_1   *     0         0.531   0        0.235       0           26    Complete
5_3   *     0         0.398   0        0.235       0           24    Complete
5_2         0         0.174   0        0.175       0           22    Complete
5_4         -         -       -        -           -           21    Skip
5_5         -         -       -        -           -           18    Skip
```

However, if setup timing is not met, or if the hold time fix is not turned on (see “Auto Hold-Time Correction” on page 1146 and PARHOLD), then the hold time information will not be reported, as shown by the following example:

```
Level/      Number    Worst    Timing   Worst       Timing      Run    NCD
Cost [ncd]  Unrouted  Slack    Score    Slack(hold) Score(hold) Time   Status
----------  --------  -----    ------   ----------- ----------- -----  ------
5_3   *     0         -0.507   6583     -           -           19     Complete
5_2   *     0         -0.700   8195     -           -           20     Complete
5_5         0         -0.822   13747    -           -           20     Complete
5_4         0         -0.869   16325    -           -           20     Complete
5_1         0         -0.914   23897    -           -           24     Complete
```

By default, the Cost Table Summary is sorted by worst slack for multiple placement seeds, as follows:

1. NCD status (completed or not)
2. worst slack (setup)
3. timing score (setup)
4. worst slack (hold)

5. timing score (hold)
6. seed #.

If you would rather that the cost table be sorted by timing score for multiple placement seeds, select the Timing Score option for “Placement Sort Best Run” in the Place & Route Design section of the active strategy. The table will then be sorted as follows:

1. NCD status (completed or not)
2. timing score (setup)
3. worst slack (setup)
4. timing score (hold)
5. worst slack (hold)
6. seed #

Device Utilization Summary This section summarizes the number and percentage utilization of device resources, including I/O, logic, and global signals. Except for PIOs, a single device SITE resource is used for each design COMP of the Native Circuit Description (.ncd) database. For PIOs, twice the number of PIO SITE resources are required for differential I/Os. A single differential PIO COMP uses two PIO SITE resources, whereas non-differential PIO COMPs use one PIO SITE resource.

The PIO report summary counts the number of bonded and unbonded PIOs required to implement single-ended and differential signal standards. PIO utilization reflects the preliminary results reported by the design mapper (map). See the I/O Usage Summary section for details on final results. Utilization reported by Map might be lower, because some SITE resources, such as VREF assignments, are made automatically by PAR.

Report Syntax:

SITE TYPE <# *sites used*> / <# sites of type available on device> <x>% used

Consider the example below. The first column identifies the device type. The second column provides the actual number of available sites versus those used for that device type, and the third column provides the percentage of

available sites used. For PIOs, you will see a breakdown of available versus used bonded pads and a percentage:

```
Device utilization summary:

   APIO                24/36           66% used
   GSR                  1/1           100% used
   IOLOGIC            110/506          21% used
   PIO (prelim)       194/504          38% used
                      194/372          52% bonded
   DQSBUF               8/16           50% used
   EBR                135/225          60% used
   DQSDLL               1/2            50% used
   MULT18               1/88            1% used
   PCS                  2/2           100% used
   SLICE          17827/23832          74% used

   PLL                  3/8            37% used
```

For total PIO resources, a preliminary (prelim) report shows that out of a possible 504 total PIO resources on the device, the design uses 194 or about 38 percent. The following line shows that 194 bonded out pads are being used out of a possible 372 bonded I/Os, which is about 52 percent.

The term “used” means that these I/O are in the design and will be programmed on the device. This report is considered preliminary (prelim) because VREF assignments have not yet been placed. The difference in resource utilization is accounted for later in the PAR report in the I/O Usage Summary (final).

An I/O is considered “bonded” when the packaging of the chip connects the bond pad to a pin on the package.

Note

Bonded pad availability is based on packaging, which varies within a device family from part to part. See the Package Diagrams documentation in addition to the Product Selector Guide on the Lattice web site for details when selecting a device and package for your application.

The rest of the example report shows IOLOGIC, PLL, SLICE and other various resource type usage. As utilization percentage approaches 100 percent on logic or any specific key resource types reported in this section, you might want to consider a larger device that can accommodate better design performance.

Placement This section provides a log of messages produced during the placement phase.

Clock Report This section provides a complete listing of all of the clocks used in the design. Aside from the example, the Clock Summary report would reflect a scenario where only global clocking is used as follows:

```
   Quandrants All (TL, TR, BL, BR) - Global Clocks
      PRIMARY  : 1 out of 4 (25%)
        DCS    : 1 out of 2 (50%)
     SECONDARY : 0 out of 4 (0%)
```

I/O Usage Summary (final) This section Summarizes the final number and percentage utilization of device resources, including I/O, logic, and global signals.

Report Syntax:

```
I/O Bank Usage Summary (final):
   <#PIO sites used> out of <#PIO sites of device> (x%) PIO
   sites used.
<#PIO sites used> out of <#PIO sites of device/pkg> (x%) bonded
PIO sites
used.
Number of PIO comps: <#PIO comps which are in the NCD>; <#PIO
comps in NCD which represent differential IO>
Number of Vref pins used: <#VREF pins>
```

Routing This section provides a log of messages produced during the routing phase.

Completion This section shows statistics of the run, including time to route, number and percentage of successfully routed connections, errors and warnings, and final timing score.

Notes regarding the sample place and route report:

- Placer score is a rating of the relative “cost" of a placement. A lower score indicates a better, less costly placement.
- Timing score will always be 0 (zero) if all timing preferences have been met. If not, the figure will be other than 0. This tells you immediately whether your timing preferences have been met.
- Underneath the “Completed router resource pre-assignment” line, warning messages might appear, indicating that a clock signal can suffer excessive delay or skew due to conflicts in clock routing resources.

  For example, the placer will avoid placing two clock signals in the same PIC pair that share the same clock spine. If more than one clock signal are hard-located in the same PIC pair that share a common clock spine, the router will write out a warning message in the PAR Report File (.par) at this point.

- The “Starting iterative routing” section contains figures in parentheses (125818). This represents the timing score for the design (not to be confused with the PAR score) at the end of the particular iteration. When the timing score reaches 0 (as it does in this example after iteration 2), this means that all timing preferences have been met. This timing score (0) also appears at the end of the Delay Summary Report section. Note that the Delay Summary Report is only generated when you use enable the “Create Delay Statistic File” option in the Strategies dialog box or use the **-**y option in the command line.

  The timing score at the end of the “Starting iterative routing” section might not agree with the timing score at the end of the Delay Summary Report. This can occur if a MAXSKEW preference is scored and not met. The score shown in the Delay Summary Report section will always be the correct one.
- Sometimes the design will be completely routed but the router continues to route in the attempt to adhere to timing preferences.
- There is a section before the “Starting Constructive Placer” message that will list all selected primary clocks.
- When you specify the -y option on the command line, the last section of the .par file summarizes the delay information for the routed design. The first column of this section gives the actual averages for the design. The figures in the second column, which are enclosed by parentheses, indicate a "worst case" scenario for the delay. The PAR run also produces a .dly (delay) file that contains more detailed timing information.

Note

Timing scores can rise when attempting to meet timing constraints, because the router might move a signal to a less favorable path to make a resource available for another signal.

I/O Bank Usage Summary:
+----------+----------------+------------+------------+------------+
| I/O Bank | Usage          | Bank Vccio | Bank Vref1 | Bank Vref2 |
+----------+----------------+------------+------------+------------+
| 0        | 1 / 28 (  3%)  | -          | -          | -          |
| 1        | 0 / 22 (  0%)  | -          | -          | -          |
| 2        | 22 / 26 ( 84%) | 2.5V       | -          | -          |
| 3        | 19 / 24 ( 79%) | 2.5V       | -          | -          |
| 4        | 0 / 26 (  0%)  | -          | -          | -          |
| 5        | 1 / 24 (  4%)  | -          | -          | -          |
| 6        | 2 / 27 (  7%)  | 2.5V       | -          | -          |
| 7        | 1 / 24 (  4%)  | 2.5V       | -          | -          |
+----------+----------------+------------+------------+------------+

                    DSP Utilization Summary:
                    --------------------------------------
                    DSP Block #:              1 2 3 4 5
                    # of MULT36X36B
                    # of MULT18X18B
                    # of MULT18X18MACB
                    # of MULT18X18ADDSUBB
                    # of MULT18X18ADDSUBSUMB
                    # of MULT9X9B
                    # of MULT9X9ADDSUBB
                    # of MULT9X9ADDSUBSUMB

                    Total placer CPU time: 13 secs

                    Dumping design to file attributes_attributes.dir/5_1.ncd.

                    0 connections routed; 892 unrouted.

                    Starting router resource preassignment

                    Completed router resource preassignment. Real time: 19 secs

                    Start NBR router at 12:12:21 06/06/13

                    ************************************************************
                    Info: NBR allows conflicts(one node used by more than one
                    signal)in the earlier iterations. In each iteration, it tries
                    to solve the conflicts while keeping the critical connections
                    routed as short as possible. The routing process is said to
                    be completed when no conflicts exist and all connections are
                    routed.
                    Note: NBR uses a different method to calculate timing slacks.
                    The worst slack and total negative slack may not be the same as
                    that in TRCE report. You should always run TRCE to verify
                    your design. Thanks.
                    ************************************************************

PAD Specification File

The PAD specification (.pad) file is an ASCII report file that lists all Programmable I/O Cells (PICs) used in the design and their associated primary pins. The PICs are listed by port name and by pin names.

To view the PAD Specification Report File in the Diamond environment:

- In the Design Summary pane of the Reports window, select **Signal/Pad**. Your report will appear in the pane to the right.
- Alternatively, use a text editor to open the .pad ASCII file from your project directory.

The .pad file includes the following information:

- Pinout by Port Name – This section lists the port names with primary pin designations. It also shows the buffer type and any associated attributes. Buffer type indicates the PIO mode. For example, a PIO in LVDS or LVPECL mode needs two bonded pads for differential signals that are both included in the .pad file.

  In most designs, the top-level HDL or schematic design will not include both true and complement sides of differential port signals. The designer assigns I/Os to pads (via the LOCATE preference) using a single signal, assuming that it will represent the true (+) signal. Based on an IOBUF preference type of LVDS or LVPECL, Diamond will automatically infer the complement (-) signal and assign it to the appropriate site on the device package.

  Port signals are reported using the syntax: <port name>+ for positive differential and <port name>- for negative differential in the Pinout by Pin Number table. If the source native generic database (.ngd) file does include LVDS or LVPECL type buffers where both true and complement ports exist, then the original signal names without +/- notation are used in the report.
- Vccio by Bank – This section lists the voltage by bank.
- Vref by Bank – This section shows the name and location of on-chip voltage references that have been set and the associated port groups or signals.
- Pinout by Pin Number – This section lists pin numbers, which includes primary pin number, the component name or reference voltage type, the buffer type, and any preferences assigned to the component. The Dual Function column identifies pins that can be used for I/O assignments or for another function, such as Vref. In the Pin info column, the status of any "unused" pin is reported as "unused, PULL:UP," because these pins will have an internal pull-up.
- Locate Preferences – This section lists LOCATE preferences that are in the .prf file. The list includes user-defined LOCATE preferences that were assigned during design entry and those that were set automatically by Place & Route.

Delay Statistics Report File

When you use the -y option from the command line or the “Create Delay Statistics File” option in the Strategies dialog box, each PAR run will generate a delay file (.dly). This file contains delay information for each net in the design. It includes:

- A listing of the 20 nets with the longest delays.

  An "e" preceding a maximum delay indicates that the delay shown is only approximate.

- A delay analysis for each net, including the net name, followed by the driver pin and the load pin(s).

The “Create Delay File” or -y option also appends a Delay Summary Report to the end of the Place & Route report. The first column of this summary gives the actual averages for the design. The figures in the second column, which are enclosed by parentheses, indicate a "worst case" scenario for the delay.

Cost-Based Place & Route

The standard PAR package is a cost-based tool. This means that placement and routing are performed using various cost tables that assign weighted values to relevant factors such as constraints, length of connection, and available routing resources.

Placement The PAR process places the mapped physical design (.ncd file) in two stages: a constructive placement and an optimizing placement. PAR writes the physical design after the completion of each of these two stages.

During constructive placement, PAR places components into sites based on factors such as the following:

- Constraints specified in the input file (for example, certain components must be in certain locations)
- Length of connections
- Available routing resources
- Cost tables that assign random weighted values to each of the relevant factors. There are 100 possible cost tables.

Constructive placement continues until all components are placed. Optimizing placement is a fine-tuning of the results of the constructive placement.

Routing Routing also is done in two stages: iterative routing and delay reduction routing, which is also called cleanup. PAR writes the physical design (.ncd) only after iterations where the routing score has improved.

During iterative routing, the router performs an iterative procedure to converge on a solution that routes the design to completion or minimizes the number of unrouted nets.

During reduction routing, the router takes the result of iterative routing and reroutes some connections to minimize the signal delays within the device. There are two types of reduction (cleanup) routing that you can perform:

- A faster cost-based cleanup routing. This type of routing makes decisions by assigning weighted values to factors, such as the type of routing resources used, that affect delay times between sources and loads.
- A more intensive delay-based cleanup routing. This type of routing makes decisions based on computed delay times between sources and loads on the routed nets.

If PAR finds timing preferences in the preference file, timing-driven placement and routing is automatically invoked.

See Also ▶"Place and Route" on page 600

- "Timing-Driven Place & Route" on page 629

Timing-Driven Place & Route

In addition to cost-based PAR, you can run timing-driven placement and routing using the timing analysis engine.

This means that placement and routing is executed according to timing constraints (preferences) that you specify up front in the design process. The timing analysis engine interacts with PAR to ensure that the timing preferences you impose on the design are met.

To use timing-driven PAR, you simply write your timing preferences into a logical preference (.lpf) file in the design entry stage. The mapping process writes these preferences to the physical preference file (.prf), which serves as input to the Timing Wizard. If PAR finds timing preferences in the preference file, timing-driven placement and routing are automatically invoked.

Below is a brief description of timing preferences that PAR supports. For additional information, see "Applying Design Constraints" on page 358.

FREQUENCY Identifies the minimum operating frequency for all sequential input pins clocked by a specified net.

PERIOD Specifies a maximum clock period for all sequential input pins clocked by a specified net.

MAXDELAY Identifies a maximum total delay for a circuit net, path, path class, or bus in the design. Also specifies a maximum delay from a starting point or to an endpoint.

MAXSKEW Identifies a signal skew between the loads on a specified signal.

BLOCK Blocks timing checks on path classes, nets, buses, or component pins that are irrelevant to the timing of the design.

DEFINE STARTPOINT Identifies a starting point for the MAXDELAY FROM/TO preference (see MAXDELAY).

DEFINE ENDPOINT Identifies an ending point for the MAXDELAY FROM/TO preference (see MAXDELAY).

DEFINE PATH Specifies a path from a source component to a destination component.

DEFINE BUS Specifies a grouping of nets.

MULTICYCLE Allows for relaxation of previously defined PERIOD or FREQUENCY constraints on a path.

Each timing preference can generate many timing constraints for the design. For example, a PERIOD or FREQUENCY preference generates a timing constraint for every data path clocked by a specified net. A MAXDELAY for a designated path class generates a timing constraint for every path in the path class. Depending upon the types of timing preferences specified and the values assigned to the preferences, PAR run time might be increased.

When PAR is complete, you can verify that the design's timing characteristics (relative to the preference file) have been met by running TRACE (Timing Reporter and Circuit Evaluator), Diamond's timing verification and reporting utility. TRACE issues a report showing any timing warnings and errors and other information relevant to the design.

Improving PAR Results for Highly Congested Routing

Some FPGA designs can exhibit a high degree of routing congestion after placement and routing. This can be due to design logic with many high fanout signals and a high degree of signal interconnect. Large state machines and control logic are common types of designs that lead to routing congestion.

Congestion can lead to large route delay or even prevent the routing phase of place and route from completing. If route delay represents a large fraction (>80%) of overall delay, the design might be a good candidate for constraint-driven and negotiation-based router options.

The default router is the negotiation-based router (NBR). The NBR involves an iterative routing that routes connections to achieve minimum delay cost. It does so by computing the demand on each routing resource and applying cost values per node. It will finish when an optimal solution is arrived at or the number of iterations is reached.

Congestion-driven PAR options for placement (CDP) and routing (CDR) can improve performance for a design that has multiple congestion hot-spots. The congestion display in Floorplan View or Physical View can help you visualize the routing congestion. Large congested areas might prevent congestion-based PAR options from finding a successful solution.

A combination of NBR, CDP, and CDR options can yield improved results.

Relative PAR run time and quality of results by option:

- Very congested, slower run time: NBR + CDP
- Moderate congestion, faster run time: CDR + CDP

To access options in Diamond for highly congested routing:

1. Choose **Project > Active Strategy > Place and Route Design Settings**.
2. In the Strategies dialog box, select **Routing method**.
3. Double-click the Value cell and choose a routing method—**NBR** or **CDR**.
4. In addition, set the following options based on the degree of congestion shown in your design:
   - Congestion-Driven Placement – 1 (on) enables congestion-driven placement under any circumstance. The Auto option automatically turns on congestion-driven placement when it is needed.
   - Congestion-Driven Routing – 1 (on) enables congestion-driven routing under any circumstance. The Auto option automatically turns on congestion-driven routing when it is needed.
5. Click **OK**.

These options are also available from the command line, as follows:

-exp parCDP (congestion-driven placement)

-exp parCDR (congestion-driven routing)

-exp parUseNBR (negotiation-based routing)

See Also ▶PAR Explorer options

▶ “Run Time Reduction” on page 607

Place & Route Considerations

Each Lattice device provides a clock distribution network that includes primary, secondary, and edge clocks for distributing high-performance clocks.

Primary clocks are automatically selected by the place and route process according to the load number and driver type. You can also define a signal as a primary clock using the USE PRIMARY preference. For details on the number of primary clocks available in your device target, refer to the device data sheet.

In primary clock placement, if the primary clock is a PIO, the placer will automatically place it into a "sweet site," a site that can be routed easily to the center. However, if the primary clock is driven by a PFU (internally generated primary clock), the placer will attempt to place it on a sweet site or a proximal location. If you locate a primary clock driver on a non-sweet site, the placer will issue a warning. During pre-placement, all PIO constraints are observed, which means that the pre-placement is always legal.

The placer prints out a list of selected primary clocks before the constructive placement. You should check that the primary clocks are selected properly.

See Also ▶“USE PRIMARY” on page 1268

Reducing Run Time in PAR

For all Lattice FPGA devices, the placer and router algorithms in Diamond have been optimized to improve run time in PAR. You do not have to set any options to benefit from these improvements. Additionally, the default negotiation-based router (NBR) helps reduce run time on designs that are difficult to route.

NBR uses a negotiation technique to arrive at viable routing solutions. At first, the NBR Router works to establish a minimum delay cost of each connection, allowing wiring shorts and assuming all nodes are available for use. Using this as a basis, the NBR Router algorithm implements an iterative process that places demand value on node resources, using a cost-based system. During this iterative process, signals that used nodes in congested areas are reprioritized to less expensive areas of congestion and shorts are resolved. The tool “negotiates” the expense of each connection based on this cost system until it reaches the most effective routing solution for the design.

For a moderately congested design, you might want to switch to the congestion-driven routing method (CDR). The NBR and CDR Routing Method options are available in the Place & Route Design settings of the Strategy

dialog box. You can also set the routing method from the command line using the PARUSENBR and PARCDR options.

- “Run Time Reduction” on page 607

Running Multiple PAR Jobs in Parallel

The PAR Multi-tasking option allows you to use multiple machines (nodes) to run multiple place-and-route jobs at the same time instead of serially. You can run this feature in the Diamond environment. Use the “Multi-tasking Node List” option in the Place and Route Settings of the Strategies dialog box, or use the PAR-m option from the command line.

This ability to run multiple jobs on different nodes simultaneously can significantly reduce the time it takes to complete these runs. Otherwise, it would take the cumulative time for each job to complete by itself in a consecutive manner, and this could mean the difference between 1 hour and 10 hours of total time.

The PAR multi-tasking option is supported three ways:

- Local multi-tasking, where multiple PAR runs are executed on a single machine.
- Networked multi-tasking, where multiple PAR runs are executed on multiple machines.
- A combination of local and networked.

Creating a Node List File For a PC or for UNIX/Linux, you must first create an ASCII-based node list file input that specifies the candidate machines that will allow multiple PAR jobs to be run in parallel.

The node list file contains node description blocks of information on separate lines for each machine in the format shown below:

[<*node_name*>]

System = <*linux* | *pc*>

Corenum = <*number_of_cores*>

Env = <*file_name*>

Workdir = <*directory_name*>

[<*node_name2*>]

System = <*linux* | *pc*>

Corenum = <*number_of_cores*>

Env = <*file_name*>

Workdir = <*directory_name*>

where:

The [<*node_name*>] value contains the machine name in square brackets. For example, if your machine name is *jsmith*, this line would simply show [jsmith] on the first line.

Note

For UNIX/Linux, you can use many networked nodes to run the PAR job, so the node list will have a corresponding number of node description blocks in it. For PC, there will only be one node description block in the node list since you can only employ one PC that has multiple cores. This feature does not currently support a host of networked PCs.

The System node description line lists the platform the machine runs on. This line can only take Linux or PC as a value.

Corenum specifies how many CPU cores there are on the machine. Changing it to zero disables the node from running PAR tasks.

Env specifies an environment setup file to be run before the multiple PAR job is run on the remote machine. If the remote machine environment is ready, then this line can be omitted. To test if a remote machine is ready, run the following command to see if PAR can be run remotely:

ssh <*remote_machine*> <*par_cmd_options*>

Workdir specifies in which working directory on the remote machine the PAR multi-task job should be run. If account permissions allow you to get into that directory automatically after login, this line can also be omitted. You can test if a remote user account needs to set the working directory by running the following command and see if the design can be found:

ssh <*remote_machine*> ls <*ncd_file*>”

If the design is found after issuing the above command, there is no need to specify this line.

If Workdir is set to a location, it must be set to a directory where ssh into that nodename has read/write access in that directory.

General Node List Rules:

- You must use the equals sign for each node description line.
- Only the names of files and directories are case sensitive on UNIX and Linux. Node description line markers, for example, “Corenum **=**” can appear in upper, lower, or mixed case.

- The [<*node_name*>], Corenum and System lines are required for any node list file.
- The Env and Workdir node description lines are optional.
- For PC, the nodelist file should only include one node description block on the local machine. Remotely networked PCs are not supported. Any entries for remote nodes on a PC network will be discarded by the PAR multi-tasking feature.
- For UNIX/Linux, the nodelist file can have multiple machine nodes; but it should not include PC type nodes.
- Any text following double forward slashes, "//", will be considered as a comment and ignored, except when those double forward slashes are enclosed in double quotation marks. If you need to specify a path containing a double forward slash, you can do so by enclosing it in quotes. Comments can be added at any position in a line.
- Whitespace around node description line markers is ignored.
- Blank lines, including those with comments, are ignored.

PAR Multi-Tasking Environment Setup For PC, running PAR remotely is not supported, so multiple PAR processes can only run in parallel on one PC. Since the child PAR process takes the environment from the parent, no environment variable setup is necessary.

For UNIX/Linux, there are two ways to set up the environment:

- Use the account login profile and source files.

  For the account to allow PAR to be run remotely, it should have an .rc file (.bashrc if the bash shell used) that runs automatically when a secure shell (ssh**)** call is received. This script file needs to set up the environment to the correct Diamond path and “cd” to the directory where the NCD file exists.

  The following three environment variables have to be set properly for PAR to run: PATH, FOUNDRY, and LD_LIBRARY_PATH. To set the environment variables, see “Setting Up the Environment to Run Command Line” on page 2438. You can test if the remote environment is set up correctly by running the following command locally:

  ssh <*remote_machine*> par

  You will see the PAR help page if the environment setup is correct.

- Use Env and Workdir node description lines in the node list file.

  The PAR Multi-tasking option will know which script to run and in which working directory to run the par command after it reads the node list. The spawned task on the remote machine will run the “Env” file, then it will “cd” to the working directory before it runs PAR.

  Note

  The result of MAP (_map.ncd) must be in a directory location in which every ssh to every nodename has access.

There is also UNIX/Linux environment setup information for this feature in the Using the PAR Multi-Tasking (-m) Option section of the topic “Running PAR from the Command Line” on page 2473.

Running Multiple PAR Jobs in Parallel in Diamond When running the multi-tasking option on the PC, you should use a dual processor or multiple processor configuration, or the feature will provide no benefit. Currently, you cannot run the multi-tasking option using multiple networked PCs.

To run the PAR Multi-tasking on the PC with multiple processors:

1. Prepare a node list ASCII text file that identifies your machine (lpass4), system type (PC), and number of core processors (2). Include any desired comment lines.

   ```
   // This file contains a profile node listing for a multipar
   // PC job.
   [lpass4]
   SYSTEM = PC
   CORENUM = 2
   ```

   You must use the format above for the node list file and fill in all required parameters. Parameters are case insensitive. The node or machine names are given in square brackets on a single line.

   The System parameter can take the Solaris, Linux, or PC values, depending upon your platform. However, the PC value cannot be used with either Solaris or Linux because it is not possible to create a multiple computer farm with PCs. Corenum refers to the number of CPU cores or processors available on that single PC. Setting it to zero will disable the node from being used. Setting it to a greater number than the actual number of CPUs will cause PAR to run jobs on the same CPU, lengthening the run time. No further parameters are necessary on the PC.

2. Save your node list file and copy it to your top-level project directory. In our example, we named the node list my_nodelist.txt.
3. In Diamond, click **Project > Active Strategy > Place and Route Settings**.
4. Double click the **Value** cell for the **Multi-Tasking Node List** option and click the browse button.
5. Navigate to the file name in your project directory. If the file is located somewhere else, you must use an absolute file and path name, for example, *C:/my_projects/my_nodelist.txt*. PAR will issue an error message if it cannot find your node list file, for example:

   ```
   ERROR - par: Node name file  does not exist.
   ```

   If it cannot find your node list, PAR will continue in a serial fashion without using the node list file to specify the use of multiple processors.

6. Click **OK**.

   In our example, we opted to change the number of placement iterations to 3, the placement iteration starting point to 3, and limit the number of best saved runs to 2.

7. In the Process view in the Diamond environment, right click **Place & Route Design** and choose **Run** from the pop-up menu to run the flow through the Place & Route process.

   Rerun will run just the one process over again and nothing else. Rerun All will rerun the design flow up to the place and route process if selected.

   In the Output view or Automake Log, the multipar run will show that it ran all jobs and completed successfully.

```
---- Multipar Tool ----
Running par. Please wait . . .
Starting job 5_3 on node lpass4
Starting job 5_4 on node lpass4
Finished job 5_4 on node lpass4
Starting job 5_5 on node lpass4
Finished job 5_3 on node lpass4
Finished job 5_5 on node lpass4
Exiting par with exit code 0
Exiting multipar with exit code 0
Done: completed successfully.
```

   Notice that we chose the starting point of 3, so the jobs start at 5_3 instead of 5_1.

   After the run, PAR creates a <project_name>.dir directory in your top-level project directory with the respective NCD design files along with their .par and .pad report files. The following are example directory contents:

```
my_project.dir:
5_3.ncd        5_3.par        5_4.pad        test_view.par
5_3.pad        5_4.ncd        5_4.par
```

   In this example output directory only the best two runs were saved, as specified. Because the start point was the third iteration, it starts with 5_3. The 5 represents the effort level and the 3 the number of the run.

To learn more about how to use this feature from the command line, see the subsection Using the PAR Multi-Tasking (-m) Option of the topic “Running PAR from the Command Line” on page 2473. There is also information there about general usage, environment setup, screen output, interrupting jobs, and requirements.

See Also ▶“Running PAR from the Command Line” on page 2473

▶ “Using the PAR Multi-Tasking (-m) Option” on page 2487

Bit Generation

The **Bitstream File** process in the Process view or bit generation (**bitgen**) program takes a fully routed physical design, in the form of a circuit description (.ncd) file as input and produces a configuration bitstream (bit images). The bitstream file contains all of the configuration information from

the physical design that define the internal logic and interconnections of the FPGA, as well as device-specific information from other files associated with the target device.

The data in the bitstream can then be downloaded directly into the FPGA's memory cells or used to generate files for PROM programming. You can run **bitgen** from the Diamond window by double-clicking the **Bitstream File** process or from the command line.

See Also "Generating Bitstream Files" on page 641

- "Bit Generation Considerations" on page 642
- "Bit Generation Input Files" on page 640
- "Bit Generation Output Files" on page 640
- "Bit Generation Options" on page 638
- "Running Bit Generation from the Command Line" on page 2506

Bit Generation Options

Bit generation options provide you with control over the bit generation process. Bit generation options are accessed from the Strategy dialog box or the **bitgen** program from the command line. These options allow you to control the format of the bitstream output.

For more information on bit generation options see the following online help topics:

- Create Bit File, (ECP5, LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeSC/M only) will create or prevent creation of a bitstream file.
- No Header, (ECP5, LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeSC/M only) allows you to preclude the header information from the output bitstream.
- Output Format, (ECP5, LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeSC/M only) specifies the type of bitstream to create.
- Run DRC, runs a physical design rule check and saves the output to the Bit Generation report (.bgn file).
- Search Path, (LatticeSC PCS and some Sysbus only) specifies a file path or paths you want **bitgen** to search for a auto-configuration file.

Advanced Options:

- Address, (LatticeSC/M) is the bitstream mode.
- Chain Mode, allows daisy chaining with other devices.
- Enable I/O in Re-configuration, (LatticeSC/M only) programs the FPGA to drive outputs (not be tristated) during configuration/reconfiguration.
- External Clock, (LatticeSC/M only) is used for testing Master configuration modes.

- Grant Timeout, (LatticeSC/M only) controls an internal system bus grant counter that counts the number of HCLK (sysbus clk) cycles that go by before the grant signal is taken away from the master.
- LengthBits, (LatticeSC/M only) allows you to specify the number of allowable bits in the length field.
- Output Zero Frames, (LatticeSC/M) controls whether zero frames are written to the output bitstream.
- Register Configuration, (LatticeSC/M only) resets the PFU registers before configuration.
- Reset Config RAM in Re-configuration, re-initializes the device (reset) when you download a bitstream by default. If No reset is selected, the current configuration is retained allowing for additional bitstream configuration.
- SPI Start Address, specifies SPI start address. The SPI start address is a 6 or 8 digit hex string prefixed with 0x. The default is 0x00000000.
- Startup Clock, (LatticeSC/M only) uses CCLK or a User clock during startup.
- Sysbus Clock Config, (LatticeSC/M only) sets the system bus clock to either reset or not to reset after reconfiguration.
- Sysbus Config, (LatticeSC/M only) sets the system bus to either reset or not to reset after reconfiguration.
- Wait State Timeout, (LatticeSC/M only) controls an internal system bus timeout counter.
- XRES Calibration Control, (LatticeSC/M only) controls the calibration circuit connected to XRES pin.

JEDEC File Options: These options are for a separate process that generates JEDEC standard files for MachXO, MachXO2, MachXO3D, MachXO3L, and LatticeXP/2 devices instead of those by the generated Bitstream File (bitgen) for the other FPGA device families.

- Chain Mode, allows daisy chaining with other devices.
- Disable UES, (MachXO, MachXO3D, MachXO2, MachXO3L, LatticeXP/2 only) will generate JEDEC file that will not contain User Electronic Signature Data.
- ReadBack, (LatticeXP/2 only) allows you to extract the configuration data stored in an FPGA in order to verify the configuration.
- ReadCapture, (LatticeXP/2 only) enables or disables readback of the configuration bitstream.
- Reset Config RAM in Re-configuration, re-initializes the device (reset) when you download a bitstream by default. If No reset is selected, the current configuration is retained allowing for additional bitstream configuration.
- Run DRC, runs a physical design rule check and saves the output to the Bit Generation report (.bgn file).

See Also "Bit Generation" on page 637

- "Bit Generation Input Files" on page 640
- "Bit Generation Output Files" on page 640

Bit Generation Input Files

The following files are input to the **Bitstream File** process or the **bitgen** program:

- **Native Circuit Description File** (.ncd) — Input file for bit generation is an active, fully routed NCD file. This file is a physical description of the design in terms of the components in the target device.

See Also "Bit Generation" on page 637

- "Bit Generation Output Files" on page 640

Bit Generation Output Files

The following files are possible output to the **Bitstream File** process or the **bitgen** program:

- **Bit File** (binary) — binary (.bit) bitstream. Binary bitstream files are the default output of the bitstream process and contain the configuration information in bitstream (zeroes and ones) that is represented in the physical design (.ncd) file.
- **Raw Bit File** (ASCII) — ASCII (.rbt) bitstream. The Raw Bit File is a text file containing ASCII ones and zeros representing the bits in the bitstream file. If you are using a microprocessor to configure a single FPGA, you can include the Raw Bit file in the source code as a text file to represent the configuration data. The sequence of characters in the Raw Bit file is the same as the bit sequence that will be written into the FPGA. The .rbt file differs from the .bit file in that it contains design information in the first six lines.
- **Mask File** — mask (.msk) bitstream. Used to compare relevant bit locations for executing a read back of configuration data contained in an operating FPGA.
- **Bit Generation Report File** — bit generation report (.bgn). Outputs information on a bit generation (**bitgen**) run and displays information on options that are set. This file is output by default and will be given the name, design_name>.bgn.

See Also "Bit Generation" on page 637

- "Bit Generation Input Files" on page 640

Generating Bitstream Files

In Lattice Diamond, bitstream generation is automatically performed when you run the **Bitstream File** process for a a full design flow or a partial design flow. You can set bit generation options before running a design flow by setting a strategy.

To generate bitstream files from Diamond:

1. In the Diamond File List view, double-click the target strategy.

   The Strategy dialog box opens.

2. Under Process, select **Bitstream**.
3. In the right-hand pane, double-click the Value box for the Bitstream option that you want to edit, enter the new value or select a value from the drop-down list, and click **Apply**.

   Note

   When you highlight an option, its brief definition is displayed at the bottom of the dialog box. You can also click **F1** to view the detailed description.

4. When you finish, click **OK** to close the Strategies dialog box.
5. In the Diamond Process view, double-click **Bitstream File** to generate the bitstream files..

   Note

   MachXO3LF designs that do not use User Flash Memory (UFM) can be migrated to lower-cost MachXO3L devices, and a valid bitstream can be generated. The following two options are available when MachXO3LF is the selected device:

   - JEDEC File (XO3L Migration)
   - Bitstream File (XO3L Migration)

   This migration path is a time-saving feature that allows users to validate functionality and timing on a MachXO3LF project without having to recompile the design for the MachXO3L device. MachXO3L devices also do not support soft error correction or security encryption.

See Also ▶"Bit Generation" on page 637

- "Bit Generation Input Files" on page 640
- "Bit Generation Output Files" on page 640
- "Bit Generation Considerations" on page 642
- "Running Bit Generation from the Command Line" on page 2506

JTAG Setup

Using the **bitgen** program from the command line, you can generate setup bitstreams (.jbt) files to set JTAG port read and write for the FPGA device using the -J option. Downloading these setup bitstreams requires the serial cable with a JTAG cable connector.

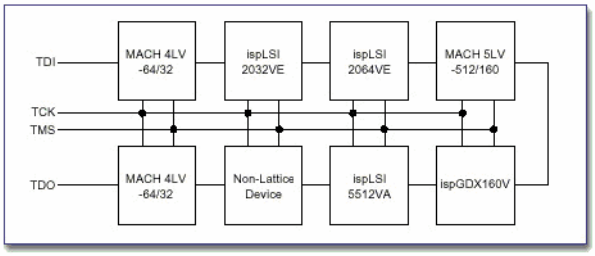
See Also ▶"Running Bit Generation from the Command Line" on page 2506

JTAG Scan Chains

A scan chain can include any programmable or non-programmable device compliant with IEEE-1149.1. It can also include any programmable devices that are compatible with IEEE-1149.1 but do not have a boundary scan register. This decision should be made on the basis of the test methodology employed for the board. If the test methodology employed is the traditional bed-of-nails approach used on board test systems, all the devices can be included in the same chain.

All scan chains use the simple four-wire TAP. The TCK and TMS pins are common to all devices included in the chain. TDI and TDO are daisy-chained from one device to the next. The input to the chain is TDI, and the output from the chain is TDO. A diagram demonstrating a simple scan chain is shown below.

Figure 110:



Bit Generation Considerations

Note the following user information that may require additional steps to implement bit generation options properly.

- If the device is to be configured in other than a serial (master or slave) mode, there are some limitations involving startup options and configuration pins used as outputs after configuration.
- Some former **-g** options for **bitgen**, which correspond to former strategy settings for **Bitgen** in the Strategies dialog box, are now handled by setting SYSCONFIG preference keyword values. See the preference "SYSCONFIG" on page 1250 topic for details and usage.

Analyzing your Design using Soft Error Injection

Ambient radiation occasionally collides with a circuit component in a way that alters its logical state. This effect is strongest at high altitudes, where the Earth's protective electromagnetic field is weaker. SEI (Soft Error Injection) Editor allows you to generate single-bit errors, insert them into a bitstream, and detect them for analysis, simulating the effect of radiation damage on the device's configuration memory. SEI Editor currently supports the following devices:

- ECP5U
- ECP5UM
- MachXO2
- MachXO3D
- MachXO3L/LF

SEI Editor is available after you have placed and routed your design and generated a bitstream.

See Also "Running SEI Editor" on page 643

- "Adding and Configuring a New Error with SEI Editor" on page 645
- "Removing an Error with SEI Editor" on page 645
- "Inserting an Error into a Device Using SEI Editor" on page 645

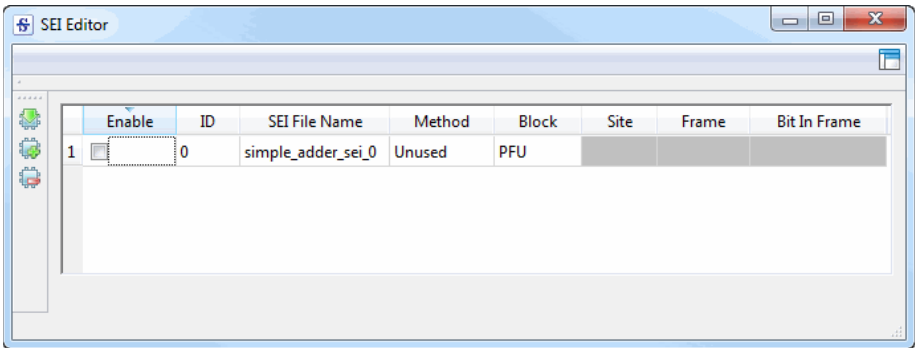
Running SEI Editor

You can run SEI Editor after you have placed and routed your design and generated a bitstream.

To run SEI Editor:

- Choose **Tools > SEI Editor**

  SEI Editor appears.



SEI Editor can manage multiple errors with a variety of options. The SEI Editor toolbar has three buttons:

- **Run** — Run all selected error insertions.
- **Add** — Add a new error for insertion.
- **Remove** — Remove the selected error insertion.

SEI Editor has the following columns:

- **Enable** — Select this option to insert the error described on the current row.
- **ID** — The error's ID number. This value is read-only.
- **SEI File name** — The name of the file containing the inserted error. You can modify this filename by double-clicking it and entering a new name.
- **Method** — This option determines whether the error is inserted into an unused or random block. Selecting Unused inserts the error into an unused block, which will not affect the design logic. Selecting Random inserts the error into a random block, which may or may not affect the design logic. You can change an error's Method by double-clicking it and selecting a new value from the drop-down menu.
- **Block** — The block where the error was inserted, in one of the following categories:
  - PFU
  - EBR
  - DSP
  - ANY
  - Routing
  - Unclassified

  You can direct errors into unused PFU, EBR, or DSP blocks, or into a randomly-chosen unused block. You can change the destination Block by double-clicking it and selecting a new value from the drop-down menu.
- **Site** — The exact Site of the inserted error. Errors inserted into a Routing block or Unclassified block do not have a Site. This field is read-only.
- **Frame** — The data frame of the inserted error. This field is read-only.
- **Bit In Frame** — The bit of the inserted error within the displayed data frame.

- "Analyzing your Design using Soft Error Injection" on page 643
- "Adding and Configuring a New Error with SEI Editor" on page 645
- "Removing an Error with SEI Editor" on page 645
- "Inserting an Error into a Device Using SEI Editor" on page 645

Adding and Configuring a New Error with SEI Editor

You can use SEI Editor to add new errors to your design.

To add and configure a new error:

1. Click **Add** .

   The tool adds a new, unconfigured error to the list.

2. Select the option in the Enable column to enable the new error.
3. Choose a new filename for the inserted error by double-clicking the current filename, typing a new one, and pressing Enter.
4. Choose a method by double-clicking the current method and selecting your preferred method from the drop-down menu.
   - If this error's method is Unused, you can choose a block by double-clicking the current block and selecting your preferred block from the drop-down menu.

See Also "Analyzing your Design using Soft Error Injection" on page 643

- "Running SEI Editor" on page 643
- "Removing an Error with SEI Editor" on page 645
- "Inserting an Error into a Device Using SEI Editor" on page 645

Removing an Error with SEI Editor

You can remove a previously inserted error from your design using SEI Editor.

To remove an error:

1. Click a cell in the row of the error you want to remove.
2. Click **Remove** .

See Also "Analyzing your Design using Soft Error Injection" on page 643

- "Running SEI Editor" on page 643
- "Adding and Configuring a New Error with SEI Editor" on page 645
- "Inserting an Error into a Device Using SEI Editor" on page 645

Inserting an Error into a Device Using SEI Editor

Once you have inserted an error into your design, you can insert the error into your device using Diamond Programmer.

To insert the selected errors into a device:

1. Click **Run** .

   The SEI tool generates a partial bitstream with the selected errors.

2. Program the original bitstream into the device using Diamond Programmer. Refer to "Programming the FPGA" on page 799.
3. In Diamond Programmer, program the partial bitstream into the device using the **Static RAM Cell Background Mode** and **XSRAM SEI Fast Program** Programmer settings**.**

See Also "Analyzing your Design using Soft Error Injection" on page 643

- "Running SEI Editor" on page 643
- "Adding and Configuring a New Error with SEI Editor" on page 645
- "Removing an Error with SEI Editor" on page 645

PROM Generation

After creating a bitstream file through bit generation, you can store the configuration information in a PROM file. The **PROM File** process takes one or more bitstreams (.bit or .rbt files) and creates a PROM-formatted file in one of three widely used PROM formats: Intel's MCS-86, Motorola's EXORMACS, or Tektronix's TEKHEX.

There are three common storage methods:

- One design in one PROM.
- Individual designs stored separately in one PROM. This is useful when you want to use a single PROM to reprogram the same device with different designs.
- Several different designs concatenated in the same or multiple PROMs. This approach is likely when you want to program several devices in a daisy chain or when using a PROM that is too small to store the complete bitstream for the target FPGA.

See Also "Generating PROM Files" on page 647

- "PROM Generation Input Files" on page 647
- "PROM Generation Output Files" on page 647

PROM Generation Options

PROM generation options provide you with control over the PROM generation process. PROM generation options are accessed from Properties of the **PROM File** process. These options allow you to control the format of the PROM file output. PROM.

For more information on PROM generation options see the topic "PROM Data Output Format" on page 1159.

See Also "PROM Generation" on page 646

- "PROM Generation Input Files" on page 647

▶ “PROM Generation Output Files” on page 647

PROM Generation Input Files

The following files are possible input to the **PROM File** process:

- **Bit File** (binary) — binary (.bit) bitstream. Binary bitstream files are the default output of the bitstream process and contain the configuration information in bitstream (zeroes and ones) that is represented in the physical Native Circuit Description (.ncd) file.
- **Raw Bit File** (ASCII) — ASCII (.rbt) bitstream. The Raw Bit File is a text file containing ASCII ones and zeros representing the bits in the bitstream file.

The input to the Prom Generation process is one or more bitstreams (.bit or .rbt files). These files are generated in the **Bitstream File** process during a design flow run in Diamond or by using the Bit Generation (**bitgen**) command from the command line.

See Also ▶“PROM Generation” on page 646

▶ “PROM Generation Output Files” on page 647

PROM Generation Output Files

The following files are possible output to the **PROM File** process or the **promgen** program:

- **PROM file** — contains configuration information used to program the PROM. This file will have an extension of .mcs (Intel MCS-86), .exo (Exormacs), or .tek (TekHex), depending upon the selected PROM format.
- **PROM Image File** — contains a memory map of the newly created PROM file showing the starting and ending PROM address for each bitstream (.bit file) loaded. This file has a .prm extension.

See Also ▶“PROM Generation” on page 646

▶ “PROM Generation Output Files” on page 647

Generating PROM Files

After creating a bitstream file with bit generation, you may want to store the configuration information in a PROM. You can use the bitstream file you have created by running the design flow as your input for the PROM Generation. When using the Diamond window, the bitstream file will be in the project directory.

PROM options should be set before running the PROM generator. The PROM generator takes bitstreams and creates PROM image files for PROM configuration. You can set PROM options in the Strategy dialog box.

To generate PROM files from the Diamond window:

1. In the Diamond File list view, double-click the target strategy.

   The Strategies dialog box opens.

2. Under Process, select **Bitstream**.
3. In the right-hand pane, double-click the Value box for the Bitstream setting that you want to edit, enter or select the new value, and click **Apply**.
4. When you finish, close the Strategies dialog box.
5. In the Diamond Process view, double-click the **PROM File** process to generate the PROM files.

Using Incremental Design Flow

The Incremental Design flow feature is supported for LatticeECP2M and LatticeECP3 devices. Incremental Design is a design methodology that preserves certain process results and performance on portions of a design while reducing re-processing time by focusing on other parts of the design during multiple design processing iterations. It accomplishes this by using design partitions you define in synthesis. Partitions allow you to lock down and preserve timing stability by preventing specified modules from being changed in the next design iteration.

In addition to partitions, the Incremental Design flow uses a previous design file to guide the rest of your design implementation toward smaller, more incremental changes. Using this strategy, you no longer have to re-implement your design from the beginning which forces changes that effect the technology mapping and layout of your entire design. Using a reference design, your previous I/O placement also remains intact.

You might consider using the Incremental Design flow for the following reasons:

- It reduces re-processing runtime during multiple iterations.
- It preserves previous timing results on portions of a design during multiple iterations.
- It minimizes runtime variations for design changes during multiple iterations.
- It helps achieve timing closure by partition planning and coding improvement.

The Incremental Design flow in Diamond requires you to first specify design partitions during synthesis in the top-level Synplify FPGA Design Constraints (.fdc) file. Design partitions are defined by the “Compile Points” feature in Synplify Pro, which enables you to create constraints in the .fdc file that tell the synthesis compiler to preserve and timestamp modules. So, partitions allow you to “lock” these portions of your design to preserve the logic through synthesis and mapping if there is no source code change to a partition. Place and Route (PAR) later will determine how components fall into the design layout with the aid of a partition planning utility within the PAR tool that is specific to this flow in Diamond.

Once you associate your .fdc file with your Diamond project and turn on the incremental flow mode, the PAR output of this mode is a reference physical design (NCD) file. Diamond incremental flow will use this placed-and-routed reference NCD to help guide your design through the next processing iteration and take advantage of improved runtime and timing stability.

Through appropriate partition planning and coding improvement, the incremental design methodology will help achieve timing closure through multiple iterations. With today's ever-increasing FPGA densities to meet more complex applications, it can be challenging to meet your design goal. These designs are usually comprised of multiple function blocks and each block may have significant amount of logic or it may perform a specific task that requires being addressed separately using "divide and conquer" approach.

Incremental Design allows you to isolate and lock down satisfactory portions of such a design and focus on others. At a minimum, reducing your runtime on larger designs using this methodology will give you more time to work on portions of your designs that need more work.

The Incremental Design Data Flow The section describes each design entry and implementation phase of the Incremental Design flow in terms of how data is processed in the Diamond environment through its various core tools. Figure 1 below illustrates the flow to provide you with a good basic understanding of how the flow works within the system.

The following list provides a high-level outline on how the Diamond Incremental Design flow works and how data is processed through each step:

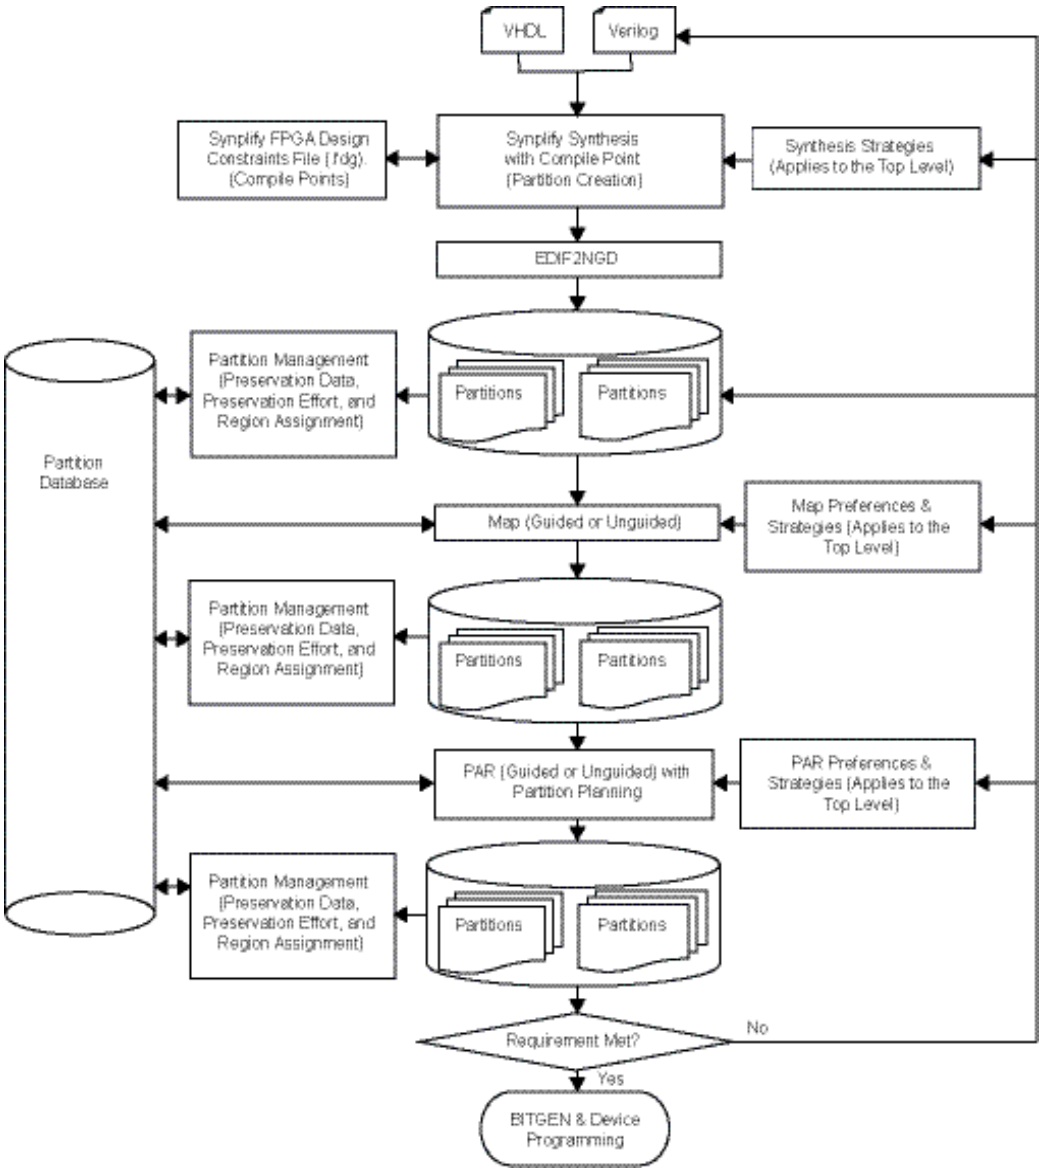
1. You begin by defining your design partitions using "compile points" in top-level .fdc file using Synplify Pro. The type of compile point that is required for Incremental Design flow in Synplify Pro is {locked, partition}.
2. Synplify Pro runs a partition-based synthesis using compile point constraints. The output EDIF file has "partition" properties labeled on modules instances. These include timestamps from Synplify Pro.
3. The Design Translation process (EDIF2NGD and NGDBUILD) recognizes and honors "partition" properties and passes them onto their output NGO and NGD files, respectively. Other than passing the properties, these two processes are exactly the same as in the normal flow.
4. The Map process can optionally use the previous PAR NCD result as the reference to guide the process for each partition, according to user settings set through the Partition Manager. Otherwise, new mapped data for a partition (or the whole design, depending on user settings) will be generated.
5. The PAR process can optionally use the previous PAR NCD result as the reference to guide the process for each partition, according to user settings set through the Partition Manager. Otherwise, new PAR data for a partition (or the whole design, depending on user settings) will be generated.
6. View process reports in the Diamond Report window. If the PAR process finished successfully (err code 0, regardless of timing score), its result is ready to be used as the reference for the next iteration.

This guide consists of the following sections.

"Running the Incremental Design Flow" on page 652

This section focuses on running the actual Incremental Design flow in Synplify-Pro and Lattice Diamond.

Figure 1: Incremental Design Data Flow



"Using Partition Manager" on page 661

This section describes the Diamond Partition Manager tool in detail and its role in the flow.

"Recommended Strategies for Incremental Design" on page 674

This section provides advice to make the best strategic design decisions to help you avoid issues during the flow and get the best results.

"Troubleshooting Error and Warning Messages" on page 682

This section lists any common errors or warnings that you might encounter in the flow and provides you solutions for working around them.

Running the Incremental Design Flow

This section provides all description and procedural information you need to know to run a complete Incremental Design flow through Diamond software. A list of Tcl commands is provided in “Incremental Design Flow Tcl Commands” on page 2601.

Along with the steps provided within this chapter, there are two additional requirements for running the Incremental Design flow in Diamond. These requirements are as follows:

- Create a Synopsys FPGA Design Constraints (.fdc) file with compile points in Synplify Pro so that the Incremental Design flow can function properly within Diamond.
- All work in your Diamond project directory should be kept within one Diamond project implementation so that your reference files do not become disassociated with your target design.

Take the following steps to implement an incremental design in Diamond:

1. Create a new Diamond project and implementation; add HDL files as necessary.
2. Turn on incremental flow by choosing **Design > Enable Incremental Design Flow.**
3. Launch the Lattice OEM version of Synplify Pro from within Diamond. The Synplify Pro project should be created automatically for you. In Synplify Pro, create a top-level Synopsys FPGA Design Constraints (.fdc) file. This file is necessary for defining design partitions for synthesis. See “Creating Partitions in Synplify Pro” on page 653.
4. In Diamond, add your .fdc file to incremental flow enabled implementation. See “Running Incremental Design in Diamond” on page 655.
5. Run synthesis, Map, and PAR in Diamond. You can run this from the Tcl Console if you prefer to do so. See “Running Incremental Design in Diamond” on page 655.
6. Analyze static timing using the Timing Analysis view (Timing Preference file) or the Place & Route Trace process (TRACE Report file) to determine how close you are to meeting your design’s timing constraints.

   The TRACE report and Timing Analysis view analysis tools should provide indicators that tell you about resource utilization and alert you to any possible timing issues. You should also review Map and PAR reports. Review these reports to ensure that the data results make sense in regard to what you would expect to see in your design.

   If you are not already aware of the module or modules that you need to re-implement without locking down its logic using synthesis directives for recompile and re-synthesis, the reports should make this clearer. See “Viewing Reports for Incremental Design” on page 659.
7. if PAR finishes successfully, the PAR NCD will be used as a reference automatically during the next processing iteration. If necessary, you can modify your code; change strategies, preferences or partition management settings; and run the next processing iteration

To perform these steps follow the detailed procedures described in “Creating Partitions in Synplify Pro” on page 653 and “Running Incremental Design in Diamond” on page 655, respectively.

Creating Partitions in Synplify Pro

You create design partitions for your source files by creating a top-level Synopsys FPGA Design Constraints (.fdc) file in Synplify Pro. You need to generate an .fdc file and later associate it with your Diamond project for the Incremental Design flow to work properly and generate data later in the flow.

To create an .fdc file using the standalone Synplify Pro tool:

1. Open your incremental design flow project in Diamond. This procedure assumes that you have already created a project and an implementation, turned on the incremental flow for the implementation for your design (see “Running Incremental Design in Diamond” on page 655), and imported your source files into your Diamond project.
2. In Diamond, choose **Tools > Synplify Pro for Lattice** or click the  toolbar button. Synplify Pro opens.

   Notice that Synplify Pro automatically imports in all of your source HDL files and uses your project name in Diamond but appends “_syn” to the project name. In addition, it sets the same device family in both implementation and synthesis projects. It is important to open Synplify Pro from Diamond instead of launching from the Start menu or from some other installation so that the synthesis project inherits the project characteristics from Diamond.

   Now you will see your source files in a folder in your Project view. For example, if they are Verilog files the folder will be named accordingly.
3. Choose **Run > Compile Only** or **F7**. This enables the Synopsys FPGA Design Constraints (.fdc) file to be initialized, which allows you to define compile points.
4. Click the  **New Constraint File** toolbar icon.
5. In the New Constraint File dialog box, click **Constraint File (Scope)** and, in the Create a New Scope File dialog, ensure that the default options are checked or selected and click **OK**:

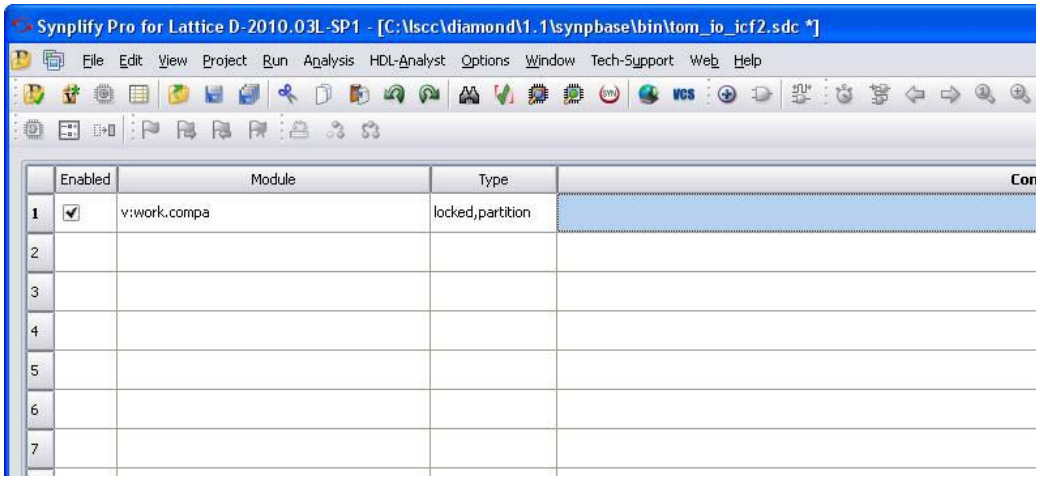
   - Initialize Constraints tab: **Clocks, I/O Delays**
   - Select File Type tab: **Top Level**

   An interactive SCOPE spreadsheet referred to as the Compile Points panel opens. This panel allows you to specify the compile points of your design, and to enable or disable them. Compile points specify design partitions. Note that this panel is only available when defining a top-level constraint file, and only if the device technology supports the compile points.
6. Click on the Maximize button on the top right of the window’s title bar to view the entire SCOPE spreadsheet and choose the **Compile Points** tab.

You now will see a blank spreadsheet with Enabled, Module, Type, and Comment columns.

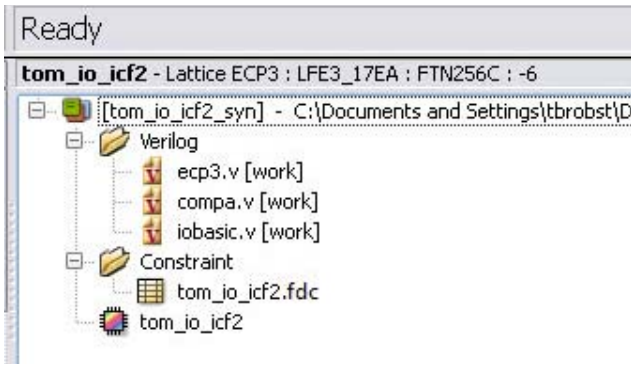
7. Double click on the top row's Module column cell and choose a module that you want it to be a partition from the drop-down menu that appears to the right. In addition, in the Type cell, choose **locked, partition** for each chosen module and ensure that each module is enabled with the check box in the far left column. Repeat these steps for each module that you want it to be a partition in your design.

Figure 2: Creating Locked Partition Constraints in SCOPE Spreadsheet



8. To save your FPGA Design Constraints (.fdc) file in the default synthesis project location, choose **File > Save** and click **Yes** in the prompt dialog.

Figure 3: Project View in Synplify Pro after .fdc File Creation



Please take notice that in the Project view a Constraint folder is created that contains your newly created .fdc file. After you complete this procedure, you should begin the procedure described in the next section "Running Incremental Design in Diamond" on page 655.

Note

You can create an .fdc file using any text editor. It is strongly recommended that you open your .fdc file inside the Synplify Pro constraints editor to check whether the module names are correct. Undefined module names, for example, due to parameterized modules having a name that includes their parameter values, will show in yellow and can be easily corrected here.

See Also ▶"Running the Incremental Design Flow" on page 652

Running Incremental Design in Diamond

After you have created a FPGA Design Constraints (.fdc) file using Synplify Pro as described in "Creating Partitions in Synplify Pro" on page 653, you can begin the procedure of implementing your incremental design in Diamond. This topic describes how to associate that .fdc file with your project, turn on the incremental run modes, and implement your design.

To run the Incremental Design flow in Diamond:

1. Open your incremental design project in Diamond. To enable the incremental design flow for the active implementation, choose **Design > Enable Incremental Design Flow,** or enter the following command in the Tcl Console window at the prompt:

   ```
   prj_incr set -enable
   ```

   The words "Incremental Design Flow" will appear in a yellow box in the upper right corner of the Diamond main window, indicating that the Incremental Design flow is enabled.

   Note

   This procedure presumes that you have completed the first step described in the "Creating Partitions in Synplify Pro" on page 653 topic aand have created an .fdc file to associate with your Diamond project. The Incremental Design flow is only possible if the design includes compile points created during synthesis..

2. Right-click the Synthesis Constraint Files folder in the File List view, and choose **Add**.
3. Choose **Existing File**, and in the Add Existing File dialog box, browse to the .fdc file you generated in the procedure "Creating Partitions in Synplify Pro" on page 653, and click **Add** to target it for use during synthesis. Right-click the added .fdc file, and choose **Set As Active**.
4. In the Process view, double click the **Place & Route Design** process to run the incremental design flow through synthesis, mapping, and place & route.

Be aware that after this point the Map program generates partition database data that contains partition definitions, packing, and optimization strategies that Map uses based on the defined partition.

If this first processing iteration completes successfully, the software automatically creates a backup copy of the placed-and-routed data and stores them in a subfolder called “inc1” inside the Diamond implementation folder. In future design iterations. If PAR completes successfully, these files in “inc1” will be overwritten with the results of the new run and the previous results files in “inc1” are copied to “inc2”, so you have a backup reference design available to you.

Note

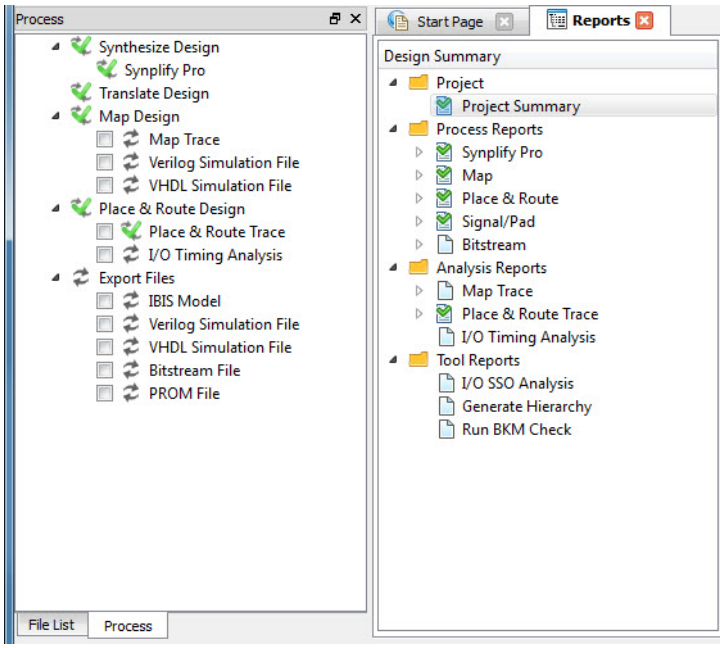
These folders (inc1, inc2, etc.) and files in them are not directly accessible in the Diamond GUI. You must navigate to them using Windows. These folders, and the files in them, are managed by Diamond. You should not manually manipulate them.

For more information on restoring or backing up previous incremental design runs, see the “Backing Up an Incremental Design Run” on page 657 and “Restoring Previous Incremental Design Results” on page 658 topics in this chapter.

It is highly recommended that you use the **File > Archive Project** command (archiving all files) to save the state of your project. See “Archiving Incremental Design Results” on page 659.

5. In the Process view, double click the **Place & Route Trace** process to run post PAR trace and get the timing results on your placed-and-routed NCD file.

Figure 4: Process List Indicating Successful Design Run



6. Use the Report viewer tab in the center panel to open your Map and Place & Route Process Reports; and your Map Trace and Place & Route Trace Analysis Reports.

   To ensure that the results of your design run are satisfactory, see “Viewing Reports for Incremental Design” on page 659, which describes what key elements of the reports you should be viewing.

7. After reviewing the result, you can make necessary HDL code changes, adjust preferences and strategies, set partition controls, and then repeat the process from step 4. above. For setting partition controls in order to fine control the next core processing iteration, use Partition Manager. Refer to “Using Partition Manager” on page 661.

   When you rerun the design flow to start another core processing iteration, the NCD file in “inc1” will be used as the reference design for both Map and PAR. The flow will copy the reference files from “inc1” to the working directory before Map is run.

   Note

   So that Synplify Pro correctly handles partition information, you must stay in your original Diamond project implementation in which you began your incremental design. If you want to create a new implementation and copy source correctly, Synplify will still not reference its partition files. This flow is not ideal for using across multiple project implementations because it relies on a referencing files it uses to guide synthesis and implementation in a relative way.

   Note

   If you perform the **Rerun** process on a synthesized design, or the **Rerun All** process, your synthesis result will be erased and regenerated. Any runtime savings that were gained by preserving the result will be lost, because the preserved result will have been erased.

See Also ▶“Running the Incremental Design Flow” on page 652

▶ “Incremental Design Flow Tcl Commands” on page 2601

Backing Up an Incremental Design Run

You can preserve a “golden” set of PAR reference files from a successful Incremental Design run into a “ref” folder in your Diamond project.

To back up a set of design files in the Incremental Design flow:

- In the Run Manager, right-click on the selected Implementation <strategy > and choose **Incremental > Backup as Golden Reference.**

or

- In the Tcl Command Console, enter the following command:

  ```
  prj_incr backup_golden -impl <implementation name>
  ```

Performing this task saves a backup of your current files in “inc1” to a newly generated “ref” folder and prevents them from being overwritten on future design runs. This allows you to start your design over again from an ideal starting point that you chose rather than from a possible undesirable point in a later iteration.

See Also ▶See “Running the Incremental Design Flow” on page 652

- “Incremental Design Flow Tcl Commands” on page 2601

Restoring Golden Backup Files

If for some reason you want use the golden backup files as the reference to guide the next core processing iteration, you can restore them.

To restore your golden backup files in the Incremental Design flow:

- In the Run Manager, right-click on the selected Implementation <strategy > and choose **Incremental > Restore Golden as Reference.**

or

- In the Tcl Command Console, enter the following command:

  ```
  prj_incr restore -impl <implementation name> golden
  ```

  Performing this task copies your “golden” backup files in “ref” folder and overwrites your file set in the “inc1” folder, restoring them as the reference for future design runs.

See Also ▶“Running the Incremental Design Flow” on page 652

- “Incremental Design Flow Tcl Commands” on page 2601

Restoring Previous Incremental Design Results

When a core processing iteration completes successfully, this iteration's reference files are copied from /inc1 to /inc2, and this iteration's PAR results are copied to /inc1 and will be used as reference for the next iteration. If for some reason you still want to use the previous reference (in /inc2) to guide the next iteration, you can restore it.

Note

Whenever you run an iteration of your Incremental Design project, your previous results are overwritten in the “inc1” folder in your project implementation directory and moved to the “inc2” folder. However, the software will automatically use whatever is in “inc1” as reference input into its next iteration, not those files in “inc2”.

To restore the previous reference files for Incremental Design:

- In the Run Manager, right-click on the selected Implementation <strategy> and choose **Incremental > Restore Previous Reference.**

or

- Enter the following command in the Diamond Tcl Console window at the prompt:

```
prj_incr restore -impl <implementation name> previous
```

This command restores the previous design run as your reference design in “inc1”, overwriting your last results with the file that was moved to the “inc2” folder. You should have matching file sets in both “inc1” and “inc2” folders.

Note

For the Incremental Design flow to work, the Map process must be rerun on the new reference design. So, restoring a previous result will force the Process List to reset its run status before the Map process.

See Also “Running the Incremental Design Flow” on page 652

- “Incremental Design Flow Tcl Commands” on page 2601

Archiving Incremental Design Results

It is recommended that you use the **File > Archive Project** command to retain the original state of your project. There may be a case in which you might wish to return to your original input source file set or you might want to know what the original file set contained. After many iterations and result files overwrites, it could be difficult to keep track of this.

In addition, you may wish to archive incremental design runs that are close to satisfying your design goals so if future iterations take you further away from your goals you can go back to a point that does not force you to start over.

See Also “Running the Incremental Design Flow” on page 652

Viewing Reports for Incremental Design

This section introduces you to the reports and the specific subsections in them that you should view to evaluate your incremental design run. It also will give you tips and clues to better go about verifying what resources were generated and if they meet expectations.

To view reports for your incremental design:

1. Double click on the appropriate report in either the **Process Report** or **Analysis Report** folder. This assumes that you have run a design flow and that there are generated report files.

2. View the report in the panel to the right and use the scroll bars to navigate to portions of the report that you wish to view.

To use the Timing Analysis view to analyze your incremental design:

1. After you have run through Place & Route design, choose **Tools > Timing Analysis view**.
2. In Timing Analysis view, click on a defined timing preference in the preference window in the lower left corner of the view. The Path Table and the Detailed Path Table spreadsheet information is populated with various data on delay and timing related to that preference.
3. In the bottom right of the Timing Analysis view, click on the **Reports** tab. Notice that as you scroll through the timing report, the elements reported on are highlighted in blue.
4. Right click on some design element in the report and choose either **Show in FP View** or **Show in Physical View** from the popup menu.

See Also ▶"Running the Incremental Design Flow" on page 652

Using Partition Manager

Partition Manager is the Diamond graphical user interface (GUI) used to perform such tasks such as preservation data control, re-implementation effort control, region assignment, and acts as the central interface between the user and partition database.

Partition Manager is only available if Incremental Flow is enabled for an implementation in the project and can be run when the flow is at the pre-Map, post-Map, or post-PAR stage.

Partition Manager can be used after the post-Map stage to create new partitions, edit partition information or remove existing partitions. New partitions can be created for hierarchical modules. You can edit existing partition information such as partition's preservation data level, reimplementation effort, anchor and bounding box. Existing partitions can be deleted and the flow rerun without the deleted partitions.

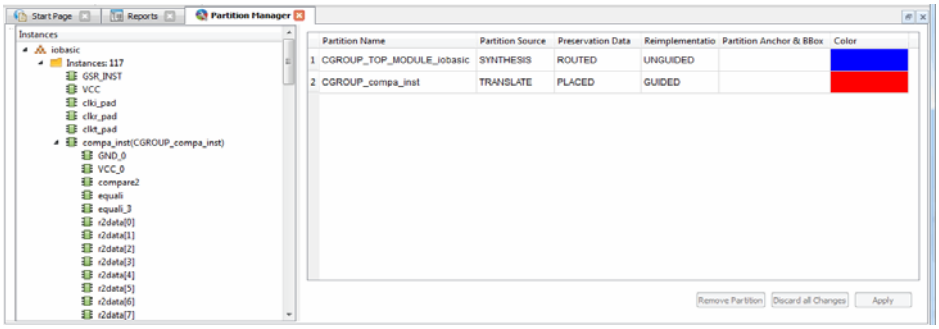
When a partition's information has been updated in either Partition Manager or Floorplan View, the Diamond process is reset to the Translate process.

The GUI for the Partition Manager is in the form of a table. Each row corresponds to a partition in the project. The columns for each row are for the partition name, partition source, the preservation data, the reimplementation effort, the partition anchor and bounding box. All attributes except Partition Name and Partition Source may be edited.

Default values are shown in blue. Anchor and bounding box cells are blank if they are not set for the partition. The top partition module in the project is always in the first row. A color selection box allows you to change the color of the partition in as it appears in Diamond Floorplan View.

The Partition Manager view is shown in Figure 5.

Figure 5: Partition Manager View



An asterisk will appear in the Partition Manager title bar, as shown in Figure 5, if any partition parameters have been modified. Changes can be discarded before they are applied by clicking the **Discard All Changes** button. Changes must be applied by clicking the **Apply** button.

A partition can be added by right-clicking a hierarchical module in the Instances pane on the left side and choosing Create Partition from the pop-up menu.

A partition can be removed by highlighting the partition and clicking the Remove Partition button, or by highlighting a partitioned hierarchical module in the Instances pane on the left side and choosing Remove Partition from the pop-up menu.

Preservation Data Preservation Data allows the user to define partition based implementation process data to be preserved during the next core processing iteration. When it is defined, and if there is no change to invalidate the defined preservation data for the partition, the defined data will be copied from the reference files during the next iteration. All the data after the defined data will be regenerated and the reference is ignored.

Levels of preservation data include:

- Synthesis
- Mapped
- Placed
- Routed

For example, if a partition's preservation data is set to “Mapped”, during the next core processing iteration, if there is no change (such as source code change) to invalidate this partition's mapped result, the new mapped result for this partition will be copied from the reference files. Placed and routed results for this partition will be regenerated regardless of the reference files. If the reference doesn't exist, the new mapped result will be regenerated as well.

Reimplementation Effort If the Preservation Data defined above is invalidated (due to the source code change, for example) and cannot be preserved, Reimplementation Effort allows the user to specify during the next core processing iteration whether the core processes (Map, Placer and Router) should use the reference to guide it (Guided) and generate a new result, or ignore the reference (Unguided) and regenerate a new result.

Preservation Effort has two choices

- Guided
- Unguided

Using the same example as above, if the preservation data was set to “Mapped” and the reimplementation effort was set to “Guided”, during the next core processing iteration:

1. If there is no change to invalidate the defined “mapped” data for the partition, the mapped result will be copied from the reference. Placed and routed results will be regenerated regardless of the reference.
2. If there are changes (such as source code changes) that invalidates the defined “mapped” data for the partition, the reference will be used to “guide” Map to generate a new mapped data. Placed and routed results will be regenerated regardless of the reference.

Similarly, if the preservation data was set to “mapped” and the preservation effort was set to “Unguided”, during the next core processing iteration:

1. If there is no change to invalidate the defined “mapped” data for the partition, the mapped result will be copied from the reference. Placed and routed results will be regenerated regardless of the reference.
2. If there are changes (such as source code changes) that invalidates the defined “mapped” data for the partition, the reference will be ignored. Map will generate new mapped data. Placed and routed results will be regenerated regardless of the reference.

The expected result of the Reimplementation Effort setting, combined with Preservation Data setting, for each partition, is described in Table 1.

Table 1: Preservation Data and Reimplementation Effort Setting Description

Preservation Data Setting	Reimplementation Effort Setting	Expected Result
Synthesis	Guided	Map, place, and route results will be regenerated without using the reference.
Mapped	Guided	If the mapped data is still valid, copy from the reference. Otherwise, use the reference to guide and regenerate mapped data. Placed and routed data will be regenerated regardless of the reference.
Placed	Guided	If the placement data is still valid, copy from the reference, Otherwise, use the reference to guide and regenerate placement data. Routing data will be regenerated regardless of the reference.
Routed	Guided	If the routing data is still valid, copy from the reference. Otherwise, use the reference to guide and regenerate routing data.
Synthesis	Unguided	Map, place, and route results will be regenerated without using the reference
Mapped	Unguided	If the mapped data is still valid, copy from the reference. Otherwise, ignore the reference and regenerate map data. Placed and routed data will be regenerated regardless of the reference.
Placed	Unguided	If the placement data is still valid, copy from the reference. Otherwise, ignore the reference and regenerate placement data. Routing data will be regenerated regardless of the reference.
Routed	Unguided	If the routing data is still valid, copy from the reference. Otherwise, ignore the reference and regenerate routing data.

Preservation Data and Reimplementation Effort settings control only Map, Place and Route. The synthesis process is not controlled by these settings. Synthesis is controlled by Synplify Pro.

Changing only preservation data and/or reimplementation effort settings will not reset the flow. To force any changes to take effect without changing the source code, in the Diamond Process view, right-click on Place and Route Design and choose **Rerun All**.

The default preservation data setting is “Placed.” The default reimplementation effort setting is “Guided.”

Anchor and Bounding Box The partition's anchor and/or bounding box (BBox) are editable with the Partition Anchor and BBox dialog box. The dialog box specifies, based on the device, acceptable values for row, column, height, and width.

After making the desired changes to the partitions, the changes will be applied to the implementation. If the anchor or bounding box changes were made after a successful PAR, the process will be reset to before PAR.

When the user closes the Partition Manager, if changes were made but not applied or reverted, a dialog appears asking “Do you want to save your in-memory ICF changes into <*file_name*>.icf?” with the options of **Yes**, **No**, and **Cancel**.

When the user closes Diamond, if changes were made but not applied or reverted, a dialog appears listing changes that need to be saved. The user may select the file if he wants changes to be saved to it before closing.

Running the Partition Manager

If you have an active implementation with incremental design flow enabled, after synthesis and translation, you can run the Partition Manager.

To run the Partition Manager:

1. Diamond, choose **Tools > Partition Manager** or click the  toolbar button.

- “Removing a Partition Using Partition Manager” on page 669

Creating a New Partition with the Partition Manager

You can create a new partition to hierarchical modules in an incremental design after the MAP process has been run.

To create a new partition with Partition Manager:

1. Right-click a hierarchical module in the Instances pane on the left side and choose **Create Partition** from the pop-up menu.
2. In the Partition Anchor and BBox dialog box, you can either accept the default Anchor and Bounding box settings, or you can specify Anchor and Bounding box locations, and then click **OK**.

- “Removing a Partition Using Partition Manager” on page 669

Setting Preservation Data

You can set the partition data to be preserved and used for the next incremental iteration in Partition Manager. Preservation data includes partition processing results including synthesized data, mapped data, placement data and routed data.

To set Preservation Data in Partition Manager:

1. Double-click the Preservation Data cell of the Partition Name row you wish to set. You can also right-click on the cell to display a menu with the preservation data options. This menu has a “Clear” option to reset the preservation data level to the default value.
2. In the drop-down menu, select from **Synthesis**, **Mapped**, **Placed**, or **Routed** data you wish to preserve.
3. Click **Apply** when finished editing. To discard all changes and revert to the last save, click **Discard All Changes**.

- “Removing a Partition Using Partition Manager” on page 669

Setting Reimplementation Effort

You can set the partition effort for changed partitions to determine how previous processing results are used during the current incremental iteration.

To set Reimplementation Effort in Partition Manager:

1. Double-click the Reimplementation Effort cell of the Partition Name row you wish to set. You can also right-click on the cell to display a menu with the reimplementation effort options. This menu has a “Clear” option to reset the reimplementation effort level to the default value.
2. In the drop-down menu, select from **Guided** or **Unguided**.
3. Click **Apply** when finished editing. To discard all changes and revert to the last save, click **Discard All Changes**.

- “Cross-Probing Partitions from Partition Manager” on page 669
- “Removing a Partition Using Partition Manager” on page 669

Setting Preservation Data or Reimplementation Effort for Some or All Partitions at the Same Time

You can set the partition effort or Reimplementation Effort for some or all partitions at the same time.

To set some or all partitions to same Preservation Data or Reimplementation Effort in Partition Manager:

1. Select some items, or all items, from the Preservation Data column or Reimplementation column, and right-click.
2. In the pop-up menu, choose one of the following:

- For Preservation Data, select from **Synthesis**, **Mapped**, **Placed**, or **Routed** data you wish to preserve.
- For Reimplementation Effort, select from **Guided** or **Unguided**.

3. Click **Apply** when finished editing. To discard all changes and revert to the last save, click **Discard All Changes**.

- "Removing a Partition Using Partition Manager" on page 669

Specifying Partition Anchor and Bounding Box

You can set the partition anchor and bounding box within the device architecture using Partition Manager. As values are changed, the number of LUTs, REGs, and EBRs encompassed by the bounding box will be shown in the dialog.

To set specify partition anchor and/or bounding box:

1. Double-click the Partition Anchor & BBox cell of the Partition Name row you wish to set, or right click the cell and choose Edit Anchor and BBox, to display the Position Anchor and BBox dialog box.
2. If modifying anchor, check the **Anchor** box and specify Row and/or Column.
3. If modifying bounding box, check the **BBox** box and specify Height and/or Width.
4. Click **OK**

When a partition has been edited and applied in Partition Manager, the Diamond process is re-set to the pre-Map process**.**

Note

Anchor and bounding box can also be edited in the Floorplan View. Refer to "Editing Partitions in Floorplan View" on page 672.

- “Removing a Partition Using Partition Manager” on page 669

Changing Partition Colors

You can change the partition colors that display in Diamond Floorplan View by using the Color selection box in Partition Manager.

To change the color of a partition in Partition Manager:

1. Double-click the item you want to change. The Select Color dialog box opens.
2. Select a color by doing one of the following:
   - Click one of the basic colors on the left.
   - Click in the color pallet on the right.
   - Enter values in the boxes at the bottom right. Work in one column or the other as they are two separate methods of coding color.

     The rectangle in the lower-middle changes to show the selected color. You can change the darkness with the vertical slider at the upper-left.
3. Click **OK**.

Cross-Probing Partitions from Partition Manager

You can cross probe and view partitions in either Diamond Floorplan View or Physical View from Partition Manager. In order to perform cross probing, the partitions must have anchor and bounding box set.

To cross probe a partition in Floorplan View from Partition Manager:

1. In Partition Manager, highlight the Function Name, Preservation Data, Reimplementation, Partition Anchor & BBox, or Color box in a partition.
2. Right-click, and in the dropdown menu, choose either **Show In > Floorplan View** or **Show In > Physical View**.

Removing a Partition Using Partition Manager

You can remove a partition using Partition Manager.

To remove using Partition Manager:

1. In Partition Manager, highlight the partition you wish to remove.
2. Click **Remove Partition,** then click **Apply**.

   or:

   Right-click a partitioned hierarchical module in the Instances pane on the left side and choose **Remove Partition** from the pop-up menu.

   The partition will be removed when the Translate process is re-run.

Floorplan View and Physical View Partition Support

Both Floorplan View and Physical View can display partition information to support the Incremental Design Flow. Partitions can be edited in Floorplan View, but not in Partition View.

- Floorplan View loads partition information that has not yet been loaded into memory. Data is only loaded after the Translate process. See “Displaying Partitions in Floorplan View” on page 671.
- Physical View can display partition information to support the Diamond Incremental Design Flow. Data is only loaded after the Translate process. See “Displaying Partitions in Physical View” on page 672.

Displaying Partitions in Floorplan View

Partitions are displayed nearly identically to UGROUPs and REGIONs in Floorplan View. If a partition has an anchor and bounding box, then it can be displayed in Floorplan View. However, if a partition does not have either an anchor or bounding box, the partition will not be displayed in Floorplan View. Refer to “Specifying Partition Anchor and Bounding Box” on page 667 for information on how to specify anchor and bounding box.

Partitions will have a solid border with a patterned background, similar to UGROUP bounding boxes. The patterned background is different than that of a UGROUP.

Note

REGIONs have a solid background.

To display partitions in Floorplan View:

1. Choose **Tools > Floorplan View.**
2. By default, partitions are displayed in Floorplan View. If they do not appear on the layout, click the  button on the vertical toolbar, or click **View > Preference Placement Display > Display Partitions**.

See Also

- “Editing Partitions in Floorplan View” on page 672
- “Cross-Probing Partitions from Partition Manager” on page 669
- “Displaying Partitions in Physical View” on page 672

Editing Partitions in Floorplan View

If an anchor and bounding box have been specified for a partition in Partition Manager, the anchors and bounding boxes can be viewed and edited in Floorplan View.

To edit partitions in Floorplan View:

1. Choose **Tools > Floorplan View.**
2. By default, partitions are displayed in Floorplan View. If they do not appear on the layout, click the button on the vertical toolbar, or click **View > Preference Placement Display > Display Partitions**.
3. Right-click the partition you wish to edit and chose **Edit Partition** to display the Position Anchor and BBox dialog box.
4. If modifying anchor, check the **Anchor** box and specify Row and/or Column.
5. If modifying bounding box, check the **BBox** box and specify Height and/or Width.
6. Click the Save Partitions button on the vertical toolbar.

When a partition has been edited and applied in Floorplan View, the Diamond process is re-set to the pre-Map process**.**

Note

Anchor and bounding box can also be edited in the Partition Manager. Refer to "Specifying Partition Anchor and Bounding Box" on page 667.

Displaying Partitions in Physical View

Physical View displays partition information with the similar way as UGOUP or REGION. The color used for partitions are different than that of the UGROUP or REGION.

To display partitions in Physical View:

1. Choose **Tools > Physical View.**
2. By default, partitions are displayed in Physical View. If they do not appear on the layout, click **View > Show Layers > Partition**.

Recommended Strategies for Incremental Design

This chapter provides recommended strategies for using Incremental Design. It outlines the circumstances that can dictate when using this flow is the best approach and when it is not. For the most part, what might lead you to use this flow will likely be a matter of trial and error, but it is useful to gain an understanding as to when Incremental Design should be your first approach to implementing your design.

Although incremental flow in general will provide shorter runtime and relatively consistent result, there will be situations it may take longer. For example, it might be possible that incremental flow can not meet the timing goals while normal flow can. Incremental flow is suitable for well-partitioned designs. Flat designs or designs with many critical paths crossing partitions may actually result in a drop-off in performance using the Incremental Design flow.

The following are common terms used in incremental design flow:

Unguided iteration A core processing (Map, Place and Route) iteration where the physical reference design (NCD) doesn't exist, or it does exist but is ignored. To run an unguided iteration if the reference NCD is available but needs to be ignored, set all partitions' preservation data to “Synthesis” in Partition Manager

Guided iteration A core processing (Map, place and route) iteration where the reference NCD is used for all partitions or certain partitions, based on the user settings through the Partition Manager.

ICF file The partition data base/file that holds all of the partition’s related information and user settings set through the Partition Manager. Each reference NCD has its own ICF file associated with it.

Recommended Incremental Design Flow: Scenario 1

This scenario applies to designs in which timing closure can be easily achieved, or has been previously addressed using incremental flow by locking down the timing critical partitions. The majority of the of design is locked down, meaning no further source code changes are allowed, and the number of partitions that need to be changed are very limited.

1. In Diamond, create a new project and implementation, and add HDL codes.
2. Add synthesis constraints and adjust synthesis strategies if necessary, and complete a synthesis iteration.
3. Open the Hierarchy window, examine resource usage information for each module in order to guide partition creation.

4. Launch Synplify Pro, compile the design, then define compile points based on the observations in step 3.
5. Adjust synthesis, Map and PAR strategies if necessary, and complete synthesis, Map and PAR.
6. Examine the process reports. For these types of designs, timing closure should be easily achieved.

   Optionally, use Partition Manager to change Preservation Data of all partitions to **Routed** or **Placed** (default) and leave Reimplimentation Effort as **Guided** (default).
7. If required, modify HDL code to certain partitions, and repeat step 5.
8. If required, repeat step 6 and step 7.

For these types of designs, timing closure can be easily achieved and runtime reductions for each iteration should be obvious.

Recommended Incremental Design Flow: Scenario 2

This scenario applies to designs in which timing closure can be easily achieved for certain part of a design but not in other parts of the design. For example, timing critical paths fall into certain partitions.

1. In Diamond, create a new project and implementation, and add HDL codes.
2. Add synthesis constraints and adjust synthesis strategies if necessary, and complete a synthesis iteration.
3. Open the Hierarchy window and examine resource usage information for each module in order to guide partition creation.
4. Launch Synplify Pro, compile the design, then define compile points based on the observations in step 3.
5. Adjust synthesis, Map and PAR strategies. If necessary; it is recommended that:
   a. Multi-seeds PAR is enabled.
   b. Routing method option is set to NBR.
6. Complete synthesis, Map and PAR.
7. Examine the process reports. Find timing critical paths and identify partitions that have timing problems. For these types of designs, timing problems should fall into certain partitions but not the others.
8. Using Partition Manager:
   a. For partitions with identified timing problems, set Preservation Data to **Synthesis**.

   b. For partitions without timing issue, set Preservation Data to **Routed** or **Placed** (default) and leave Reimplementation Effort to **Guided** (default).

9. If required, modify HDL code to identified partitions in order to improve the timing
10. Repeat step 5 and step 6
11. If required, repeat step 7 through step 10
12. When all timing issues are fixed, the design will be in a condition as described in “Recommended Incremental Design Flow: Scenario 1” on page 674. At this point, Partition Manager can be used to set all partitions Preservation Effort to **Routed** or **Placed** (default), and Reimplementation Effort to **Guided**.

    If there is any need to do a minor change to certain partitions, we can follow the step 7 of “Recommended Incremental Design Flow: Scenario 1” on page 674.

Recommended Incremental Design Flow: Scenario 3

This scenario applies to designs in which timing closure is hard to achieve for the whole design and partitions need to be redefined in order to isolate critical paths

1. In Diamond, create a new project and implementation, and add HDL code.
2. Add synthesis constraints, adjust. synthesis strategies if necessary, and complete a synthesis iteration
3. Open the Hierarchy window and examine resource usage information for each module in order to guide partition creation.
4. Launch Synplify Pro, compile the design, and define compile points based on the observations in step 3.
5. Adjust synthesis, Map and PAR strategies if necessary. It is recommended that:

   a. Multi-seeds PAR is enabled.

   b. Routing method option is set to NBR.

6. Complete synthesis, Map and PAR.
7. Examine the process reports and identify timing critical paths. For these types of designs, there may be more than one critical path across multiple partitions. Isolate each critical path, identify modules that are included in the path, and use the information as the guideline for partition modification.
8. Using Partition Manager, set all partition Preservation Data to **Synthesis**.
9. If required, modify HDL code to identified critical paths in order to improve timing.

10. Based on the observation in step 7, you might need to change the partition definitions. Using Synplify Pro, add or remove compile points, as needed. It may be necessary to group certain modules that cover a critical path to create a new module to be able to define a new compile point to cover a complete critical path. In some cases, you might also want to set the partitions without timing issue with Preservation Data to **Routed** or **Placed** (default) and leave Reimplementation Effort to **Guided** (default)
11. Repeat step 5 and step 6.
12. If required, repeat step 7 through step 11
13. When all timing issues are fixed, the design will be in a condition as described in “Recommended Incremental Design Flow: Scenario 1” on page 674, we can use Partition Manager to set all partitions Preservation Data to **Routed** or **Placed** (default), and the Reimplementation Effort to **Guided**.

    If there is any need to do a minor change to certain partitions, we can follow the step 7 of “Recommended Incremental Design Flow: Scenario 1” on page 674.

General Incremental Design Flow Limitations

The following is a list of general limitations that you should use as a guideline for determining whether or not your design is a good candidate for running through the Incremental Design flow.

- Although the Incremental Design flow in general will provide shorter runtimes and a relatively consistent result, there will be situations it may take longer. For example, in some cases the incremental flow might not meet timing goals whereas the normal flow can.
- The Incremental Design flow is suitable for well-partitioned designs. A flat design or a design with many critical paths crossing partitions may actually result in poorer performance using the incremental flow.
- Designs that have a very high resource utilization may not be a good candidates for running in the Incremental Design flow because typically this flow requires ample resource availability.
- Designs with congestion may also not be good candidates for the Incremental Design flow for the same reason, that is, incremental designs tend to require more resource availability to resolve congestion, such as loose placement and detour routing.
- The partition floorplanning that occurs in this flow can automatically generate partition constraints. A completed design is required to generate a reasonable partition. Running incremental flow on partial design is not recommended. Oftentimes the auto-generated partition constraint is not optimal. It is strongly recommended that if you must adjust partition constraints, that you do so based on your knowledge of the design.
- To achieve the best stability and quick timing loop closure, it is strongly recommended that you keep the changes from one iteration to the next

iteration to a minimum. Any major change or a lot of minor changes will result in a completely different result which may undermine the overall effectiveness of the incremental design flow's inherent strategy.

- The Incremental Design flow may yield loose packing and lesser performance due to partition constraints. Also, if the incremental router is applied, longer runtime and worse performance may result, if, from iteration to iteration, the change is significant or some congestion occurs.
- Reveal is not generally recommended for use with the Incremental Design Flow. Any module that Reveal needs to trigger or trace into will be a changed module, so its implementation will not be preserved from the reference design. Additionally, it is likely that these debug connections will cross multiple partitions.
- The Timing Driven Mapping (-tdm), Timing Driven Packing (-td_pack), and Timing Driven Node Replication (-split_node) Map strategy options are not supported in the Incremental Design flow. These timing-driven options are not supported because they do not honor design partition region boundaries.

General Synthesis Recommendations

This section lists any general recommendations to ensure the Incremental Design flow can be run in the Diamond environment and to eliminate or minimize any error or warning messages you encounter.

The synthesis recommendations for Incremental Design are as follows:

- A minor RTL change may result in significant difference in your mapping and place-and-routing result. For this reason, it is recommended that you make any HDL source changes before using the incremental design flow, or certainly not when you are using the guided iteration run flow mode that uses an NCD as a reference file to guide implementation. To set the next iteration as unguided iteration, change all of the partitions preservation data to "Synthesis" using Partition Manager.
- To avoid issues during synthesis, you must use Synplify Pro version of the Synplify software since Compile Points feature is not supported in other versions. The Synplify Pro version in Diamond supports the Incremental Design flow.
- In the beginning of the Incremental Design flow you must create a top-level FPGA Design Constraints (.fdc) file in Synplify Pro and associate it with the Diamond project you are running. If you do not do this, the Incremental Design will not work properly and the flow is actually running as in a normal flow.
- Create your .fdc file in the graphical user interface of the Synplify Pro tool, not the command line. If you do not do this, module names to apply your compile points types (locked,partition) may not be recognizable to you in the command line because the modules are parameterized and appear with names such as "ro_cnt_8s_0_6s" and the like. All of these extra prefixes or suffixes like this are the parameterization.

- To discover and analyze error and warning conditions for your partitioned modules, open Synplify Pro (synplify_pro) and open the SCOPE editor panel which allows you to edit your .fdc file. Click on the Compile Points tab and observe that all of the compile points are marked in yellow, which indicates an error or warning condition.

Avoiding Common Design Flow Issues

You should go about using the Incremental Design flow as prescribed in this guide in a step-by-step fashion to ensure that you have initiated the flow correctly and you get the expected outputs when you run it. It is probable in these cases you have not performed a step and this has prevented Diamond from recognizing your active implementation of your project as an incremental design.

See "Troubleshooting Error and Warning Messages" on page 682 on diagnosing common usage issues.

Defining Design Partitions How you define your partitions is design-dependent and will have an impact on how effective using the Incremental Design flow in Diamond will be. This section provides you with useful information you can employ when you are defining partitions with compile points when you are creating your .fdc file in Synplify Pro.

Below is a list of factors involved in defining partitions that can effect the quality of results you might achieve using the Incremental Design flow. The list also includes how partitions are treated in regard to resource utilization.

The following describe how partitions can affect the incremental design flow:

Number of Partitions It is recommended that you limit the number of partitions in your design to a reasonable figure, for example, 30, with respect to the percent partitions in total utilization which is described later in this section. If your design has too many partitions it will lose the global placement picture. Also, it is best to contain the portions of the design that could change to the smallest partition possible, thus preserving other parts of the design. As a general rule, if more than about 10 percent of the design is changing, it is usually advisable to re-run an unguided incremental pass.

As a recommended practice, you should not change the number of partitions in your design when running guided iterations, or you may encounter unexpected results. Defining what gets partitioned in your design should be done prior to using an NCD reference design for more incremental changes.

Size of Partitions There is no size limit for a design partition. In general, partition size is defined by a given functional module where a compile point is applied. However, any changes to a large partition can result in significant changes in how Map and PAR pack, place and route components and hence your Fmax result as well.

Shape of Partition Regions A partition's region is always in the shape of a rectangle. A non-rectangular shape is not allowed. However, overlapping among partitions is allowed in the Incremental Design flow to achieve optimal results.

Percent Partitions in Total Utilization It is suggested that at least 75 percent of your incremental design is covered by partition instances. To find out what percentage of your design is covered by partitions, look at the "PARTITION Utilization" section in the Map Report (.mrp) file. This section of the file is shown below to illustrate how this percentage is given along with the total number of design partitions:

```
Total comps 450 (92.78%) in 65 partitions.
```

Please understand that the limit on the number of design partitions mentioned previously in this section is a more critical factor in the successful implementation of your incremental design.

Components within Partitions Understand that partition BBOX definitions keep those components in a particular design partition confined to a region that is SLICE-based but the region will not include in its boundaries the placement of special elements such as EBRs, DSP, and DDR because they are row-based. However, EBR and DSP will be placed close to a relative partition.

So, the BBOX definition does not affect the placement of these special elements at all, only logic that is placed in SLICE components or PFU/PFF elements. If you want to place special elements within a specific physical region, use the UGROUP or LOCATE preferences as appropriate. In addition, due to architecture limitations, not all global resources will be able to be included in an individual partition. For example, global resources such as PLL, DLL, PCS, DCS, CLKDIV, and DLLDEL may not be used in the same partitions due to complicated rules and shape of ring. PIO/IOL (particularly clock PIO) are considered a global resource as well, which means PIO/IOL will not be included in a partition.

Note

Any conflict between a user preference and a partition definition must be resolved by the user. The placer will simply error out when encounters a conflict, such as a PGROUP or carry-chain crossing different partitions.

Placement Variability in Guided Iterations It is important to understand how guided iterations use the reference design to guide placement. The major concept to understand is that when you are using the incremental flow, the default settings in the data file preserve placement of the reference design unless the design's source HDL changes. This is implemented that way by design.

So, you need to be aware that a poor placement result will be preserved as readily as a good placement result. For this reason, we recommend that you get your design close to timing closure in the unguided iteration run flow mode before switching to the guided iteration run flow mode.

You should expect to see no variation in timing inside a partition with unchanged HDL in incremental flow when you run multiple cost tables with default data file settings. Also, if you attempt to change placement in the guided iteration by changing UGROUP or LOCATE preferences, you may see unexpected results. See “Troubleshooting Error and Warning Messages” on page 682 for related issues.

Handling Timing Issues in Guided Iterations If you are already in guided iteration and are seeing timing errors reported in your TRACE report, you have the following three options:

- Go back to unguided iteration run flow mode. This would be the appropriate choice if you believe changes to the partition planning or major HDL changes throughout the design are required.
- If the timing errors can be addressed by making HDL changes (e.g., adding pipeline stages), stay in guided run flow mode and use default preservation data and re-implementation effort settings for all partitions.
- If you believe the timing errors could be addressed by allowing some variability into the placement of a partition where HDL is not changed, you can achieve this by changing settings through the Partition Manager.

  To do this, open Partition Manager, and for all partitions that you want variability, change their preservation data to “mapped” and reimplementation effort to ‘guided.” Then, run multiple cost tables and force a PAR rerun. After doing this you will see some variability in the result for that partition within the constraints of the partition planning that appear in the data file.

Adding Pipeline Registers to Incremental Designs The Incremental Design flow is well suited to the case where you want to add pipeline registers and keep the rest of the design unchanged for placement. In guided iteration run flow mode, add the registers to your HDL and rerun the flow. No manual intervention should be necessary.

If for some reason you require that the new registers go into a specific area that is within their partition boundary and that has enough open sites to place the new registers, you can do this. In this particular case, add a UGROUP to the new registers with bounding box (BBOX) and anchor point (SITE). Note that this is only an option with changed logic. For more information, see the troubleshooting section on UGROUPs in incremental mode.

Troubleshooting Error and Warning Messages

This chapter provides a listing of error and warning messages that are specific to running the Incremental Design flow in Diamond. The chapter also includes a list of current known issues that you might encounter during the flow and provides some information to help you work around them effectively.

Troubleshooting Missing Files and Folders This section provides some examples of common issues that occur to users who are missing some file or folder inherent to the Incremental Design flow and they cannot understand the cause of it and cannot proceed.

An Incremental Design flow user could encounter cases where they expect that there is some file or folder in a certain location, but for some reason it does not exist. In most cases, this happens because they have skipped an important step in the design flow steps as they are described in “Running the Incremental Design Flow” on page 652

The following is a list of the most common reasons why you are not seeing the files and folders you would expect to see in the Incremental Design flow:

- You did not create an FPGA Design Constraints (.fdc) file in Synplify Pro.
- You did not create any compile point constraints in your .fdc file in Synplify Pro.
- You did not associate your .fdc file with your Diamond project.
- You did not enable the Incremental Design flow.

Known Issues The section lists known issues that you might encounter in the Incremental Design flow. If there is a workaround, that information is provided.

Extra partition is defined by Incremental Design flow In some cases, after Synthesis, an extra partition is defined by the Incremental Design flow. For example, if you have 10 compile points defined in Synplify Pro, the Map or PAR may report more than 10 partitions. There are two possible reasons:

- The top level design is always treated as a partition.
- Synplify Pro compile points are module based. Therefore, if a module contains a compile point defined with “n” number of instances, then effectively there will be “n” number of partitions for that module.

Missing SITE/BBOX definition for partition in ICF Sometimes after running, the PAF utility does not assign an anchor SITE and regional BBOX to the PARTITION setting in the ICF file. In these cases you will see a message in the .par file (i.e., if the PAF is run inside par as in Diamond) similar to the following:

```
INFO: PARTITION CGROUP_serdes_quad has no valid comp, this
partition will be ignored.
```

And then later,

```
PARTITION 2 : “CGROUP_serdes_quad” (SITE and BBOX are not
assigned)
```

There will be no usage information shown in this case because there are no slices in the partition.

Issue: One reason PAF does not define a SITE and BBOX for a given partition in the ICF is that your compile point constraint does not include any SLICEs. This could happen for the following reasons:

- They are optimized away. This may be expected behavior, but also may happen if inputs or outputs do not connect to ports. check tool logs)
- There are actually no contents of the partition that are slices. This could happen, for example, if you put a compile point on a module which only contains a SERDES block, or only I/O. This is not an error condition but a compile point like this does serve any purpose for Map and PAR.

Solution: Check your tool log files in Synplify and attempt to determine why your inputs and outputs are not connecting to ports.

Using I/O buffers with tristate controls in modules with compile points If I/O buffers with tristate controls are present within modules with compile points defined in your design, you will encounter error messages during implementation in Diamond.

Issue: The synplify_pro synthesis tool cannot support I/O buffers with tristate controls inside of modules with compile points. If the buffers are instantiated, it will detect them, issue a warning message, and disable the compile point. Check the Synplify log or the warning tab in Diamond. The message will appear similar to the following example shown below:

```
@W: BN106 |Cannot apply constraint syn_compile_point to
v:work.immir

@W: BN106 |Cannot apply constraint syn_cptype to v:work.immir
```

If you miss this warning message, you will only see this after the Map process, when you are missing partitions in the Map Report (.mrp) PARTITION report and the ICF file.

Solution: Either do not use a compile point on the module or move the buffers up to the top level of the design's hierarchy in the HDL.

Unused design elements may generate Map errors in modules with compile points Using compile points with designs that contain unused logic may result in the unintended functionality and Map error messages.

Issue: If you use compile points during synthesis and your design contains unused elements, for example, a multiplier exists in a test case that is driven by a driver in another partition, but the outputs are not intended to be used, it will likely result in Map errors with messages similar to the following.

```
ERROR - map: Mico32_u/LM32/cpu/multiplier/product_2_36_71 : Pin
A13 has no driver. Possible causes are (1) redundant logic or
(2) undriven input.

ERROR - map: Mico32_u/LM32/cpu/multiplier/product_2_36_71 :
Input B Pin B0 is not connected but the Source is statically
connected to GND(Parallel Input)
```

Solution: Either do not use a compile point on the module or remove any unused logic from your design before mapping.

Changing I/O placement and function The Incremental Design flow tries to preserve the I/O placement of the reference design. In the incremental flow, you can change I/O placement via new LOCATE preferences, where the new placement is feasible – that is, where the pins are available, and support the function of the I/O.

The new preferences will be honored and you will see messages, as shown below, in the PAR Report (.par) file that inform you that the placement in the reference design is being overridden by the new LOCATE preferences.

```
WARNING - par: Comp 're' has been LOCATE'd and will not be
placed as per guided file
```

Issue: Changing I/O function in the incremental flow can potentially cause an I/O placement failure. An example of a problem like this might be changing a non-DDR I/O to a DDR, or changing an I/O type from LVCMOS to LVDS. The original placement may no longer be feasible due to the resource availability at the reference design's pin locations.

Solution: If you see an I/O placement failure in the Incremental Design flow, change your LPF preference file to manually locate the changed I/O to the appropriate pins or, instead of using the incremental flow, use the normal run flow mode.

Parameterized modules in standalone Synplify Pro Using the standalone Synplify Pro software for Incremental Design, parameterized modules in a design make it impossible to determine what their actual module names are and results in error messages later in the design flow that are difficult to interpret.

Issue: In this specific case, a user encountered an Map error that prevented the ICF file from being opened which occurred using an unguided iteration run flow mode they attempted to process through Diamond's Place & Route Design process. The following Map error message was reported in the Output view:

```
WARNING - map: There is no partition, and the option "-inc" is
ignored.
```

This warning implies that there were no PARTITION properties or constraints recognized by Map so they were not passed through the implementation flow. The .fdc file contains compile points that become PARTITION settings in the Incremental Design flow.

This condition occurred when the user attempted build their .fdc constraints file in a standalone Synplify Pro software and because of parameterized module naming not matching the actual module names, it appears to the software that there were no compile points. In the Synplify Report the following "Cannot apply constraint" error message occurred:

In addition, if you reopen the standalone version of Synplify Pro, choose **Run > Compile Only** and open the .fdc file using the SCOPE editor spreadsheet

```
@W: BN106 |Cannot apply constraint syn_compile_point to v:work.ud_cnt
@W: BN106 |Cannot apply constraint syn_cptype to v:work.ud_cnt
@W: BN106 |Cannot apply constraint syn_compile_point to v:work.ro_cnt
@W: BN106 |Cannot apply constraint syn_cptype to v:work.ro_cnt
@W: BN106 |Cannot apply constraint syn_compile_point to v:work.ud_cnt_uniq_1
@W: BN106 |Cannot apply constraint syn_cptype to v:work.ud_cnt_uniq_1
@W: BN106 |Cannot apply constraint syn_compile_point to v:work.ro_cnt_uniq_2
@W: BN106 |Cannot apply constraint syn_cptype to v:work.ro_cnt_uniq_2
```

panel. Now, click on the Compile Points tab and observe that all of the compile points are marked in yellow. This indicates that there is an error condition you have to resolve before you proceed.

Solution: You should create your .fdc file inside of the Synplify Pro graphical user interface and it is highly recommended that you run Synplify Pro for Lattice from within the Diamond interface and associate the file in the Synthesis strategy settings as prescribed. This ensures that source and .fdc constraints files are recognized and associated with your Incremental Design flow project in Diamond.

Preference/net naming issues Preference and net names can vary from design to design in the Incremental Design flow for several possible reasons.

Issue: In some cases preferences that are honored in the normal flow are not honored in the incremental flow. For example, a clock name has significantly changed which leads to a FREQUENCY constraint, related to that clock not honored; a net name has changed which leads to a MAXDELAY constraint, related to that net, not honored; or a Dynamic Clock Select (DCS) name has changed which leads to USE PRIMARY DCS NET "<net_name>" "<quadrant_location>" not honored. This may be due to synthesis optimization being performed differently with compile points present as opposed to when they are absent from a design.

Solution: When using incremental design, you should double check Map warnings about preferences. If you see warnings indicating that preferences are ignored which are accepted in normal flow, you may need to modify your preference file, or use synthesis attribute “syn_keep” to preserve net names. Another method, for checking changed clock names, is to open Spreadsheet View after running the Translate Design process in Diamond. In the Spreadsheet View, check the Clock Resource tab. This tab lists all of the clock names that are recognized by the tool, including those that have their names changed. Users should use the names listed in this tab to set their constraints. As always, it is better to constrain ports rather than nets if possible, as they will not be renamed.

UGROUPs in guided iterations In certain cases UGROUPs you assign to unchanged SLICE components as attributes or preferences are not honored.

Issue: When you are running in the guided iteration run flow mode and you attempt to move unchanged SLICEs relative to the reference design by adding a UGROUP to HDL or preference file, the placer will not, by default, honor the new UGROUP location. There is no error or warning messages to alert you to this condition.

Solution: To avoid this situation, have your UGROUPs defined where you desire them to be located when you run the first implementation. While changed logic can be located via a UGROUP, this will only work where there are empty sites available. The placer will not rip up any unchanged placed logic from a reference design by default.

Tcl Commands Can Only Be Run Through Tcl Shell The database extended Tcl commands and Partition Extended Tcl commands can only be run through a Tcl Shell, and cannot be run in the Diamond GUI.

General Warnings & Errors You may encounter the following general warnings and errors when using the Incremental Design flow.

- If the user's command has a reference file specified, such as par -w ... <*file_name*>.ncd, but file.ncd does not exist, PAR will switch to Unguided iteration with the following warning message:

  ```
  Failed to open reference file %s, switch to unguided
  iteration
  ```

- If the user's .icf file has no partition, or all partitions are disabled, PAR will switch to normal flow with the following error message:

  ```
  No partition is defined or all partitions are disabled,
  switch to normal flow.
  ```

- If the user's command + d has a reference file specified, such as par -w ... -<*file_name*>.ncd, and the level and effort settings in the Partition Manager meet one or both of the following conditions:

  - Preservation data = synthesis and any reimplementation effort.
  - Preservation data = Map, reimplementation effort = unguided.

  PAR will switch to Unguided iteration with the following warning message:

  ```
  Because of the level/effort setting in icf file, redo
  unguided iteration.
  ```

Note

If this warning occurs, the Floorplan view will be invoked, so the regions of partitions will be changed.

- If the user's command has a reference file specified, such as par -w ... -<*file_name*>.ncd, but one of partitions has changed the anchor or bbox through the Partition Manager, PAR will switch to unguided iteration with the following warning message:

  ```
  Because some of the partitions changed partition_plan, guide
  iteration is disabled; The regions in icf files will be
  honored but the locations of comp will be changed.
  ```

Map Warnings & Errors You can encounter the following warning and errors in the Incremental design flow when using the Map process.

```
WARNING – map: There is no partition, and the option "-inc" is
ignored.
```

This condition may be the result of the following:

- No partition has been found so Map will run in normal mode.
- No ICF file will be created.
- The “par -inc -icf” command may fail due to missing ICF file.
- There is no partition, so you cannot use the incremental flow.

```
WARNING – map: The time stamp %s for partition %s in current
design is older than the reference one %s.
```

This condition may be the result of the following:

- The time stamp for a given partition in current design is older than the reference one. This condition may have occurred when a modified design is used as a reference for the previous design. This practice is not recommended in the Incremental Design flow.
- The partition will be marked as “CHANGED”.

```
ERROR – map: Sorry, there is no license for %s.
```

This condition may be the result of the following:

- The Incremental Design flow requires a special feature license. If you do not have it in your license file, you will see the message. Go to the Lattice web site and contact Sales support to obtain a license.

```
ERROR – map: Sorry, device %s is not supported for %s.
```

This condition may be the result of the following:

- Incremental flow may not be supported for all Lattice FPGA/CPLD families. You get this message because the selected device is not supported for incremental flow.

Placer Warnings & Errors You can encounter the following warning and errors in the Incremental design flow as a result of the placer processing your design.

- For running in a multi-par (multiple seeds) format, after each seed, par may issue one of the following three kind of messages during the Incremental Design flow:

  `WARNING: “message …”`

  PAR continues after this warning message is issued.

  `ERROR: “message …”`

  PAR will exit after it issues this error message.

  ```
  WARNING: placement not success in this seed and will
  continue next seed if exists.
  “message …”,
  ```

PAR will abort running for the current seed after this warning message and try the next seed. The message could be one of the follows:

```
ERROR :
“Internal database corrupted:  NULL site in slice
placement”

NOT SUCCESS :
“Fatal Error in preferplace(): cannot find initial
placement for UPGROUPs. Please check the UPGROUP
preferences to alleviate constraints.”

“Impossible to place SLICE_10 in UPGROUP GROUP1 in prefer
location.”

“Placer could not relatively place comp SLICE_10 at
R15C8D(x=61/y=8.”

“Failed to find the anchored location.”
```

- Anchoring error during PGROUP pre-placement:

```
pgroup=SLICE_10 anchor=R15C8D. Not enough available sites
in bbox for all group comps. Please check for multiple
LOCATE/REGION/QUADRANT design preferences leading to
highly constrained PGROUP placement regions.

Error in pgroup initial placement!

Comp ‘SLICE_10' remains unplaced after Phase 0
flattening.

set_initial_anchors failure on PGROUP placement"

WARNING:

switch to high-effort for PGROUP initial placement due to
congestion...
```

The following are messages issued by the placer. For each PAR incremental design run, the PAR file will have the following info:

```
Starting incremental place and route ...
```

Incremental design will exit if you encounter any of the following PAR error messages:

```
ERROR: No *.icf file for incremental par flow.
ERROR: Failed to open file design.icf for incremental par flow.
ERROR: Incremental flow can't support guide file with option “-
g filename”.
ERROR: option -g and -ref can't be appeared in command line
simultaneously.
ERROR: file name missing after "-ref".
ERROR: Failed to open reference file design_ref.ncd.
```

ICF Parser Warnings & Errors The following are messages issued by the ICF parser. If the ICF file was loaded successfully, it will issue the following message:

```
Completed loading 3 partition data.
```

- If the ICF parser detects an error, it may issue any of the following error messages listed below:

```
ERROR: comp%d %s belong to both partition %s and %s.
ERROR: Illegal keyword XXX
ERROR: Must assign value for keyword XXX for partition P0.
ERROR: Invalid icf string
ERROR: Fail to open ICF file XXX.
ERROR: No statement in ICF file XXX.
ERROR: Illegal icf key-value XXX.
ERROR: XXX YYY is an illegal pair , value must be in "ZZZ".
```

Then PAR will exit after printing out the following line:

```
There are %d errors in icf file.
```

Router Warnings & Errors You can encounter the following warning and errors in the Incremental design flow as a result of the router processing your design.

- Usually, in incremental flow, the positions of primary clock signals are copied according to the reference design. However, for any reason, if the position of a primary clock signal has been preassigned, the copy will be skipped and you will encounter the following warning message:

```
WARNING – par: The pclk position for the signal %s has been
already assigned, and the assignment from the guided/
reference design is ignored.
```

- As mentioned in the prior case, in incremental flow, the clock assignment is usually copied from reference design. However, for any reason, if the target position has been used by other signals, the copy will be skipped and you will encounter the following message:

```
WARNING – par: The pclk position %d has been already
occupied. The pclk assignment for the signal %s copied from
guided/reference design is ignored.
```

- Usually in the incremental flow, the positions of secondary clock signals are copied according to the reference design. However, for any reason, if the position of a secondary clock signal has been preassigned, the copy will be skipped and you will encounter the following message:

```
WARNING – par: The sclk position for the signal %s has been
already assigned, and the assignment from the guided/
reference design is ignored.
```

- As mentioned above, in incremental flow, the clock assignment is usually copied from reference design. However, for any reason, if the target position has been used by other signals, the copy will be skipped and you will encounter the following message:

```
WARNING – par: The sclk position %d has been already
occupied. The sclk assignment for the signal %s copied from
guided/reference design is ignored.
```

Supplying Archives for Technical Support As a general advisory, if you encounter issues that require debugging by Lattice technical support, it would be extremely helpful to provide project archives both for the initial reference design files and the guided iteration run flow mode version where the issue was encountered.

As described earlier in this guide in the section, “Archiving Incremental Design Results” on page 659, make sure that at the appropriate points in the flow that you archive your project.

Chapter 9

Analyzing Static Timing

Static timing analysis (STA) is a method for determining if your circuit design meets timing constraints. It is a method that does not require the use of simulation. The STA process employs conservative modeling of gate and interconnect delays that reflect different ranges of operating conditions on various dies, providing complete verification coverage.

This section explains how to use Diamond's static timing analysis tools and reports to help meet your design's timing constraints.

See Also ▶"Static Timing Analysis Tools" on page 691

- "Running TRACE" on page 693
- "Using Timing Analysis View" on page 729

Static Timing Analysis Tools

Diamond provides two primary tools for performing static timing analysis on timing preferences: the timing reporter and circuit evaluator (TRACE) and the Timing Analysis view.

Additionally, the I/O Timing Analysis process, which is available after Place & Route, generates an I/O Timing Report (.ior) that is not limited to timing preferences.

TRACE TRACE analyzes timing preferences that are present in the logical preference (.lpf) file. These timing preferences are defined in the Timing Preferences sheet of Spreadsheet View or in a text editor before the design is mapped. A TRACE report file, which shows the results of timing preferences, is generated each time you run the **Map Trace** process or the **Place & Route Trace** (PAR) process. The results can then be viewed in the Report View window. The Map TRACE report (.tw1) contains estimated routing that can be used to verify the expected paths and to provide an estimate of the delays before you run Place & Route. The PAR TRACE report (.twr) contains delays based on the actual placement and routing and is a more realistic estimate of the actual timing. See "Running TRACE" on page 693.

Timing Analysis View The Timing Analysis view is a graphical view of the post-route TRACE report. It provides path tables, schematic views of timing paths, and a report of each timing preference. It also allows you to cross-

probe to Floorplan View or Physical View to see where these paths exist on the chip. See "Using Timing Analysis View" on page 729 and "Cross-Probing from Timing Analysis View" on page 750.

Timing Analysis view also includes a simplified version of Spreadsheet View that enables you to create flow-independent timing preference files (.tpf) for a given implementation. With the .tpf file input, the Timing Analysis view computes the results of your hypothetical timing constraints and allows you to discover how they might affect your design. You can later copy revised timing preferences from the .tpf file to the logical preference file. See "Creating a New Timing Preference File" on page 744 and "Modifying Preferences for Timing Analysis" on page 731.

I/O Timing Analysis The I/O Timing Analysis process, which is available after placement and routing, generates an I/O Timing Analysis Report (.ior). Unlike TRACE, the I/O analysis is not limited to defined timing preferences. Paths that have not been constrained with timing preferences will still be reported. Also, the verbose version of the I/O timing analysis sweeps across multiple performance grades to find the worst case results. See "Running I/O Timing Analysis" on page 719.

- "Setting Timing Preferences" on page 490

Strategies for Timing Analysis

Reporting options for TRACE and I/O timing analysis are defined using strategies. Strategies are located in the Strategies folder of the File List view. You can associate a strategy with an active project implementation by right-clicking a strategy and choosing **Set As Active Strategy** from the pop-up menu.

By default, the Timing Analysis view will use your active strategy as its default TRACE settings when you initially open the view. Your Map and PAR Worst Case Paths setting defaults to reporting 10 in the TRACE report; however, Diamond will automatically run 30 to cache timing data in memory so that performance in the Timing Analysis view is not diminished.

For more general information on setting strategies in Diamond, see "Using Strategies" on page 47.

See Also
- "Using Timing Analysis View" on page 729
- "Setting Options in Timing Analysis View" on page 730

Running TRACE

You can access the TRACE program from the Diamond Process window for Map Design and Place & Route Design. You can also access it using the `trce` command in the Tcl Console, a DOS console, or from an xterm in Linux. TRACE runs analysis on timing preferences that have been specified in the logical preference file (.lpf) or the HDL source, and it generates a report of the results. You can view the TRACE report in the Reports window.

To run TRACE in the Diamond environment:

- In the Process view, double click **Map Trace** or **Place & Route Trace**.

  TRACE runs static timing analysis on your design and generates a map TRACE report (.tw1) or a PAR TRACE report (.twr).

To run TRACE from the command line:

- Type **`trce`** on the command line with, at minimum, the names of your input .ncd and .prf files. For example,

  ```
  trce <file_name>.ncd <file_name>.prf
  ```

For more information, see "Running TRACE from the Command Line" on page 2494.

See Also "Static Timing Analysis Tools" on page 691

- "Using Timing Analysis View" on page 729

Setting TRACE Options

TRACE options are available in the active Strategy for an implementation. The options provide you with control over how timing data is reported.

To set TRACE options in the Diamond environment:

- Choose **Project > Active Strategy**, and then choose either **Map Trace Settings** or **Place & Route Trace Settings** from the drop-down menu.

  Optionally, double click the active Strategy in the Strategies folder of File List view, and then select **Map Trace** or **Place & Route Trace**.

The following STA options are available for both Map and Place & Route TRACE:

- Analysis Options
  - Standard Setup and Hold Analysis (default) – Performs both the Standard Setup Analysis and the Hold Analysis.
  - Hold Analysis – Performs hold analysis.
  - Standard Setup Analysis – Performs setup time checks on applicable preferences. For post-route analysis, you can override the default

performance grade (the performance grade of the target device) by using the Speed for Setup Analysis option.

- Standard Setup with Hold Analysis on IOs – Performs standard setup analysis and a hold time analysis on applicable I/O preferences in the same report file. For post-route analysis, you can override the default performance grade (the performance grade of the target device) by using the Speed for Setup Analysis option.

- Auto Timing – lists the auto-generated timing preferences in the TRACE report.

  If you do not define any timing preference for your FPGA design, Diamond will automatically generate timing preferences for you. Set this to True (default) if you want your TRACE report to list the auto-generated timing preferences.

- Check Unconstrained Connections – lists the connections that are not covered by any timing preference.

  Note

  The Check Unconstrained Connections option will be discontinued after the next two Diamond releases.

- Check Unconstrained Paths – reports the paths that are not constrained and shows the start point and end point of each path. TRACE will suggest some timing preferences to constrain the given paths. The unconstrained paths are shown only in the “setup” timing check report to avoid duplication of these same paths in the “hold” timing check report.

  Based on the design and the required performance, only necessary paths should be constrained so that PAR focuses only on the optimization of the important paths. However, the Unconstrained Paths section of the TRACE report is very useful for identifying whether any missing timing constraints are really important to the design. This option does not require you to add more preferences in an attempt to constrain all paths. Instead, it serves as a reminder that there might be a necessary preference that is missing, which could impact the desired performance of the design.

  Important points about connection coverage:

  - Some signal connections might not be constrained by any of the four predefined types of preferences. It is possible that all pairs of source and sink are covered by the given preferences, but there could still be connections not covered by any of the given preferences. Therefore, the connection coverage might be less than 100% even though no unconstrained path of the four predefined preference types is found.

  - Sometimes an unconstrained path is found even though the connection coverage is reported as 100%. The unconstrained path is about the path between a source and sink pair. If a legal source and sink pair is not covered by a preference, it will be reported as an unconstrained path. But because the connections on this

unconstrained path could already be covered by some other preferences, the connection coverage could still be 100%.

Note

The Check Unconstrained Paths option cannot be used with the -allprefpath command-line option.

- Full Name – when set to True, the TRACE report will show full-length component names instead of the truncated names.

  This option defaults to having truncated COMP names appear in the TRACE report (.tw1 or .twr) file. COMP names are truncated to a certain character limit and preceded by an asterisk. The expanded option allows the entire name to be reported; however, longer COMP names can cause some tabular formats in the ASCII file report sections to become misaligned, making the report less readable.

- Number of Unconstrained Paths (0 to 4096) – controls the number of unconstrained paths that are reported. When set to 0, all unconstrained paths are reported.

Note

If you enter a value of 500 or more for the number of paths to be reported, you might experience problems related to excessive file size.

If the -allprefpath option is used in the command line, it will override the unconstrained paths option.

- Report Asynchronous Timing Loops – produces a report of paths that could not be analyzed because they are asynchronous loops.
- Report Style – sets the format of the TRACE report.
  - Verbose Timing Report (default) – lists detailed logic and route delays for all constrained paths and nets in the design.
  - Error Timing Report – lists logic and route delays for each path and net that causes a timing error.
- Route Estimation Algorithm (%) – configures the route estimation algorithm for pre-route static timing analysis.

  0 (default) – Enables route delay estimation based on a suite of Lattice benchmark designs. Note that delay estimates are based on the default performance grade of the target device.

  The default 0 value will run an algorithm that considers only the most critical paths of each design in a suite of designs. For each critical path, an average route delay is determined for each logic-logic connection. This is further decomposed to the number of switches per connection, and delay per switch. Each device family and performance grade will have its own unique value(s). Special cases that deviate significantly from the general routing scenario are excluded in the calculation and also handled separately by PAR. For example, carry chains are not included in the average route delay value, and the average route delay value is not used by MAP to estimate the delay in a carry chain.

1~100 – specifies logic delay as a percentage of the overall path delay where the total delay is the sum of logic and route delays.

The % Logic Delay option is a simple method that correlates the logic delay to the routing delay. If a 50/50 correlation is chosen (50 percent), then the routing delay of a path is assumed to be the same as the logic delay of that path. However, there is not necessarily any correlation between a path's logic delay and its routing delay; for example, an adder's carry chain has very low routing delay versus logic delay. So this method does not lead to accurate estimates, but it can still be used for such tasks as checking the number of logic levels in the design and syntax checking the preferences.

- Worst Case Paths (0-4096) – specifies the number of paths to be reported for each timing preference. Enter zero or a greater value. The default value is 10; however, Diamond will automatically run 30 to cache timing data in memory so that performance in the Timing Analysis view is not diminished. You will see additional data in your reports for this reason.

Note

If you enter a value of 500 or more for the number of paths to be reported, you might experience problems related to excessive file size.

When Verbose Timing Report is selected, the value you specify limits the number of paths reported for each timing preference (0 = no limit). There is no practical limit, although unlimited reporting can exhaust available memory and disk space.

Scoring a path refers to the timing extraction performed by the static timing analysis engine. TRACE will always extract the worst case paths, but you can choose to analyze and score more than the system default.

Given a large design with many paths to examine, you might wish to limit the report size by using more specific preferences or BLOCK type exceptions temporarily to mask paths that are not of interest.

When Error Timing Report is selected, the specified number of paths with timing error will be printed out. If you enter 0, no path will be reported.

- Speed for Hold Analysis – allows you to override the default -M (minimum) performance grade for hold time analysis, which represents faster silicon than the fastest performance grade of the device being targeted.
- Speed for Setup Analysis – allows you to override the default performance grade which runs setup analysis against the performance grade of the device currently targeted by the project implementation.

Viewing TRACE Reports

TRACE reports are outputs of the Map Trace and Place & Route Trace processes. After running either of these processes in Diamond's Process view, you can examine the associated TRACE reports in the Reports window. The Map TRACE report (.tw1) and the Place & Route TRACE report (.twr) files are written out to your project directory in ASCII format using the current project name for the file name.

To view the TRACE report file in the Report window:

1. Click the **Reports** tab to activate the Report window.
2. In the Design Summary pane, select **Map Trace** or **Place & Route Trace** from the Analysis Reports folder.

   The selected report appears in the Reports window. The Design Summary pane presents a hierarchy view of the report.

   - Expand a section of the report in the Design Summary pane and click a subsection name to open the section in the Reports window.
   - In the Report window, right-click and choose Find in Text to search for a specific preference or a design element.

To view the TRACE report file in a text editor:

- Open your text editor and navigate to the project directory. The TRACE reports are usually located in the <project_name><project_name> folder.
  - To open the Map TRACE report, select the <project_name>.**tw1** file.
  - To open the Place & Route TRACE report, select the <project_name>.**twr** file.

See Also "TRACE Report File" on page 697

- "Running TRACE" on page 693
- "Setting TRACE Options" on page 693
- "Setting Options in Timing Analysis View" on page 730

TRACE Report File

The TRACE Report File (.tw1/.twr) is an ASCII report that enables you to determine to what extent the timing constraints for a design have been met. The .tw1 TRACE report output file is a result of the Map Trace process in Diamond. The .twr TRACE report output file is a result of the Place & Route Trace process.

Two levels of reporting are available for TRACE reports: verbose and error. By default, Diamond generates a verbose timing report. If desired, you can change this setting in the active strategy dialog box so that an error timing report is generated.

Facts regarding Error and Verbose levels of TRACE timing reporting:

- Both report styles conclude with Timing Summary subsections.
- The number of items reported can be limited for each preference in either error or verbose mode.
- The TRACE output format supports logical names.
- The error report lists timing errors and associated net/path delay information.
- The error and verbose reports also contain an asynchronous loop report that shows all paths that cannot be analyzed.
- The verbose report lists delay information for all nets and paths.
- For both types of reports, if you specify a preference file that contains invalid data, a list of preference file errors appears at the beginning of the report.
- If preferences for process, temperature, or voltage exist in a preference file, these preferences are included in the timing report.
- In both error and verbose reports, the details of the paths that contribute to clock skew are reported.
- The result of maximum frequency (f_{MAX}) in TRACE is potentially the highest frequency that the design can achieve. However, there are factors that can change the way in which f_{MAX} is reported. For example, if the f_{MAX} path is PLL-relevant and the PLL is configured as cycle "SHIFT", then the maximum frequency will change PLL "SHIFT" delay accordingly, which might impact clock skew and f_{MAX} results. Final f_{MAX} results depend upon how PLL is used in each individual case.

Note

TRACE supports the preferences "CLKSKEWDIFF" on page 1206 and "CLKSKEWDISABLE" on page 1207, which allow you to control clock skew computation.

TRACE Error Report

The main body of the error report lists all timing preferences as they appear in the input preference file. For each preference that is met, the report simply states the number of items scored by TRACE, reports no timing errors detected, and issues a brief report line that indicates important information such as the maximum delay for the particular preference.

For each preference that is not met, the report shows the number of items scored by TRACE, the number of errors encountered, and a detailed breakdown of the error. In addition, TRACE reports clock skew details for placed and routed designs.

A Timing Summary always appears at the end of the report. The Timing Summary will include any preferences that are not met and mark them with an asterisk.

The Logical Details section, which reports circuit path source and destination information, appears at the beginning. If a path begins or ends at a sequential element, such as a flip-flop, the clock signal associated with the flip-flop is reported in the path delay report. For example:

```
10.150ns delay CLKD1 to CLKD1' exceeds
 10.000ns delay constraint less
  3.000ns setup requirement (totaling 7.000ns) by 3.150ns
  Delay   Site    Resource
 3.000ns CLB_R2C1.K to CLB_R2C1.XQ CLKD1 (from CLK)
 1.310ns CLB_R2C1.XQ to CLB_R2C1.G2 CLKD1
 4.500ns CLB_R2C1.G2 to CLB_R2C1.Y CLKD1
 1.340ns CLB_R2C1.Y to CLB_R2C2.C1 CLKD1D2 (to CLK)
 -------
 10.150ns (73.9% logic, 26.1% route), 2 logic levels.
```

Source and destination clock signals are listed because the path originates at a flip-flop (CLKD1.K, signal CLK) and terminates at a flip-flop with a 3 ns setup requirement relative to the signal CLK. This allows you to determine what the source and destination clock signals are for sequential paths.

The following example has source and destination clock signals that are different. Identifying these clocks allows you to determine whether or not the timing constraint on the path needs modification based on the phase relationships of the different clock signals.

```
4.830ns delay CLKD2 to CLKD2' meets
 20000ns delay constraint less
 3.000ns setup requirement (totaling 17.000ns) by 12.170ns
  Delays   Site     Resource
 3.000ns CLB_R3C1.K to CLB_R3C1.XQ CLKD2 (from CLK2)
 1.830ns CLB_R3C1.XQ to CLB_R3C2.C1 CLKD2 (to CLK)
 -------
 4.830ns (62.1% logic, 37.9% route), 1 logic levels.
```

Verbose TRACE Report

The verbose report is similar to the error report but provides more details on delays for all constrained paths and nets in the design. As in the other two types of reports, descriptive material appears at the top.

The body of the verbose report enumerates each preference as it appears in the input preference file, the number of items scored by TRACE for that preference, and the number and description of errors detected for the preference. A report line for each preference provides important information, such as the amount of delay on a net and by how much the constraint is met.

For path preferences, if there is an error, the report indicates the amount by which the preference is exceeded. If there are no errors, the report indicates that the preference passed and by how much. Each logic and route delay is analyzed, totaled, and reported.

The TRACE report includes all paths that are covered with the BLOCK PATH preference. Details for a BLOCK NET preference are not included. In TRACE, the signal defined in a BLOCK NET preference is removed from the timing-graph analysis completely. Because there is no path or coverage related to this signal any longer, all paths through the signal are blocked/removed and considered covered.

TRACE Report Sections

Shown below are the possible sections that a given TRACE Report (.tw1/.twr) file might include. These sections will vary, depending on the FPGA architecture, timing preferences, design elements, and reporting style (error or verbose).

Report Title and Design Information At the top of each type of report is descriptive information about your design. For example, it includes the software version of the application, the input preference file name, the NCD design file name, device specifications (device, package, performance grade), and environment path name. The example below identifies this as a PAR TRACE report instead of a Map TRACE Report.

```
Place & Route TRACE Report

Loading design for application trce from file
attributes_attributes.ncd.
Design name: top
NCD version: 3.2
Vendor:      LATTICE
Device:      LFXP2-17E
Package:     FTBGA256
Performance: 5
Loading device for application trce from file
'mg5a50x47.nph' in environment: C:/lscc/diamond/2.1/
ispfpga.
Package Status:                     Final
Version 1.63
Performance Hardware Data Status:   Final
Version 10.6
Setup and Hold Report
```

Version, Build, Time Stamp, and Copyright This section shows the date and time the file was generated and the software version that created it. All relevant copyright information is also displayed.

Report Information This section tells you about the report file that TRACE generated, the exact command that generated it, the preference file (PRF) and design NCD file associated with it, and the reporting level of the file.

Preference Summary The Preference Summary lists all the timing preferences that you specified in the LPF file. It shows the actual preference line syntax, the number of errors, and the number of items scored by TRACE.

```
Preference Summary

FREQUENCY NET "dec_pll_clk_c" 200.000000 MHz (28 errors)

            511 items scored, 28 timing errors detected.
Warning: 184.298MHz is the maximum frequency for this
preference.

FREQUENCY NET "enc_pll_clk_c" 200.000000 MHz (4 errors)

            101 items scored, 4 timing errors detected.
Warning: 196.232MHz is the maximum frequency for this
preference.

FREQUENCY NET "dec_clk_c" 200.000000 MHz (0 errors)
            0 items scored, 0 timing errors detected.

FREQUENCY NET "enc_clk_c" 200.000000 MHz (0 errors)
            0 items scored, 0 timing errors detected.

BLOCK PATH TO CELL "u1_decoder/cnt_enb" (0 errors)
            112 items scored, 0 timing errors detected.

BLOCK ASYNCPATHS
BLOCK RESETPATHS
```

Preference Details The Preference Details section shows the logical details and delays of each scored path covered by a given timing constraint.

It provides timing error details or warnings on a constraint requirement for physical path delay. It also shows attributes associated with I/O logic, interface timing AIL, and DDR input dynamic timing settings. The boldfaced line in the following example shows where the 2.528ns DIN_SET delay originates:

```
================================================================
Preference: FREQUENCY PORT "CLK" 1000.000000 MHz ;
            1 item scored, 1 timing error detected.
----------------------------------------------------------------

Error:  The following path exceeds requirements by 2.272ns

 Logical Details:  Cell type  Pin type       Cell/ASIC name  (clock net +/-)

   Source:         Port       Pad            d
   Destination:    FF         Data in        Q_0io  (to CLK_c +)

   Delay:               0.744ns  (100.0% logic, 0.0% route), 1 logic levels.

 Constraint Details:

      0.744ns physical path delay d to d_IOLOGIC_S exceeds
      1.000ns delay constraint less
      2.528ns DIN_SET requirement (totaling -1.528ns) by 2.272ns

IOLOGICB20A attributes: COARSE=CDEL1, FINE=FDEL10

 Physical Path Details:

   Name    Fanout   Delay (ns)          Site               Resource
IN_DEL      ---     0.744         R9.PAD to       R9.PADDI d
ROUTE         1     0.000       R9.PADDI to IOLOGICB20A.DI d_c (to CLK_c)
                  --------
                    0.744   (100.0% logic, 0.0% route), 1 logic levels.

Warning: 305.623MHz is the maximum frequency for this preference.
```

The Logical Details subsection reports circuit path Source and Destination information:

- instance names as they appear in the EDIF file for the following cell types: Registered elements, Ports, RAM instances
- a description of the type of function performed at the destination; for example, Data in, Write enable, or Carry in
- indication of the triggering edge of the clock using (+/-)

The section includes source component logical name, cell type, pin type, clock name and edge; and it includes destination component logical name, cell type, pin type, clock name and edge.

The Physical Path Details shows the paths connected to their source and destination sites on the chip. At the bottom of the Delays column, it shows the total amount of delay for the path, the percentages of the total allocated to logic and to route delays (in parentheses), and the number of logic levels (components) involved in the preference.

This part of the TRACE report will also alert you to any timing warnings or errors associated with the specific preference. Timing warnings point out potential timing problems. Timing errors, however, indicate absolute timing constraint violations. Timing errors may indicate a need for design modifications and/or multiple placement and/or reentrant routing.

The most critical paths are reported from top to bottom in this section. These paths are all ranked in terms of weighted slack values based on one full clock cycle. If the path is not a full cycle, you might see something like “weighted slack = 2.000ns” following the pass/fail statement. This simply indicates that the actual timing value is scaled up to a full clock cycle value and that the path was scored at 1.00ns at a half cycle.

To discover the multiplier that was used to scale the clock time to one full cycle, look at the source and destination clocks in the Logical Details section of a given path. For example, if the clock frequency is the same and you go from a positive to positive edge clock or negative to negative, you have a full cycle. If your clocks with the same frequency go from a positive to a negative or vice versa, that will be a half cycle. If you have clocks with different frequencies, interdomain clocks, your cycle time will vary; the multiplier will not be readily apparent, but it will be scaled up appropriately with a weighted slack value.

```
   ================================================================================
   Preference: FREQUENCY PORT "clk" 150.000000 MHz ;
               6 items scored, 0 timing errors detected.
   --------------------------------------------------------------------------------

   Passed:  The following path meets requirements by 0.235ns

    Logical Details:  Cell type  Pin type       Cell/ASIC name  (clock net +/-)

      Source:         FF         Q              c_0  (from clk_c +)
      Destination:    FF         Data in        c_0  (to clk_c +)

      Delay:               0.236ns  (75.8% logic, 24.2% route), 2 logic levels.

    Constraint Details:

          0.236ns physical path delay SLICE_0 to SLICE_0 meets
          0.001ns DIN_HLD and
          0.000ns delay constraint less
          0.000ns skew requirement (totaling 0.001ns) by 0.235ns

    Physical Path Details:

           1.434ns         J2.PADDI to R15C18B.CLK

Warning:   2.034ns is the maximum delay for this preference.
```

When the design contains a pulse width error—for example, when a FREQUENCY preference that specifies an unachievable clock speed on a DSP in your design is not met—TRACE reports these conditions as shown below:

```
============================================================
Preference: FREQUENCY PORT "clkfast" 300.000000 MHz ;
            169 items scored, 1 timing errors detected.
Note: Component internal maximum frequency has been exceeded.
------------------------------------------------------------
```

Note

These examples show an input design that is placed and routed. If the input design is neither placed nor routed, estimated delays will all show up as 0 and will be signified by the letter **e**.

Unconstrained Paths This section will be included in the report if you have selected the Check Unconstrained Paths Trace option for the active strategy. In the Unconstrained Paths section, TRACE reports the paths that are not constrained and shows the start point and end point of each path. Suggested timing preferences are provided to constrain the given paths.

Based on the design and the required performance, only necessary paths should be constrained so that PAR focuses only on the optimization of the important paths. However, the Unconstrained Paths section of the TRACE report is very useful for identifying whether any missing timing constraints are really important to the design. This option does not require you to add more preferences in an attempt to constrain all paths. Instead, it serves as a reminder that there might be a necessary preference that is missing, which could impact the desired performance of the design. See "Setting TRACE Options" on page 693 for important points about connection coverage.

As shown in the following example, TRACE reports only the "setup" timing of unconstrained paths to avoid duplication of these same paths in a "hold" timing report.

```
Preference: Unconstrained Paths
            101 items scored, 0 timing errors detected.
--------------------------------------------------------------
Unconstrained Preference:

Report Summary This part of the report provides a matrix that illustrates the pass or fail status of the timing preferences analyzed. If all preferences are met, you will see a statement to that effect at the bottom of the summary. If not all preferences are met, each unmet preference will be marked with an asterisk in the Levels column of the summary.

```

HOLD_MARGIN 0.100000 nS ;             |  250.000 MHz|  207.039 MHz|   1 *

6 preferences(marked by "*" above) not met.
```

Timing Summary At the end of each report is a timing summary, which reports the following information for the design:

- the number of timing errors found
- a timing score showing total errors in picoseconds for all timing preferences
- the number of paths and connections covered by the constraints and the percentage coverage over the whole design
- a common errors matrix, which reports critical nets that are responsible for more than 10 percent of timing errors.

```
Timing summary (Hold):
---------------

Timing errors: 0  Score: 0
Cumulative negative slack: 0

Constraints cover 6 paths, 1 nets, and 12 connections (80.0%
coverage)

Timing summary (Setup and Hold):
---------------

Timing errors: 0 (setup), 0 (hold)
Score: 0 (setup), 0 (hold)
Cumulative negative slack: 0 (0+0)
```

Clock Domains Analysis The Clock Domains Analysis section helps you understand the clocking resources used by the design and the interaction between the clock domains. This section will not be included in the TRACE report if a physical preference is used.

You can use the Clock Domains Analysis section to determine the following information about your design:

- Which FREQUENCY, MULTICYCLE, MAXDELAY and BLOCK preferences are applied to a given clock domain. Note this does not include tSU, tCO, etc.
- Which clock domains transfer to another clock domain.
- The number of loads on a clock domain. A load on a clock net is simply the number of routed destination points of that clock net.

The Clock Domains Analysis section is broken down into separate subsections that report on each clock domain. A specific clock domain covered in a subsection is referred to here as a *Reported Clock Domain*. Each subsection contains information on *Transfer From Clock Domains*. A Transfer From Clock Domain starts a path that terminates in the subsection's Reported Clock Domain. So each subsection describes transfers within a specific clock domain and transfers to that specific clock domain.

Within a subsection, the term *Loads* refers to the number of synchronous elements clocked by the clock of the subsection's Reported Clock Domain. Paths to these synchronous elements may or may not originate in the Reported Clock Domain. These synchronous elements will be the end of paths that may originate from inside or outside the Reported Clock Domain.

The term *Transfers* refers to the number of synchronous elements clocked by the clock in the Transfer From Clock Domain that are the source of at least one path that terminates in the Reported Clock Domain.

Note

This Clock Domains Analysis section covers clock transfers between different physical components only. Clock transfers inside multiple clock components, such as DDR or PCS, are not covered in this section.

Below are examples from the Clock Domains Analysis section of the TRACE report and explanations:

Example 1

```
Clock Domain: txs4ls2_ck   Source: ehxplla_tx/
ehxplla_tx_0_0.CLKOS   Loads: 20
   Covered under: MULTICYCLE TO CELL "*ODDRX2A*" 2.000000 X ;
   Covered under: FREQUENCY NET "txs4ls2_ck" 250.000000 MHz ;
```

In this example, there are 20 loads on the clock domain txs4ls2_ck. The preferences that cover the data transfers of clock domain txs4ls2_ck are MULTICYCLE and FREQUENCY. There are no data transfers from another clock domain to txs4ls2_ck.

Example 2

```
Clock Domain: txs4ls4_ck   Source: TXS4LS4_CK.Q0   Loads: 26
   Covered under: FREQUENCY NET "txs4ls4_ck" 125.000000 MHz ;

   Data transfers from:
   Clock Domain: pll_sdck   Source: ehxplla_sdck/
ehxplla_sdck_0_0.CLKOS
      Blocked under: BLOCK PATH FROM CLKNET "pll_sdck" TO
CLKNET "txs4ls4_ck" ;
```

In this example, there are 26 loads on the clock domain txs4ls4_ck. The preference that covers the data transfers of clock domain txs4ls4_ck _ck is FREQUENCY. There is a data transfer from the clock domain pll_sdck to txs4ls4_ck. A BLOCK preference covers the clock domain crossing from pll_sdck to txs4ls4_ck _ck.

Example 3

```
Clock Domain: rdclki   Source: rdclk_p.PAD   Loads: 1
   No transfer within this clock domain is found
```

In this example, there is one load on the clock domain rdclki. There are no data transfers on the clock domain rdclki.

There are no Frequency, Multicycle, or Block preferences that cover the clock domain rdclki. There are no data transfers from another clock domain to rdclki.

Example 4

```
Clock Domain: txs4hs_ck   Source: ehxplla_tx/
ehxplla_tx_0_0.CLKOP   Loads: 19
   No transfer within this clock domain is found

   Data transfers from:
   Clock Domain: txs4ls2_ck   Source: ehxplla_tx/
ehxplla_tx_0_0.CLKOS
     Covered under: FREQUENCY NET "txs4hs_ck" 500.000000 MHz ;
Transfers: 1
```

In this example, there are 19 loads on the clock domain txs4ls4_ck. There are no data transfers on the clock domain txs4hs_ck. There are no FREQUENCY, MULTICYCLE, or BLOCK preferences that cover the clock domain txs4hs_ck. There is a data transfer from the clock domain txs4ls4_ck to txs4hs_ck. A FREQUENCY preference covers the clock domain crossing from txs4ls4_ck to txs4hs_ck and there is one data transfer.

Example 5

```
Clock Domain: pll_sdck   Source: ehxplla_sdck/
ehxplla_sdck_0_0.CLKOS   Loads: 413
   Covered under: FREQUENCY NET "pll_sdck" 150.000000 MHz ;

   Data transfers from:
   Clock Domain: txs4ls2_ck   Source: ehxplla_tx/
ehxplla_tx_0_0.CLKOS
      Not reported because source and destination domains are
unrelated.
      To report these transfers please refer to preference
CLKSKEWDIFF to define
      external clock skew between clock ports.
```

In this example, the clock domain pll_sdck and txs4ls2_ck are driven by two unrelated external clocks. Because there are no skew relationships defined between the external clocks, these two clock domains do not have a meaningful skew. Although there are data transfers between these two domains, they will not be reported by default. Preference CLKSKEWDIFF can be used on the external clocks in order to report these transfers.

Interclock Domain Transfers Between Unrelated Clocks
Two clock signals are defined as unrelated if they are not driven by the same clock input pad and you have not defined a relationship between them using the CLKSKEWDIFF preference.

Prior to ispLEVER 7.2, data transfers between unrelated clocks were reported as if those clocks were related and had a skew of 0. In ispLEVER 7.2 and later, data transfers between unrelated clocks are not reported. If you want to have those transfers reported, they must define a clock relationship between the two external clocks using the CLKSKEWDIFF preference. This updated behavior in TRACE avoids needlessly over-constraining a design. For example, data crossing between two asynchronous clocks should be analyzed during simulation. Static timing analysis cannot be used to guarantee proper operation. The former default constraint adds no value, and could negatively impact design performance.

The following is an example from the Clock Domains Analysis section, where two clocks are considered unrelated and the data crossing between them is not reported.

```
Clock Domain: Comclk_i_int   Source: Comclk_i.PAD
    Not reported because source and destination domains are
    unrelated.
    To report these transfers please refer to preference
    CLKSKEWDIFF to define external clock skew between clock
    ports.
```

The Clock Domains Analysis section will list all data transfers between clocks that are not reported as the clocks are considered unrelated. You should verify that all clock pairs considered unrelated are actually unrelated. A good design practice is to use simulation to verify the proper operation of data

crossing unrelated clock domains. The following is an example of a Clock Domains Analysis section.

```
Clock Domains Analysis
------------------------
Found 37 clocks:
Clock Domain: pll_sdck   Source: ehxplla_sdck/ehxplla_sdck_0_0.CLKOS   Loads: 696
   Covered under: FREQUENCY NET "pll_sdck" 150.000000 MHz ;

   Data transfers from:
   Clock Domain: txs4ls4_ck   Source: ehxplla_tx/ehxplla_tx_0_0.CLKOS
      Not reported because source and destination domains are unrelated.
      To report these transfers please refer to preference CLKSKEWDIFF to define
      external clock skew between clock ports.

   Clock Domain: rdclki   Source: rdclk_p.PAD
      Not reported because source and destination domains are unrelated.
      To report these transfers please refer to preference CLKSKEWDIFF to define
      external clock skew between clock ports.

   Clock Domain: iobuf/iobuf_tstatus_ckii   Source: tstatus_ck.PAD
      Not reported because source and destination domains are unrelated.
      To report these transfers please refer to preference CLKSKEWDIFF to define
      external clock skew between clock ports.

   Clock Domain: pll_sdck2   Source: ehxplla_sdck/ehxplla_sdck_0_0.CLKOP
      Covered under: FREQUENCY NET "pll_sdck" 150.000000 MHz ;   Transfers: 1

   Clock Domain: spi4_256ch/rxs4ls2_ck   Source: spi4_256ch/gearbox/rxgb/
CLKDIV_RXIO.CLKO
      Not reported because source and destination domains are unrelated.
      To report these transfers please refer to preference CLKSKEWDIFF to define
      external clock skew between clock ports.

   Clock Domain: txs4ls2_ck   Source: spi4_256ch/gearbox/txgb/CLKDIV_TXIO.CLKO
      Not reported because source and destination domains are unrelated.
      To report these transfers please refer to preference CLKSKEWDIFF to define
      external clock skew between clock ports.

Clock Domain: rxlt10_trerr   Source: spi4_256ch/s4dp/deskew/SLICE_1395.Q0   Loads: 2
   No transfer within this clock domain is found

   Data transfers from:
   Clock Domain: txs4ls4_ck   Source: ehxplla_tx/ehxplla_tx_0_0.CLKOS
      Covered under: FREQUENCY PORT "txref" 100.000000 MHz ;   Transfers: 1

Clock Domain: rxlt40_trerr   Source: spi4_256ch/s4dp/deskew/SLICE_1396.Q0   Loads: 2
   No transfer within this clock domain is found

   Data transfers from:
   Clock Domain: txs4ls4_ck   Source: ehxplla_tx/ehxplla_tx_0_0.CLKOS
      Covered under: FREQUENCY PORT "txref" 100.000000 MHz ;   Transfers: 1

Clock Domain: N_105_iZ0   Source: SLICE_2784.F0   Loads: 1
   No transfer within this clock domain is found

   Data transfers from:
   Clock Domain: txs4ls4_ck   Source: ehxplla_tx/ehxplla_tx_0_0.CLKOS
      Not reported because source and destination domains are unrelated.
      To report these transfers please refer to preference CLKSKEWDIFF to define
      external clock skew between clock ports.
```

Loop Report This section of the TRACE report lists all paths that cannot be analyzed because of asynchronous loops in the circuit. This loop report is available in both Error and Verbose levels of reporting. Path name, fanout, delay (ns), destination, and source information are provided.

- "Setting Options in Timing Analysis View" on page 730

Cross-Probing to Synplify Pro HDL Analyst

Lattice Diamond, together with the Synplify Pro for Lattice software, enables you to cross-probe a path from the TRACE report to HDL Analyst view. This provides you with a schematic view of the path and helps you diagnose problem areas to improve the timing.

To cross-probe from TRACE to the Synplify Pro HDL Analyst:

1. In Diamond, run the **Place & Route Trace** process.
2. Click the Synplify Pro button on the toolbar to launch Synplify Pro for Lattice.
3. In the Synplify Pro main window, click the **Run** button to synthesize the project and create the schematic views for the active implementation.
4. Click the Technology View button on the Synplify Pro toolbar to open HDL Analyst.
5. Choose **File > Open**, navigate to the TRACE report file (.twr) that you generated in Step 1, and open it.

   The Synplify Pro Text Editor View opens and displays the TRACE report.
6. In the Text Editor View, highlight the path in the TRACE report that you want to examine by dragging your mouse over it.
7. Right-click the selected path and choose **Filter in Analyst** from the pop-up menu.
8. Click the Technology View tab at the bottom to return to the HDL Analyst view.

   A schematic view of the selected path is displayed in HDL Analyst.

To view the critical path:

- Right-click anywhere in HDL Analyst and choose **Show Critical Path**.

TRACE Timing Arc Descriptions

The following table provides definitions of timing arcs for setup time, hold time, delays, and minimum pulse width that you encounter within the TRACE report (.tw1/.twr) file. Timing arcs refer to intra-cell path delays—the time it takes for a signal to flow from a given logic cell's input transition to a resulting output rise (or fall) output transition. TRACE timing analysis reports timing arcs as a part of constraint calculation.

Table 2: Setup Time Timing Arcs in TRACE

Identifier	Description
ADDR_SET	Address setup
CE_SET	CE setup
CLK2ECLK_SET	ODDR CLK to Edge CLK setup
CNTL_SET	DQSDLL UDDCNTL pin to CLK setup
CS_SET	EBR CS to CLK setup
DATA_SET	EBR DI (data in) setup
DIN_SET	SLICE DIN to CLK setup
DI_SET	IOLOGIC DI to CLK setup
ECLK2CLK_SET	IDDR Edge CLK to CLK setup
LSRREC_SET	LSR Recovery setup
LSR_SET	LSR setup
M_SET	SLICE/FSLICE M pins to CLK setup
ONEG0_SET	IOLOGIC ONEG0 to CLK setup
ONEG1_SET	IOLOGIC ONEG1 to CLK setup
ONEG2_SET	IOLOGIC ONEG2 to CLK setup
OPOS0_SET	IOLOGIC OPOS0 to CLK setup
OPOS1_SET	IOLOGIC OPOS1 to CLK setup
OPOS2_SET	IOLOGIC OPOS2 to CLK setup
RST_SET	Reset to CLK setup
SMI_SET	DLL SMI address pins to SMICLK setup
TCK_SET	JTAG JTDO pin to TCK setup.
TD_SET	IOLOGIC TD pin to CLK setup
WAD_SET	SLICE WAD pin to WCK setup
WD_SET	SLICE WD pin to WCK setup
WE_SET	EBR WE to CLK setup
WRE_SET	SLICE WRE pin to WCK setup

Table 3: Hold Time Timing Arcs in TRACE

Identifier	Description
ADDR_HLD	Address hold time
CE_HLD	Clock Enable (CE) hold
CLK2ECLK_HLD	IOLOGIC CLK to edge CLK hold
CNTL_HLD	DQSDLL UDDCNTL pin to CLK hold
CS_HLD	EBR CS to CLK hold
DATA_HLD	EBR data hold
DIN_HLD	SLICE DIN to CLK hold
DI_HLD	IOLOGIC DI to CLK hold
ECLK2CLK_HLD	IDDR edge CLK to CLK hold
LSR_HLD	LSR hold
M_HLD	SLICE/FSLICE M pins to CLK hold
ONEG0_HLD	IOLOGIC ONEG0 to CLK hold
ONEG1_HLD	IOLOGIC ONEG1 to CLK hold
ONEG2_HLD	IOLOGIC ONEG2 to CLK hold
OPOS0_HLD	IOLOGIC OPOS0 to CLK hold
OPOS1_HLD	IOLOGIC OPOS1 to CLK hold
OPOS2_HLD	IOLOGIC OPOS2 to CLK hold
RST_HLD	Reset to CLK hold
SMI_HLD	DLL SMI address pins to SMICLK hold
TCK_HLD	JTAG JTDO pin to TCK hold
TD_HLD	IOLOGIC TD pin to CLK hold
WAD_HLD	SLICE WAD pin to WCK hold
WD_HLD	SLICE WD pin to WCK hold.
WE_HLD	EBR WE to CLK hold
WRE_HLD	SLICE WRE pin to WCK hold

Table 4: Delay Timing Arcs in TRACE

Identifier	Description
C0TOFCO_DEL	SLICE/FSLICE A0/B0/C0/D0 to FCO delay
C1TOFCO_DEL	SLICE/FSLICE A1/B1/C1/D1 to FCO delay
C2OUT_DEL	IOLOGIC CLK to INFF delay
C2Q_DEL	DSQCLK to Q delay
CK2DVAL_DEL	DQS CLK to DATAVALID delay
CK2OUT_DEL	DLL CLKI or CLKFB to CLKOP/CLKOS; CLKI to CLKO; SMICLK to SMIRDATA.
CLKI2OP_DEL	PLL CLKI to CLKOP delay
CLKI2OS_DEL	PLL CLKI to CLKOS delay
CLKI2OK_DEL	PLL CLKI to CLKOK delay
CLKFB2IFB_DEL	PLL CLKFB to CLKINTFB delay
CLKI2IFB_DEL	PLL CLKI to CLKFB delay
CLKFB2OK_DEL	PLL CLKFB to CLKOK delay
CLKFB2OP_DEL	PLL CLKFB to CLKOP delay
CLKFB2OS_DEL	PLL CLKFB to CLKOS delay
CLKOUT_DEL	CLKDIV CLKI to CDIV* or RELEASE to CDIV* delay
CLKTOF_DEL	SLICE WCK to F0 or F1 delay
CTOF1_DEL	SLICE/FSLICE A0,B0,C0,or D0 to F1 delay
CTOF_DEL	SLICE/FSLICE A0,B0,C0,D0 to F0 or A1,B1,C1,D1 to F1 delay.
CTOOFX_DEL	SLICE/FSLICE A0,B0,C0,D0 to OFX0 or A1,B1,C1,D1 to OFX0 delay.
DOPAD_DEL	PIO IOLDO to PAD delay
DQI2DQC_DEL	DQS DQSI to DQSC delay
DQI2DQO_DEL	DQS DQSI to DQSO delay
DQI2PT_DEL	DQS DQSI to PRMBDET delay
DQSI2POL_DEL	DQS DQSI to DDRCLKPOL delay
DTPAD_DEL	PIO IOLTO to PAD delay
FCITOF0_DEL	SLICE/FSLICE FCI to F0 delay
FCITOF1_DEL	SLICE/FSLICE FCI to F1 delay
FCITOFCO_DEL	SLICE/FSLICE FCI to FCO delay
FXTOOFX_DEL	SLICE/FSLICE FXA or FXB to OFX1 delay

Table 4: Delay Timing Arcs in TRACE (Continued)

Identifier	Description
JTCK_DEL	JTAG TCK to JTCK delay
LSR2Q_DEL	SLICE/FSLICE LSR to Q0 or Q1 delay
MTOOFX_DEL	SLICE/FSLICE M0 to OFX0 or M1 to OFX1 delay
MUX_DEL	DCS CLK0 or CLK1 to DCSOUT delay
PADI_DEL	PIO PAD to PADDI delay
REG_DEL	SLICE/FSLICE CLK to Q0 or Q1 delay
RST2LOCK_DEL	DQSDLL RST to LOCK delay
RST_DEL	DLL RSTN to LOCK delay
TLATCH_DEL	IOLOGIC DI to INFF or ONEG0 to IOLDO or TD to IOLTO delay
ZERO_DEL	Connection with zero delay
LSR_OUT	IOLOGIC LSR to INFF, IOLDO, or IOLTO delay

Table 5: MPW (Minimum Pulse Width) Timing Arcs in TRACE

Identifier	Description
CLKH_MPW	DLL CLKI, CLKFB, or SMICLK minimum high pulse width
CLKL_MPW	DLL CLKI, CLKFB, or SMICLK minimum low pulse width
CLK_MPW	CLK minimum pulse width
LSR_MPW	DLL RSTN or SMIRSTN minimum pulse width
PAD_MPW	PIO PAD minimum pulse width
RST_MPW	EBR RSTA or RSTB minimum pulse width

Running I/O Timing Analysis

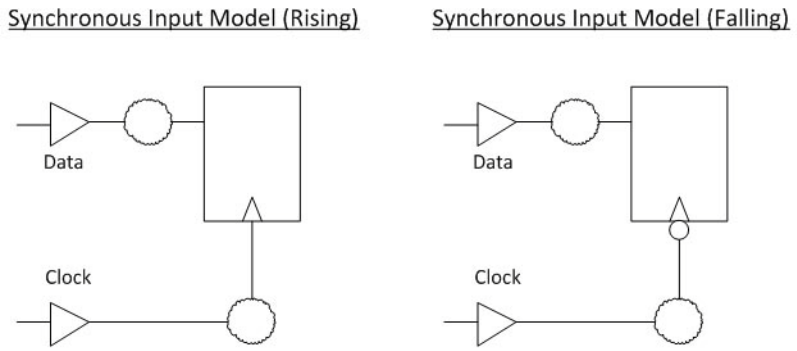
The I/O Timing Analysis process generates a report (.ior) of worst case input setup/hold and min/max clock-to-out I/O results for the design. For each input data port in the design, it provides the setup and hold time requirements in relation to an input clock port. For each output data port or forwarded clock in the design, it provides the minimum and maximum clock-to-out timing in relation to an input clock port.

Unlike the TRACE report, the I/O Timing Analysis report is not limited to reporting paths covered by timing preferences. The report is focused on FPGA I/O timing characteristics for the full range of the device performance grades. The final numbers reported are based on the worst-case timing across all of the performance grades. To find the details on any of the ports listed, the TRACE report will need to be utilized.

What Gets Analyzed in I/O Timing Analysis

I/O Timing Analysis reports on FPGA I/O port timing. The following are descriptions of the I/O models, showing how they are presented in the report file (.ior).

Synchronous Input Model The following diagrams show rising edge and falling edge synchronous input timing models. They will be analyzed by I/O Timing Analysis, which will provide the worst-case setup and hold requirements.



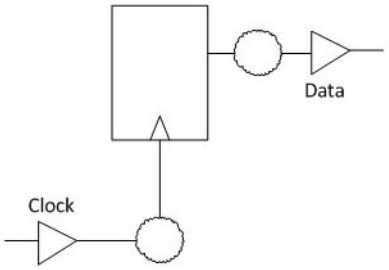
The rising edge and falling edge timing models are shown differently in the .ior report file, as shown in the following example.

```
Port     Clock     Edge  Setup Performance_Grade  Hold Performance_Grade
------------------------------------------------------------------------
din_f    clkin     F    -0.855      M            2.344     7
din_r    clkin     R    -0.855      M            2.344     7
```

In the example, port “din_f” is clocked on the falling edge of clock input port “clkin”. The worst-case setup time for port “din_f” with respect to clock input “clkin” is -0.855ns. A negative input setup time means that the data will not be latched by the clock until after the clock edge. This type of timing happens often in today’s FPGAs with flip-flops located in or near the I/O. For this worst-case input setup, the device performance grade was the –M. The –M performance grade is the fastest performance grade possible for this device. All other performance grades have an input setup which is less than -0.855ns.

On the hold timing side, input port “din_f” must hold its data until 2.344ns after the input clock “clkin”. This worst-case hold timing was found in the -7 performance grade. All other performance grades hold timing is less than the 2.344ns requirement.

Synchronous Output Model The following diagram shows a synchronous output timing model. This model will be analyzing by I/O Timing Analysis and provide the worst-case clock-to-out requirements.



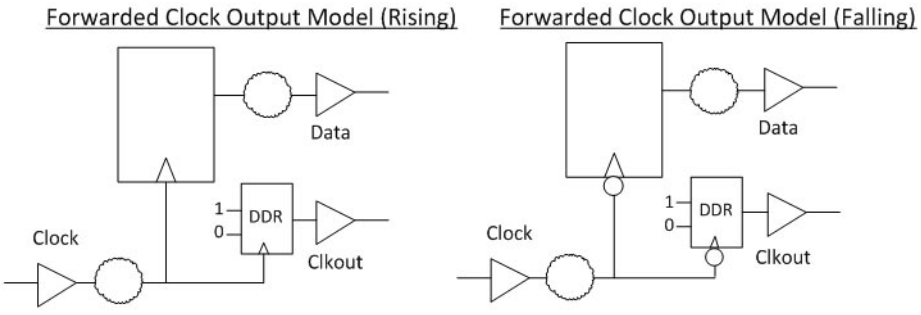
The synchronous output model produces a minimum and maximum clock-to-out line in the .ior report, as shown in the following example:

```
Port       Clock     Edge  Max_Delay Performance_Grade  Min_Delay Performance_Grade
------------------------------------------------------------------------------
dout       clkin      R     7.031         7               3.365          M
```

In this example, port “dout” is clocked on the rising edge of clock input port “clkin”. The worst-case maximum delay from the clock input to the data out time is 7.031ns using a -7 performance grade. All other performance grades have a faster clock-to-out time.

On the minimum side, using –M performance grade, the clock-to-out is reported as 3.365ns. All other performance grades have a longer clock-to-out time.

Forwarded Clock Output Model The following diagram shows rising edge and falling edge forwarded clock output models. Forwarded clocks are commonly used in today’s FPGA I/O parallel interfaces.



Both of these models use a DDR element as the source of the forwarded output clock. This is the recommended method for using a forwarded clock,

because it keeps the clock routing consistent for the data as the clock output. This way, both the data and the clock go through the same logic in the I/O, which results in minimal skew between the clock output and data.

Note

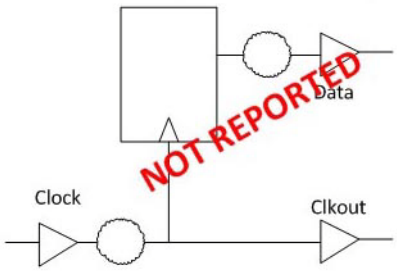
To find out about specific Lattice FPGA architectures and high-speed interface recommendations, visit the Lattice website at www.latticesemi.com and search for device-specific application notes.

To understand the relationship between the data output and forwarded clock, it is important to examine both in the .ior report, as shown in the following example. Each output port will show a clock-to-out number with respect to the input clock. The difference in the clock-to-out will be the skew between the data and clock.

```
Port       Clock     Edge  Max_Delay Performance_Grade  Min_Delay Performance_Grade
------------------------------------------------------------------------------
clkout     clkin      R     7.031         7               3.365          M
dout       clkin      R     7.031         7               3.365          M
```

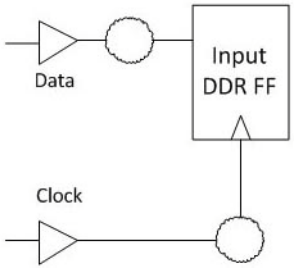
In this example, the clock output “clkout” takes 7.031ns from the input clock “clkin,” and the data output “dout” takes exactly the same time, resulting in an aligned relationship.

It is important to note that the forwarded clock analysis can only happen using the model shown in “Forwarded Clock Output Model” on page 721. The following traditional forwarded clock timing model will not be reported properly in the I/O Timing Analysis .ior report file, because there is no clocked element on the forwarded clock output.



This non-supported timing model will always result in a relatively large amount of skew between the output data and the forwarded clock, since different logical paths are used. The data path will add a clock-to-out delay of the output flip-flop. The clock output path will add a routing delay to an output pin. These paths can have a relatively large difference in timing.

Double-Data-Rate Input Model The following diagram shows a double-data-rate (DDR) input timing model. This model will be analyzed by the I/O Timing Analysis and provide the worst-case setup and hold requirements.



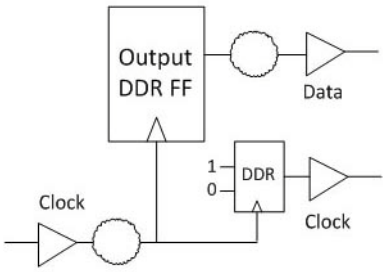
Input DDR interfaces latch data on both the rising and falling edge of the clock. Traditionally, there are two modes of an input DDR interface: centered and aligned. A centered interface has the clock edge centered in the middle of the data valid of the data input before entering the device. An aligned interface has the clock edge and data edge aligned together. Depending on the interface mode, setup and hold numbers need to be understood differently to apply them to the system design. Each current Lattice FPGA architecture family has an application note on designing high-speed interfaces that explains how to use the setup and hold numbers reported in the I/O analysis report.

The following is an example report line for an input DDR interface.

```
Port       Clock     Edge  Max_Delay Performance_Grade  Min_Delay Performance_Grade
------------------------------------------------------------------------------
din_ddr  clkin_ddr     R     0.234             8          0.258        7
```

Double-Data-Rate Output Model The following diagram shows a double-data-rate (DDR) output timing model. Like the forwarded clock model, a DDR element is used to produce the clock output. This ensures that the same logical path is used for both the data and the clock output. This model will be

analyzed by I/O Timing Analysis and provide the worst-case maximum and minimum delay requirements.



Output DDR interfaces launch data on both the rising and falling edge of the clock. Traditionally, there are two modes of an output DDR interface: centered and aligned. A centered interface has the clock edge centered in the middle of the data valid of the data output when leaving the device. An aligned interface has the clock edge and data edge aligned together. Using the I/O analysis report, you can identify the relationship of the clock output and the data output to determine the skew of an aligned or centered interface.

Below is an example report line for an output DDR interface.

```
Port       Clock     Edge  Max_Delay Performance_Grade  Min_Delay Performance_Grade
------------------------------------------------------------------------------------
clkout     clkin_ddr   R     7.031         7               3.365          M
dout_ddr   clkin_ddr   R     7.031         7               3.365          M
```

Generating the I/O Timing Analysis Report

There are two options for generating the I/O Timing Report: you can generate a report with only the worst-case I/O timing reported across all performance grades, or you can generate a report that includes the worst-case I/O timing at the top followed by the results of each available performance grade of the device.

All Performance Grade = False By default, the IO Timing Analysis “All Performance Grade” option in the active strategy is set to False. When the setting of False is used, the given performance grade and any grade faster than the given performance grade are analyzed for each port of the design, and the worst case across all the analyzed grades is reported. These analyzed performance grades include the minimum (M) grade, which is the virtual performance grade that is the fastest with minimum delay. The generated report includes the summary only.

To generate the default I/O Timing Analysis report:

- In the Process View, double-click **I/O Timing Analysis**.

  Diamond computes the data of the given performance grade and any faster performance grades for the device and generates a summary report.

All Performance Grade = True When the IO Timing Analysis “All Performance Grade” option in the active strategy is set to True, all performance grades (including M) of the target device are analyzed, and the worst case across all the grades is reported. The generated report includes the summary, followed by a detailed report for each grade.

To generate the detailed I/O Timing Analysis report:

1. Choose **Project > Active Strategy > IO Timing Analysis Settings**.

   The Strategy dialog box opens and displays the IO Timing Analysis settings.

2. In the IO Timing Analysis pane, change the All Performance Grade value from False to **True** and click **OK**.

3. In Diamond, select the Process tab and double-click **I/O Timing Analysis**.

   Diamond computes the data over all available performance grades and generates a detailed report and summary.

Viewing the I/O Timing Analysis Report The I/O Timing Analysis Report becomes available in the Reports Window as soon as the I/O Timing Analysis process has finished.

To view the I/O Timing Analysis report:

- In the Reports view, expand the Analysis Reports folder and select **I/O Timing Analysis**.

```

Using Timing Analysis View

The Timing Analysis view is a graphical user interface for the static timing analysis program, TRACE. The Timing Analysis view's main window allows you to view the path delay tables and TRACE report of your timing preferences after placement and routing. Additionally, Timing Analysis View includes a TPF version of Spreadsheet View, which allows you to experiment with different sets of timing preferences through the use of timing preference files (.tpf).

Timing Analysis View Main Window Timing Analysis View's main window provides multiple panes, path delay tables, and cross-probing features for viewing key timing data in your design, as well as the start points, end points, and categories of unconstrained paths. For example, you can click on a preference you defined on a particular clock net or port and see the slack associated with it, the delay value, and the source and destination pins. Or you can click on a listed preference for an unconstrained path and view the start point, end point, classification, and clocks. In addition, you can cross-probe a timing path to Floorplan View or Physical View. This can be useful for reconfiguring or regrouping elements to optimize the timing on a critical path.

TPF Spreadsheet View The TPF version of Spreadsheet View provides a way for you to modify timing preferences and see the results without having to rerun Place & Route. After making changes, you simply click the Update button in the Timing Analysis View main window to examine the updated report and delay tables. When you save the changes, they are written to a timing preference file (.tpf) so that your project's logical preference source file (.lpf) is not affected. You can experiment with multiple sets of .tpf files, compare the results, and associate .tpf files with different implementations. You can later copy the modified preferences to your project's .lpf file.

- "Modifying Preferences for Timing Analysis" on page 731
- "Cross-Probing from Timing Analysis View" on page 750
- "Rearranging the Timing Analysis View Layout" on page 742

Opening Timing Analysis View

Timing Analysis View becomes available after placement and routing. When you first open Timing Analysis View, it displays timing information based on constraints in the HDL source files and the active logical preference file (.lpf). After you have created a timing preference file (.tpf) and set it as active, Timing Analysis View will display the .tpf file information when it opens.

To open Timing Analysis view:

- In Diamond, choose **Tools > Timing Analysis View**.

  A progress indicator message box opens, showing that Diamond is calculating the delays. When the progress indicator closes, the timing

preferences, settings, and analysis are displayed in the delay path tables, schematic, and report panes to the right.

Note

Each time you start Timing Analysis view, Diamond loads the NCD file with default timing constraints from the active timing preference file (.tpf), and it does all the necessary calculation. The first time you start Timing Analysis View, it appears to take longer.

To prevent a performance lag, 30 worst case paths are automatically cached in memory for each timing preference even if you have this option set to a lower number. This behavior is set up so that the tool does not have to spend performance time recalculating timing. If you want to analyze more than 30 worst case paths, or if you change any other parameters such as performance grade for setup analysis, the Timing Analysis view will recalculate all paths.

- "Modifying Preferences for Timing Analysis" on page 731
- "Importing In-Memory Timing Preferences" on page 733
- "Setting Options in Timing Analysis View" on page 730
- "Rearranging the Timing Analysis View Layout" on page 742

Setting Options in Timing Analysis View

The Settings pane of Timing Analysis View displays the timing analysis settings in blue font. You can change the values of these settings for your current session of Timing Analysis view by opening the Settings dialog box.

To change the timing analysis settings:

1. Click the **Settings**  **button** on the vertical toolbar.

   Optionally, right-click anywhere inside the Settings pane, and choose **Settings** from the pop-up menu.

2. In the dialog box, select a performance grade for Setup and Hold analysis.
3. Select one or more of the following options:
   - Check Unconstrained Connections – lists the paths that are not covered by any timing preference. This legacy option will be discontinued after the next two Diamond releases. It is recommended that you use the Check Unconstrained Paths option instead.
   - Check Unconstrained Paths – reports paths that are not constrained and shows the start point and end point of each path. In the report, TRACE will suggest some timing preferences to constrain the given paths. If you select this option, you will be able to view the unconstrained paths in Timing Analysis View by category and cross-probe to Floorplan View, Physical View, and the TRACE report.

     Based on the design and the required performance, only necessary paths should be constrained so that PAR focuses only on the optimization of the important paths. However, the Unconstrained Paths section of the TRACE report is very useful for identifying

missing timing constraints that could be important to the design. This option does not require you to add more preferences in an attempt to constrain all paths. Instead, it serves as a reminder that there might be a necessary preference that is missing, which could impact the desired performance of the design. When you select this option, “Unconstrained Paths” will be added to the “Other Reports” section in the Preferences pane of Timing Analysis View’s main window. See also Important points about connection coverage.

Note

The Check Unconstrained Paths option cannot be used with the -allprefpath command-line option.

- Report Asynchronous Timing Loops – reports paths that cannot be analyzed because they are asynchronous loops.
- Full Name – reports the full-length component names instead of truncated names.

4. Select the Report Style.

   The Verbose Timing Report, which is the default, lists detailed logic and route delays for all constrained paths and nets.

   The Error Timing Report lists logic and route delays for each path and net that causes a timing error.

5. Select the number of worst-case paths to be reported for each timing preference. You can select a value from 1 to 200. The default is 10.
6. If you selected the Check Unconstrained Paths option, select the number of unconstrained paths to be reported.
7. Click **OK**.

   The Settings pane in Timing Analysis View displays the settings you selected.

See Also “Setting TRACE Options” on page 693

Modifying Preferences for Timing Analysis

The TPF version of Spreadsheet View enables you to make modifications to your timing preferences for the purpose of experimentation with timing analysis. After you modify timing preferences in the TPF Spreadsheet View, you can view the results by updating them in the Timing Analysis View main window. You can then save the modified preferences to a timing preference file (.tpf).

To modify preferences for timing analysis:

1. From the Timing Analysis View main window, choose **Edit > TPF Preferences** or click the Spreadsheet View button on the vertical toolbar.

2. In the TPF Spreadsheet View, select the tab for the preference you want to define:
   - On the Global Preference sheet, double-click the cell for the preference value you want to change and enter the new value.
   - On the Timing Preference sheet, double-click the desired preference type and select the desired options in the dialog box.
   - On the Group sheet, double-click the desired Define Group type to open the dialog box. Specify the name and select the desired options.
3. Return to the Timing Analysis View main window.

   The tabs of Timing Analysis View and Spreadsheet View – TPF are now marked with asterisks, indicating that changes have been made that have not yet been saved to a .tpf file.

   The Update button  on the toolbar is rotating, which indicates that timing preference changes need to be updated for timing analysis. Any time a data source changes after the view is initialized, the view will detect this condition and prompt you to refresh the changes with the Update button.

   Note

   Updating the timing preference changes does not affect your project's logical preference file.

4. Click the **Update** button.

   The button immediately becomes dim and a progress indicator message appears, showing that Diamond is calculating the results.

   When the progress indicator closes, you can view the results in the delay path tables, schematic, and report of the Timing Analysis View main window.

Note

The asterisks will remain on the tabs of Timing Analysis View and the TPF Spreadsheet View until you save the modified timing preferences to a .tpf file.

When you update your preference changes, they are updated in system memory in your Diamond session so that the views all display the same information. These changes are not automatically written to your current .tpf file. You must save them to a .tpf file separately. You can do this before or after updating the view. See "Creating a New Timing Preference File" on page 744.

See Also
- "Importing In-Memory Timing Preferences" on page 733
- "Creating a New Timing Preference File" on page 744

Importing In-Memory Timing Preferences

When you first open Timing Analysis View, it displays the timing preferences that are in the logical preference file (.lpf). It also displays any unsaved timing preferences that you created in the regular Spreadsheet View after running Place & Route. These in-memory timing preferences get added automatically to the timing preference file (.tpf) when you save them in Timing Analysis View.

However, if you edit timing preferences in the regular Spreadsheet View after you have launched Timing Analysis View, you must import these in-memory timing preferences in order to run timing analysis on them.

To import in-memory timing preferences:

1. In the Timing Analysis View main window, choose **Edit > TPF Preferences** or click the Spreadsheet View button on the vertical toolbar.
2. In the TPF Spreadsheet View, choose **File > Import > Copy LPF to TPF**.
3. Return to the Timing Analysis View main window.

   The Update button on the toolbar is rotating, which indicates timing changes that need to be updated for timing analysis.
4. Click the **Update** button.

   When the progress indicator closes, you can view the results in the delay path tables, schematic, and report of the Timing Analysis View main window.

See Also ▶"Modifying Preferences for Timing Analysis" on page 731

Timing Analysis View Features

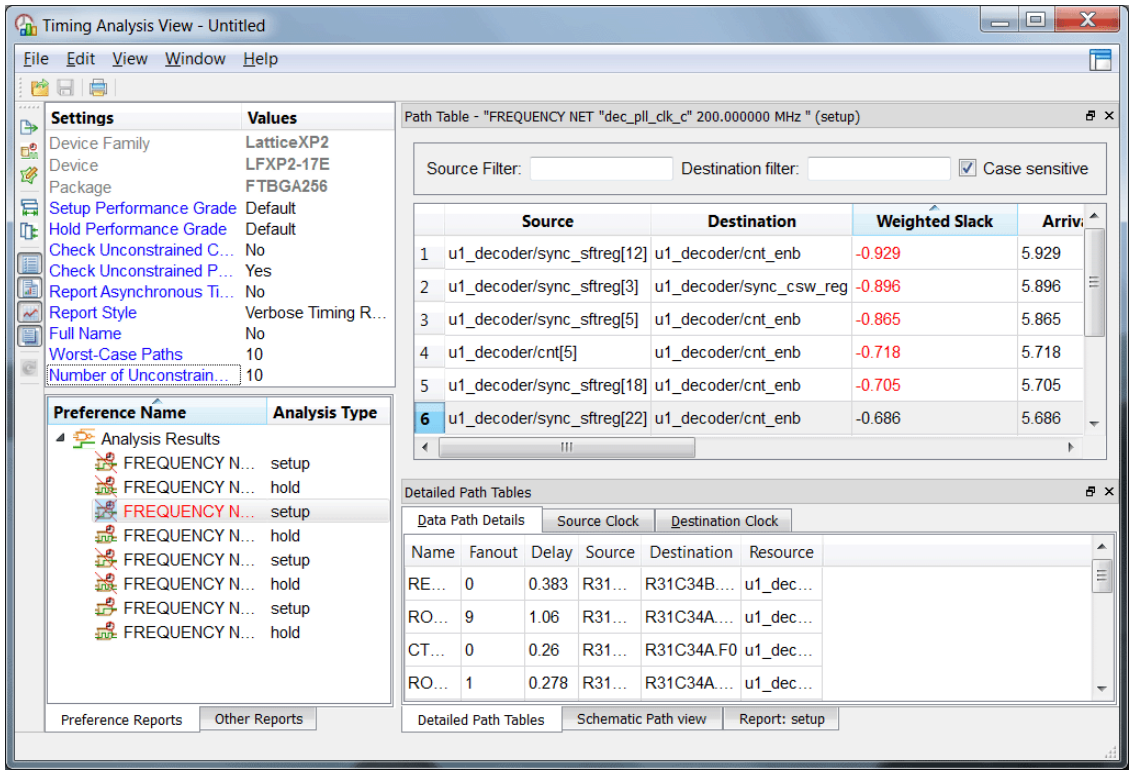
Timing Analysis View provides two main views: a main window consisting of multiple panes for viewing timing preferences, path tables, and the TRACE report; and a TPF Spreadsheet View consisting of Global, Timing, and Group preference sheets. The main window enables you to examine the results of timing preferences, cross-probe delay paths to Floorplan View and Physical View, and troubleshoot paths of the design that restrict performance. The TPF Spreadsheet View enables you to modify timing preferences and then return to the Timing Analysis View main window to examine the results and save the changes to one or more timing preference files (.tpf).

See Also ▶"Rearranging the Timing Analysis View Layout" on page 742

- "Cross-Probing from Timing Analysis View" on page 750
- "Setting Options in Timing Analysis View" on page 730

Timing Analysis View Main Window

When you open Timing Analysis View, its main window displays the settings and preference list pane on the left. It displays the delay path information for a selected preference in the panes to the right. Each of the panes on the right can be detached from the main window, rearranged, and resized. You can use the Settings pane to view or modify the timing analysis report settings. When you select a preference from the Preference pane, you can view the path tables, schematic details, and TRACE report in the other panes. If you have enabled the Check Unconstrained Paths option in Settings, the analysis results for Unconstrained Paths will appear in the Other Reports section of the Preference pane.



Toolbar

The vertical toolbar gives you quick access to commands for exporting timing path data, changing settings, editing timing preference files (.tpf), sizing the path table columns, and displaying or hiding views.

 exports timing path delay data to a .csv file.

 allows you to edit the settings shown in the Settings pane.

 opens the Timing Preference File (TPF) version of Spreadsheet View.

 adjusts table column widths so that complete headings are visible.

 adjusts table column widths so that all of them fit inside the pane.

toggles the display of the Path Table.

toggles the display of the TRACE Report.

toggles the display of the Schematic Path view.

toggles the display of the Detailed Path Tables.

updates the .tpf file with timing preference changes made in the TPF Spreadsheet View.

Settings

The Settings pane displays the targeted device, TRACE analysis, and report settings. You can edit a setting that is displayed in blue font. To edit a setting, right-click anywhere inside the Settings pane and choose **Settings** or click the Settings button on the toolbar.

Settings	Values
Device Family	LatticeXP2
Device	LFXP2-17E
Package	FTBGA256
Setup Performance Grade	Default
Hold Performance Grade	Default
Check Unconstrained Connections	No
Check Unconstrained Paths	Yes
Report Asynchronous Timing Loops	No
Report Style	Verbose Timing Report
Full Name	No
Worst-Case Paths	10
Number of Unconstrained Paths	0

The following settings are included:

- Device Family – the product series name of the Lattice FPGA part, for example, LatticeXP2. This setting is read-only.
- Device – the product's alpha-numeric part name that appears within the software and for ordering. The name's components indicate device family, package, and device size. This setting is read-only.
- Package – the type of package that will house the FPGA chip and is concerned with facilitation of pin connectivity using package leads from device pads. This setting is read-only.
- Setup Performance Grade – the performance grade that will be used for setup analysis and reporting. The default is the minimum performance grade for the targeted device.
- Hold Performance Grade – the performance grade that will be used for hold analysis and reporting. The default is the minimum performance grade for the targeted device.

- Hold Window Performance Grade – the performance grade value of the device itself. It cannot be modified here.
- Check Unconstrained Connections – lists the paths that are not covered by any timing preference. This is a legacy option that will be discontinued after the next two Diamond releases. It is recommended that you use the Check Unconstrained Paths option instead.
- Check Unconstrained Paths – reports the paths that are not constrained, shows the start point and end point of each path, and suggests preferences to constrain the given paths.
- Report Asynchronous Timing **–** shows whether you have chosen to report asynchronous timing paths that cannot be analyzed because they are asynchronous loops.
- Report Style – shows the report style that has been selected: Verbose Report or Error Timing Report. The verbose style includes everything; whereas the error timing report only shows timing errors related to the constraints you have specified in the LPF file.
- Full Name **–** shows whether the full name setting has been selected for displaying COMP names in reports. TRACE defaults to having abbreviated COMP names in the reports, truncating names to a character limit with asterisks. The selection of Yes reports full names. This might cause some tabular formats in the ASCII file report sections to be misaligned, making reports less readable.
- Worst-Case Paths **–** the limit on the number of worst-case timing paths to be reported by TRACE. The default is 10; however, Diamond will report on and cache 200 in its memory without diminishing performance in Timing Analysis view.
- Number of Unconstrained Paths – the limit on the number of unconstrained timing paths to be reported by TRACE. Up to 200 paths can be reported. If you enter a value of 0, all unconstrained paths will be reported, up to 200.

Preferences

The Preferences pane includes two sections: Preference Reports, which shows the analysis results for all timing preferences, and Other Reports, which lists unconstrained paths that might benefit from suggested timing constraints.

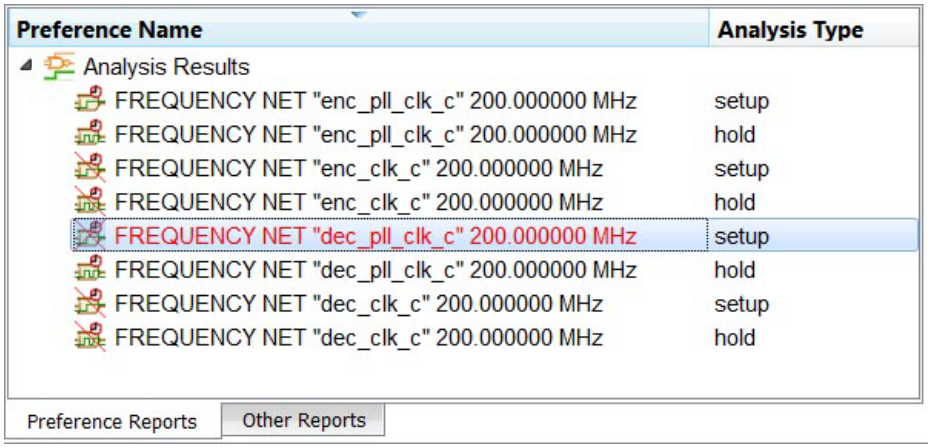
In the Preference Reports section, red font is used to highlight preferences that do not meet timing requirements. You can select a preference from the list to examine the timing paths and reports in the other panes.

The icons in front of the listed preferences have the following significance:

Delay path information is available, and the preference passes timing.

Delay path information is available, and the preference fails timing.

No delay path information is available for the preference.



Preferences Path Tables

When you select a preference from the Preferences Reports section of the Preferences pane, the path tables pane displays the available path data. For large tables, you can use the Source and Destination filters to search for items that contain a combination of different characters.

	Source	Destination	Weighted Slack	Arrival	Required	Data Delay	Route %	Levels	Clock Skew	Setup/Hold	Jitter	Color
1	u1_decoder/sync_sftr...	u1_decoder/cnt_enb	-0.929	5.929	5	5.685	75.0	5	0	0.244	0	
2	u1_decoder/sync_sftr...	u1_decoder/sync_csw...	-0.896	5.896	5	5.652	74.8	5	0	0.244	0	
3	u1_decoder/sync_sftr...	u1_decoder/cnt_enb	-0.865	5.865	5	5.621	74.7	5	0	0.244	0	
4	u1_decoder/cnt[5]	u1_decoder/cnt_enb	-0.718	5.718	5	5.474	78.8	4	0	0.244	0	
5	u1_decoder/sync_sftr...	u1_decoder/cnt_enb	-0.705	5.705	5	5.612	74.6	5	0	0.093	0	
6	u1_decoder/sync_sftr...	u1_decoder/cnt_enb	-0.686	5.686	5	5.442	69.1	6	0	0.244	0	
7	u1_decoder/sync_sftr...	u1_decoder/sync_csw...	-0.671	5.671	5	5.427	73.8	5	0	0.244	0	
8	u1_decoder/sync_sftr...	u1_decoder/cnt_enb	-0.651	5.651	5	5.558	74.4	5	0	0.093	0	
9	u1_decoder/cnt[1]	u1_decoder/cnt_enb	-0.648	5.648	5	5.404	78.5	4	0	0.244	0	

The following data is included in the path tables:

- Source – the registered cell or pad that launches data.
- Destination – the registered cell or pad that receives data.
- Weighted Slack – a measure of the amount of time that a path passes or fails the timing preference. A positive slack indicates the margin by which the path surpasses the clock preference. Negative slack indicates a failing path. The slack is “weighted” or scaled to one full clock cycle so that paths that have different cycles can be ranked according to their severity so that the most critical paths are ordered properly in the table.
- Arrival – the amount of elapsed time in arriving at the destination.
- Required – the maximum amount of time that can elapse in arriving at the destination.
- Data Delay – the total delay for the path.

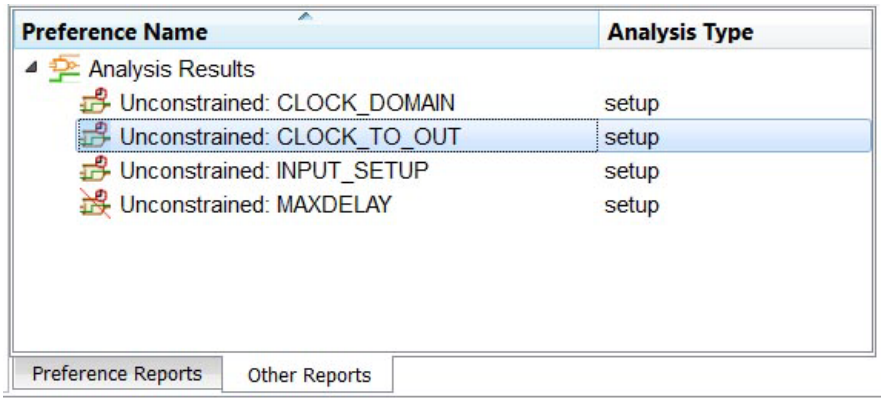
- Route **% –** the percentage of the delay that is contributed by routing resources.
- Levels – the number of combinatorial levels related to the path.
- Clock Skew – time differential between two or more destinations.
- Setup/Hold – the amount of setup and hold time required.
- Jitter – the total jitter in nanoseconds for the delay path. This is a combination of system jitter, clock jitter, and phase shift error.
- Color – how each path will be colored-coded when cross-probed to Floorplan or Physical views.

Unconstrained Paths Report

If you have selected the “Check Unconstrained Paths” option in TRACE settings, select the **Other Reports** tab in the Preferences pane to view a list of suggested constraints for unconstrained paths.

Note

The “Check Unconstrained Paths” option for Place and Route must be enabled in the strategy options or in the Timing Analysis View Settings in order for the results to appear in the Other Reports section. The Clock Path section of the Detailed Path table for unconstrained paths might be empty, since it will display only what is in the TRACE report file.

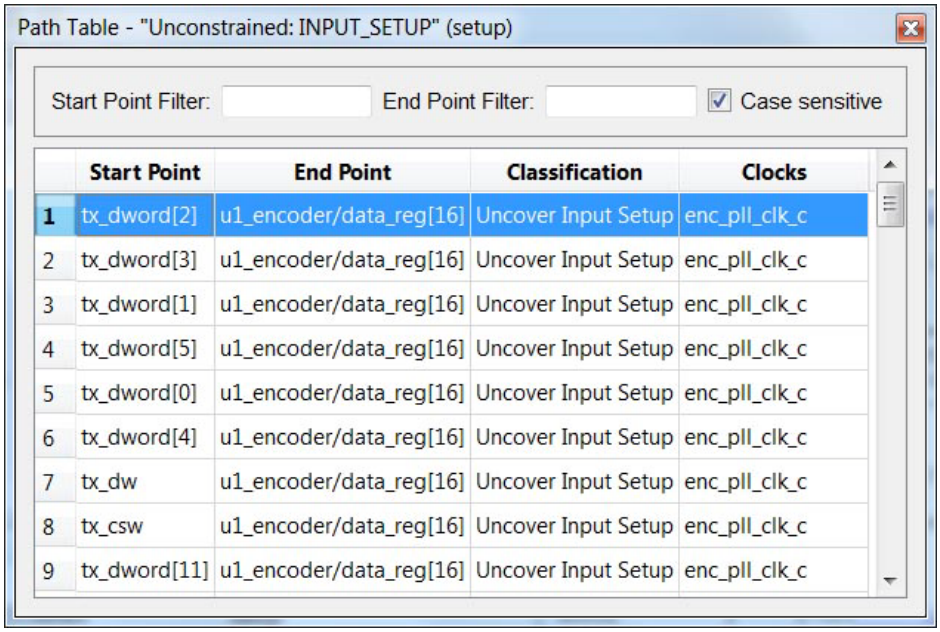


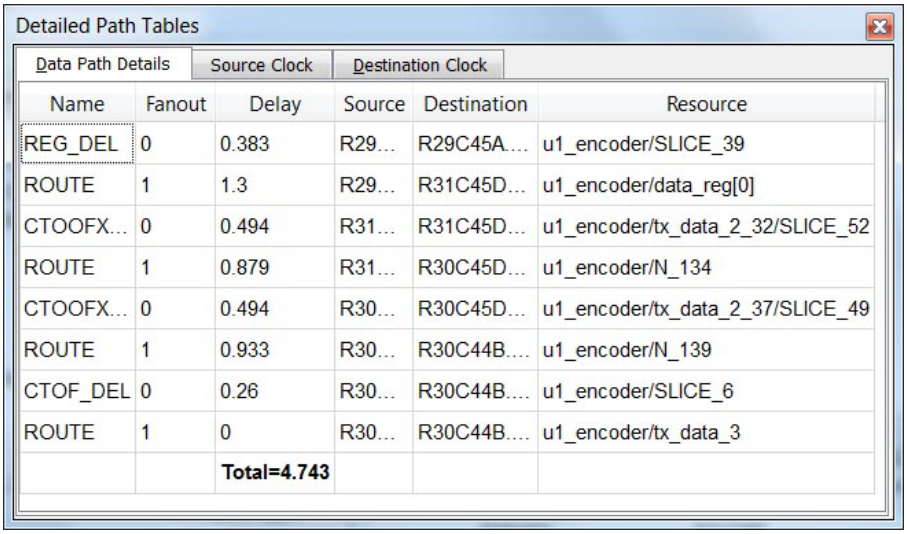
Unconstrained Paths Table

When you select a constraint from the list, the unconstrained paths are displayed in the path tables pane. The paths table shows the start point and end point of each unconstrained path and its classification. You can cross-probe a selected unconstrained path to Floorplan View, Physical View, or the TRACE report.

Detailed Path Tables

The Detailed Path Tables enable you to examine details of a selected delay path for a given timing preference. Depending on the type of preference, you can use the tabs at the top of the table to view the information by Data Path Details and Clock Path or by Data Path Details, Source Clock, and Destination clock.



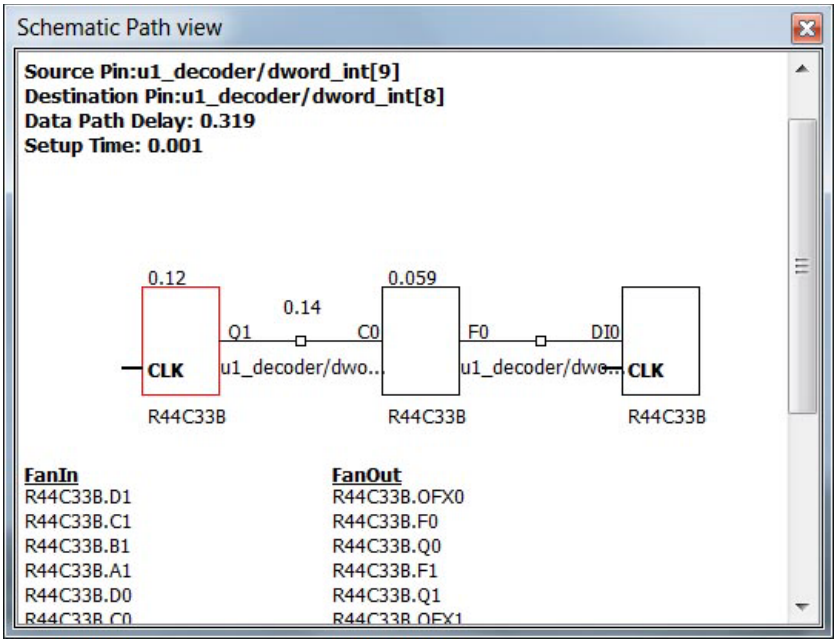


The following data is included:

- Name – the unique path identifier.
- Fanout – the number of inputs an output logic gate of the same type has in the design.
- Delay – the time related to the path in nanoseconds. This value is typically a composite of multiple timing arcs including data and clock arrival times.
- Source – the label of the device site location that contains the path's source registered cell.
- Destination – the label of the device site containing the path's destination registered cell.
- Resource – the component or net resource.

Schematic Path View

The Schematic Path View displays a graphical image of the timing path. Each component is represented by a large square box, and the location is shown beneath the box. Each net is represented by a small square. Double-click a component box to view the fanin and fanout.



Report View

The Report View presents the timing analysis report in a text format and shows each preference that is applied by the timing analysis program TRACE.

You can access a timing preference section in the report by right-clicking a timing preference from the Preference Name pane and choosing **Show in Report**. You can access timing path information by right-clicking a path from the Path Tables pane at the top and choose **Show In > Report**

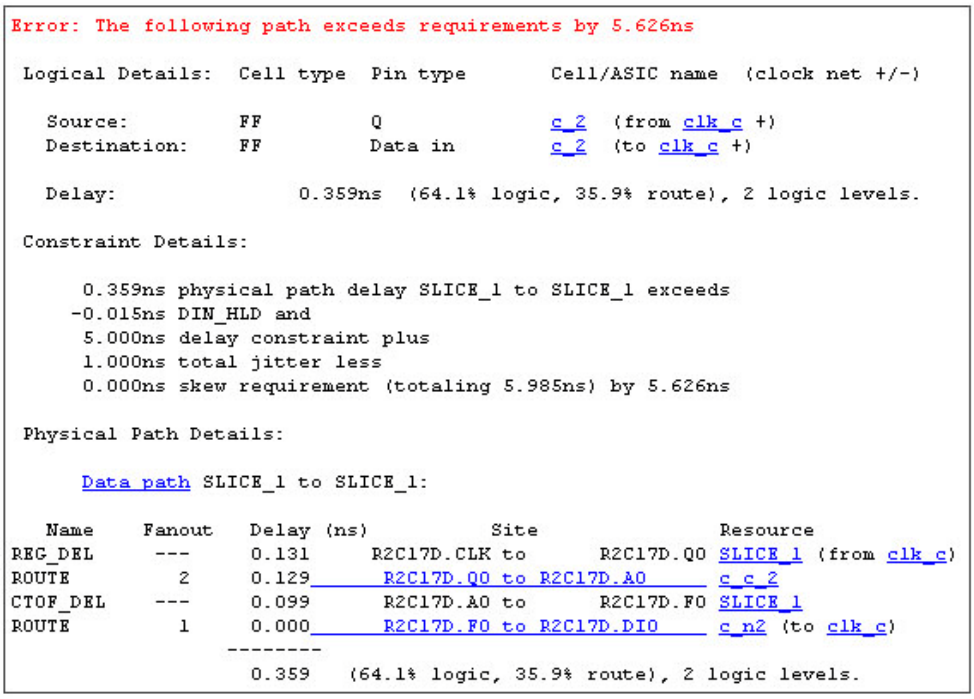
If a timing error is present in the report, the preference will appear in red font in the Preference Name listing and also in the TRACE report in the Report pane.

Blue font indicates a hyperlinked component name or net name. Right-click the blue text to access the “Show In” command. This allows you to cross-probe the component or net to Floorplan View or Physical View.

See Also ▶“Rearranging the Timing Analysis View Layout” on page 742

▶ “Cross-Probing from Timing Analysis View” on page 750

▶ “Setting TRACE Options” on page 693



```
Error: The following path exceeds requirements by 5.626ns

 Logical Details:  Cell type  Pin type       Cell/ASIC name  (clock net +/-)

   Source:         FF         Q              c_2  (from clk_c +)
   Destination:    FF         Data in        c_2  (to clk_c +)

   Delay:               0.359ns  (64.1% logic, 35.9% route), 2 logic levels.

                   --------
                     0.359   (64.1% logic, 35.9% route), 2 logic levels.
```

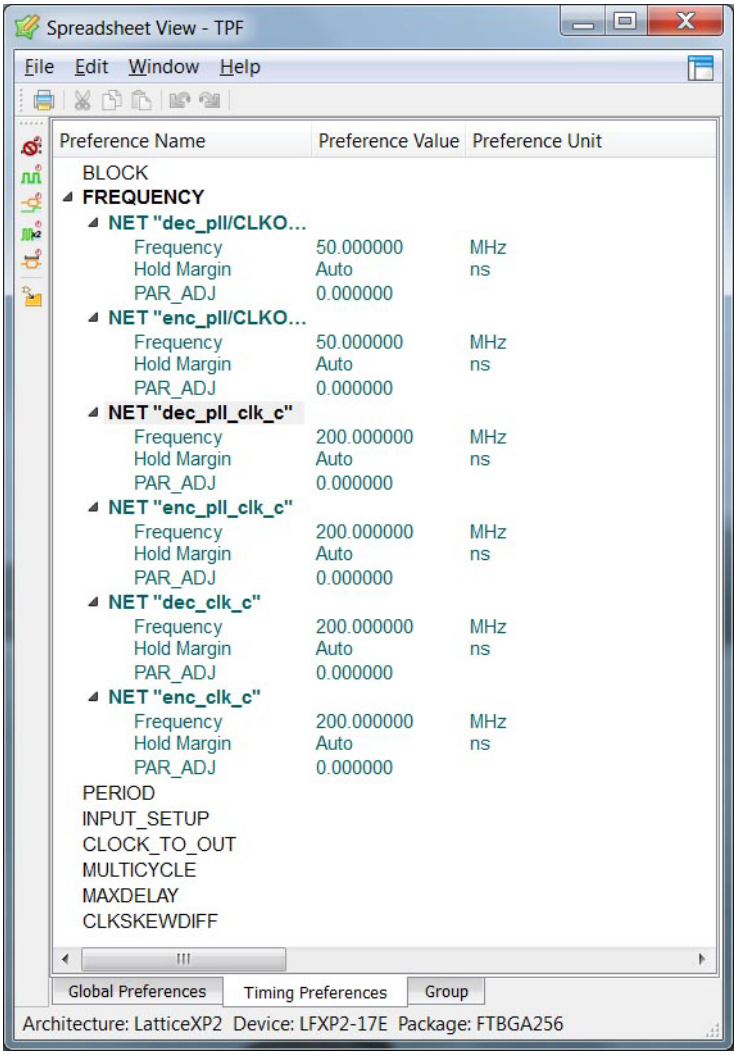
Spreadsheet View – TPF

The Timing Preference File (TPF) version of Spreadsheet View contains three preference sheets that allow you to modify timing preferences: Global Preferences, Timing Preferences, and Group. It enables you to modify or create new timing preferences, such as PERIOD or FREQUENCY; global preferences such as voltage and Block Path; and new port, cell, or ASIC groups. The interface, including the dialog boxes, is very similar to the regular Spreadsheet View. However, when you return to the Timing Analysis View to save your timing preference changes, the changes are written to a timing preference file (.tpf) instead of the active logical preference file (.lpf). The .tpf file is then added to the Analysis Files folder in Diamond's File List pane.

The TPF Spreadsheet View can be detached and reattached in the same manner as the Timing Analysis View main window.

See Also ▶"Modifying Preferences for Timing Analysis" on page 731

- "Importing In-Memory Timing Preferences" on page 733
- "Creating a New Timing Preference File" on page 744
- "Exporting Timing Preferences to a Logical Preference File" on page 748



Rearranging the Timing Analysis View Layout

Timing Analysis View's flexible interface enables you to detach the different panes, rearrange them, and resize them to make the timing details easier to view.

Detaching or Reattaching Timing Analysis View You can detach Timing Analysis View from Diamond's main window to give you more room to examine timing data and rearrange the layout of panes.

To detach Timing Analysis View:

- Click the Detach Tool button at the top right of the Timing Analysis View main window..

  This detach button is represented by a dim graphic, which distinguishes it from the detach button of the individual panes.

To reattach Timing Analysis View:

- Choose **Window >**  **Attach Window**.

Detaching or Reattaching a Pane Each pane of Timing Analysis View, except the Settings pane and the Preferences pane, can be detached as a separate view or repositioned to a different area of the Timing Analysis View window.

To detach a pane, do one of the following:

- Click the detach button  at the top right of the pane.
- Click and hold the pane's title bar and drag it out of the Timing Analysis View window.

To reattach a pane, do one of the following:

- Click and hold the pane's title bar and drag it back to the desired position in Timing Analysis View.
- Double-click the pane's title bar to attach it back into the Timing Analysis View window.

Repositioning a Pane You can rearrange the positions of the panes inside or outside of the Timing Analysis View window.

To reposition a pane inside or outside of Timing Analysis View:

- Click and hold the pane's title bar and drag it to the desired position.

  If you are repositioning a pane inside the Timing Analysis View window, it will snap into place when you release the mouse button.

Resizing a Pane You can resize any of the panes of Timing Analysis View, including the Settings and Preferences panes.

To resize a pane that is inside the Timing Analysis View window:

1. Hold your mouse over the vertical or horizontal border that separates the pane from the neighboring pane.
2. When you see the arrows and lines symbol, hold the mouse down and drag the border to the desired width or height.

To resize a pane that is outside the Timing Analysis View window:

- Hold down any border or corner and drag the pane to the desired size.

See Also "Timing Analysis View Main Window" on page 734

- "Cross-Probing from Timing Analysis View" on page 750

Working with Timing Preference Files

Timing preference files (.tpf) are files that you create in order to experiment with timing preferences without having to rerun Place & Route. When you first open Diamond to begin a new project implementation, you have no timing preference files (.tpf) associated with your project. A default Untitled.tpf file is auto-generated that uses constraints from your project's HDL source or logical preference (.lpf). To save any changes to your timing preferences, you must use the Save As command and save the Untitled file with a different name.

One way to create your first .tpf file is to modify timing preferences using the TPF Spreadsheet View, and then return to the Timing Analysis View main window and save the changes using the Save As command. After you have set the new .tpf file as the active one, you can simply use the Save command to save further changes.

You can create multiple sets of timing preference files for your project. They will appear in the Analysis Files folder of the File List pane. The .tpf files are not used directly by Diamond as input into your project implementation; instead, they are used for experimentation and analysis. You can later copy and paste the preferences from the .tpf file into your logical preference file (.lpf). You can also export a selected timing preference from the TPF Spreadsheet View to the .lpf file.

See Also ▶"Modifying Preferences for Timing Analysis" on page 731

Creating a New Timing Preference File

You can create a new timing preference file (.tpf) after placement and routing by modifying preferences in the TPF Spreadsheet View and saving the changes to a new .tpf file. You can also create a new .tpf file at any time by using the file commands in Diamond's main window.

To create a new .tpf file from preferences in TPF Spreadsheet View:

1. In the TPF Spreadsheet View, modify timing preferences or create new ones. See "Modifying Preferences for Timing Analysis" on page 731.
2. Return to the Timing Analysis View main window.

   The tabs of Timing Analysis View and Spreadsheet View – TPF are now marked with asterisks, indicating that changes have been made. If a .tpf file has not already been loaded, the title bar of Timing Analysis View shows "Untitled *." The Update button on the vertical toolbar is rotating.

   Note

   If desired, click the **Update** button to immediately view the results of the changes.

3. In Timing Analysis View, choose **File > Save Untitled As** and specify a name and location for the .tpf file.
4. Click **Save**.

The file name and path of the new .tpf file are displayed in the title bar of Timing Analysis View. The new .tpf file is listed in the Analysis Files folder of the File List pane.

To create a new .tpf file from Diamond's main window:

1. Choose **File > New >**  **File**.

   Optionally, right-click the Analysis Files folder in the File List pane and choose **Add > New File**.

2. In the dialog box, select **Source Files** from the Categories list, and then select **Timing Preference File** from the Source Files list.

3. Type a name in the Name box and browse to the desired location and click **OK**.

4. To add the .tpf file to the active implementation, make sure that the **Add to Implementation** option is selected.

   Note

   If you clear this option, the new .tpf file will not appear in the Analysis Files folder in the File List pane.

5. Click **New**.

   Diamond opens Timing Analysis View if it is not already open. The new .tpf file name and path appear in the title bar. If you selected the "Add to Implementation" option, the .tpf file appears in the Analysis Files folder of the File List pane.

See Also
- "Opening a Timing Preference File in Timing Analysis View" on page 747
- "Setting a Timing Preference File as the Active File" on page 746
- "Adding a Timing Preference File to the Analysis Files Folder" on page 745

Adding a Timing Preference File to the Analysis Files Folder

If you have created timing preference files (.tpf) without selecting the "Add to Implementation" option, they will not appear in the Analysis Files folder in the File List pane. Adding .tpf files to the Analysis Files folder gives you immediate access to them in Timing Analysis View and enables you to select one of them as the active .tpf file.

To add a .tpf file to the Analysis Files folder:

1. Right-click the **Analysis Files** folder and choose **Add > Existing File** from the pop-up menu.

2. In the Add Existing File dialog box, navigate to the .tpf file that you want to add, select it, and choose **Add**.

The .tpf file you selected is added to the Analysis Files folder.

See Also ▶"Creating a New Timing Preference File" on page 744

- "Removing a Timing Preference File from the Analysis Files Folder" on page 746

Removing a Timing Preference File from the Analysis Files Folder

When you remove a .tpf file from the Analysis Files folder, it is only deleted from the list. The file remains in your project directory or the folder where you saved it, and you can always add it back to the Analysis Files list.

To remove a .tpf file from the Analysis FIles Folder:

- Expand the Analysis Files folder, right-click the .tpf file that you want to remove, and choose **Remove**.

See Also ▶"Creating a New Timing Preference File" on page 744

- "Adding a Timing Preference File to the Analysis Files Folder" on page 745

Setting a Timing Preference File as the Active File

A timing preference file (.tpf) that has been designated as active will be loaded automatically when you open Timing Analysis View. Your active .tpf file is the one displayed in bold font in the Analysis Files folder of the File List pane.

To set a .tpf file as the active file:

1. In Diamond, select the File List tab, and then expand the Analysis Files folder.
2. Right-click the .tpf file that you wish to designate as the active one and choose **Set as Active TPF** from the pop-up menu.

   The .tpf file that you selected now appears in bold font, indicating that it is the active one. The next time you open Timing Analysis View, it will be loaded automatically.

   If Timing Analysis View is already open with a different .tpf file, the newly activated .tpf file will not be loaded automatically. In this case, you must reopen Timing Analysis View in order to load the active .tpf file. You can do this in one of the two following ways:

   - Close Timing Analysis View manually and reopen it.
   - Right-click the active .tpf file in the Analysis Files folder, choose **Open With > Timing Analysis View**, and click **OK**.

See Also ▶"Creating a New Timing Preference File" on page 744

- "Opening a Timing Preference File in Timing Analysis View" on page 747
- "Adding a Timing Preference File to the Analysis Files Folder" on page 745

Opening a Timing Preference File in Timing Analysis View

After creating one or more timing preference files (.tpf) you can open one of them in Timing Analysis View. You can open a .tpf file from Diamond's File List pane or from the File menu of Timing Analysis View if it is detached.

To open a .tpf file in Timing Analysis View from Diamond's File List pane:

1. In the File List pane, expand the Analysis Files folder.
2. Right-click the .tpf file that you want to open and choose **Open With** from the pop-up menu.
3. In the Open With dialog box, select **Timing Analysis View**.
4. If you want to set Timing Analysis View as the default for opening and viewing a .tpf file, click **Set as Default**.

   This will enable you to double-click a .tpf file from the Analysis Files folder to open it in Timing Analysis View instead of the source editor.
5. Click **OK**.

   Diamond opens Timing Analysis View if it is not already open, and it loads the .tpf file that you selected.

To open a .tpf file from within Timing Analysis View:

1. In Timing Analysis View, click the Detach Tool button  .in the upper right corner.
2. From the detached Timing Analysis View, choose **File > Open File**.
3. In the Open Timing Preference File dialog box, select the desired .tpf file and click **Open**.

See Also "Creating a New Timing Preference File" on page 744

- "Adding a Timing Preference File to the Analysis Files Folder" on page 745
- "Opening a Timing Preference File in the Source Editor" on page 747

Opening a Timing Preference File in the Source Editor

Although you can only open one timing preference file (.tpf) at a time in Timing Analysis View, you can have multiple .tpf files open at the same time in Diamond's Source Editor. Multiple .tpf files that are open in the Source Editor are arranged in tabs at the top of the window, allowing you to make quick

comparisons of timing preference usage. Timing preferences that you edit in the Source Editor will be reflected when you next load the .tpf file into Timing Analysis View.

You can use the Analysis Files folder or Diamond's File menu to open a .tpf file in the Source Editor.

To open a Timing Preference File in the Source Editor using the Analysis Files folder:

1. From the Analysis Files folder, right-click the desired .tpf file and choose **Open With** from the pop-up menu.
2. In the Open With dialog box, select **Source Editor**.
3. If you want to set the Source Editor as the default for opening and viewing a .tpf file, click **Set as Default**.

   This will enable you to double-click a .tpf file from the Analysis Files folder to open it in the Source Editor instead of Timing Analysis View.
4. Click **OK**.

   The file opens as a text file in the Source Editor window, and the name of the .tpf file is displayed on the tab.

To open a Timing Preference File in the Source Editor using Diamond's File menu:

1. In Diamond, choose **File > Open > File**.
2. In the Open File dialog box, choose **Timing Preference File (*.tpf)** from the Files of type drop-down menu.
3. Select the desired .tpf file and click **Open**.

   The file opens as a text file in the Source Editor window, and the name of the .tpf file is displayed on the tab.

See Also ▶"Creating a New Timing Preference File" on page 744

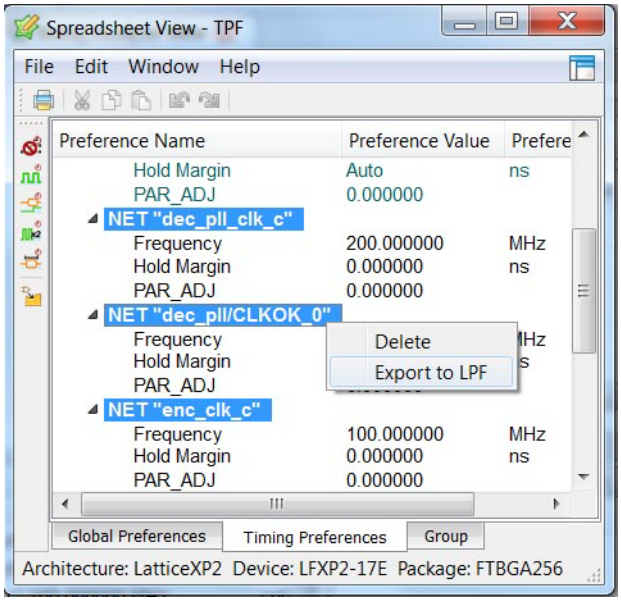
▶ "Adding a Timing Preference File to the Analysis Files Folder" on page 745

Exporting Timing Preferences to a Logical Preference File

After experimenting with timing preferences in the Timing Analysis view, you can use the TPF Spreadsheet View to export some of the preferences from the timing preference file (.tpf) to a logical preference file (.lpf). You can do this with preferences that are on the Timing Preferences sheet or the Group sheet.

To export timing preferences from the .tpf file to the .lpf file:

1. In Timing Analysis view, click the **Change timing preferences** button to open the TPF Spreadsheet View.
2. Select the Timing Preferences sheet or the Group sheet.
3. Select the preferences that you want to export. Hold down the Ctrl key to select multiple preferences.



4. Right-click the selected preferences and choose **Export to LPF**.

   The regular Spreadsheet View opens. Its tab contains an asterisk, indicating that unsaved preferences are in memory. The Timing Preferences or Group sheet shows the preference changes that you exported.

5. Save the changes to the currently active .lpf file using the **Save** command, or choose **File > Save As** to save the changes to a different .lpf file.

   Note

   To implement the preference changes to the currently active .lpf file, you must rerun your design flow through Place & Route Design.

See Also
- "Modifying Preferences for Timing Analysis" on page 731
- "Creating a New Timing Preference File" on page 744
- "Copying Timing Preferences to a Logical Preference File" on page 750

Copying Timing Preferences to a Logical Preference File

You can copy and paste timing preferences from the .tpf file to a .lpf file using the Source Editor, or you can save the entire .tpf file as an .lpf file.

To copy timing preferences from the .tpf file to the .lpf file:

1. Open the desired .tpf and .lpf files in the Source Editor.
2. In the .tpf file, select the timing preference text that you want to copy and choose **Edit > Copy**.
3. In the .lpf file, choose **Edit > Paste**, and then choose **File > Save <file_name>.lpf.**

To save the entire .tpf file as an .lpf file:

1. Open the .tpf file in the Source Editor.
2. Choose **File > Save <file_name>.tpf As** and in the Save as type box, choose **Preference Files**.
3. Navigate to the directory where you want to save the .lpf file.
4. In the File name box, type a file name and change the .tpf extension to .lpf.
5. Click **Save**.

See Also ▶"Opening a Timing Preference File in the Source Editor" on page 747

▶ "Exporting Timing Preferences to a Logical Preference File" on page 748

Cross-Probing from Timing Analysis View

In Diamond, many views contain corresponding cross-reference data that allow you to "jump" between views. This cross-probing feature allows you to gain new perspectives on your layout and connectivity for particular design elements that are critical for meeting your constraints. This can be very useful in guiding your design run iterations toward specific goals.

Timing Analysis View enables cross-probing within the view, and it allows you to cross-probe selected elements to Floorplan View and Physical View. You can also use this feature to group components along an individual signal. See "Grouping Components Along an Individual Signal" on page 513.

You can cross-probe an unconstrained path as well as a path that is constrained by a defined preference.

To cross probe from Timing Analysis View:

1. In the Preferences pane, do one of the following:

   - Select the Preferences Reports tab, and then select a defined timing preference. For example, you might have created setup and hold time analysis with a FREQUENCY preference for a clock in your design.
   - Select the Other Reports tab, and then select a preference for unconstrained paths.

     The Other Reports lists each unconstrained path by suggested preference and shows the analysis type. When you select a preference from the list of unconstrained paths, the Path table shows the start point, end point, and clocks. It also shows the classification: register-to-register, input-setup, clock-to-out, or port-to-port.

   The Path Table and the Detailed Path Table become populated with various data on delay and timing related to that preference.

   Note

   If you have not set any timing preferences, see "Modifying Preferences for Timing Analysis" on page 731.

2. Do one or more of the following:

   - Right-click a timing preference in the Preference Name pane and choose **Show in Report**.

     The preference is immediately highlighted in the Report pane.
   - Right-click a path from the Path Table and choose **Show In > Floorplan View**.

     Floorplan View opens with a zoomed-in view of the path. The path is highlighted with the same color shown in the Path Table for the selected delay path.
   - Right-click a path from the Path Table and choose **Show In > Physical View**.

     Physical View opens with a zoomed-in view of the path. The path is not differentiated in color according to the Path Table, but is highlighted with the default color for delay paths.
   - Right-click a path from the Path Table and choose **Show In > Report**.

     The Report pane jumps to the path section and displays the path in blue.
   - In the Reports pane, right-click an element that is highlighted in blue and choose **Show In > Floorplan View** or **Show In > Physical View**.

     The path is highlighted in the layout view you selected.

See Also "Timing Analysis View Main Window" on page 734

Exporting Timing Path Delay Data from Timing Analysis View

The path delay data displayed in the Path and Detailed Path tables of Timing Analysis view can be exported to a comma-separated value file (.csv). This enables you to view the data in an external spreadsheet program.

To export timing path delay data to a .csv file from Timing Analysis view:

1. In Timing Analysis View, select a timing preference from the Preference Name pane.

   The Path Table and Detailed Path Table should automatically be populated with timing data associated with the preference.

2. Choose **File > Export** or click the Export button on the vertical toolbar.

3. In the Export dialog box, type a name in the File Name text box, browse to the desired location, and click **Save**.

   The .csv file is saved in the location you specified.

Chapter 10

Analyzing Power Consumption

Included with the Diamond software is Power Calculator, which estimates the power dissipation for a given design. Power Calculator uses parameters such as voltage, temperature, process variations, air flow, heat sink, resource utilization, activity, and frequency to calculate the device power consumption. It reports both static and dynamic power consumption.

Power Calculator allows you to import frequencies from the post-PAR trace report file (.twr file), and it allows you to import activity factors from the post-PAR simulation file (.vcd file). After the design information is added, Power Calculator provides accurate power consumption analysis for the design.

Power Calculator provides two modes for reporting power consumption: estimation mode, which can be used before completing the design; and calculation mode, which is based on the physical netlist file (.ncd) after placement and routing.

You can open Power Calculator from within Diamond or as a stand-alone tool from the Windows Start menu. Either method provides both estimation mode and calculation mode functionality. A stand-alone Power Estimator is also available, which allows you to estimate power consumption without having Lattice Diamond installed.

Calculation Mode Within the Diamond environment, Power Calculator calculates power consumption based on the project's files, including device information. This information is automatically extracted when you open Power Calculator from within Diamond. In the stand-alone Power Calculator, power consumption is calculated based on a selected native circuit description (.ncd) file or power calculator file (.pcf)

Estimation Mode Within the stand-alone Power Calculator or Power Estimator, the Startup Wizard enables you to estimate power based on a selected device, and it gives you the option of including a template of resource settings. Within the Diamond environment, Power Calculator will estimate power for a unrouted design. After the design is routed, it enables you to change the device family or other data and obtain the estimated power consumption.

See Also ▶"Software Mode" on page 759

- "Starting Power Calculator from Diamond" on page 754
- "Starting Power Calculator as a Stand-Alone Tool" on page 754

- "Power Analysis Design Flow" on page 756

Starting Power Calculator from Diamond

Power Calculator is available from Diamond as soon as you have opened a project.

To start Power Calculator from the Diamond Tools menu or toolbar:

1. In Diamond, open a project or create a new one.
2. Choose **Tools > Power Calculator** or click the  button on the toolbar.

   Power Calculator opens in estimation mode or calculation mode, depending on the design stage, and displays the Power Summary page.

   When Power Calculator opens in calculation mode, it imports any Bank VCCIO settings that are in the preference file and displays these settings on the I/O page.

You can also start Power Calculator by creating or opening a new Power Calculator file (.pcf):

- Use the File menu or the Analysis Files folder to create a new Power Calculator file (.pcf).

  Power Calculator opens and loads the newly created .pcf file.

- Use the File menu or the Analysis Files folder to open an existing .pcf file.

  Power Calculator opens in estimation mode or calculation mode, depending on the status of the selected .pcf file. If it opens in calculation mode, it will import any Bank VCCIO settings that are in the preference file and display these settings on the I/O page.

See Also
- "Running Power Calculator from the Tcl Console" on page 756
- "Saving a Power Calculator File" on page 770
- "Adding Power Calculator Files to the Analysis Files Folder" on page 773
- "Setting a Power Calculator File as the Active Analysis File" on page 774

Starting Power Calculator as a Stand-Alone Tool

Power Calculator is available as a stand-alone tool from the Windows Start menu. This allows you to work with a Power Calculator project, in calculation mode or in estimation mode, without opening Diamond. The Startup Wizard enables you to create a new Power Calculator project, based on a selected device or a processed design, or to open an existing Power Calculator project file (.pcf).

To start Power Calculator as a stand-alone tool:

1. Choose **Start > Programs > Lattice Diamond > Accessories > Power Calculator**.

   After a few moments, the Power Calculator Startup Wizard appears.

2. Do one of the following, and then click **OK**:

   - To calculate power consumption based on a mapped or placed and routed design, select **Calculate power with design (NCD)**.

     Click the NCD File Browse button to navigate to the .ncd file.

     After you select the .ncd file, the File Name and File Directory boxes are automatically filled in by the Startup Wizard. If you want to give the Power Calculator project file a different name than the .ncd file name, type the name in the File Name box.

     When you click OK, Power Calculator opens in calculation mode. If any VCCIO bank preferences have been set in the preference file, they will be imported and displayed on the I/O page.

   - To estimate power consumption based on a selected device, select **Estimate power with device selection**.

     The device selection menus appear at the bottom of the Startup Wizard.

     Type a name for the Power Calculator project file in the File Name box and browse to the desired directory for the project. Make your selections from the device menus.

     If you would like to use a template of resource settings, select the **Use Template** option, click **Select**, and do one of the following:

     - Select **Specify Resource by Design Type**, and then select the design type from the drop-down menu and click **OK**.
     - Select **Specify Resource by Component Utilization**, and then select from the options provided and click **OK**.

       The Use Template text box displays the resource settings or the design type that you selected.

     When you click OK, Power Calculator opens in estimation mode and loads the device settings you specified.

   - To open an existing Power Calculator project, select **Open existing PCF file**.

     Click the Browse button to navigate to the .pcf file.

     When you click OK, Power Calculator opens in estimation mode or calculation mode, depending on the status of the .pcf file.

     If Power Calculator opens in calculation mode, it will import any Bank VCCIO settings that are in the preference file and display these settings on the I/O page.

See Also "Running Power Calculator from the Tcl Console" on page 756

- "Saving a Power Calculator File" on page 770

Running Power Calculator from the Tcl Console

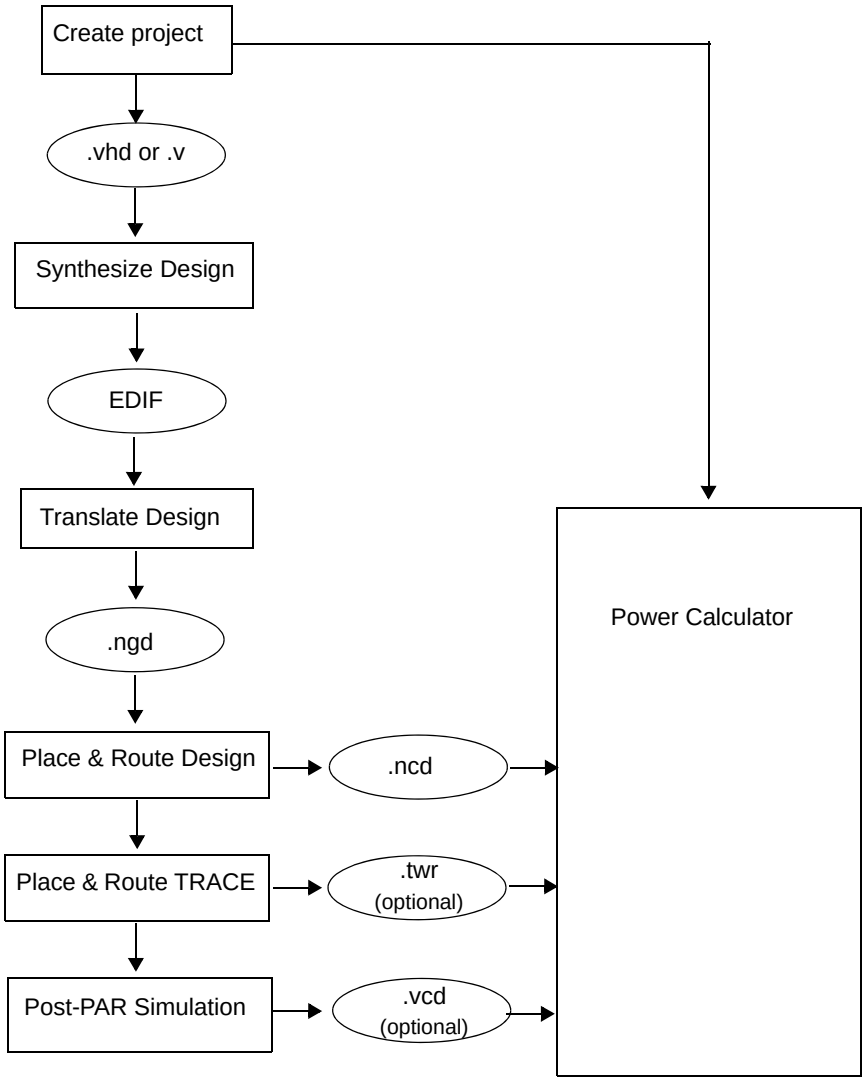
Diamond's Tcl console window enables you to use Tcl commands to perform many power analysis functions. For a complete list and descriptions of Power Calculator Tcl commands, see "Power Calculator Tcl Commands" on page 2583 in the Tcl Command Reference Guide.

See Also ▶"Tcl Command Reference Guide" on page 2554

Power Analysis Design Flow

Power Calculator supports all Lattice FPGA devices. The design flow involved in using Power Calculator in Diamond is as follows.

Figure 8:



See Also "Inputs" on page 757

"Outputs" on page 757

Inputs

When you first launch Power Calculator from Diamond, it displays information from your design project. For an unrouted design, it shows default resource information based on the targeted device. For a routed design, it extracts information from the placed and routed .ncd file.

Additionally, Power Calculator accepts the following files as optional input.

- Value change dump file, <*project_name*>.vcd, which is an ASCII file containing activity and frequency information. Its format is specified by the IEEE 1364 standard. It should be in the format of gate-level simulation and match the design. The .vcd file preserves waveform information that can be displayed in third-party tools such as Active-HDL.

  If you provide a post-routed simulation .vcd file, Power Calculator looks up the clock signals in the .vcd file and compares them to each clock in the Power Calculator pages. If the clock names match, Power Calculator takes the frequency data from the .vcd file and populates the frequency columns, the activity factor (AF(%)) columns, or both, in the pages that contain these columns.

- Trace report file, <*project_name*>.twr, which is an FPGA timing report file produced by the Place & Route Trace process in Diamond. The .twr report file enables you to determine to what extent the timing constraints for a design have been met. When you import this file, Power Calculator obtains from it the frequencies with which to populate the frequency columns. To obtain frequencies from a .twr file, you must have a frequency constraint on the clock net or the clock port; otherwise, no frequencies will be entered into Power Calculator. You can set the frequency constraint in Spreadsheet View's PERIOD/FREQUENCY Preference dialog box.

See Also "Importing a Value Change Dump (.vcd) File" on page 780

"Changing the Global Default Activity Factor" on page 780

Outputs

Power Calculator generates power calculation results in tabular format from information extracted from the design project. All of this information, when saved, is kept in the project's Power Calculator file (.pcf).

Power Calculator also generates a power calculation report, which can be viewed in HTML or text format. It also generates power graphs that show how power consumption is affected with varying voltage, temperature, and clock frequency.

See Also "Saving a Power Calculator File" on page 770

- "Generating Power Graphs" on page 792
- "Viewing the Power Calculator Report" on page 794

Static and Dynamic Power Consumption

Power Calculator reports the dynamic and static portion of the power dissipation. Power refers to the power consumed by the design. It is based on the extracted data from a placed and routed design file (.ncd) or on the estimation information that you provide.

The dynamic portion is the power consumed by the used resources while they are switching. The power dissipation of the dynamic portion is directly proportional to the frequency at which the resource is running and the number of resource units used.

The static portion of power consumption is the total power consumed by the used and unused resources.

Activity Factor Calculation

To calculate the power consumption for the routing interconnect, logic, and the read/write ports in an embedded block, Power Calculator requires the frequency and an activity factor percentage. The activity factor percentage is the percentage of time that a registered output node is active relative to a specified clock. Most of the resources associated with a clock domain run or toggle at a percentage of the frequency at which the clock runs.

The frequency appears as the "Freq. (MHz)" column on most pages. The activity factor percentage appears as the "AF (%)" column.

- "Changing the Global Default Activity Factor" on page 780
- "Changing the Global Default Frequency Setting" on page 781

Power Calculator Window Features

Power Calculator's main window displays the software mode being used and the currently selected page of power consumption information. When you first open Power Calculator, the Power Summary page appears by default. All other pages of information for the device are made available from the tabs arranged at the top of the main window. This section describes these features and the color coding of cells.

Software Mode

The Software Mode in the top right corner of the Power Calculator window indicates whether Power Calculator is running in estimation or calculation mode. This field is read-only.

Estimation Mode In estimation mode, Power Calculator provides estimates of power consumption based on the device resources or template that you provide. This mode enables you to estimate the power consumption for your design before the design is complete or even started. It is useful for “what if” analysis. You must supply the frequency, activity factor, and voltage.

Calculation Mode In calculation mode, Power Calculator calculates power consumption on the basis of device resources taken from a design’s .ncd file, or from an external file such as a value change dump (.vcd) file, after placement and routing. This mode is intended for accurate calculation of power consumption, because it is based on the actual device utilization.

Reverting to Estimation Mode Power Calculator will revert to estimation mode from calculation mode in the following circumstances:

- If you start using Power Calculator in calculation mode and change the data in any cell other than AF (%), Freq., V., Dynamic Power Multiplier, Ambient Temperature, Performance Grade, Operating Condition, or Process Type, Power Calculator will automatically revert to estimation mode.
- Rerunning a process will change the software mode if you are working with the unsaved “untitled” temporary power calculator file. For example, if you rerun Map Design while in calculation mode using the “untitled” file, the tool will revert to estimation mode. If you are working with a saved .pcf file, the software mode will not change when you rerun a process.

Reverting to Calculation Mode For many types of changes, Power Calculator enables you to revert to calculation mode from estimation mode, if you have not yet saved the changes to the .pcf file. See “Reverting to Calculation Mode” on page 779 for more information.

Power Summary

The Power Summary summarizes the conditions of power consumption. It is the first page to open when you run Power Calculator. The Power Summary enables you to change the targeted device, operating conditions, voltage, and other basic parameters. Updated estimates of power consumption are then displayed based on these changes.

Device The Device section enables you to select a device family, package, part name, performance grade, and operating conditions. It displays power information based on these selections.

You can specify one of the following operating conditions, depending on the device:

- Industrial – Devices are rated at 105 degrees Celsius.

- Commercial – Devices are rated at 85 degrees Celsius.
- Automotive – Devices are rated at 125 degrees Celsius.

Device Power Parameters Section The Device Power Parameters section contains information pertaining to the device process conditions and power model status.

The process type specifies the corners or conditions under which the device was manufactured. It can be one of the following:

- Typical – to reflect the typical amount of current consumed by the circuit.
- Worst – to reflect the maximum amount of current consumed by the circuit.

The Power File Revision displays the status of the model:

- Advanced – The power file has all the constants, functions, formulas, and defaults. The constants are based on silicon simulation data without extracted layout parameters. The status of this file is “advanced.”
- Preliminary – The power file has all the constants, functions, formulas, and defaults. The constants are based on nominal silicon characterization data rather than simulation data. The status of this file is “preliminary.”
- Final/Production – The power file has all the constants, functions, formulas, and defaults. The constants are based on silicon characterization data that includes characterization of corner lots and conditions rather than simulation data. The status of this file is “production.”

Device Power Saving Selection Section The Device Power Saving Selection section, available for LIFMD devices, allows you to select Normal mode or Sleep mode from the drop-down menu. This affects the coefficients used in calculations.

Power Control The Power Control button is available for MachXO2, MachXO3D, MachXO3L, ECP5, LIFMD, and Platform Manager 2 devices. It opens the Power Option Controller, which enables you to dynamically change the power of certain blocks through the use of standby mode and other options. See “Controlling Power Options for Low-Power Devices” on page 787 for more information.

Environment Section The Environment section displays information about the operating temperature of the device. The Thermal Profile button enables you to choose the thermal impedance model for the power-consumption or current-consumption calculation. The Ambient Temperature cell allows you to specify the surroundings at which the device is expected to operate, in degrees Celsius. Temperature values must be between -40 and +125 degrees Celsius.

Effective Theta-JA specifies the cumulative thermal impedances of a particular system. This figure is used in calculating the junction temperature (Tj) of a die in a particular environment according to the following formula:

Tj = *power* * *theta_effective* + *ambient_temperature*

Junction Temperature specifies the temperature of the die within the device package, in degrees Celsius. You can adjust the junction temperature by using the models in the Thermal Profile dialog box. If the calculated value in the Junction Temperature box is either larger than 125 degrees Celsius or larger than the maximum junction temperature allowed for a particular device and operating conditions, a red background appears in the Junction Temperature box.

Maximum Safe Ambient specifies the maximum safe operating temperature for a die. If this temperature is exceeded, the semiconductor physics of the silicon change, so the die can operate erratically. The life of the device is also shortened.

Voltage/Dynamic Power Multiplier This section contains information about the estimated power or current consumption by power supply. The Dynamic Power Multiplier specifies the derating factor for the dynamic portion of the power consumption. Power Calculator does not include derating for dynamic power. This factor enables you to change the number by the derating factor that you want to apply. The derating factor specified must be between 0.5 and 2. The default is 1.0.

Current by Power Supply This section displays the static, dynamic and total current consumption in amperes.

Power by Power Supply This section displays the static, dynamic, and total power consumption in watts.

Power by Block This section displays the total power consumption by the different types of blocks, in watts.

Peak Startup (A) This section shows how much peak startup current each supply in the design draws, in amperes. When the “N/A” notation appears in this column, it means that no data is available yet. However, you can call Lattice Semiconductor Technical Support for this information.

Note

The peak startup current for LatticeECP3 devices LFE-70EA and LFE-95EA is at the commercial temperature limit of 85^{O} Celsius.

Power Calculator Pages

Each time Power Calculator opens, it displays the Power Summary, which shows the targeted device, operating conditions, voltage, and other basic information. Additional pages are available from the tabs arranged at the top of the window. Except for Graph and Report, each of these pages allows you to view, edit, and add elements. The number and types of pages that are available will depend on the selected device.

Pages Available for All Device Families

Power Matrix The Power Matrix page shows the amount of power pulled by each component in the design from multiple power sources. Two tabs are provided, allowing you to view the current usage (A) and power usage (W) of each type of component. Power Calculator enables you to view the power matrix as an HTML report. It also allows you to generate a .csv file of the matrix that you can open in a spreadsheet application.

Logic Block The Logic Block page displays the estimated power consumed by the logic in the design and the factors that affect it. Power-consumption calculation in the Logic section requires both the frequency and an activity factor per clock domain. Power calculation is also based on the specified number of LUTs, distributed RAMs, ripple-carry logic circuits, and registers driven by the clock.

Clocks The Clocks page displays the estimated power consumed by the clocks in the design and the factors that affect it. Dynamic power calculation is based on the frequency of each clock.

The Clocks page only reports clocks that go to the clock tree, such as Primary Clock, Secondary Clock and Edge Clock.

For ECP5 devices, a digital clock control (DCC) column is included, which allows the operation of clock components downstream to be stopped to save power.

I/O The I/O page displays the estimated power consumed by the I/Os in the design and the factors that affect it. The power-consumption calculation for this page requires the frequency, activity factor, and number of inputs or outputs per clock domain. For bidirectional signals, it requires the number of bidirectional I/Os, input and output frequency, and input and output activity factor per clock domain. If you use an .ncd file, Power Calculator will extract the information for the I/O page directly from the .ncd file. If you do not use an .ncd file, Power Calculator will assign the default resource usage values according to the design's family.

For low-power devices, the I/O page includes the following additional columns for controlling power options:

- Power Guard (PG) – Power Guard can be turned on to enable the blocking of signals at the input buffers. Power Guard's biggest impact is in standby mode when it can be used to switch off clock inputs that are distributed using general routing resources. After you turn Power Guard on, you can use the Power Controller to enable it.
- Allow InRD Shut-off – Selecting **Yes** in this column in the Bank Voltage section allows the disabling of the dynamic referenced and differential input buffers.
- Allow LVDSO Shut-off – Selecting **Yes** in this column in the Bank Voltage section allows the LVDS output buffer driver to be turned off.

See "Controlling Power Options for Low-Power Devices" on page 787 for more information.

I/O Termination The I/O Termination page enables you to provide information about external terminations for the I/Os. You can specify the average equivalent thevenin resistive load in ohms (Rth) and the equivalent thevenin voltage in volts (Vth). Power-consumption calculation is based on the power consumed by the external termination that you provide. In certain cases, such as in a LatticeSC device, the termination can also be internal to the device.

Graph The Graph page displays three types of graphs: Power vs. VCC Supply Voltage, Power vs. Ambient Temperature, and Power vs. Frequency. Each graph displays two plots—typical and worst case. Use the Edit > Graph Settings command to change the graphs to be displayed. The dialog box enables you to specify the range, step, X axis, and Y axis of each graph. See "Generating Power Graphs" on page 792 for more information.

To prevent any unnecessary calculations and additional processing time, graphs are only generated when you select the Graph tab. During the graph generation time, you cannot change tabs and must wait for the graph calculations to finish before performing any other action. If you switch tabs and change any information that will alter the power, the graphs will be regenerated when you next select the Graph tab.

Report The Report page contains a summary of the estimated power-consumption or current-consumption data calculated by Power Calculator. Information is taken from the Power Summary and from each page of the Power Calculator user interface.

In the Power Model section, the Status can be Preliminary, Advanced, or Final.

- Preliminary – The power file has all the constants, functions, formulas, and defaults. The constants are based on nominal silicon characterization data rather than simulation data.
- Advanced – The power file has all the constants functions, formulas, and defaults. The constants are based on silicon simulation data without extracted layout parameters.
- Final/Production – The power file has all the constants, functions, formulas, and defaults. The constants are based on silicon characterization data that includes characterization of corner lots and conditions rather than simulation data.

The report is available in text (ASCII) format and in HTML format. It is updated each time you make a change to any of the data in the editable cells.

Pages Dependent on Selected Device

Block RAM The Block RAM page displays the power consumed by the embedded block RAM (EBR) in the design and the factors that affect it. Power-consumption calculation for the Block RAM page requires the frequency and activity factor per clock domain. This page separates different EBR modes into individual sections, such as single-port RAM (SP RAM), pseudo-dual-port RAM (DP RAM), true dual-port RAM (DP RAM True) and single- and dual-clock FIFOs (FIFO DC).

The Block RAM page is available for all devices except MachXO 256 and 640 and Platform Manager.

Power Modes/Avg. Power The Power Modes/Avg. Power page allows you to calculate power consumption in your device for given ratios of time spent in Normal mode and Sleep mode. To use this feature, enter a value from 0 to 100 in the **Normal Mode Time(%)** or **Sleep Mode Time(%)** field. When focus leaves that field, Power Calculator will automatically populate the other field with the remaining percentage, calculate the average power consumption, and display the result.

The Power Modes/Avg. Power page is available for LIFMD devices.

MIPIDPHY The MIPIDPHY page allows you to select the MIPI DPHY channel by ID (0 or 1), and then select Tx or Rx mode for that channel. Power is directly proportional to that channel's MIPI DPHY Data Rate and AF.

EFB The EFB page enables you to specify settings for an embedded function block (EFB). The EFB block, which is connected to the device from a WISHBONE bus, includes the following peripherals: a SPI, two I2Cs, and a timer/counter (TC). For MachXO2 devices, it also includes a user flash memory (UFM). The EFB page is divided into separate sections for each of the peripherals. Frequency, activity factor, and one peripheral are required for power-consumption calculation in each section. Use of the WISHBONE bus for Timer/Counter is optional.

The EFB page is available for MachXO2, MachXO3D, MachXO3L, and Platform Manager 2 devices.

Misc The Misc page enables you to allow standby for the master clock (MCLK), which will enable you to turn off the on-chip oscillator during low-power operations, and set the frequency for MCLK. For MachXO2, MachXO3D, and MachXO3L devices, standby options for power on reset (POR) and BANDGAP are also included. Allowing standby on the Misc page enables you to use the Power Option Controller to place selected components in standby mode. See "Controlling Power Options for Low-Power Devices" on page 787 for more information. The Misc page also enables you to select and enable the mode for soft error detect (SED).

For ECP5 devices, the Misc page enables you to set the frequency and activity factor for digital temperature readout (DTR). The DTR circuit provides the junction temperature of the die while running.

For LIFMD devices, the Misc page enables you to place its High Frequency Oscillator (OSCI) output in Standby mode.

The Misc page is available for MachXO2, MachXO3D, MachXO3L, Platform Manager2, LIFMD, and ECP5.

ASC The ASC page displays the calculated power consumed by Analog Sense and Control (ASC) devices including the internal ASC component that is part of the Power Manager 2 device. The power consumed by an ASC device is determined by the number of HVOUTs used in the design. The data file generated by the Platform Designer tool includes the number of HVOUTs

used and the power model equation. The data file lists all ASCs and the power used by each and is located in the design implementation directory. This file is read by Power Calculator and then the additional power from the ASC devices is added to the total power displayed. This data is displayed in the Power Summary tab, Power by Block (W) section and the ASC page.

This ASC page is available for MachXO2, ECP5, and Platform Manager 2 devices.

Note

This data is only used when Power Calculator is in calculation mode integrated in Diamond software. If standalone Power Calculator or Power Estimator project files (.pcf) contain ASC information, it reads the project file and calculates ASC power.

PLL The PLL page displays the estimated power consumed by the phase locked loops in the design and the factors that influence it. The power-consumption calculation is based on the input frequency, the number of PLLs in the design, and the following device-dependent parameters:

- N – the feedback divider count in voltage-controlled oscillator (VCO) frequency calculation.
- V – the VCO output divider in the VCO frequency calculation
- M – the reference clock divider count in the VCO frequency calculation.

PLL standby can be enabled on the PLL page for MachXO2, MachXO3D, MachXO3L, Platform Manager2, and ECP5. This allows you to use the Power Option Controller to place selected blocks in standby mode. See “Controlling Power Options for Low-Power Devices” on page 787 for more information.

The PLL page is available for all devices except MachXO 256 and 640 and Platform Manager.

DLL The DLL page displays the estimated power consumed by the delay locked loops in the design and the factors that influence it. The power-consumption calculation for this page requires the frequency and the number of DLLs.

The DLL page is available for the following device families: LatticeECP2/M, LatticeECP3, LatticeSC/M.

DQSDLL The DQSDLL page displays the estimated power consumed by the data strobe signal delay block in the design and the factors that influence it. The power-consumption calculation for this page requires the frequency and the number of DQSDLLs driven by each clock.

The DQSDLL page is available for all device families except LatticeSC/M, MachXO, MachXO3D, ECP5, and Platform Manager.

DQS The DQS page displays the estimated power consumed by the data strobe signal block in the design and the factors that influence it. The power-consumption calculation for this page requires the frequency and the number of DQSs driven by each clock.

The DQS page is available for Platform Manager 2 and for most MachXO2 devices, including MachXO2-640U, MachXO2-1200/U and larger devices. It is also available for ECP5.

DLLDEL The DLLDEL page displays the estimated power consumed by the clock slave delay cell (DLLDEL) and the factors that influence it. The DLLDEL is used with the DQSDLL to create a 90° clock shift/delay for aligned receiver interfaces. The power-consumption calculation for this page requires the frequency and the number of DLLDELs driven by each clock.

The DLLDEL page is available for MachXO2, MachXO3D, MachXO3L, Platform Manager2, LIFMD, and ECP5.

DDRDLL The DDRDLL page displays the estimated power consumed by the double data rate delay locked loops in the design and the factors that influence it. The power-consumption calculation for this page requires the frequency and the DDRDLL ID.

The DDRDLL page is available for ECP5 and LIFMD devices.

DSP The DSP page displays the estimated power consumed by the digital signal processors in the design and the factors that affect it. The power-consumption calculation for this page requires the frequency, activity factor, and the type and number of DSPs driven by each clock.

The DSP page is available for the following device families: LatticeECP, LatticeECP2/M, LatticeECP3, ECP5, LatticeXP2.

MACO The MACO page displays the estimated power consumed by the Masked Array for Cost Optimization (MACO) blocks in the design and the factors that affect it. The power-consumption calculation for this page requires the frequency, activity factor, and the type and number of MACOs driven by each clock. For LatticeSCM devices, the type of MACO can be one of the following:

- MTCL – a memory controller core
- SPI4 – a system packet interface level 4 core
- FlexiMAC – a media access controller core
- LTSSM – a link-training and status state machine core

The MACO page is available for LatticeSCM devices.

SERDES The SERDES page displays the estimated power consumed by the serializer/deserializer SERDES blocks in the design and the factors that affect it.

The SERDES page is available for LatticeECP2M, LatticeECP2MS, LatticeECP3, ECP5UM, LatticeSC, and LatticeSCM devices. The SERDES power-consumption calculation for each of these device families requires the frequency and number of channels active in the PCS instance.

The following parameters for each PCS SERDES channel are device-dependent:

- Gearing Ratio – specifies whether the FPGA interface to the PCS SERDES block is geared to produce a 16-bit data bus or an 8-bit data bus. The Gearing Ratio column is available only for LatticeSC and LatticeSCM devices.
- TX Pre-emphasis – specifies the Tx buffer pre-emphasis level. The Tx Pre-emphasis column is available only for LatticeECP3, LatticeSC and LatticeSCM devices. See the PCS SERDES data sheet for more information on the settings.
- Mode – specifies the mode in which the PCS SERDES block operates. The Mode column is available for LatticeECP2M, LatticeECP2MS, LatticeECP3, and ECP5UM.
- Dual Channel – specifies the PCS channel for the dual-channel-based ECP5UM device.
- Receive Max Data Rate (Gbps) – specifies the maximum receive data rate. The Receive Max Data Rate column is available for ECP5UM devices.
- Rx Rate – specifies the receive rate divider: Full, Div2, or Div11. The Rx Rate column is available for ECP5UM devices.
- Tx Max Data Rate (Gbps) – specifies the maximum transmit data rate. The Tx Max Data Rate column is available for ECP5UM devices.
- Tx Rate – specifies the transmit rate divider: Full, Div2, or Div11. The Tx Rate column is available for ECP5UM devices.
- Differential Amplitude – specifies the voltage differential amplitude. The Differential Amplitude column is available for ECP5UM devices.
- Output Termination – specifies the amount of resistance for the termination. The Output Termination column is available for ECP5UM devices.
- De-emphasis Pre-cursor Select – specifies a pre-cursor differential output voltage ratio. The De-emphasis Pre-cursor Select column is available for ECP5UM devices.
- De-emphasis Post-cursor Select – specifies a post-cursor differential output voltage ratio. The De-emphasis Post-cursor Select column is available for LatticeEC4UM devices.
- Receive Loss-of-Signal Port – enables or disables the receive loss-of-signal port. The Receive Loss-of-Signal Port column is available for ECP5UM devices.
- SERDES AUX – turns on or off the TX PLL for each AUX channel of the dual-channel-base PCS SERDES. The SERDES AUX section is available for ECP5UM devices.

Color Coding of Cells

The background colors of the cells on Power Calculator pages have the following significance:

- White – The cell is editable. When you edit the contents of this type of cell, the software mode does not change. If the software is in calculation mode, it will remain in calculation mode. If the software is in estimation mode, it will remain in estimation mode.
- Gold – The cell is read-only or contains output from the software.
- Cyan (turquoise) – The cell contains data extracted from a design file, such as an .ncd file. If you enter data into this type of cell and the software is in calculation mode, it will change to estimation mode, unless you enter data into the Performance Grade, Operating Conditions, and Process Type boxes. If the software is in estimation mode, it will remain in estimation mode.
- Red – The calculated value in the Junction Temperature box is either larger than 125 degrees Celsius or larger than the maximum junction temperature allowed for a particular device and operating conditions. The Junction Temperature box is the only cell that can display a red background.

The font colors in the cells on Power Calculator pages have the following significance:

- Blue – Indicates default values.
- Red – Indicates values that cannot be edited on the I/O page. Since the I/O page has columns for inputs, outputs, and bidirectionals, red font prevents you from altering an I/O that is not valid. For example, if the I/O type belongs only to an I/O input, the cell in the # of Inputs column would display a value in black font, indicating that it is editable, but the cells in the # of Outputs and the # of Bidi columns would display values in red font to indicate that they cannot be edited.
- Black – Indicates all other text.

Working with Power Calculator Files

When you first open Power Calculator for a design project, it creates a temporary file that appears in the title bar as “Untitled.” This file contains default information, based on the device, or information extracted from the .ncd file. When you enter data into Power Calculator pages and save the changes, the information gets stored in a Power Calculator file (.pcf). You can create a new Power Calculator file (.pcf) by saving the “Untitled” file. Or you can create a new .pcf file from the File menu before or after Power Calculator is opened.

When you use a .pcf file, rather than the “Untitled” temporary file, Power Calculator maintains the information it has already extracted from the .ncd file. The saved .pcf file will not get overwritten when you rerun Map or Place & Route Design, and the software mode will not change.

This section describes how to create new Power Calculator files, how to work with multiple existing .pcf files, and how to activate a .pcf file and load it into Power Calculator. It also shows how to import a value change dump file (.vcd) and a trace report file (.twr) for power calculation.

Creating a New Power Calculator File in Diamond

You can create a new Power Calculator file (.pcf) from the File menu or from the Analysis Files folder pop-up menu. You can do this before or after opening Power Calculator.

To create a new .pcf file:

1. In Diamond, do one of the following to open the New file dialog box:
   - choose **File > New > File**
   - Press **Ctrl+N**.
   - Right-click the Analysis Files folder in the File List pane and choose **Add > New File** from the pop-up menu.
2. In the New file dialog box, select **Power Calculator Files** from the Source Files list.
3. Type a name for the new .pcf file in the name box.
4. In the Location box, enter the path and name of the directory where the Power Calculator file (.pcf) will be stored. You can use the Browse button to navigate to the desired directory. By default, the file is stored in the current project folder.

   The “Add to project” option, which will add the new .pcf file to the Analysis files folder, is selected by default. If you do not wish the .pcf file to be added to the Analysis files folder for the current project, clear the “Add to project” option. You cannot clear this option if you are using the Analysis Files folder to add a new file.
5. If your project contains more than one design implementation, select the desired implementation from the drop-down menu. By default, the active implementation is already selected.
6. Click **New** to create the .pcf file in the selected directory.

   If Power Calculator is already open and contains unsaved changes to the current .pcf file, the Confirm dialog box will appear. Click **Yes** if you want to save the changes or **No** to discard them.

   Power Calculator opens, if it is not open already. This might take a few seconds. The new .pcf file is loaded into Power Calculator and its name is displayed in the title bar. The .pcf file is added to the Analysis Files folder where its name is highlighted in bold type, indicating that it is set as the active .pcf file for the current implementation. Because the .pcf file is set as active, it will be loaded automatically when you close and reopen

Power Calculator. When you rerun a process in Diamond, the .pcf file will not get overwritten.

Note

Each time you create a new Power Calculator file through the File menu or the Analysis Files pop-up menu, the new .pcf file is automatically set as the active one for the current implementation unless you have cleared the “Add to project” option. To make the .pcf file inactive, right-click the file name in the Analysis Files folder and choose **Set as Inactive**.

See Also ▶“Inputs” on page 757

- “Saving a Power Calculator File” on page 770
- “Outputs” on page 757
- “Opening an Existing Power Calculator File in Diamond” on page 771

Creating a New Power Calculator File in the Stand-Alone Power Calculator

If you have started Power Calculator as a stand-alone tool, you can create a new Power Calculator project file (.pcf) from the File menu.

To create a new .pcf file from the stand-alone Power Calculator:

1. From the stand-alone Power Calculator, choose **File > New File**.
2. In the Power Calculator – New Project dialog box, type a name for the file and browse to the desired directory.
3. To use an existing .ncd file for the project, browse to the location of the .ncd file. Otherwise, leave the .ncd box empty.
4. Click **OK**.

   If you selected an .ncd file in Step 3, Power Calculator loads the new project in calculation mode. If you did not select an .ncd file, Power Calculator loads the new project in estimation mode.

See Also ▶“Inputs” on page 757

- “Saving a Power Calculator File” on page 770
- Figure on page 757
- “Opening an Existing Power Calculator File in the Stand-Alone Power Calculator” on page 772

Saving a Power Calculator File

When you enter data into Power Calculator, an asterisk appears in both the title bar and the Power Calculator tab to indicate that there are unsaved changes. If you have not yet created a Power Calculator file (.pcf) for your

project, or if no .pcf file has been set as the active file, “Untitled” will appear in the title bar. The “Untitled” file is a temporary file that contains default settings based on the device. To add power analysis changes to your project, you must save the “Untitled” as a .pcf file, open an existing .pcf file, or create a new one. Afterwards, you can simply click the Save button to write any changes to the .pcf file. You can also save an existing .pcf file to a different directory or file name.

To save the Untitled file:

1. Choose **File > Save Untitled As**, and in the dialog box, navigate to the desired directory.
2. Type a name in the file name box and click **Save**.

   The information entered in your project is saved in the .pcf file, and the .pcf file is automatically added to the Analysis Files folder in the File List pane.

To save changes to an existing Power Calculator file:

- Choose **File > Save** or press **Ctrl+S** or click  .

To save a Power Calculator file to a different directory or file name:

1. Choose **File > Save <file_name>.pcf As** to open the Save dialog box.
2. In the Save In box, navigate to the directory in which to save the .pcf file.
3. Type a different name in the File Name box.
4. In the Files of Type box, select **Power Calculator File (.pcf)**.
5. Click **Save**.

   The saved .pcf file is added to the project’s Analysis Files folder in the File List pane.

Opening an Existing Power Calculator File in Diamond

You can open an existing Power Calculator (.pcf) file in Diamond before or after opening Power Calculator. When you open a .pcf file in Diamond, the design information must match the information in the current project. You can open an existing .pcf file from the File menu, or from the Analysis Files folder.

To open an existing .pcf file from the File menu:

1. Choose **File > Open > File** or press **Ctrl+O**.

2. In the Open File dialog box, select **Power Calculator Files (.pcf)** from the Files of Type drop-down menu. If Power Calculator is already open, this will already be selected.
3. Navigate to the directory that contains the desired .pcf file, select the file, and click **Open**.

   Power Calculator opens automatically, if it is not already open. The Power Summary page is displayed and the information from the selected .pcf file is loaded. The name of the .pcf file appears in the title bar. If Power Calculator is in calculation mode, it will import any Bank VCCIO settings that are in the preference file and display these settings on the I/O page.

To open a recently opened .pcf file:

- Choose **File > Recent Files > *filename*** from the list of the four most recently opened files.

Note

When you open a .pcf file from the File menu, it is not automatically added to the Analysis Files folder. You must add it to the folder manually.

To open an existing .pcf file from the Analysis Files directory:

1. In Diamond, select the File List tab in the pane on the left.
2. Expand the Analysis Files folder.

   You can open the active .pcf file, if it is not already open, or one that is not active. An active .pcf file appears in bold type.
3. Double-click the name of the .pcf file that you want to open. Optionally, right-click the file name and choose **Open**.

   The information from the .pcf file is loaded into Power Calculator, and the name of the file appears in the title bar.

See Also
- "Adding Power Calculator Files to the Analysis Files Folder" on page 773
- "Setting a Power Calculator File as the Active Analysis File" on page 774

Opening an Existing Power Calculator File in the Stand-Alone Power Calculator

If you have opened Power Calculator as a stand-alone tool, you can open an existing Power Calculator file (.pcf) from the File menu.

To open an existing .pcf file from the stand-alone Power Calculator:

1. Choose **File > Open File**.

2. Navigate to the desired .pcf file and click **Open**.

   If you have unsaved changes in the currently loaded .pcf file, a Confirm message box will appear. Click **Yes** if you want to save the changes. Otherwise, click **No**.

   If an .ncd file is associated with the selected .pcf file, Power Calculator loads the project in calculation mode. If no .ncd file is associated with the .pcf file, Power Calculator loads the new project in estimation mode.

See Also ▶"Saving a Power Calculator File" on page 770

- "Creating a New Power Calculator File in the Stand-Alone Power Calculator" on page 770

Adding Power Calculator Files to the Analysis Files Folder

Diamond enables you to add existing Power Calculator files (.pcf) to the Analysis Files folder. This gives you easy access to the .pcf files in your project and enables you to designate a .pcf file as the active one for a design implementation. When a .pcf file has been set as the active analysis file, it will be loaded into Power Calculator automatically when you close Power Calculator and reopen it.

You can add a .pcf file to the Analysis Files folder before or after starting Power Calculator.

To add an existing .pcf file to the Analysis Files directory:

1. In Diamond, select the File List tab in the pane on the left.
2. Right-click the Analysis Files folder and choose **Add > Existing File** from the pop-up menu.
3. In the dialog box, select **Analysis Files (*.pcf)** in the Files of Type box.
4. Navigate to the directory that contains the desired .pcf file, select it, and click **Add**.

   The file is added to the Analysis Files folder. You can double-click the .pcf file to open it in Power Calculator.

Note

When you add a .pcf file to the Analysis Files folder, it is not automatically set as the Active .pcf file for the implementation. You must set it as the active file manually.

See Also ▶"Removing Power Calculator Files from the Analysis Files Folder" on page 774

- "Creating a New Power Calculator File in Diamond" on page 769
- "Setting a Power Calculator File as the Active Analysis File" on page 774

Removing Power Calculator Files from the Analysis Files Folder

At times, you may want to remove files from the Analysis Files folder to make room for others. When you remove a Power Calculator File (.pcf) from the Analysis Files folder, it is not deleted from your project. You can always add it back later.

To remove a .pcf file from the Analysis Files folder:

- Right-click the file name and choose **Remove**.

  The file is removed from the Analysis Files list, but it remains in your project directory.

Setting a Power Calculator File as the Active Analysis File

In Diamond, if you want Power Calculator to load a specific Power Calculator File (.pcf) each time it opens, you must designate the .pcf file as the active one for the implementation. This is done automatically when you create a new .pcf file. If no .pcf file has been set as the active one, Power Calculator will extract information from the placed and routed .ncd file when you open Power Calculator. If no .ncd file is available, it will display default resource information based on the targeted device.

To set a .pcf file as the active analysis file:

1. Make sure that you have added the desired .pcf file to the Analysis Files folder.
2. Right-click the desired .pcf file in the Analysis Files folder and choose **Set as Active Analysis File**.

   Diamond displays the .pcf file name in bold type, indicating that it is the active power analysis file for the current design implementation. Diamond does not automatically load the newly activated file into Power Calculator if a different .pcf file was already open.
3. To open the active .pcf file, if a previous file was already open, double-click the activated .pcf file name in the Analysis Files folder; or right-click it and choose **Open**.

   When you close and reopen Power Calculator for the current design project, the active .pcf file will be loaded.

Changing an Active Power Calculator File to Inactive

In Diamond, it is not required that a Power Calculator File (.pcf) be set as the active one for a design implementation. You can always open a .pcf file manually from the File menu or from the Analysis Files folder.

To change an active Power Calculator File to inactive:

- Right-click the name of the active .pcf file in the Analysis File folder and choose **Set as Inactive** from the pop-up menu.

  When you close and reopen Power Calculator, it displays default information or information from the routed .ncd file. “Untitled” appears in the title bar.

Entering Data

When you have a design open in Diamond, Power Calculator extracts information such as device, package, part, performance grade, and operating conditions. You can modify the device settings and the editable cells on any page. If Power Calculator is in calculation mode when you make any change other than Activity Factor, Frequency, Voltage, Dynamic Power Multiplier, Ambient Temperature, Performance Grade, Operating Condition, or Process Type, it will revert to estimation mode. You can revert to calculation mode after making many types of changes, if they have not been saved to the .pcf file.

Power Calculator allows you to enter data directly in the editable cells. It also enables you to make global changes to frequency and activity factors by changing the default setting in the Frequency Settings and Activity Factors Settings dialog boxes. You can also use a timing report file (.twr) to make global frequency changes or a simulation file to populate both Frequency and AF (activity factor) cells.

- “Software Mode” on page 759
- “Reverting to Calculation Mode” on page 779
- “Power Calculator Pages” on page 761

Editing Cells

Power Calculator includes built-in design rule checks. It automatically checks values that you enter into editable cells to ensure that they do not violate design rules. If you attempt to enter an inappropriate value in the Type, # I/P, # O/P, or # Bidi cell in the I/O page, Power Calculator will block the invalid value and display the previous value in the cell.

Power Calculator also provides tool tips that display the valid range of values for an editable cell. To ensure that the value you are entering is a valid one, hold your mouse over the cell to view the tool tip.

Most cells on Power Calculator pages are editable text cells that enable you to type a modified value. Others cells, such as the Device and Power parameters sections of the Power Summary page, contain visible drop-down menus for making a selection. Still others, such as those in the Type column on the I/O page, contain hidden drop-down menus that become visible when you double-click a cell.

To edit a cell:

- Depending on the type of cell you are editing, do one of the following:
  - Double-click the editable cell, type a new value, and then press **Enter** or click anywhere outside the cell.
  - Select a value from the visible drop-down list.
  - Double-click the cell and select a value from the drop-down list that appears.

  Power Calculator calculates the results automatically and displays them. It also updates the Report page.

See Also "Power Calculator Pages" on page 761

- "Color Coding of Cells" on page 767
- "Cutting and Pasting Cell Contents" on page 778
- "Copying and Pasting Cell Contents" on page 779
- "Changing Values Automatically" on page 779

Editing the I/O Type for LatticeSC/M Devices

For LatticeSC and LatticeSCM devices, Power Calculator provides an IO Type selection dialog box that enables you to specify an I/O type based on its properties, such as drive strength and VTT termination.

To specify the I/O type for a LatticeSC/M device based on its properties:

1. On the I/O page, select the cell in the Type column that you want to change. Make sure that you click the cell only once.

   The cell is highlighted and no drop-down arrow appears.

   Note

   If you double-click the cell, the drop-down menu will become available instead of the pop-up menu. If the drop-down arrow appears, click outside the cell, and then return and click the cell only once.

2. Right-click the highlighted cell and choose **IO Type Edit** from the pop-up menu.

The IO Type Selection dialog box lists all available I/O types in the frame on the left. The properties of each selected I/O type are shown in the frame on the right.

3. Scroll through the IO Type list, select a type, and examine its properties.
4. Repeat Step 3 until you have decided on the I/O type for the selected clock, based on the I/O type properties.
5. Click **OK** to place the selected I/O type in the cell on the I/O page.

Editing Pages

You can change the settings and values on any Power Calculator page and, if desired, save the results to a separate Power Calculator File (.pcf) in the Analysis Files folder.

To edit Power Calculator pages:

1. On the Power Summary page, modify any settings in the Device section as desired.

   When you select a different device, Power Calculator compares the design's requirements against the available resources in the selected device. If the selected device is not suitable for the design—for example, if the number of LUTs in the design exceeds those available in the device—Power Calculator will generate an error message and not allow the change. To proceed with the change, you would need to reduce the design size to fit the smaller device.
2. In the Device Power Parameters section of the Power Summary page, set the Process Type option, which specifies the process corners or conditions under which the device was manufactured. It can be one of the following:
   - Typical – specifies typical conditions to reflect the typical amount of current consumed by the circuit.
   - Worst – specifies fast conditions to reflect the maximum amount of current consumed by the circuit.
3. In the Environment section of the Power Summary page, do the following:
   - Click **Thermal Profile** to select a thermal impedance model or enter your own Effective Theta-JA value.
   - Change the ambient temperature, as desired.

   See "Controlling Operating Temperature" on page 783
4. In the Voltage/Dynamic Power Multiplier section, enter new values, as desired, for voltage and DPM.

   The voltage is the estimated power consumption by power supply. DPM is the derating factor for the dynamic portion of the power consumption.
5. Select other tabs and enter values into the editable cells of the other Power Calculator pages. The number and types of pages varies according to the device family.

6. Save your changes.

Adding and Deleting Clock Rows

You can easily add and delete clock rows on the Power Calculator pages.

To add a clock row to a page:

1. Right-click inside the desired table and choose **Add Row** from the pop-up menu.
2. Enter the appropriate data in the cells that have a white or cyan (turquoise) background. Some columns with a cyan (turquoise) background, such as Type, offer drop-down menus from which you can select settings.

To delete a clock row from a page:

- Right-click in the row that you want to delete and choose **Remove Row**.

See Also ▶"Editing Cells" on page 775

Cutting and Pasting Cell Contents

You can cut the contents of a cell in a clock row and paste them in a cell in the same row or another row.

To cut and paste cell contents:

1. Double-click the desired cell to select its contents, and then right-click.
2. From the pop-up menu, select **Cut**. Alternatively, you can press **Ctrl+x**.

   You cannot cut the contents of any cells or columns that include a drop-down menu or text that is read-only.
3. Double-click the cell into which you want to paste the contents that you have cut, and then right-click.
4. From the pop-up menu, select **Paste**. Alternatively, you can press **Ctrl+v**.

See Also ▶"Editing Cells" on page 775

- "Changing Values Automatically" on page 779

Copying and Pasting Cell Contents

You can copy the contents of a cell in a clock row to a cell in the same row or another row.

To copy and paste the contents of a cell:

1. Double-click the desired cell to select its contents, and then right-click.
2. From the pop-up menu, select **Copy**. Alternatively, you can press **Ctrl+c**.
3. Double-click the cell into which you want to paste the contents that you have copied, and then right-click.
4. From the pop-up menu, select **Paste**. Alternatively, you can press **Ctrl+v**.

See Also ▶"Editing Cells" on page 775

- "Changing Values Automatically" on page 779

Changing Values Automatically

When you change values on any of the pages, Power Calculator recalculates the results automatically. For example, when you change the frequency of a clock in one cell and press Enter, Power Calculator automatically changes the frequency for that clock in all Frequency cells.

You can also use the Activity Factor Settings and Frequency Settings dialog boxes to make changes to all frequency and activity factor cells.

See Also ▶"Changing the Global Default Activity Factor" on page 780

- "Changing the Global Default Frequency Setting" on page 781
- "Importing a Value Change Dump (.vcd) File" on page 780

Reverting to Calculation Mode

After you have made changes that causes the software to run in estimation mode, Power Calculator allows you to revert to calculation mode, under the following circumstances:

- You are working with a saved .pcf file and not the "untitled" default .pcf file.
- The changes you made have not been saved to the .pcf file.

To revert to calculation mode from estimation mode:

1. Choose **Edit > Revert to Calculation Mode**.
2. In the Confirm dialog box, click **Yes** to confirm that you want to discard all the changes that you made in estimation mode.

   Power Calculator removes all the changes you made and reverts to the settings in the .pcf file.

See Also ▶"Software Mode" on page 759

Changing the Global Default Activity Factor

Power Calculator automatically assigns a global default activity factor of 10 percent in the cells of the pages that display an activity factor, such as AF (%), or that use an activity factor in calculations, such as Input AF (%). These default values appear in blue font. You can use the Edit menu to globally change this default activity factor.

To globally change the default activity factor:

1. Choose **Edit > Activity Factor Settings**.
2. In the Power Calculator - Activity Factor Settings dialog box, enter the new activity factor in the **Activity Factor Default** text box.
3. Click **OK**.

All the default activity factors appearing in blue font are changed to the new activity factor. Power Calculator automatically saves the new default.

If you manually change an activity factor in only one cell, the font becomes black to indicate that it is not a default value.

You can use a .vcd file to populate the cells that display or use activity factors. The resulting values are not considered defaults and therefore appear in black font.

See Also ▶"Activity Factor Calculation" on page 758

- "Importing a Value Change Dump (.vcd) File" on page 780

Importing a Value Change Dump (.vcd) File

Power Calculator enables you to import a value change dump (.vcd) file of simulation results into your project. Normally, you would import a .vcd file only when you want the Frequency and AF (activity factor) cells on Power Calculator pages to be populated with frequency and activity factor data from the .vcd file.

To ensure that Power Calculator populates the Frequency and AF cells with the VCD information, make sure that you follow these requirements:

- The .vcd file should be in the format of gate-level simulation, and it should match the design.
- A post-PAR timing simulation netlist must be used for name matching. You cannot use the RTL design.
- A stimulus must be used in the simulator that actually toggles the signals you are interested in; otherwise, you will see no difference in Power Calculator after the VCD is read.

To import a .vcd file into your project:

1. Choose **Edit > Open Simulation File** to open the Power Calculator – Open Simulation File dialog box.
2. In the VCD File box, type or select the path and name of the .vcd file that you want to open.
3. In the Module Name in VCD box, specify the name of the module in the .vcd file from which to take the frequency and activity factor data.
4. Select the Case Sensitive option if the name of the .vcd file to be imported is case-sensitive.
5. Click **OK**.

   Power Calculator's Frequency and AF cells are now populated with the data from the .vcd file.

See Also ▶"Changing the Global Default Frequency Setting" on page 781

Changing the Global Default Frequency Setting

You can globally change the default frequency values for the clocks listed in the Power Calculator pages. These default values appear in blue font in the Freq. (MHz) columns.

You can change this global frequency value either by specifying a value or by indicating that the frequency value be taken from the constrained or actual frequency in the trace report (.twr) file.

To globally change the default frequency setting by specifying a value:

1. Choose **Edit** > **Frequency Settings**.
2. In the Power Calculator - Frequency Settings dialog box, enter the new activity factor in the Frequency Default cell, in megahertz.

   The default is 0 megahertz.
3. Click **OK**.

To globally change the default frequency setting by using values from the .twr file:

1. Choose **Edit** > **Frequency Settings**.
2. In the Power Calculator - Frequency Settings dialog box, select one of the following options in the Frequency TWR box. For all these options, the .twr file must contain the names of the clocks in the pages for which you want default frequency values.
   - Minimum of Preference And Trace – Specifies that the default frequency in the Frequency (MHz) column of the Power Calculator pages be taken from the lesser of the constrained frequency or the actual frequency in the trace report (.twr) file, if you have imported this file into your project. The frequency is in megahertz.

- Always Use Preference – Specifies that the default frequency in the Frequency (MHz) column of the Power Calculator pages be taken from the constrained frequency in the trace report (.twr) file, if you have imported this file into your project. The frequency is in megahertz.
- Always Use Trace – Specifies that the default frequency in the Frequency (MHz) column of the Power Calculator pages be taken from the actual frequency in the trace report (.twr) file, if you have imported this file into your project. The frequency is in megahertz.

3. Click **OK**.

   Power Calculator now populates the Frequency cells of its pages with the frequency data from the imported .twr file.

See Also ▶"Inputs" on page 757

Estimating Resource Usage

Power Calculator allows you to specify an estimate of resources that the design will use, for the purpose of power analysis. The estimate can be based on design type or on component utilization. Based on your selections, Power Calculator immediately displays the number of resources that will be utilized for each type.

To estimate resource usage based on design type:

1. Choose **Edit > Resource Settings**.
2. In the dialog box, select **Specify Resource by Design Type**.
3. Select the design type from the drop-down menu.

   Power Calculator calculates the resource usage based on the design and displays the utilization in the bottom portion of the dialog box.
4. Click **OK**.

To estimate resource usage based on component utilization:

1. Choose **Edit > Resource Settings**.
2. In the dialog box, select **Specify Resource by Component Utilization**.
3. Do one or both of the following:
   - Select a Small, Medium, or Large option based on the design size.

     Power Calculator displays a percentage of Logic, I/O, and EBR based on your selection.
   - Select a percentage from the Logic, I/O, and EBR drop-down menus.

   Power Calculator calculates the resource usage based on your selections and displays the utilization in the bottom portion of the dialog box.
4. Click **OK**.

See Also ▶"Estimating Routing Resource Usage" on page 783

Estimating Routing Resource Usage

You can estimate the amount of routing resources that your design will use, for the purpose of power analysis.

To estimate routing resource usage:

1. Choose **Edit > Estimation Mode Settings**.

   The Power Calculator - Estimation Mode Settings dialog box appears.

2. From the Routing Resource Utilization drop-down menu, select the amount of routing resources that you expect your design to use. You can select from the following:

   - Low – Uses a small amount of routing resources.
   - Medium – Uses an average amount of routing resources. This setting is the default.
   - High – Uses a large amount of routing resources.

3. Click **OK**.

See Also ▶"Estimating Resource Usage" on page 782

Controlling Operating Temperature

Minimizing the device's operating temperature is critical to reducing power consumption.

A device has two parts: the die, which is the silicon inside the device, and the package, which is the outer shell. Each die-package combination has a thermal resistance value (often referred to as theta), which is a measure of how well the combination can dissipate heat. Lower values indicate better heat dissipation for the device.

Thermal impedance is the cumulative individual thermal resistances of a defined network. Power Calculator offers different models that provide ways to calculate the thermal impedance for a given device when it is mounted on the board. These models cover scenarios related to board sizes, air flows, and heat sinks that affect the thermal impedance. You can use these models to calculate the thermal impedance for the scenario that you choose.

You can choose the thermal impedance models by clicking the **Thermal Profile** button in the Environment section at the top right of the Power Summary page.

These thermal impedance models use the following terminology:

- Junction temperature – the temperature of the die in the device package, in degrees Celsius. You can adjust the junction temperature by choosing a

model that applies a heat sink and changes the air flow value. Junction temperature is also affected by the package that you select in the Package Type box. In addition, the changes that you enter in many of the editable (white and turquoise) cells on the Power Summary page affect junction temperature.

- Heat sink – any material or object that dissipates unwanted heat from a device by absorbing it and conducting it away to a surface from which it dissipates into its surroundings. The reduction of junction-to-ambient thermal impedance depends on different factors, such as the speed and direction of the air flow over the heat sink and the materials used to attach the heat sink to the package. For heat-sink properties and proper attachment methods, contact your heat-sink manufacturer for specifications.
- Air flow – the movement of air around the device in a package to cool it. It is measured in linear feet per minute (LFM). The higher the air flow value you select, the greater the cooling effect on the device.
- Ambient temperature – the expected operating temperature, in degrees Celsius, of the medium surrounding a device in a package.
- Theta JA – the thermal impedance between the silicon die and the ambient air within a JEDEC-defined environment. The boards used to measure these values have four layers, and their size is defined by JEDEC specifications.
- Effective Theta JA – similar to Theta JA, but defined as the sum of all the package and board thermal resistances outside of a JEDEC-defined environment. It indicates how well the heat dissipates from the die to the ambient (air) for a particular thermal network as a whole outside of a JEDEC-defined environment.
- Theta JB – indicates how well the heat dissipates from the junction on the silicon die to the board.
- Theta JC – indicates how well the heat dissipates from the junction of the die to the package case in which it is enclosed, as defined by the JEDEC specifications.
- Theta BA – indicates how well the heat dissipates from the board to the ambient (air).
- Theta CS – indicates how well the heat dissipates from the package case to the heat sink. It is a measure of the thermal resistance of the interface material that makes contact between the package case and the heat sink attached to the package. It can be thermal grease, double-sided sticky tape, glue, or phase-shift material.
- Theta SA – indicates how well the heat dissipates from the heat sink to the ambient (air).

See Also ▶"Power Calculator Pages" on page 761

Selecting a Thermal Impedance Model

You can experiment with various board sizes, heat sinks, and air flow settings to select a thermal impedance model for your design. The choice of board affects the Theta JB and Theta BA values, and the heat sink and air-flow selections affect the Theta SA and Theta JA values.

Note

The current values provided with the thermal models are averages of different values, and they are provided as a courtesy. To produce better predictions, it is advised that you submit your own thermal values.

To select a thermal impedance model:

1. In the Environment section of the Power Summary page, click **Thermal Profile**.

   The Effective Theta-JA specifies the cumulative thermal impedance of a particular system. This figure is used in calculating the junction temperature (Tj) of a die in a particular environment according to the following formula:

   Tj = *power * theta_effective + ambient_temperature*.

2. In the Power Calculator - Thermal Profile dialog box, select the source of the effective thermal impedance (effective Theta JA) value:

   - If you want Power Calculator to calculate the effective Theta JA value from the selections that you make in the Board Selection, Heat Sink Selection, and Airflow Selection drop-down menus, choose **Use Thermal Models**.
   - If you want to provide your own effective Theta JA value, choose **User-Defined Theta-JA Effective**.

3. If you chose Use Thermal Models:

   a. Select the size of the board that you will be using from the Board Selection drop-down menu:

      - JEDEC Board (2S2P) – Specifies that a board defined by JEDEC specifications be used. These specifications are based on real boards and measurements conducted in the lab used by Lattice Semiconductor. For packages < 27.0 mm in length, the buried planes are 74.2 mm x 74.2 mm (3” x 3”). For packages larger than or equal to 27.0 mm, the buried planes are 99.6 mm x 99.6 mm (4” by 4”). Power Calculator uses Theta JA or Theta JC, depending on the type of heat sink selection you make in the Heat Sink Selection menu. Theta JA is used only if you choose No Heat Sink. The ThetaJA value is the published value measured in the lab.
      - Small Board – Specifies that a board that is slightly larger than the JEDEC board be used. The board is assumed to be 6” to 8” square. This setting adds the Theta JB value to the board thermal impedance.

- Medium Board – Specifies that a medium board be used, one that is assumed to be 8” to 12” square. This setting adds the Theta JB value to the board thermal impedance.
- Large Board – Specifies that a large board be used, one that is assumed to be larger than 14” square. This setting adds the Theta JB value to the board thermal impedance.

Note

Many factors can affect the actual thermal properties and change the values: the number of board layers, airflow over the board, number of devices powered up around the device package and their distance from the package, the thickness of the copper and the width of the traces on each layer, the number of thermal vias, and the shape and thickness of each power and ground plane below the transfer of heat from the die to the ambient environment. Users are encouraged to make their own thermal measurements or simulations and use them in Power Calculator to see what kind of junction temperature might result.

b. Select the type of heat sink from the Heat Sink Selection drop-down menu:
   - No Heat Sink – Specifies that no heat sink be used. Theta JA is used, and you must choose the air flow from the Airflow Selection menu. The No Heat Sink setting is the default.
   - Low-Profile Heat Sink – Specifies that a short heat sink be used.
   - Medium-Profile Heat Sink – Specifies that a medium heat sink be used. This setting adds the Theta JC value to the Heat Sink thermal impedance.
   - High-Profile Heat Sink – Specifies that a tall heat sink be used.
   - Custom-Profile Heat Sink – Enables you to specify your own heat-sink value in the Theta-SA for Custom Heat Sink box. The Airflow Selection option is not available when you select Custom-Profile Heat Sink.

c. Select the air flow in linear feet per minute (LFM) from the Airflow Selection drop-down menu:
   - 0 LFM
   - 200 LFM
   - 500 LFM

   If you use a heat sink, the 0 LFM setting is not available.

   The Airflow Selection option is not available when you select Custom-Profile Heat Sink from the Heat Sink Selection menu.

4. If you chose User-Defined Theta-JA Effective, enter your effective thermal impedance value in the Effective Theta-JA box. Values entered must be greater than 0.

   This box is not available if you selected Use Thermal Models.

5. Click **OK**.

The new effective Theta JA value now appears in the Effective Theta-JA box in the Environment section of the Power Summary page.

See Also ▶"Controlling Operating Temperature" on page 783

- "Changing the Ambient Temperature" on page 787

Changing the Ambient Temperature

The ambient temperature is the expected operating temperature, in degrees Celsius, of the medium surrounding a device in a package. You can select an ambient temperature in the range of -40 to 125 degrees Celsius.

To change the ambient temperature:

- In the Environment section of the Power Summary page, enter a value, in degrees Celsius, in the Ambient Temperature box and press **Enter** or click anywhere outside the cell.

  The value entered must be between -40 and +125 degrees Celsius. The default value is 25 degrees Celsius for all devices.

When you change the value in the Ambient Temperature box, Power Calculator updates the following cells:

- Junction Temperature
- Values in the Static and Total columns of the Current by Power Supply Details and Power by Power Supply Details sections
- The totals in the Power by Block Column

If you enter a value that is beyond the commercial, industrial, or automotive device limits, you will receive an error message that displays the range of valid values.

See Also ▶"Controlling Operating Temperature" on page 783

- "Selecting a Thermal Impedance Model" on page 785

Controlling Power Options for Low-Power Devices

The MachXO2, MachXO3D, MachXO3L, ECP5, and Platform Manager 2 devices include many low-power architectural features. Power Calculator provides tools for taking advantage of these features, including the Power Option Controller. The Power Option Controller enables you to dynamically change the power of certain blocks through the use of standby mode and other options. A chart is provided that compares the amount of power used by components when standby is on and when it is off.

Three power modules are available, which you can generate from IPexpress: Power Controller, Dynamic Bank Controller, and Power Guard. To get the full benefit of Power Calculator's Power Option Controller, it is recommended that

you add these modules to your design. You can still use the Power Option Controller without adding these modules, but the calculations will be in estimation mode only.

Note

Power Guard is not available for ECP5.

For more information about these power modules, refer to the "Lattice Module Reference Guide" on page 1399.

Added Features for Low-Power Architecture

Power Calculator provides an EFB page for the low-power MachXO2, MachXO3D, MachXO3L, and Platform Manager 2 devices. The EFB page enables you to specify settings for an embedded function block (EFB). The EFB block, which is connected to the device from a WISHBONE bus, includes a SPI, two I2Cs, and a timer/counter peripheral. For higher-density devices, the EFB also includes user flash memory (UFM).

Other pages—including I/O, PLL, and Misc—allow you to set standby mode or power guard (PG) for components that you want to allow to be dynamically turned off during low-power operation modes. You can then use the "Power Option Controller" on page 788 to select the components to be turned off. Many of these features are also available for ECP5 devices.

Power is calculated with a precision of six decimal places instead of four.

See Also "Power Calculator Pages" on page 761

- TN1198, *Power Estimation and Management for MachXO2 Devices*
- TN1289, *Power Estimation and Management for MachXO3L Devices*
- TN1307, *Power Management and Calculation for CrossLink Devices*

Power Option Controller

The Power Option Controller gives you control over power management features. It enables you to conserve power by turning on and off blocks in the chip that consume power, manage the entrances and exits of signals, and use power guard (PG) to stop signals from entering the chip. First, set the standby, shut-off, and power guard options that you want to allow, using the appropriate Power Calculator pages. Afterwards, return to the Power Summary page, open the Power Option Controller, and select the elements to be turned off during low-power operation.

For MachXO2, MachXO3D, MachXO3L, and Platform Manager 2 devices, the Power Option Controller includes the following options for turning off elements that have been placed in standby mode:

- Disable Bandgap – turns off the Bandgap. When this options is selected, analog circuitry such as the PLLs, on-chip oscillator, and referenced and differential I/O buffers are also turned off.
- Disable POR – turns off the power-on-reset circuit, which monitors VCC levels. When the POR circuitry is turned off, limited power detection circuitry is still active. This option is only recommended for applications in which the power supply rails are reliable.
- Disable OSC – turns off the on-chip oscillator.
- Disable PLL – turns off the selected phase-locked loop.

The Power Option Controller includes the following dynamic bank options:

- Disable InRd – turns off the referenced and differential input buffers for a selected bank.
- Disable LVDSO – turns off the LVDS output buffer for a selected bank.
- Enable PG – enables Power Guard for the selected bank.

For ECP5 devices, the following elements that have been placed in standby can be turned off in the Power Option Controller: OSC, PLL, InRd, LVDSO, DDRDLL.

For LIFMD devices, the following elements that have been placed in standby can be turned off in the Power Option Controller: InRd, LVDSO, PLL, OSC, and MIPI DPHY.

See TN1198, *Power Estimation and Management for MachXO2 Devices*

TN1289, *Power Estimation and Management for MachXO3L Devices*

Enabling Low-Power Options

For the low-power MachXO2, MachXO3D, MachXO3L, Platform Manager 2, and ECP5 devices, Power Calculator enables you to set options for selected components that will allow them to be dynamically turned off during low-power operation modes. The options include Allow Standby, Allow Shut-off, and Power Guard. You first allow these options for selected components by using the appropriate Power Calculator pages. Afterwards, the Power Option Controller enables you to choose those that you want to be dynamically turned off for low-power operations.

To enable the Power Option Controller low-power options:

1. Select the **Misc** tab. In the MCLK Allow Standby column, choose **YES** if you want to allow standby for the on-chip oscillator. Choose **Yes** for the other standby options that you want to allow.

2. Select the **PLL** tab. In the Allow Standby column, choose **Yes** for each of the PLL standby options that you want to allow.
3. Select the **I/O** tab and do the following:
   a. In the PG column of the Inputs and Outputs section, select the input clock signals for which you want to turn on the power guard, and then choose **On**. Do the same in the Bidirectional I/Os section.

      The power guard settings are displayed in the read-only PG column of the Bank Voltage section.

   b. For each bank in the Bank Voltage section, choose **Yes** in the Allow InRD Shut-off column if you want to allow the referenced and differential input buffers to be turned off.

   c. In the Allow LVDSO Shut-off column of the Bank Voltage section, choose **Yes** for a selected bank if you want to allow the LVDS output buffer driver to be turned off.
4. On the Power Summary page, click the **Power Control** button.

   The Power Option Controller shows the dynamic power options that you have allowed on the Power Calculator pages. Options that you have not allowed remain dimmed.
5. Select the desired dynamic power options that have been enabled and click **OK**.

See Also ▶"Power Calculator Pages" on page 761

- "Power Option Controller" on page 788
- "Lattice Module Reference Guide" on page 1399

- TN1307, *Power Management and Calculation for CrossLink Devices*

Comparing Power Results for Standby Mode

For the low-power MachXO2,MachXO3D, MachXO3L, ECP5, and Platform Manager 2 devices, Power Calculator estimates the amount of power used by components that can be placed in standby mode and compares this usage with non-standby mode. The results are presented in a comparison chart that you can access from the Edit menu.

The comparison chart gives you a good idea of the amount of power that can be saved by enabling standby mode for the different components.

To compare power results for standby mode:

- Choose **Edit > Comparison chart of power awareness**.

The Comparison chart of power (W) displays the standby and non-standby power usage for each type of component that can be placed in standby mode for the targeted device.

See Also ▶"Obtaining Time-Based Average Power Usage" on page 791

Obtaining Time-Based Average Power Usage

When you target a MachXO2, MachXO3D, MachXO3L, ECP5, or Platform Manager 2 device, you will typically be using standby mode, regular mode, and shutdown mode for various periods of time. Power Calculator enables you to obtain an estimate of the average power used, based on the percentage of time taken by each of these modes.

To obtain an estimate of time-based average power usage:

1. Choose **Edit > Average power and thermal over time**.
2. In the dialog box, type an estimated percentage of time that will be taken by shutdown mode (T1), standby mode (T2), and full power mode (T3). The percentage total for all three modes must equal 100.

   Power Calculator calculates the average power usage and displays it beneath the equation at the bottom.

See Also ▶"Comparing Power Results for Standby Mode" on page 790

Comparing Power Consumption Among Multiple Implementations

Power Calculator enables you to compare the power consumption among multiple implementations of your design. Each implementation must target the same device and have at least one power calculator project file (.pcf).

If you are using Power Calculator within the Diamond environment, Power Calculator will display the comparison table using the .pcf files that are in the Analysis Files folder for each implementation. If you are using the stand-alone Power Calculator, you will need to add the .pcf files.

To compare power consumption among multiple design implementations:

- Choose **Edit > Compare power of implementations**.

  Power Calculator generates a comparison table of power usage for all the implementations that contain .pcf files. If an implementation contains more than one .pcf file in the Analysis Files folder, the table will show multiple comparisons for the implementation.

- Click **View HTML** to view the table in your browser.
- To save the table as a text file, click **Generate Text Report**.

Viewing and Printing Results

In addition to the automatically generated reports from power settings, Power Calculator provides graphs of power consumption and enables you to print information from the pages and generate a comma-separate value file (.csv) from the command line.

Generating Power Graphs

Power Calculator can create graphs showing how power consumption is affected when you vary the voltage, temperature, and clock frequency in the design. You can generate three default power graphs on the Graph page: Power vs. Supply Voltage, Power vs. Ambient Temperature, and Power vs. Frequency. Each graph displays a typical and worst case plot. You can select the X axis and Y axis for each graph.

Graphs are only generated when you select the Graph tab. During graph generation, you cannot select a different tab until the calculations are finished. If you change the information in any other page that alters the power, the graphs will be regenerated when you again select the Graph tab. If you do not change any power information, the graphs will not be regenerated.

To generate the Power vs. Supply Voltage graphs:

1. Choose **Edit > Graph Settings**.
2. In the Power by Section part of the Graphs Settings dialog box, set the following options:
    a. In the Y Axis box, select Total Power or the type of block power, such as I/O or Block RAM, to place on the Y axis of the graph.
    b. In the X Axis box, select the type of supply voltage to place on the X axis of the graph.
    c. In the Lower Limit box, enter the lower boundary of the voltage range on the X axis. The lower limit can be 5 percent lower than the nominal supply value.
    d. In the Upper Limit box, enter the upper boundary of the voltage range on the X axis. The upper limit can be 5 percent higher than the nominal supply value.
    e. In the Resolution box, enter the step in which the supply voltage values on the X axis should appear. The voltage supply step is limited to a resolution of .01.
3. Click **OK** to close the dialog box and apply the settings.
4. Click the Graph tab to see the resulting charts.

To generate the Power vs. Ambient Temperature graphs:

1. Choose **Edit > Graph Settings**.
2. In the Power by Temperature part of the Graphs Settings dialog box, set the following options:
   a. In the Y Axis box, select Total Power or the type of block power, such as I/O or Block RAM, to place on the Y axis of the graph.
   b. In the X Axis box, select **Ambient Temperature** for the X axis of the graph. Temperature is in degrees Celsius.
   c. In the Lower Limit box, enter the lower boundary of the temperature range on the X axis. The range limits are determined by the device's operating condition:
      - Industrial: –40 through 105
      - Commercial: 0 through 85
      - Automotive: –40 through 125
   d. In the Upper Limit box, enter the upper boundary of the temperature range on the X axis. The range limits are determined by the device's operating condition:
      - Industrial: –40 through 105
      - Commercial: 0 through 85
      - Automotive: –40 through 125
   e. In the Resolution box, enter the step in which the temperature values on the X axis should appear. The temperature step is limited to resolution of 10 degrees Celsius.
3. Click **OK** to close the dialog box and apply the settings.
4. Click the Graph tab to see the resulting charts.

To generate the Power vs. Frequency graphs:

1. Choose **Edit > Graph Settings**.
2. In the Power by Frequency part of the Graphs Settings dialog box, set the following options:
   a. In the Y Axis box, select Total Power or the type of block power, such as I/O or Block RAM, to place on the Y axis of the graph.
   b. In the X Axis box, select the clock to place on the X axis of the graph. It can be any of the clocks listed on the Clocks page.
   c. In the Lower Limit box, enter the lower boundary of the frequency range on the X axis. The lower boundary is limited to 0 MHz.
   d. In the Upper Limit box, enter the upper boundary of the frequency range on the X axis. The upper boundary is limited to 10000 MHz.
   e. In the Resolution box, enter the step in which the frequency values on the X axis should appear. The default frequency increment is 20 MHz.
3. Click **OK** to close the dialog box and apply the settings.

4. Click the Graph tab to see the resulting charts.

Viewing the Power Calculator Report

The report page contains a summary of the estimated power-consumption or current-consumption data calculated by Power Calculator. It is available in text (ASCII) format and in HTML format, and it is updated each time you make a change to any of the data in the editable cells.

To view the Power Calculator report:

- To view the results in text format, click the Report tab.
- To view the results in HTML format, click the Report tab, and then click **View HTML Report**.

See Also "Entering Data" on page 775

"Printing Information" on page 794

Printing Information

After calculating power, you can print the results displayed on any of the pages, including the Report and Graph pages. Optionally, you can preview pages before printing.

To preview and print:

1. In the Power Calculator window, click the tab of the desired page.
2. Choose **File > Print Preview** to activate the Print Preview dialog box.

   Use the zoom tools and the Fit Page and Fit Width buttons on the toolbar to position the page in the window.

   When there are multiple pages, use the Next, Last, Previous, and First buttons to navigate through them.
3. Select the Portrait or Landscape button on the toolbar.
4. Click **Print** to queue the results to a printer.
5. In the Print dialog box, click **Print**.

To print information from a page:

1. In the Power Calculator window, click the tab of the desired page.
2. Choose **File > Print**.
3. In the dialog box, click **Print**.

See Also "Entering Data" on page 775

"Power Calculator Pages" on page 761

Chapter 11

Analyzing Signal Integrity

Signal integrity analysis enables characterization of interconnect discontinuities and behaviors. You can use signal integrity analysis models to perform a simulation on your board or to trace setup before laying out the board to look for signal integrity issues, such as crosstalk, reflection, ringing, overshoot, undershoot, impedance mismatch, and line termination.

Lattice Semiconductor supports signal integrity (SI) analysis at the PC board level using IBIS or HSPICE format models. For information on its PCB design support, see the following Web site:

http://www.latticesemi.com/support/pcbdesignsupport.cfm

Lattice Semiconductor IBIS Models

The Input/Output Buffer Information Specification (IBIS) is a a behavioral model used for simulation. It was developed originally by Intel in the early 1990s and has become a device-modeling standard that is regulated and developed by a forum of electronic design automation (EDA) vendors, computer manufacturers, semiconductor vendors, universities, and end users.

IBIS is a standard supported by all popular signal integrity analysis tool vendors, including Cadence, Mentor Graphics, and Zuken. You can generate design-specific IBIS models for an FPGA project from Lattice Diamond or you can download general-purpose models by family on the IBIS Models by Product web page on the Lattice web site.

About IBIS Models

IBIS models help you analyze signal integrity and electromagnetic compatibility (EMC) on printed circuit boards. Unlike conventional behavioral simulation models that contain such modeling elements as schematic symbols and polynomial expressions, IBIS models consist of tabular data. This tabular data contains current and voltage values in the output and input pins, as well as the voltage and time relationship at the output pins under rising or falling switching conditions. The IBIS model data represents realistic

device behavior, based on collected data at varied operating conditions. IBIS models provide this data without disclosure of any proprietary design information.

IBIS provides more accurate models because it accounts for non-linear aspects of the I/O structures, the ESD structures, and the package parasitics. It has several advantages over other traditional models such as SPICE, including faster simulation times and no non-convergence problems. Finally, IBIS can be run on nearly any industry-wide platform because of an almost universal EDA vendor support for the IBIS standard.

Lattice Semiconductor IBIS Model Files

In the Lattice Diamond software, Lattice Semiconductor provides IBIS model files for behavioral simulation. IBIS models are located in the following installation directory path in Diamond:

<*install_dir*>/cae_library/ibis

The following table lists all available IBIS model files in the software.

Table 6: Available Lattice IBIS Models

Family	Lattice Semiconductor IBIS Model Files
LatticeEC	ec.ibs
LatticeECP	ecp.ibs
LatticeECP2	ecp2.ibs
LatticeECP2M	ecp2m.ibs
LatticeECP2MS	ecp2ms.ibs
LatticeECP2S	ecp2s.ibs
LatticeECP3	ecp3.ibs
ECP5	ecp5u.ibs
LIFMD	lifmd.ibs
MachXO	machxo.ibs
MachXO2	machxo2.ibs
MachXO3L	machxo3l.ibs
LatticeSC	sc.ibs
LatticeXP	xp.ibs
LatticeXP2	xp2.ibs
Platform Manager	platform_manager.ibs

An IBIS model file is not an executable; it is an ASCII file of all the pertinent data that represents a device's electrical behavior and can be used in a simulator. IBIS files consist of three primary parts:

- file header information that describes the file (revision, date, conventions, source), the device, and the company
- device name, pinout, and pin-to-buffer mapping
- I/O-voltage (I/V) and voltage-time (V/T) data for each model

Lattice Semiconductor IBIS models characterize all available devices in a given device family. Files contain multiple data matrixes that contain similar data for a given device in the same family.

Note

The collected IBIS source code data in these files is only representative of how a given Lattice Semiconductor device operates. It is still your responsibility to verify your design for consistency and functionality through the use of formal verification methods. There are no guarantees regarding the use or functionality of the IBIS data in the files listed in Table 6.

Lattice Semiconductor IBIS-AMI Model Files

In the Diamond software, Lattice Semiconductor provides IBIS Algorithmic Modeling Interface (IBIS-AMI) models for SERDES, which enable fast and accurate behavioral simulation. Regular IBIS models are not suitable for modeling high speed interfaces such as SERDES, because they lack the ability to emulate its wave shaping techniques designed to counteract the detrimental effects of the channel on the transmitted signal. IBIS-AMI models resolve this issue by enhancing a normal IBIS model with an algorithmic model that provides these essential features.

Two IBIS-AMI models are provided: one that models the SERDES transmitter, and one that models the SERDES receiver. Each IBIS-AMI model contains three parts:

- a regular IBIS model of the SERDES that is used as the base of the IBIS-AMI modes
- a compiled object file (*.dll or *.so) that contains the algorithmic model, which takes in the user parameters and applies pre-emphasis on the transmitter side and equalization and gain on the receiver side
- a parameter file used by the compiled object to choose different levels of emphasis, equalization, or gain

The IBIS-AMI models are located in the following installation directory path in Diamond:

<*install_dir*>/cae_library/ibis_ami

The following table lists all available IBIS-AMI model files in the software for PC and Linux.

Table 7: Available Lattice IBIS-AMI Models

Family	Lattice Semiconductor IBIS-AMI Model Files
ECP5	ecp5um_serdes.ibs
	LSC_ecp5um_rx_ami.dll
	LSC_ecp5um_rx_ami.so
	LSC_ecp5um_tx_ami.dll
	LSC_ecp5um_tx_ami.so
	[userdesign]_rx_params.ami
	[userdesign]_tx_params.ami

Note

The following platforms and tools are supported for Lalttice Semiconductor IBIS-AMI models:

Hyperlynx on Windows 7 (both 32 bits and 64 bits)
Hyperlynx on Linux (RedHat 3 and RedHat 4 64 bits
SystemSi on Linux (RedHat 3 and RedHat 4 64 bits)

Generating IBIS Models in Lattice Diamond

You can generate your own IBIS models by double-clicking the IBIS Model process or IBIS-AMI process beneath Export Files in the Process view. This process generates a design-specific model file, *project_name*.ibs, or project_name.ami, in your project directory.

HSPICE Models for FPGA Devices

Encrypted HSPICE models provide support for Lattice Semiconductor device families that feature SERDES input and output buffers. Encrypted HSPICE provides very accurate models based on the source Lattice Semiconductor chip design and can portray dynamic behavior of buffers like SERDES.

For high-speed interfaces over 1 gigahertz, the HSPICE I/O Kit is available by request from the following Web site:

http://www.latticesemi.com/support/hspiceiokit.cfm

Chapter 12

Programming the FPGA

After you have created and verified your design, you can use the final output data file (JEDEC or bitstream) to download or upload a bitstream to or from an FPGA device using Diamond Programmer.

Diamond Programmer supports serial, concurrent (turbo), and microprocessor programming of Lattice devices in PC and Linux environments. Device chains can be scanned automatically using the Diamond Programmer graphical user interface.

Diamond Programmer is integrated into the Diamond software environment, and is also available in a standalone version.

Features include:

- Scan chain and display chain contents (.xcf file)
- Download data files to devices
- Create/modify/display .xcf file
- Generate files based on the .xcf file (Tcl/command line only)

Diamond Programmer uses a Single Document Interface (SDI) where a single .xcf project is displayed per Diamond Programmer instance. Opening additional .xcf files in Diamond-integrated mode will close the current .xcf and open the specified .xcf. To open additional .xcf files in standalone mode, a separate instance of Diamond Programmer will need to be launched.

The main view displays the devices in the current Diamond Programmer project resulting from the JTAG Scan action, or from manual creation in a table.

Double-clicking on an uneditable cell or right-clicking and selecting **Device Properties** opens the “Device Properties Dialog Box” on page 926 that displays more information about the selected device. Additionally, some entries may be edited directly on the table by clicking.

Columns can be displayed or hidden by choosing **View > Columns**. The default columns that are displayed are Process, Status, Device Family, Device, Operation, File Name, File Date/Time, Checksum, USERCODE, BSDL File Name, and Verbose Logging.

Additional columns are available, but are hidden by default. The columns are Device Vendor, Device Full Name, IR Length, Device ID, Device Package, and Device Description.

The following columns are directly editable from the table:

- Enable
- Device Family
- Device
- File Name
- Verbose Logging

Some of these columns become un-editable (grayed out) if the selected operation or other option does not support it. For example, File Name will be grayed out for a 'Bypass' operation.

Each row has a column for the device status. The status indicates whether the operation performed was successful or not. This field is also used for read back operations to display what is read back if the data to display is short. For larger data sets that are read back, a dialog box is displayed.

- "Programmer Options" on page 857
- Programming Tools User Guide

File Formats

Lattice supports the following file formats.

Serial Vector Format File

An ASCII file (with the extension .svf) that stores programming data for programming one or more fixed algorithm devices in Automated Test Equipment (ATE)-type programming environments.

Using SVF files is a way of exchanging data between the Automated Test Equipment (ATE)-type programming environment and the software driving it. This device is used to invoke the SVF processor to process the SVF file. If BYPASS is selected, other devices in the chain are processed and the SVF file is bypassed.

Current SVF specifications are available from the Asset-Intertech website at www.asset-intertech.com.

Data File

A data file can be a JEDEC, ISC, hex, or bitstream file. Each of these files is based upon an IEEE programming standard:

JEDEC The programming standard from the Joint Electron Design Engineering Committee, a committee of programmer and semiconductor manufacturers that provide common standards for programmable issues. Examples include acceptable test characters for PLDs and standard data transfer/programming formats for PLDs. The JEDEC Standard is the industry standard for PLD formats. In Diamond Programmer, JEDEC usually refers to the JEDEC fuse map of your design for the device that you have selected.

ISC The In System Configuration standard, based upon the IEEE 1532 standard for programming one or more compliant devices currently while mounted on a board or embedded in a system.

Bitstream Data files used for Configuring volatile memory (SRAM) of our FPGA's.

Hex Hexadecimal PROM data files used for Programming into external non-volatile memory, such as parallel or SPI Flash devices.

See Also ▶"Programming the FPGA" on page 799

- "Using Diamond Programmer" on page 820
- Programming Tools User Guide

Serial Peripheral Interface (SPI) Flash Support

Diamond Programmer, combined with a Lattice cable fly-wire, supports the programming of Serial Peripheral Interface (SPI) flash devices.

Lattice Devices That Support SPI Flash Configuration The LIFMD, ECP5, LatticeECP/EC, LatticeECP2, LatticeECP3, MachXO2, MachXO3L, Platform Manager 2, LatticeXP2, and LatticeSCM/SC device families of FPGAs can be configured directly from a serial peripheral interface (SPI) flash memory devices. Each of these devices contains Lattice's Reveal IP. Diamond Programmer uses the JTAG interface to program the SPI flash device. Because of their bitstream compression capability, these FPGAs allow the use of smaller-capacity SPI memory devices.

Third Party SPI Flash Devices The following tables list supported third-party SPI flash devices. Click the third-party manufacturer name to link to the table of supported third-party SPI flash devices.

Note

The Diamond software Programmer support for additional third-party SPI flash devices may be added from time to time. To see if support for third-party SPI flash devices has been added, in addition to those listed in the tables below, check the SPI Flash options in the "Device Properties Dialog Box" on page 926.

Third Party SPI Flash Devices (Legacy) The following tables list supported legacy third-party SPI flash devices. Click the third-party

manufacturer name to link to the table of supported legacy third-party SPI flash devices.

Note

The Diamond software Programmer support for additional legacy third-party SPI flash devices may be added from time to time. To see if support for third-party SPI flash devices has been added, in addition to those listed in the tables below, check the SPI Flash options in the "Device Properties Dialog Box" on page 926.

Programming Lattice Mature Devices with Standalone Diamond Programmer

The stand-alone Diamond Programmer supports mature Lattice devices. A "Mature Device" license feature (LSC_PROGRAMMER_MATURE) is required in your license file to enable these devices. Without the license, Diamond Programmer will list the mature devices in the Device Selection and will be able to Scan the devices, but will not be able to program mature devices. The only operation available is Bypass. With the Mature Device license, full support is available. The Mature Device license feature is default in the free license. The free license can be requested from http://www.latticesemi.com/en/Support/Licensing.

Diamond Integrated Programmer (Programmer integrated into the Lattice Diamond software) will list the mature devices in the Device Selection and will be able to Scan the devices, but will not be able to program mature devices, even with the Mature Device license. The only operation available is Bypass.

Full support is only available when running Diamond Programmer as a stand-alone tool.

All devices listed below require a Mature Device license. Contact Lattice Technical Support to obtain a Mature Device license.

Table 25: Devices Supported in Stand-Alone Diamond Programmer That Require "Mature Device" License

Embedded Software Device Support

This topic describes device support for the following Lattice embedded software:

- "The JTAG Full VME Embedded Device Support" on page 817
- "JTAG Slim VME Embedded Device Support" on page 818
- "sysCONFIG Embedded Device Support" on page 819
- "Slave SPI Embedded Device Support" on page 820
- "I2C Embedded Programming Device Family Support" on page 820

The JTAG Full VME Embedded Device Support The JTAG Full VME Embedded software supports the following Lattice JTAG non-volatile devices. Lattice JTAG devices are those devices that can be programmed using the IEEE 1149.1 boundary scan TAP controller interface.

Table 27: Supported JTAG Full VME Embedded Devices

Device Type	Device
CPLD	ispMACH 4A
Electronically Erasable (EE) devices	ispXPGA
	ispXPLD
	ispGDX2
	ispGAL 22V10A
	ispMACH 5000B
	ispMACH 5000VG
	ispMACH 4000V/B/C/ZC

Table 27: Supported JTAG Full VME Embedded Devices

Using Diamond Programmer

This section provides procedures for using Diamond Programmer. Topics include:

Installing/Uninstalling Parallel Port Driver and USB Driver on a PC

Parallel port or USB drivers are required to program Lattice devices using the Lattice download cables and Diamond Programmer on a PC. To install the drivers, you should have administrative privileges.

Three drivers can be installed or uninstalled with the LSC Drivers Install/Uninstall dialog box.

- **Parallel port driver** – Supports device programming through the parallel port of your PC. The driver can be installed on 32-bit and 64-bit Windows operating systems.
- **USB port driver** – Supports device programming through the USB port of your PC. The driver can be installed on Windows XP, Server 2003, Vista (32-bit or 64-bit), and Windows 7 (32-bit or 64-bit).
- **FTDI USB driver** – Supports Lattice evaluation boards with FTDI (Future Technology Devices International) USB host chip. The driver does not support Windows 2000 and earlier operating systems.

To install the driver during software installation:

1. In the LSC Drivers Install/Uninstall dialog box, select one driver or **All Drivers** to be installed.
2. If another driver is already installed, you can click **Uninstall** if you want to remove it.
3. Click **Install**.
4. Click **Close**, and follow the installation instructions on the screen.

To install the driver after Diamond has been installed:

1. In Windows choose **Programs > Lattice Diamond > Accessories > Install & Uninstall Cable Drivers**.
2. In the LSC Drivers Install/Uninstall dialog box, select one driver or **All Drivers** to be installed.
3. If another driver is already installed, you can click **Uninstall** if you want to remove it.
4. Click **Install**.
5. Click **Close**, and follow the installation instructions on the screen.

See Also ▶"Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Troubleshooting the USB Driver on a PC

If you meet problems with the USB driver, try the troubleshooting procedure as follows:

1. Uninstall the USB driver. Refer to "Installing/Uninstalling Parallel Port Driver and USB Driver on a PC" on page 822.
2. Disconnect any USB devices or cables from your PC.
3. Reboot your PC.
4. Install the LSC Windows USB driver following the steps listed above.
5. Reboot the PC.
6. After the PC boots, plug a USB cable into your PC.

   Your PC should automatically detect the cable and install the correct driver.
7. Open the Device Manager.

   You should see Lattice USB Programmer under Universal Serial Bus controllers.
8. Right-click Universal Serial Bus controllers and choose **Properties**.

   In the Drivers tab, you should see "Driver Provider: %Tril%". If not, the driver is not installed properly. Click the Uninstall button and go back to step 2.
9. Launch Diamond Programmer. In the Cable and I/O Settings tab, click **Detect Cable**.

   The Diamond Programmer should detect the USB cable as EzUSB-0.
10. Connect the cable to the target board, choose **Design > JTAG Scan** or click  in the toolbar.

    The Diamond Programmer should scan the JTAG devices on the board.

See Also "Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Installing and Configuring USB Cable and Parallel Cable on Linux

For information on installing and configuring USB and Parallel cables on Linux, refer to the *Lattice Diamond Installation Notice for Linux*.

See Also "Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Plugging the Cable into the PC

You can plug the USB cable into the PC when the PC is turned off or when it is on. Make sure that the Diamond Programmer is closed before plugging the cable into your PC or unplugging it from your PC.

To plug the cable into the PC:

1. Make sure you have installed the USB port driver. See "Installing/ Uninstalling Parallel Port Driver and USB Driver on a PC" on page 822 for details.
2. Make sure that Diamond Programmer is closed, and then plug the cable into your PC.
3. If your PC is turned on, wait about one minute for the Windows operating system to recognize the USB cable. The amount of time will vary, depending on your PC's speed.

Note

Be sure to turn off the target board's power before connecting or disconnecting the USB cable to the target board.

See Also "Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Detecting a Cable

You can use the Diamond Programmer Detect Cable feature to determine which cable and port you are using.

To detect a cable:

- In the "Cable Settings Tab" on page 945, click **Detect Cable**. The Diamond Programmer detects all available cables connected to your PC, and lists the cable type, port settings, and descriptions in the Output console.

To detect or upgrade an FTDI cable:

13. To plug in FTDI cable, see "Plugging the Cable into the PC" on page 824.
14. In the "Cable Settings Tab" on page 945, click **Detect Cable**. The Diamond Programmer detects the HW-USBN-2B (FTDI) cable connected to your PC, FTUSB-0 as the port settings, and descriptions in the Output console.
15. Click on "Firmware Tab" on page 947. A new window displays fields for MachXO2 firmware and POWR607 firmware.

16. Select a JEDEC (*.jed) file to update device/devices.

Note

If firmware versions of two JEDEC files don't match, the software will display a warning message asking if you want to continue.

17. Click on **Update Firmware** to reprogram devices on cable to specified file.

See Also ▶"Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Selecting from Multiple Cables

Diamond Programmer can recognize as many as five USB cables plugged into the same PC.

The first USB cable plugged into the PC is assigned port Ez-USB-0. The second is assigned port Ez-USB-1, and so on. The first FTDI USB2 cable is assigned port FTUSB-0, and the second FTUSB-1, and so on.

If the PC is turned off, and then later turned back on, the assigned ports might change, since the PC detects the cables according to the USB port address instead of the order in which they were plugged into the PC. Since the USB cable port assignments might change during power-up, you might have to reselect the USB cable in the "Cable Settings Tab" on page 945.

To select a USB cable from multiple cables:

- In the "Cable Settings Tab" on page 945, select the USB cable you want to use from the Port drop-down list.

See Also ▶"Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Creating a New Diamond Programmer Project

By creating a new Diamond Programmer project, you create a chain file (.xcf) from a scan with default settings, create an .xcf file from a scan with custom settings, or a new blank project.

How you start Programmer also depends on whether you are using it integrated with Diamond or using the stand-alone version, and on your operating system.

Note

You can change the way Diamond Programmer writes the paths to data files in the .xcf file by editing the Diamond Programmer .ini file.

By default, the path in the .xcf file is displayed in "cross platform compatible" format, meaning forward-slashes ("/") when using Diamond Programmer on Windows and Linux. By editing the programmer .ini file, you can change the way the path is saved to "Native Delimiter" format, meaning back-slashes ("\") when using Diamond Programmer on Windows. Diamond Programmer on Linux will continue to use forward-slashes ("/"), thus, this option is not required for Linux.

To enable Native Delimiter format, add the following line to the end of the programmer.ini file:

PathDelimiter=1

If you wish to change back to the default Cross Platform Compatible format, you can change the value in the programmer.ini file to:

PathDelimiter=0

or delete the line entirely.

The programmer.ini file is located in the following directory:

<*Drive*>:\Users\<*User Name*>\AppData\Roaming\LatticeSemi

To create a new Diamond Programmer project:

1. Make sure that the board is turned on and that the Lattice parallel or USB cable is properly connected to the computer.
2. Issue the start command.
   - In the Diamond main window, choose **Tools > Programmer**; or in Windows choose **Programs > Lattice Diamond > Accessories > Programmer**; or click  in the Diamond toolbar.
   - In Linux, from the <*install_path*>/bin/lin directory, enter the following on a command line:

     ```
     ./programmer
     ```
3. In the "Getting Started Dialog Box" on page 858, choose one of the following:
   - **Create a New Diamond Programmer Project from a JTAG Scan.** This option creates a new project from a scan.
     - If you have a board connected to your computer, you can click the **Detect Cable** button to detect the cable and port. Otherwise, you can manually select cable and port from the **Cable** and **Port** puldown lists.

- **Create a New Blank Project** - This option creates a new blank programmer project.

Note

If you wish to import the .xcf file into your Diamond project, choose **Import new Programmer project to current implementation**.

4. Click **OK**.

See Also "Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Opening an Existing Diamond Programmer Project

To open an existing Diamond Programmer project, you must have an existing chain file (.xcf). The daisy chain configuration must be the same as that for which the chain configuration file was created. Each unique chain configuration requires a unique chain configuration file.

How you start Programmer also depends on whether you are using it integrated with Diamond or using the stand-alone version, and on your operating system.

To start Diamond Programmer with an existing project:

1. Issue the start command. To start:
   - In the Diamond main window, choose **Tools > Programmer**.
   - The stand-alone Diamond Programmer in Windows, go to the Windows Start menu and choose **Programs > Lattice Diamond > Accessories > Programmer**
   - The stand-alone Diamond Programmer in Linux, enter the following on a command line:

     ```
     /.programmer
     ```
2. In the "Getting Started Dialog Box" on page 858, choose **Open an Existing Diamond Programmer Project.**
   - **Browse** to the desired .xcf file.

   Note

   If you wish to import the .xcf file into your Diamond project, choose **Import new Programmer project to current implementation**.
3. Click **OK**.

See Also "Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Checking the XCF Project

The Check XCF button allows you to perform a design rule check on your XCF project setup before performing any actions. This feature is run automatically when the .xcf file is saved.

To check the XCF project:

- In Diamond Programmer, choose **Design > Check XCF Project** or click in the toolbar. Diamond Programmer checks the XCF project and indicates in the output pane whether or not the project is valid.

See Also "Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Scanning the Device Chain

There are several ways to scan a device chain. When you create a new project, you can choose to scan you board, perform a custom scan, or create a blank project without performing a scan.

Note

Not all Lattice device families support Scan capability. Refer to the *iCEcube2 Release Notes* for more information on the device family that does not support Scan.

To scan the device chain on the board that is connected to your PC:

1. Make sure that the board is turned on and that the cable is properly connected to Diamond Programmer.
2. In Diamond Programmer, choose **Design > JTAG Scan** or click in the toolbar. Diamond Programmer opens a new chain configuration file, scans the printed circuit board connected to your computer, and lists the devices in the new chain file.

See Also "Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Selecting from a Matching Device ID List

When a scanned device shares the same device ID with other devices, the software indicates this in the main window with the message “Cannot identify detected device on row *row number*>. Please manually select correct device.”

To select a different device from the matching ID list:

1. Click the device in the Device column
2. Select the device you want to use from the dropdown menu.

See Also ▶“Using Diamond Programmer” on page 820

- “Programming the FPGA” on page 799
- Programming Tools User Guide

Adding a Lattice Device to a Chain

You can add any Lattice device to an existing chain.

To add a Lattice device to a chain:

1. In Diamond Programmer, choose **Edit > Add Device,** or click the  button on the toolbar, or right-click and choose **Add Device**.
2. Select a Lattice device family from the **Device Family** column dropdown menu.
3. Select a device the **Device** column dropdown menu.

   The software inserts the new device into the active chain.

See Also ▶“Using Diamond Programmer” on page 820

- “Programming the FPGA” on page 799
- Programming Tools User Guide

Adding a Generic JTAG Device to a Chain

You can add any one of the following types of devices to a chain:

- JTAG-NOP Device
- JTAG-SVF device that has a serial vector format file (.svf)
- JTAG-ISC
- JTAG-STAPL

To add a Generic JTAG device:

1. In Diamond Programmer, choose **Edit > Add Device,** or click the button on the toolbar or right-click and choose **Add Device**.
2. Select Generic JTAG Device from the **Device Family** column dropdown menu.
3. Select a either JTAG-NOP, JTAG-SVF, JTAG-ISC, or JTAG-STAPL from the **Device** column dropdown menu.
4. Highlight the row, and choose **Edit > Device Properties**, or click the button on the toolbar, or right-click and choose **Device Properties**. In the "Device Properties Dialog Box - Device, Access Mode, and Operation Options" on page 858, click the Browse button and navigate to the .jed, .bit, .isc, or .rbt file for the device. Select the file and click **Open**.

   The software inserts the new device into the active chain.

See Also ▶"Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Removing a Device from a Chain

To remove a device from the active chain:

1. In Diamond Programmer, select the device that you want to delete.
2. Choose **Edit > Remove Device**, or click the button on the toolbar, or right-click and chose **Remove Device**.

   Note

   There is no Undo for this command.

See Also ▶"Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Editing Device Properties

To edit device properties in a chain:

1. In Diamond Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the button on the toolbar, or right-click and choose **Device Properties**.

3. In the “Device Properties Dialog Box” on page 926, edit the device properties.
4. Click **OK** to close the “Device Properties Dialog Box” on page 926.

See Also ▶“Using Diamond Programmer” on page 820

- “Programming the FPGA” on page 799
- Programming Tools User Guide

Moving a Device Up or Down

To move a device up or down:

- In Diamond Programmer, with the left mouse button, select and hold the number in the far left in the row of the device that you want to move. Then drag and drop to the row where you want to move the device.

See Also ▶“Using Diamond Programmer” on page 820

- “Programming the FPGA” on page 799
- Programming Tools User Guide

Setting Chain Operations

To set a chain operation in a device:

1. Select a device in the chain.
2. Double-click the **Operation** column for the device.
3. In the “Device Properties Dialog Box” on page 926, select the specific operation for the device in the Operation drop down menu.

See Also ▶“Using Diamond Programmer” on page 820

- “Programming the FPGA” on page 799
- Programming Tools User Guide

Setting Programming Characteristics

Use the “Settings Dialog Box” on page 944 to specify how Diamond Programmer will process the active chain configuration: process the whole chain or only a single device; override selected operations of the selected device or all the devices in the chain; process the chain in sequential or turbo mode. You can also specify other options.

To specify Programming characteristics:

1. In Diamond Programmer, choose **Edit > Settings**.

   The "Settings Dialog Box" on page 944 opens.

2. Select the options you want, and then click **OK**.

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Downloading Design Files

After you have specified all of the processing options, use the Program command to download the design files to the daisy-chained devices.

- In Diamond Programmer, choose **Design > Program,** or click  on the toolbar.

See Also ▶"Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Editing the I/O State

Editing I/O state allows you to change values of configurable pins to specified values by using the HighZ, All 1s, All 0s, Leave Alone, Custom, and Dynamic I/O options.

Controlling the I/O state allows you to edit the state of any of the I/O pins before programming.

States include:

- **HighZ** – Sets all pins to tristate. This is the default setting.
- **All 1's** – Preloads the boundary scan register with all 1's.
- **All 0's** – Preloads the boundary scan register with all 0's.
- **Leave alone** – Uses the current values for all pins throughout the programming cycle.
- **Custom** – Uses the specified pin settings from the "Edit I/O State Dialog Box" on page 948.
- **Dynamic I/O** – Custom leave-alone option that enables you to specify the setting for selected pins in the boundary scan register before programming and leave all other pins at their current state. When Dynamic I/O is selected, the "X" in the "Edit I/O State Dialog Box" on page 948 is Leave Alone.

To edit I/O state:

1. Right-click on the row corresponding to the device you would like to edit.
2. Choose **Edit I/O State**.
3. In the "Edit I/O State Dialog Box" on page 948, choose the desired I/O state option from the I/O State dropdown.
4. In the BSDL File box, browse to the appropriate BSDL file for the device that you are editing.
5. For each pin that you want to change, click the pin's square repeatedly until it displays the value you want.
6. Right-click the pin's square and select the value you want from the pop-up menu.
7. Click **OK**.

Adding a Custom SPI Flash Device

This feature allows you users to add your own SPI Flash device to the Diamond Programmer database.

To create a Custom SPI Flash device:

1. Right-click on the row corresponding to the device to which you would like to add a Custom SPI Flash device, and choose **Edit > Custom Device**.
2. In the "Edit Custom Device Dialog Box" on page 943, select **SPI Serial Flash Custom**, and click **Add**.
3. In the "Custom SPI Flash Dialog Box" on page 943, enter:
   - **Device Description** -- this can be any alpha-numeric string that describes the device (for example: M25P32-VMF6C).
   - **Device Name** -- this can be any alpha-numeric string that describes the device name (for example: SPI-M25P32).
   - **Package** -- this can be any alpha-numeric string that describes the package (for example: 16-pin SOIC).
   - **Device ID** -- this can be any alpha-numeric string that describes the device ID (for example: 0x15).
4. In the Device Vendor dropdown menu, choose device vendor.
5. In the Device Density dropdown, choose device density.
6. In the Byte Per Sector dropdown, choose the desired value.
7. If the SPI Flash device supports sector protection, check the **Protection Options ON** box.

8. Click **OK**.
9. Once the custom SPI flash has been added, it can be selected in the "Device Properties Dialog Box" on page 926.

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Editing a Custom SPI Flash Device

If you have already created a custom SPI Flash device, you can edit its properties in the "Custom SPI Flash Dialog Box" on page 943.

To edit the properties of a Custom SPI Flash device:

1. Right-click on the row corresponding to the device you would like to edit, and choose **Edit > Custom Device**.
2. In the "Edit Custom Device Dialog Box" on page 943, select **SPI Serial Flash Custom**, select the SPI Flash device you want to edit, and click **Edit**.
3. In the "Custom SPI Flash Dialog Box" on page 943, enter:
   - **Device Description** -- this can be any alpha-numeric string that describes the device (for example: M25P32-VMF6C).
   - **Device Name** -- this can be any alpha-numeric string that describes the device name (for example: SPI-M25P32).
   - **Package**-- this can be any alpha-numeric string that describes the package (for example: 16-pin SOIC).
   - **Device ID**-- this can be any alpha-numeric string that describes the device ID (for example: 0x15).
4. In the Device Vendor dropdown menu, choose device vendor.
5. In the Device Density dropdown, choose device density.
6. In the Byte Per Sector dropdown, choose the desired value.
7. If the SPI Flash device supports sector protection, check the **Protection Options ON** box.
8. Click **OK**.

- Programming Tools User Guide

Removing a Custom SPI Flash Device

f you have already created a custom SPI Flash device, and you wish to remove it from your the “Custom SPI Flash Dialog Box” on page 943.

To edit the properties of a Custom SPI Flash device:

1. Right-click on the row corresponding to the device you would like to edit, and choose **Edit > Custom Device**.
2. In the “Edit Custom Device Dialog Box” on page 943, select **SPI Serial Flash Custom**, select the SPI Flash device you want to remove, and click **Remove** and **OK**.

See Also ▶“Using Diamond Programmer” on page 820

- “Programming the FPGA” on page 799
- Programming Tools User Guide

Programming Using Custom SPI Flash Device

After a custom SPI Flash device has been created, you can program it using Diamond Programmer.

To program using a Custom SPI Flash device:

1. Right-click on the row corresponding to the device you would like to edit, and choose **Edit > Device Properties** to display the “Device Properties Dialog Box” on page 926.
2. In the Access Mode dropdown list, choose **SPI Flash Programming**.
3. In the Family dropdown list, choose **SPI Serial Flash Custom**.
4. In the Device dropdown list, choose the name of the custom device you created.
5. Click **OK.**

Setting up Dual Boot Golden Sector Protection Support

Dual boot sector support allows for write protecting sectors containing golden pattern, and prevents golden pattern from being accidentally erased or programmed.

To enable Dual Boot Golden Sector Protection support:

1. Right-click on the row corresponding to the device you would like to edit, and choose **Edit > Device Properties**.
2. In the Access Mode dropdown list, choose **SPI Flash Programming**.
3. In the Operation dropdown list, chose desired operation.
4. In the Family dropdown list, choose **SPI Serial Flash**.
5. In the Vendor list, choose the name of the vendor.
6. In the Device dropdown list, choose the device.
7. In the Package dropdown list, choose package.
8. If the SPI flash device supports protection, the **Secure SPI Flash Golden Pattern Sectors** box should be enabled. If you wish to secure the golden sector, check this box.
9. Click **OK.**

The following Lattice Technical Notes give device-specific information on using the dual boot feature:

- TN1279, MachXO3L Programming and Configuration Usage Guide
- TN1204, MachXO2 Programming and Configuration Usage Guide
- TN1216, LatticeECP2/M and LatticeECP3 Dual Boot Feature
- TN1220, LatticeXP2 Dual Boot Feature

See Also "Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Unlocking Secure SPI Flash Support

If a custom SPI flash device or a SPI flash device that supports secure golden patterns sectors was secured as described in "Setting up Dual Boot Golden Sector Protection Support" on page 836, and you wish to reprogram the SPI flash, you must first unlock the device before reprogramming.

To unlock a secure SPI flash:

1. Create a new Diamond Programmer project as described in "Creating a New Diamond Programmer Project" on page 825 or open an existing

Diamond Programmer project as described in "Opening an Existing Diamond Programmer Project" on page 827.

2. Right-click on the row corresponding to the device you would like to edit, and choose **Edit > Device Properties**.
3. In the Operation dropdown list, chose **SPI Flash Unlock Device**.
4. Ensure that the **Secure SPI Flash Golden Pattern Sectors** box is unchecked.
5. Click **OK.**
6. In Diamond Programmer, choose **Design > Program,** or click  on the toolbar.

The SPI flash is now unlocked and can be reprogrammed.

The following Lattice Technical Notes give device-specific information on using the dual boot feature:

- TN1279, MachXO3L Programming and Configuration Usage Guide
- TN1204, MachXO2 Programming and Configuration Usage Guide
- TN1216, LatticeECP2/M and LatticeECP3 Dual Boot Feature
- TN1220, LatticeXP2 Dual Boot Feature

Programming MachXO2, MachXO3D, and MachXO3L Devices Using I2C

Diamond Programmer supports I2C programming of MachXO2, MachXO3D, and MachXO3L devices. Diamond Programmer requires an FTDI 2232H chip installed on the customer board to bridge the Lattice HW-USBN-2B (FTDI) USB programming cable to the MachXO2, MachXO3D, and MachXO3L I2C sysCONFIG port. For design reference, both the Lattice MachXO2 Pico Evaluation Board and the Lattice MachXO2 Control Evaluation Board contain working examples of the FTDI circuit.

To program a MachXO3D using I2C:

1. Right-click on the row corresponding to the device you would like to edit, and choose **Edit > Device Properties**.
2. In the Port Interface dropdown list, choose **I2C Interface**.
3. In the Operation dropdown list, choose desired operation.
4. Enter the I2C slave address of the MachXO3D device.
5. Click **OK**.

6. Download the design file.

To program a MachXO2 or MachXO3L using I2C:

1. Right-click on the row corresponding to the device you would like to edit, and choose **Edit > Device Properties**.
2. In the Access Mode dropdown list, choose **I2C Interface Programming**.
3. In the Operation dropdown list, choose desired operation.
4. Enter the I2C slave address of the MachXO2 or MachXO3L device.
5. Click **OK**.
6. Download the design file.

There is also an embedded solution which included in the *<install_path>**<version_number>*\embedded_source\i2cembedded directory. The embedded solution can be modified to target your processor or to use something other than the Future device.

For more information on the MachXO2 and MachXO3L I2C programming refer to TN1204, *MachXO2 Programming and Configuration Usage Guide* or TN1279, *MachXO3L Programming and Configuration Usage Guide*.

Programming Platform Manager 2, MachXO2, or MachXO3L/LF Devices Using I2C with External ASC

Diamond Programmer supports I2C programming of Platform Manager 2 , MachXO2, or MachXO3L/LF with external ASC devices. Diamond Programmer requires an FTDI 2232H chip installed on the customer board to bridge the Lattice HW-USBN-2B (FTDI) USB programming cable to the Platform Manager 2, MachXO2, MachXO3L/LF and ASC I2C port.

To program a Platform Manager 2, MachXO2, MachXO3L/LF Devices Using I2C with External ASC:

1. Right-click on the row corresponding to the device you would like to edit, and choose **Edit > Device Properties**.
2. In the Access Mode dropdown list, choose **I2C Interface Programming**.
3. In the Operation dropdown list, choose desired operation.

4. Enter the I2C slave address of the Platform Manager 2, MachXO2, or MachXO3L/LF device.
5. In the External ASC Options box, click + to add an external ASC / LPTM21L device.
6. Select the data file, operation, and I2C slave address.
7. Repeat steps 5 and 6 for each external ASC / LPTM21L device.
8. Click **OK**.
9. Download the design file.

Editing the Security Feature Row (MachXO2 and MachXO3L Only)

You can read the contents of the feature row of the MachXO2 and MachXO3L, edit the settings, and program the new settings into the feature row of the device.

To Read the Feature Row of a MachXO2 and MachXO3L Device:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Advanced Security Keys Programming**.
4. In the Operation box, select **Security Read Feature Row**.
5. Click **OK** to close the Device Properties dialog box.
6. Choose **Design > Program,** or click  on the toolbar.

   The Feature Row dialog box displays. The fields in the dialog box are not editable.
7. Click **Close** to close the Feature Row dialog box.

- "Programming the FPGA" on page 799
- Programming Tools User Guide
- Programming Tools User Guide

Reading the Security Feature Row (MachXO3D Only)

You can read the contents of the feature row of the MachXO3D, edit the settings, and program the new settings into the feature row of the device.

To read the Feature Row of a MachXO3D Device:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Feature Row Programming**.
4. In the Operation box, select **Read Feature Row**.
5. Click **OK** to close the Device Properties dialog box.
6. Choose **Design > Program,** or click  on the toolbar.

   The Feature Row dialog box displays. The fields in the dialog box are not editable.
7. Click **Close** to close the Feature Row dialog box.

To read the non-volatile control register 1 of a MachXO3D device:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose Device Properties to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Feature Row Programming**.
4. In the Operation box, select **Display Control NV Register1**.
5. Click **OK** to close the Device Properties dialog box
6. Choose **Design > Program,** or click  on the toolbar.

   The non-volatile control register 1 dialog box displays. The fields in the dialog box are not editable.
7. Click **Close** to close the dialog box.

▶ "Programming the FPGA" on page 799

▶

Programming the Feature Row (MachXO3D Only)

You can program the contents of an .fea file to the feature row of a MachXO3D device.

To erase the feature row of a MachXO3D Device:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Feature Row Programming**.
4. In the Operation box, select **Erase Feature Row**.
5. Click **OK** to close the Device Properties dialog box.
6. Choose **Design > Program,** or click  on the toolbar.

To program the feature row of a MachXO3D Device:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Feature Row Programming**.
4. In the Operation box, select **Program Feature Row**.
5. In the Feature Row Programming Options box, browse to the Feature Row (.fea) file.
6. Click **OK** to close the Device Properties dialog box.
7. Choose **Design > Program,** or click  on the toolbar.

To Edit the Feature Row of a MachXO3D Device:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Feature Row Programming**.

4. In the Operation box, select **Update Feature Row**.
5. Click **OK** to close the Device Properties dialog box.
6. Choose **Design > Program,** or click  on the toolbar.

   The Feature Row dialog box displays.
7. Edit the fields in the dialog box as desired, then click **Program**. A dialog box asking if you wish to overwrite the selected register. If you click Yes, the MachXO3D device feature row will be programed as edited.

To edit the Non-Volatile Control Register 1 of a MachXO3D Device:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Feature Row Programming**.
4. In the Operation box, select **Program Control NV Register1**.
5. Click **OK** to close the Device Properties dialog box
6. Choose **Design > Program,** or click  on the toolbar.
7. In the non-volatile Control Register 1 dialog box displays.
8. Edit the fields in the dialog box as desired, then click Program. A dialog box asking if you wish to overwrite the selected register. If you click Yes, the MachXO3D device non-volatile Control Register 1 will be programed as edited.

-

Setting Local Lock Policies (MachXO3D Only)

The MachXO3D device family provides read, program permission to access the FPGA configuration sectors. The security setup can be applied inside each individual sector to store local security setting bits.

The sectors include:

- SRAM
- Flash A CFG0 and UFM0

- Flash B CFG1 and UFM1
- Flash C UFM2 and UFM3
- Feature Row sector
- Public Key sector
- Encryption Key sector

The detailed explanation of each central security bit is given as follows:

Local Read Security inside each Sector. Provides Read Protection for this sector. Used mainly if user does not care about the sticky security policy inside the dedicated centralized security policy sector.

Local Write Security inside each Sector. Provides Write Protection for this sector. Prevents incremental programming after writing is done.

Note

The Local Read Security settings are removed when the sector content is erased.

To setup the local lock security for the feature row in Programmer:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Feature Row Programming**.
4. In the Port Interface drop-down menu, choose the interface.
5. In the Operation drop-down menu, select **Program Feature Row Lock**.
6. Check the desired **Local Locks Options** box.
7. Select **Lock Read Access** and/or L**ock Write Access** based on choice of security.
8. Click **OK**.

To setup the local lock security for the Flash Sectors in Programmer:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Flash Programming Mode**.
4. In the **Port Interface** drop-down menu, choose the interface.

5. In the **Operation** drop-down menu, select **Flash Erase,Program,Verify,Secure**.
6. Browse to the data file (jed)
7. Select the desired **Flash Programming Options** to apply the local locks.
8. Check the desired **Local Locks Options** box.
9. Select **Lock Read Access** and/or **Lock Write Access** based on choice of security.
10. Click **OK.**

Setting Global Lock Policies (MachXO3D Only)

The MachXO3D device family provides read, program and erase permission control to access the FPGA configuration sectors in two special sectors used to store centralized security settings. The centralized security settings can be applied in USEC and CSEC sectors to store central security setting bits for all of the FPGA configuration sectors.

Sector USEC is used to store centralized security setting bits for User Flash sectors including:

- Flash A UFM0
- Flash B UFM1
- Flash C UFM2 and UFM3

Sector CSEC is used to store centralized security setting bits for configuration sectors including:

- SRAM
- Flash A CFG0
- Flash B CFG1
- Feature Row sector
- Public Key sector
- Encryption Key sector

The detailed explanation of each central security bit is as follows:

Central Read Security Policy. Inside dedicated security policy sector. This Provides Read Protection for a particular sector.

Central Erase Security Policy. Stops erase activity to the sector. Prevents accidentally erasure of user set-up. Potentially offers one-time-programmability (OTP) feature for flash-based devices.

Central Security Hard Lock Security policy. Stops both external CFG ports and internal System Bus to alter the shadow register for read, program

and erase access to the FPGA configuration sectors. This also calls as “Hard Lock” mode.

Note

The Local Read Security settings remain when the sector content is erased.

Local security setup can be applied inside the USEC and CSEC sectors to store local security setting bits for read program and erase permissions. The USEC and CSEC have no centralized security settings.

To read the central lock security for CSEC in Programmer:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the “Device Properties Dialog Box” on page 926.
3. In the Access Mode drop-down menu, choose **Flash Programming Mode**.
4. In the Port Interface drop-down menu, choose the interface.
5. In the Operation box, select **Flash Read CFG locks Policies**.
6. Click **OK** to close the Device Properties dialog box
7. Choose **Design > Program,** or click  on the toolbar.

   The CSEC register dialog box displays. The fields in the dialog box are not editable.
8. Click **Close** to close the dialog box.

To setup the central lock security for CSEC in Programmer:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the “Device Properties Dialog Box” on page 926.
3. In the Access Mode drop-down menu, choose **Flash Programming Mode**.
4. In the **Port Interface** drop-down menu, choose **JTAG Interface**.
5. In the Operation box, select **Flash Secure CFG Plus**.
6. Select the desired Configuration Sectors Central Lock Options to apply the local locks.
7. Select **Lock Ports Access**, **Lock Read Access** and/or **Lock Write Access** based on choice of security.
8. Click **OK**.

To update the central lock security for CSEC in Programmer:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Flash Programming Mode**.
4. In the Port Interface drop-down menu, choose the Interface.
5. In the Operation box, select **Flash Update CFG Locks Policies**.
6. Click **OK** to close the Device Properties dialog box
7. Choose **Design > Program,** or click  on the toolbar.

   In the CSEC Register dialog box displays.
8. Edit the fields in the dialog box as desired, then click **Program**. A dialog box asking if you wish to overwrite the selected register. If you click **Yes**, the Central Lock CSEC register will be programed as edited.

To read the central lock security for USEC in Programmer:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Flash Programming Mode**.
4. In the Port Interface drop-down menu, choose the interface.
5. In the Operation box, select **Flash Read UFM locks Policies**.
6. Click **OK** to close the Device Properties dialog box
7. Choose **Design > Program,** or click  on the toolbar.

   The USEC register dialog box displays. The fields in the dialog box are not editable.
8. Click **Close** to close the dialog box.

To setup the central lock security for USEC in Programmer:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.

3. In the Access Mode drop-down menu, choose **Flash Programming Mode**.
4. In the **Port Interface** drop-down menu, choose **JTAG Interface**.
5. In the Operation box, select **Flash Secure UFM Plus**.
6. Select **Lock Ports Access**, **Lock Read Access** and/or **Lock Write Access** based on choice of security.
7. Click **OK**.

To update the central lock security for USEC in Programmer:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Flash Programming Mode**.
4. In the Port Interface drop-down menu, choose the interface.
5. In the Operation box, select **Flash Update UFM Locks Policies**.
6. Click **OK** to close the Device Properties dialog box
7. Choose **Design > Program,** or click  on the toolbar.

   The USEC Register dialog box displays.
8. Edit the fields in the dialog box as desired, then click **Program**. A dialog box asking if you wish to overwrite the selected register. If you click **Yes**, the Central Lock USEC register will be programed as edited.

Programming the Password Key (MachXO3D Only)

You can program the password key from a .key file to the MachXO3D device.

To read the Password key of a MachXO3D Device:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Advanced Security Keys Programming**.
4. In the Operation box, select **Security Read Password Key.**
5. Click OK to close the Device Properties dialog box

6. Choose **Design > Program,** or click  on the toolbar.

To program the Password Key to a MachXO3D Device:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Advanced Security Keys Programming**.
4. In the Operation box, select **Security Program Password Key.**
5. In the Password Key Programming Options box, browse to the key (.key) file.
6. [Optional] Select **Lock Ports Access, Lock Read Access** and/or **Lock Write Access** based on choice of security to local lock the password key register.
7. Click **OK** to close the Device Properties dialog box
8. Choose **Design > Program,** or click  on the toolbar.

Programming the Encryption Key (MachXO3D Only)

You can program the encryption key from a .bek file to the MachXO3D device.

To read the Encryption key of a MachXO3D Device:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Advanced Security Keys Programming**.
4. In the Operation box, select **Security Read Encryption Key**.
5. Click **OK** to close the Device Properties dialog box
6. Choose **Design > Program,** or click  on the toolbar.

To program the Encryption Key to a MachXO3D Device:

1. In Programmer, select the device that you want to edit.

2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Advanced Security Keys Programming**.
4. In the Operation box, select **Security Program Encryption Key.**
5. In the Encryption Key Programming Options box, browse to the key (.bek) file.
6. [Optional] Select **Lock Ports Access, Lock Read Access** and/or **Lock Write Access** based on choice of security to local lock the encryption key register.
7. Click **OK** to close the Device Properties dialog box
8. Choose **Design > Program,** or click  on the toolbar.

Programming the Public Key (MachXO3D Only)

You can program the public key from a .pub file to the MachXO3D device.

To read the Public key of a MachXO3D Device:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Advanced Security Keys Programming**.
4. In the Operation box, select **Security Read Public Key.**
5. Click **OK** to close the Device Properties dialog box
6. Choose **Design > Program,** or click  on the toolbar.

To program the Public Key to a MachXO3D Device:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Advanced Security Keys Programming**.

4. In the Operation box, select **Security Program Public Key**.
5. In the Public Key Programming Options box, browse to the key (.pub) file.
6. [Optional] Select **Lock Ports Access**, **Lock Read Access** and/or **Lock Write Access** based on choice of security to local lock the public key register.
7. Click **OK** to close the Device Properties dialog box
8. Choose **Design > Program,** or click  on the toolbar.

Setting MachXO3D Dry Run Features

The MachXO3D device family can trigger a dry run bitstream downloading from either on-die flash or external flash through the master SPI port. “Dry run” means downloading the bitstream but without actually writing the configuration SRAM.

The following are done during the “dry run” process:

- Decrypting the Bitstream if it is encrypted
- Authentication with the Bitstream if it is required
- CRC check if it is enabled
- Execute command “ISC_PROGRAM_USERCODE” inside the bitstream and store the USERCODE to a special shadow register named “DRYRUN USERCODE”. The command will not override “SRAM USERCODE” nor “Flash USERCODE”.

After the “dry run” finished it will report the execution status, such as execuction pass/fail and authentication pass/fail. The user can use the command “USERCODE_DRYRUN” to read the shadow register of “DRYRUN USERCODE”.

To execute a dry run from external SPI Flash Primary Image in Programmer:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the “Device Properties Dialog Box” on page 926.
3. In the Access Mode drop-down menu, choose **Static RAM Cell Mode**.
4. In the Port Interface drop-down menu, choose the interface.
5. In the Operation box, select **SRAM External Primary Dry Run**.
6. Click **OK**.
7. Choose **Design > Program,** or click  on the toolbar.

The USERCODE from the Primary image will displayed if the “Dry Run” executed successfully.

To execute a dry run from external SPI Flash Golden Image in Programmer:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the “Device Properties Dialog Box” on page 926.
3. In the Access Mode drop-down menu, choose **Static RAM Cell Mode**.
4. In the Port Interface drop-down menu, choose the interface.
5. In the Operation box, select **SRAM External Golden Dry Run**.
6. Click **OK**.
7. Choose **Design > Program,** or click  on the toolbar.

   The USERCODE from the Golden image will displayed if the “Dry Run” executed successfully.

To execute a dry run from on-die Flash in Programmer:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the “Device Properties Dialog Box” on page 926.
3. In the Access Mode drop-down menu, choose **Flash Programming Mode**.
4. In the **Port Interface** drop-down menu, choose the interface.
5. In the Operation box, select **Flash Dry Run**.
6. Check the Flash-A and/or Flash-B box desired for “dry run.”
7. Click **OK**.
8. Choose **Design > Program,** or click  on the toolbar.

   The USERCODE from the Flash-A and/or Flash-B will displayed if the “Dry Run” executed successfully.

Setting MachXO3D Ports Interfaces Locking Features

The MachXO3D device family has read, program and erase permission control for external CFG ports and an internal system bus to access the FPGA configuration sectors. External CFG ports include JTAG, slave SPI and slave I2C.

To setup the Ports interfaces security lock policy in Programmer:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Advanced Security Keys Programming**.
4. In the **Port Interface** drop-down menu, choose the interface.
5. In the Operation box, select Security Lock Ports Interface.
6. Select **Lock Ports Access** and/or **Lock System Bus Access** based on desired choices of security.
7. Click **OK**.

Setting MachXO3D Version Rollback Protection Features

The MachXO3D device family can support version rollback downloading from either on-die flash or external flash through the master SPI port. "Version Rollback" means downloading first version or the latest version bitstream depending on user settings

The following are done during the "Version Rollback" process:

- Decrypting the Bitstream if it is encrypted
- Authentication with the Bitstream. It is always required for this feature.
- CRC check if it is enabled
- Program the Authenticated DONE
- Execute command "ISC_PROGRAM_USERCODE" inside the bitstream
- Compare the USERCODE time stamp of two FLASH Blocks
- Booting from the FLASH sector which had the first version or the latest version bitstream depending on user settings

After the “Version Rollback” finished it will report the execution status, such as execuction pass/fail and authentication pass/fail. The user can use the command “USERCODE” to read the USERCODE time stamp.

Note

The VRBP_EN bit in the feature row need to set to 1 to enable the version rollback protection feature

To execute a “Version Rollback” testing from on-die Flash in Programmer:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the “Device Properties Dialog Box” on page 926.
3. In the Access Mode drop-down menu, choose **Flash Programming Mode**.
4. In the Port Interface drop-down menu, choose the interface.
5. In the Operation box, select **Flash Version Rollback Protection**.
6. Provide the data files (jed) for both Flash A and Flash B.
7. Click **OK**.
8. Choose **Design > Program,** or click  on the toolbar.

   The USERCODE of the first version or the latest version bitstream depending on user settings will be displayed

Configuring SPI Flash Options

You can use the “Device Properties Dialog Box” on page 926 to configure SPI Flash options for LatticeXP2 devices.

To configure SPI Flash Options:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the “Device Properties Dialog Box” on page 926.
3. In the Access Mode drop-down menu, choose **SPI Flash Programming**.
4. In the Options drop-down menu, chose the desired SPI Flash option.
5. Select **Family**, **Vendor**, **Device**, and **Package**.

6. Click **Load Size from Programming File** to fill in the Data File Size box. You can change this size by typing a different file size. This feature is useful if you only want to use a portion of the file for the operation. If you change the file size, it must be no larger than the full file size or the device size.
7. Select start address and base address from **Start Address (Hex)** and **Base Address (Hex)** dropdown menus. For the AMD parallel flash, the starting address is automatically selected and cannot be changed.
8. If you want to erases the flash device if a verify error occurs, click, the **Erase Part on Program Error** box.
9. Click OK.

See Also ▶"Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Configuring Advanced Flash Programming Options

You can use the Device Properties Dialog Box to configure Parallel Flash options.

To configure Parallel Flash options:

1. In Programmer, select the device that you want to edit.
2. Choose **Edit > Device Properties**, or click the  button on the toolbar, or right-click and choose **Device Properties** to display the "Device Properties Dialog Box" on page 926.
3. In the Access Mode drop-down menu, choose **Advanced Flash Programming (FPGA Loader)**.
4. In the Advanced Flash Options box, select **Family**, **Vendor**, **Device**, **Package,** and **Operation**.
5. Click **Load Size from Programming File** to fill in the Data File Size box. You can change this size by typing a different file size. This feature is useful if you only want to use a portion of the file for the operation. If you change the file size, it must be no larger than the full file size or the device size.
6. Select start address and base address from **Start Address (Hex)** and **Base Address (Hex)** dropdown menus. For the AMD parallel flash, the starting address is automatically selected and cannot be changed.
7. If you want to erases the flash device if a verify error occurs, click, the **Erase Part on Program Error** box.
8. Click OK.

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Configuring the BSCAN2

The "BSCAN Configuration Dialog Box" on page 944 enables you to configure five different BSCAN2 types. You can access up to 16 chains for programming by selecting multiple scan ports in these dialog boxes.

To configure the BSCAN2:

1. Choose **Design > BSCAN Configuration** to display the "BSCAN Configuration Dialog Box" on page 944.
2. In the BSCAN Configuration Type dropdown, choose from the following BSCAN configuration types:
   - BSCAN2 4 Port
   - BSCAN2 8 Port Asset Model
   - BSCAN2 8 Port JTAG/Corelis Model
   - BSCAN2 12 Port JTAG/Corelis Model
   - BSCAN2 16 Port JTAG/Corelis Model.

   Note

   You can open the BSCAN2 Configuration dialog box even if you have no .xcf files open. You can also keep a BSCAN2 dialog box open and still have full access to the Programmer.
3. Select the multiple scan ports for the chains you want to access.
4. Accept the RTI default for Leave Selected Ports In.
5. To set all devices in the selected ports in the TLR state, choose **TLR** in the dropdown menu.

   Note

   Selecting Reset Selected Ports is an optional but recommended step. When you select this option, make sure you do so before selecting Configure Ports.
6. Click **Configure Ports.**

The software scans the ports and opens the chains and devices, including the BSCAN2 Linker, in the Programmer main window. A sync bit separates each device.

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Changing the Port Assignment

When you first launch the Programmer software with the cables properly connected, it connects to the first available port that it detects. You can change the connecting port, as well as other cable options, using the Cable and Port Setting dialog box.

To change the port setup:

- In the "Cable Settings Tab" on page 945, choose the options that you want. Changes are immediately applied.

  If the cable is not connected or cannot be detected (if the board power in not on, for example), Programmer software displays an error message.

See Also "Using Diamond Programmer" on page 820

- "Programming the FPGA" on page 799
- Programming Tools User Guide

Testing the Cable Signal

The Cable Signal Tests Dialog Box helps you debug or improve the cable signal. You can use an oscilloscope, while running the continuous loop feature, to test your printed circuit board.

To test the cable signal:

1. In the Cable Settings tab, click the **Debug Mode** button.

   The "Cable Signal Tests Dialog Box" on page 949 opens.

2. In the dialog box, click **Power Check** to test the connection.

   The VCC Status LED will blink green if the cable and power are detected. It will produce an error message and blink red if the cable or power is not detected.

3. In the dialog box, select an option for the pins you want to test. The options are defined as follows:

   - **Toggle** – Alternates between log 1, logic 0, and logic 1.
   - **Hold High** – Holds at logic 1.
   - **Hold Low** – Holds at logic 0.
   - **Read (TDO only)** – Reads back the data from TDO and records the read back data in the Programmer log file.

   Note

   The available options for cable signal testing will vary, depending on the type of cable you are using and the options you have selected in the Cable Settings tab. Options that are not available appear dimmed.

4. To test the settings you have selected, click **Test**.

This causes the pins that have a Toggle setting to toggle once from logic 1 to logic 0 to logic 1.

5. To perform continuous testing, click **Loop Test**.

   This causes the pins that have a Toggle setting to toggle continuously until you stop the process.

6. To stop the loop process, press **ESC**.

Viewing the Log File

An ASCII text log file summarizes the results of the Programmer operations.

To view the log file:

- Click the  button on the toolbar.

Programmer Options

This section lists the options available in Programmer.

Topics include:

- "Getting Started Dialog Box" on page 858
- "Device Properties Dialog Box - Device, Access Mode, and Operation Options" on page 858
- "Device Properties Dialog Box" on page 926
- "Edit Custom Device Dialog Box" on page 943
- "Custom SPI Flash Dialog Box" on page 943
- "BSCAN Configuration Dialog Box" on page 944
- "Settings Dialog Box" on page 944
- "Cable Settings Tab" on page 945
- "Firmware Tab" on page 947
- "Edit I/O State Dialog Box" on page 948
- "Display Status Register Dialog Box" on page 948

- "Custom Device Information Dialog Box" on page 948
- "Cable Signal Tests Dialog Box" on page 949

Getting Started Dialog Box

The following options are available in the Getting Started dialog box:

Create a New Project from a JTAG Scan Scans the attached chain with the last used cable settings.

Cable Specifies the download cable type:

- **HW-USBN-2A -** (Lattice HW-USBN-2A USB port programming cable)
- **HW-USBN-2B (FTDI)** - (Lattice HW-USBN-2B (FTDI) USB programming cable)
- **HW-DLN-3C (Parallel)** - (Lattice HW-DLN-3C parallel programming cable)

Port Specifies the serial port to which the download cable is connected. Select the port from the list or click Detect Cable.

Detect Cable Automatically detects the parallel port to which the download cable is connected.

Create a New Blank Project Creates a new blank project.

Open an Existing Programmer Project 1.Allows the user to browse to an existing .xcf configuration file and open an existing Programmer project.

Device Properties Dialog Box

The Device Properties dialog box consists of two tabs: “General Tab” on page 926 and “Device Information Tab” on page 942.

General Tab

The following options are available in the Device Properties dialog box General tab, depending on selected Access Mode and Operation.

Access Mode Selects the mode for programming the device. The following is an alphabetic list of all available access mode with a definition of each operation.

Table 67: Access Mode

Access Mode	Description
Advanced Security Encryption File Programming	This mode is used to program the device with an encrypted data file.
Advanced Security File Programming	These operations are used to program the device after the device programmed with the password keys. The password keys is required to shift in first to un-lock the device for re-configuration.
Advanced Security Keys Programming	These operations are used to program the password keys into the device and also program the password keys at the end at the same time.
Advanced Security Production Programming	These operations are used to program the device using the JTAG port and also program the password keys at the end in one shot
ATDI Pin Selected Programming	This mode is used used for devices with an Alternate TDI (ispPAC ProcessorPM and ispPAC Power Manager II).
CRAM Programming	The mode is used for Compressed Random Access Memory (CRAM) configuration.
Dual Boot SPI Flash Programming	This mode is used to program a dual boot hex file into the SPI Flash.
EE	This mode is used for device with Electronically Erasable (EE) memory while the device is not operational.
Feature Row Programming	This mode is used to program, read back, editing the Feature Row sector of the XO3D device. The mode also is used to read back, editing the non-volatile Control Register 1 (which also belong to Feature Row sector)
Flash Background Mode	This mode is used to program the embedded flash while the device is still in user mode (background programming) (XFLASH).
Flash Programming Mode	This mode is used to program the embedded Flash while the device is not operational.
I2C Interface Programming	These operations are used to program the device using the I2C port or to generate the files for embedded programming over I2C from a processor.
JTAG 1532 Mode	This mode is used to configure the device through the Joint Test Action Group (JTAG) port.
NVCM Background Programming Mode	This mode is used to program the non-volatile configuration memory (NVCM) while the device is in usermode (Background Mode).

Table 67: Access Mode (Continued)

Access Mode	Description
NVCM Programming	This mode is used to program the non-volatile configuration memory (NVCM) while the device is not operational.
I2C NVCM Programming	This mode will program the non-volatile configuration memory (NVCM) through the I2C Port.
SSPI NVCM Programming	This mode will program the non-volatile configuration memory (NVCM) through the Slave SPI Port.
PTM Background Programming	This mode is used to program the background Platform Manager while the device is in usermode (Background Mode).
PTM Programming	This mode is used to program the Platform Manager while the device is not operational.
Serial Mode	This mode is used to program through the Serial Configuration Port.
Slave SPI Interface Programming	These operations are used to program the device using the Slave SPI port.
SSPI Flash Programming	This mode is used to program the device Flash through the Slave SPI port.
SSPI SRAM Programming	This mode is used to program the devices SRAM through the Slave SPI port.
SSPI XSRAM Programming	This mode is used to program the devices SRAM through the Slave SPI port while the device is in user mode (Background Mode).
SPI Flash Background Programming	This mode is used to program the external SPI Flash while the device is in user mode (Background Mode).
SPI Flash Programming	This mode is used to program the external SPI Flash while the device is not operational.
Static RAM Cell Background Mode	The mode is used for SRAM configuration while the device is in usermode (Background Mode).
Static RAM Cell Mode	The mode is used for SRAM configuration while the device is not operational.
X-EE	This mode is used for device with Electronically Erasable (EE) memory while the device is still in user mode (background programming).

Operation Lists the available operation modes for the device. Select one from the drop-down list. The following is an alphabetic list of all available operations with a definition of each operation.

Table 68: Operation

Operation	Description
Blank Check	Checks if the device is erased (blank).
Bypass	No operation is performed on the device.
Calculate Checksum	Calculates the Checksum of the device.
Calculate Data CRC	Calculates the cyclic redundancy check (CRC) of the device.

Table 68: Operation (Continued)

Operation	Description
Calculate Device Size Checksum	Calculates the Checksum of the entire device.
Calculate File Size Checksum	Calculates the Checksum of the data contained in the device for the address range of the input file.
Display Control Register0	Reads and Displays the contents of Control Register 0.
Display Control NV Register1	Reads and Displays the content of non-volatile control register 1 which is in the same location of the Feature Row.
Display ID	Reads and Displays the device ID.
Display Programming Pins Status	Reads and Displays the status of the programming pin.
Display Status Register	Reads and Displays the device's Status Register.
Display TraceID	Reads and Displays the user's TraceID.
Display USERCODE	Reads and Displays the USERCODE.
EPS with Flash Protect	EPS (Erase, Program, Secure) after the device programmed with the flash protection password keys. The flash protection password key is required to shift in first to un-lock the device for re-configuration. Secure inhibits read back of the device.
EPS with Flash Protect, Refresh	EPS (Erase, Program, Secure) after the device programmed with the flash protection password keys and then transfers the contents of flash to SRAM. The flash protection password key is required to shift in first to un-lock the device for re-configuration. Secure inhibits read back of the device.
EPV with Flash Protect	EPV (Erase, Program, Verify) after the device programmed with the flash protection password keys. The flash protection password key is required to shift in first to un-lock the device for re-configuration.
EPV with Flash Protect, Refresh	EPV (Erase, Program, Verify) after the device programmed with the flash protection password keys and then transfers the contents of flash to SRAM. The flash protection password key is required to shift in first to un-lock the device for re-configuration.
EPV with Full OTP Option	EPV (Erase, Program, Verify) and enables One time programming (OTP) option. OTP inhibits reprogramming and erasing of the device. This operation mostly used in production programming.
EPV with OTP and my_ASSP Option	EPV (Erase, Program, Verify), enables One time programming option and then program the user's device ID. OTP inhibits reprogramming and erasing of the device. This operation mostly used in production programming.
EPV with Password	EPV (Erase, Program, Verify), after the device programmed with the password keys. The password key is required to shift in first to un-lock the device for re-configuration.

Table 68: Operation (Continued)

Operation	Description
EPV with Password Key Option	EPV (Erase, Program, Verify) the new configuration memory in offline mode. Then programs the password keys into the device in one shot This operation mostly used in production programming.
EPV with OTP Option	EPV (Erase, Program, Verify) and enables One time programming (OTP) option. OTP inhibits reprogramming and erasing of the device. This operation mostly used in production programming.
EPV with Protect Only Option	EPV (Erase, Program, Verify), and program the flash protection password keys in one shot. This operation mostly used in production programming.
EPV with Protect and Lock Option	EPV (Erase, Program, Verify), then program the flash protection password keys and the security lock in one shot. This operation mostly used in production programming.
EPV with my_ASSP Option	EPV (Erase, Program, Verify), and then program the user's device ID in one shot. This operation mostly used in production programming.
EPV with my_ASSP, Password Key Option	EPV (Erase, Program, Verify), and program the user's device ID. Then programs the password keys into the device in one shot. This operation mostly used in production programming.
EPVS with Encrypt Only Option	EPVS (Erase, Program, Verify, Secure), and then program the encryption keys into the device in one shot. Secure inhibits read back of the device. This operation mostly used in production programming.
EPVS with Encrypt and Lock Option	EPVS (Erase, Program, Verify, Secure), then program the encryption keys into the device and locks the device in one shot. Secure inhibits read back of the device. This operation mostly used in production programming.
EPVS with Encryption	EPVS (Erase, Program, Verify, Secure), after the device programmed with the encryption keys.. The encrypted data file is required for re-configuration. Secure inhibits read back of the device.
EPVS with Encryption and Flash Protect	EPVS (Erase, Program, Verify, Secure), after the device programmed with the encryption keys and the flash protect password keys. The encrypted data file is required for re-configuration. The flash protection password key is required to shift in first to un-lock the device for re-configuration. Secure inhibits read back of the device.
EPVS with Encryption and Flash Protect, Refresh	EPVS (Erase, Program, Verify, Secure), after the device programmed with the encryption keys and the flash protect password keys. And then transfers the configuration from Flash to SRAM. The encrypted data file is required for re-configuration. The flash protection password key is required to shift in first to un-lock the device for re-configuration. Secure inhibits read back of the device.
EPVS with Flash Protect	EPVS (Erase, Program, Verify, Secure), after the device programmed with the flash protect password keys. The flash protection password key is required to shift in first to un-lock the device for re-configuration. Secure inhibits read back of the device.

Table 68: Operation (Continued)

Operation	Description
EPVS with Flash Protect, Refresh	EPVS (Erase, Program, Verify, Secure), after the device programmed with the flash protect password keys. And then transfers the contents to from Flash to SRAM. The flash protection password key is required to shift in first to un-lock the device for re-configuration. Secure inhibits read back of the device.
EPVS with Full OTP Option	EPVS (Erase, Program, Verify, Secure) and enables One time programming (OTP) option. Secure inhibits read back of the device. OTP inhibits reprogramming and erasing of the device. This operation mostly used in production programming.
EPVS with OTP and my_ASSP Option	EPVS (Erase, Program, Verify, Secure), enables One time programming option and then program the user's device ID. Secure inhibits read back of the device. OTP inhibits reprogramming and erasing of the device.
EPVS with OTP Option	EPVS (Erase, Program, Verify, Secure), enables One time programming (OTP) option. Secure inhibits read back of the device. OTP inhibits reprogramming and erasing of the device. This operation mostly used in production programming.
EPVS with Protect Only Option	EPVS (Erase, Program, Verify, Secure), and then programs the flash protect password keys into the device in one shot. Secure inhibits read back of the device. This operation mostly used in production programming.
EPVS with Protect and Lock Option	EPVS (Erase, Program, Verify, Secure), then programs the flash protect password keys and lock for device in one shot. Secure inhibits read back of the device. This operation mostly used in production programming.
EPVS with full feature Option	EPVS (Erase, Program, Verify, Secure), plus program the flash protect password keys and the encryption keys into the device but no feature lock enable fuses. This operation mostly used in production programming.
EPVS with full feature and Lock Option	EPVS (Erase, Program, Verify, Secure), plus program the flash protect keys, the encryption keys and the feature lock enable fuses in one shot. This operation mostly used in production programming.
EPVS with my_ASSP Option	EPVS (Erase, Program, Verify, Secure), and then program the user's device ID. Secure inhibits read back of the device. This operation mostly used in production programming.
Erase	Erases the configuration memory.
Erase All	Erase all configuration in all forms of memory on the device
Erase CFG	Erases the configuration in the Configuration Logic Block (CFG). Leaves all other memory alone.
Erase CFG and EBR Only	Erases the Configuration Logic Block (CFG) and Embedded Block RAM (EBR) only. Leaves all other memory alone.
Erase CFG and UFM Only	Erases the Configuration Logic Block (CFG) and User Fuse Memory (UFM) only. Leaves all other memory alone.
Erase DONE bit	Erase the value of the Done bit. Sets Done bit to 0.

Table 68: Operation (Continued)

Operation	Description
Erase Feature Row	Erases the feature row.
Erase Only	Erases the configuration memory.
Erase Only with Password	Erases the configuration memory after the device programmed with the password keys. The password key is required to shift in first to un-lock the device for erasing.
Erase with Flash Protect	Erases the configuration memory after the device programmed with the flash protect password keys. The flash protect password key is required to shift in first to un-lock the device for erasing.
Erase Feature Row with Password Key	Erase the contents of the feature row after the device programmed with the password keys. The password key is required to shift in first to un-lock the device for erasing.
Erase, Program	Erases the configuration memory and then programs a new configuration into memory.
Erase, Program, Secure	Erase the configuration memory, program a new configuration into memory, and then secures the configuration block. Secure inhibits read back of the device.
Erase, Program, Secure, Refresh	Erase the configuration memory, program a new configuration into memory, secures the configuration block, and then transfers the new configuration over from Flash to SRAM. Secure inhibits read back of the device.
Erase, Program, Verify	Erases, programs, and verifies the new configuration memory. For devices with a Feature Row, this operation will erase, program, and verify the Feature Row in direct programming mode. It will not erase and verify the Feature Row in background programming mode (XFLASH).
Erase, Program, Verify, Feature	Erases, programs, and verifies the new configuration memory and the Feature Row.
Erase, Program, Verify, Feature and TransFR	Erases, programs, and verifies the new configuration memory and the Feature Row. Then freezes IO pins and transfers configuration from Flash to SRAM.
Erase, Program, Verify Quad IO SPI	Erases, programs, verifies the new configurations, and then splits up bitstream into four different sectors for Quad IO.
Erase, Program, Verify with OTP	Erases the configuration memory, programs a new configuration, verifies that the configuration is correct, and then sets the one time programming (OTP) option. OTP inhibits reprogramming and erasing of the device.
Erase, Program, Verify with my_ASSP	EPV (Erase, Program, Verify), and then program the user's device ID.
Erase,Program,Verify,I2CSA	Erases the configuration memory, programs a new configuration, verifies that the configuration is correct, and then sets the I2C Slave Address (I2CSA) register in the external ASC.
Erase, Program, Verify, Refresh	Erases the configuration memory, programs a new configuration, verifies that the configuration is correct, and then transfers the contents from Flash to SRAM.

Table 68: Operation (Continued)

Operation	Description
Erase, Program, Verify, Secure	Erases the configuration memory, programs a new configuration, verifies that the configuration is correct, and secures the configuration block. Secure inhibits read back of the device.
Erase, Program, Verify, Secure Plus	Erases the configuration memory, programs a new configuration in to memory, verifies that the contents in memory are correct, and secures both the configuration block and user fuse memory. Secure inhibits read back of the device.
Erase, Program, Verify, Secure, Refresh	Erases the configuration memory, programs a new configuration, verifies that the configuration is correct, secures the configuration block, and then transfers the contents from Flash to SRAM. Secure inhibits read back of the device.
Erase, Program, Verify with Password	Erases the configuration memory, programs a new configuration, and verifies that the configuration is correct after the device programmed with the password keys. The password key is required to shift in first to un-lock the device for re-configuration.
Fast Configuration	Shifts in a bitstream directly into device and the device take care of the rest for configuration.
Fast Configuration with Password	Shifts in a bitstream directly into device and the device takes care of the rest for configuration after the device programmed with the password keys. The password key is required to shift in first to un-lock the device for re-configuration.
Fast Program	Shifts in a bitstream directly into device and the device take care of the rest for configuration.. Also known as burst programming.
Fast Program with Encryption Option	Programs the encryption key into the device and then shifts in the encrypted bitstream directly into device and the device takes care of the rest for configuration. This operation mostly used in production programming.
Fast Program with Password	Shifts in a bitstream directly into device and the device takes care of the rest for configuration after the device programmed with the password keys. The password key is required to shift in first to un-lock the device for re-configuration.
Fast Program, Read and Save	Shifts in a bitstream directly into device and the device take care of the rest for configuration. Then the contents in memory are read and saved to an output file.
FaultLog Erase Only	Erase the FaultLog.
FLASH Bypass	Same as “Bypass”
FLASH CFG Erase Only	Same as “Erase CFG”
FLASH CFG Erase, Program, Verify	Erases, programs, and verifies the CFG arrays.
FLASH CFG Erase, Program, Verify, Secure	Erases, programs, and verifies the CFG arrays. Lock the local “read back” and/or “program” of the Flash sectors. It will not lock the “erase” of the sectors.
FLASH CFG Verify Only	Verify the content of the CFG arrays. Leave all other memory arrays alone.
FLASH Display ID	Same as “Display ID”

Table 68: Operation (Continued)

Operation	Description
FLASH Display USERCODE	Same as “Display USERCODE”
FLASH Dry Run	Trigger the downloading the bitstream from CFG array to check internally without actually writing the configuration SRAM.
Flash Erase Only	Erases the contents of Flash memory.
FLASH Erase, Program, Verify	Same as “Erase, Program, Verify”
FLASH Erase, Program, Verify, Secure	Erases, programs, and verifies the new configuration memory. Local lock the read back and/or program of the sectors Local lock will not locking erasing the sectors.
FLASH Read and Save	Same as “Read and Save”
FLASH Read CFG Locks Policies	Reads and Displays the content of the central security lock policies (CSEC) of the configuration sectors.
FLASH Read Status Register	Same as “Read Status Register”
FLASH Read UFM Locks Policies	Reads and Displays the content of the central security lock policies (USEC) of the Flash user memory sectors.
FLASH Refresh	Same as “Refresh”
FLASH Secure CFG Plus	Lock the central “read back” and/or “erase” and /or “wishbone port access” of all the configuration sectors (SRAM, CFG0, CFG1, FEA, AESKEY, PUBKEY and CSEC).
FLASH Secure UFM Plus	Lock the central “read back” and/or “erase” and /or “wishbone port access” of the Flash user memory (UFM) sectors (UFM0/UFM1/UFM2/UFM3/USEC).
FLASH UFM Erase Only	Erases the User Flash Memory (UFM) arrays. Leaves all other memory arrays alone.
FLASH UFM Erase, Program, Verify	Erases, programs, and verifies the User Flash Memory (UFM) arrays.
FLASH UFM Erase, Program, Verify, Secure	Erases, programs, and verifies the User Flash Memory (UFM). Lock the local “read back” and/or the “program” of the Flash sectors. It will not lock the “erase” of the sectors.
FLASH UFM Verify Only	Same as “Verify UFM”
FLASH Verify ID	Same as “Verify ID”
FLASH Verify Only	Same as “Verify Only”
Flash Erase with Flash Protect	Erases the contents of Flash memory after the device programmed with the flash protect password keys. The flash protect password key is required to shift in first to un-lock the device for erasing.
I2CSA Erase Only	Erases the value of the I2C Slave Address (I2CSA) register.
I2CSA Program	Sets the value of the I2C Slave Address (I2CSA) register.
Program	Programs a new configuration into memory. Issues programming instructions and then the data are taken from the data file.
Program Control Register0	Programs Control Register 0.

Table 68: Operation (Continued)

Operation	Description
Program Control NV Register1	Program the content of non-volatile control register 1 which is in the same location of the Feature Row.
Program DONE bit	Programs the Done bit. Sets the Done bit to 1.
Program Encryption Key	Programs the encryption key into a device.
Program Encryption Key Only	Only programs the encryption key into a device.
Program Encryption Key and Flash Protect	Programs the encryption key and the flash protect password keys.
Program Encryption Key and Flash Protect with Lock	Programs the encryption key, and then sets the encryption lock and the flash protect password keys.
Program Encryption Key with Lock	Programs the encryption key into the device and then sets the lock.
Program Feature Encryption Lock	Sets the Feature Row encryption lock.
Program Feature Lock	Locks the Feature Row.
Program Feature Row	Programs the Feature Row. Programs the 128-bit feature row data into a device. The setting is from the .fea file. Lock the local “read back” and/or “program” of the FEATURE sector. It will not lock the “erase” of the FEATURE sector.
Program Feature Row Lock	Lock the local “read back” and/or “program” of the FEATURE sector. It will not lock the “erase” of the FEATURE sector.
Program Flash Protect Key Only	Set the Flash Protect Password key.
Program Flash Protect Key with Lock	Sets the Flash Protect Password key, and then sets the key lock so the key cannot be changed again.
Program Key Lock	Set the Key lock so the key cannot be changed again.
Program Only	Programs a new configuration into memory. Issues programming instructions and then the data are taken from the data file.
Program USF from PROM file	Program the TAG/USF memory using a PROM file.
Program Password Key	Programs the password keys into the device.
Program Password Key with Lock	Programs the password keys into the device and locks the devices.
Program and TransFR	Programs the Flash memory, freezes the devices I/O pins and then transfers the contents of non-volatile memory to working memory.
Program, Read and Save	Configures the Flash memory, then reads the contents of that memory and then saves it to a file.

Table 68: Operation (Continued)

Operation	Description
Program, Refresh	Programs the Flash memory of the device, device goes to sleep, and then transfers the configuration from Flash to SRAM.
Program, Secure and TransFR	Programs the Flash memory, secures the configuration block, and freezes the devices I/O pins and then transfers the contents of non-volatile memory to working memory. Secure inhibits read back of the device.
Program TraceID	Programs the user's TraceID.
Program, Verify	Programs the configuration memory of the device and then verifies the contents of that memory.
Program, Verify, Secure	Programs the configuration memory of a device, verifies the contents of memory, and secures the configuration block. Secure inhibits read back of the device.
Program, Verify and TransFR	Programs, Verify the content in memory. Then freezes IO pins and transfers configuration from Flash to SRAM.
RAM Read and Save	Read the contents of SRAM and then writes the contents into a file.
RAM Verify Only	Verifies the contents of SRAM.
Recovery Erase Only	Erase only operation used to recover device. Does not check ID of the device.
Read ASC Status	Reads the status register of an external ASC.
Read DONE bit	Reads to see if the Done bit has or has not been set.
Read Device Properties	Reads the properties of the device.
Read Encryption Key	Reads the contents of encryption key.
Read FaultLog Memory	Read the contents of FaultLog memory.
Read FaultLog Registers	Read the contents of the FaultLog register.
Read Feature Row	Reads the contents of the Feature row.
Read Programming Status	Reads if the Programming Status is pass or fail.
Read TraceID	Reads the user's TraceID from the device.
Read Status Register	Reads the contents of the Status Register.
Read and Save	Reads the contents of memory and saves it to a output file.
Read and Save JEDEC	Reads the contents of memory and saves it to a JEDEC file.
Refresh	Configures the pattern in Non-volatile into SRAM.
Refresh from Flash	Configures the pattern in Flash into SRAM.
Save JEDEC with TAG	Saves to a JEDEC file with TAG memory information.
Scan SPI Flash Device	Scans the SPI Flash in the board.
Secure	Secures the configuration block. Secure inhibits read back of the device.
Secure Device	Secures the configuration block. Secure inhibits read back of the device.

Table 68: Operation (Continued)

Operation	Description
Secure Plus	Secures the configuration block and the user fuse memory. Secure inhibits read back of the device.
Security Read Status Register	Reads the contents of the Status Register for secured device.
Security EPV with Password Key option	EPV (Erase, Program, Verify). For devices with a Feature Row, this operation will erase, program, and verify the Feature Row in direct programming mode. It will not erase and verify the Feature Row in background programming mode (XFLASH). Then programs the password keys into the device. This operation mostly used in production programming.
Security EPV with my_ASSP, Password Key option	EPV (Erase, Program, Verify), and then program the user's device ID. Then programs the password keys into the device. This operation mostly used in production programming.
Security EPV with OTP Option	EPV (Erase, Program, Verify), and then performs OTP (One Time Programming) on non-volatile memory and/or OTP (One Time Programming) on SRAM. This operation mostly used in production programming.
Security EPVS with OTP Option	EPV (Erase, Program, Verify), and then Secures the device, performs OTP (One Time Programming) and/or non-volatile memory or OTP on SRAM. This operation mostly used in production programming.
Security EPV with Full OTP Option	EPV (Erase, Program, Verify), and then OTP (One Time Programming) of non-volatile memory, OTP on SRAM and OTP on FEA. This operation mostly used in production programming.
Security EPVS with Full OTP Option	EPV (Erase, Program, Verify), then Secures the device, performs OTP (One Time Programming) of non-volatile memory, OTP on SRAM and OTP on FEA. This operation mostly used in production programming.
Security Erase CSEC (internal only)	Erase the content of CSEC sector.
Security Erase Encryption Key	Erase the content of AESKEY sector.
Security Erase Public Key	Erase the content of PUBKEY sector.
Security Erase USEC (internal only)	Erase the content of USEC sector.
Security Lock Ports Interface	Disable the access to the device's configuration logics from external CFG ports (JTAG, Slave SPI, I2C) or system wishbone bus.
Security Program Auth Done FlashA	Trigger the authentication validation process for the bitstream store in FlashA without writing configuration data into SRAM. Once the authentication passes, bit "AUTH_DONE" in FlashA will be automatically programmed.
Security Program Auth Done FlashB	Trigger the authentication validation process for the bitstream store in FlashB without writing configuration data into SRAM. Once the authentication passes, bit "AUTH_DONE" in FlashB will be automatically programmed.
Security Program Encryption Key	Programs the 256-bit encryption key into a device. Lock the local "read back" and/or "program" of the AESKEY sector. It will not lock the "erase" of the AESKEY sector.

Table 68: Operation (Continued)

Operation	Description
Security Program Encryption Key Lock	Lock the local “read back” and/or “program” of the AESKEY sector. It will not lock the “erase” of the AESKEY sector.
Security Program Password Key	Same as “Program Password Key”
Security Program Public Key	Programs the 512-bit public key into a device. Enable the Authentication mode. Lock the local “read back” and/or “program” of the PUBLICKEY sector. It will not lock the “erase” of the PUBLICKEY sector.
Security Program Public Key Lock	Lock the local “read back” and/or “program” of the PUBLICKEY sector. It will not lock the “erase” of the PUBLICKEY sector.
Security Program TraceID	Same as “Program TraceID”
Security Read CSEC (internal only)	Reads and Displays the contents of CSEC sector.
Security Read Encryption Key (internal only)	Same as “Read Encryption Key”
Security Read Password Key (internal only)	Read the contents of Password Key
Security Read Public Key (internal only)	Reads the contents of Public Key.
Security Read TraceID	Same as “Display TraceID”
Security Read USEC (internal only)	Reads and Displays the contents of USEC sector.
SEI Fast Program	Soft Error Injection fast configuration Programming.
SEI Fast Program with Password	Soft Error Injection fast configuration Programming after the device programmed with the password keys. The password key is required to shift in first to un-lock the device for re-configuration.
SPI Flash Calculate Device Size Checksum	Same as “Calculate Device Size Check Sum”
SPI Flash Erase All	Same as “Erase All”
SPI Flash Erase, Program, Verify	Same as “Erase, Program, Verify”
SPI Flash Erase, Program, Verify Quad 1	Same as “Erase, Program, Verify Quad IO SPI”.
SPI Flash Read and Save	Same as “Read and Save”
SPI Flash Verify Only	Same as “Verify Only”/ Verify the content of external SPI Flash.
SRAM Bypass	Same as “Bypass”
SRAM Display Control Register0	Same as “Display Control Register0”
SRAM Display Control Register1	Reads and Displays the contents of Control Register 1

Table 68: Operation (Continued)

Operation	Description
SRAM Display ID	Same as “Display ID”
SRAM Display USERCODE	Same as “Display USERCODE”
SRAM Erase Only	Same as “Erase Only”
SRAM Erase, Program, Verify	Same as “Erase, Program, Verify”.
SRAM Fast Configuration	Same as “Fast Configuration”
SRAM Program Control Register0	Same as “Program Control Register0”
SRAM Program Control Register1	Read back, editing and programs Control Register 1.
SRAM Read and Save	Same as “RAM Read and Save”
SRAM Read Status Register	Same as “Read Status Register”
SRAM Refresh	Same as “Refresh”
SRAM Secure Plus	Lock the local “read back” and/or “program” of the SRAM sector. It will not lock the “erase” of the sector.
SRAM Verify ID	Same as “Verify ID”
SRAM Verify Only	Same as “RAM Verify Only”
SRAM Verify USERCODE	Same as “Verify USERCODE”
SSPI Flash Calculate File Size Checksum	Same as “Calculate File Size Check Sum”
TAG Erase	Erases the contents of TAG memory.
TAG Program, Verify	Programs the TAG memory with a new configuration and then verifies the contents of TAG memory.
TAG Read and Program	Reads the contents TAG memory and then programs a new configuration into TAG memory.
TAG Verify	Verifies the contents of TAG memory.
TransFR	Freezes IO pins and transfers configuration from Flash to SRAM.
Update Feature Row	Reads and Displays the Feature Row, allow user to modify the content of Feature Row, then program feature row back.
Upload to Static RAM	Upload data to SRAM.
Verify DONE bit	Verify if the Done bit has been set or not.
Verify EBR	Verifies the contents of the Embedded Block RAM (EBR) cells.
Verify Encryption Key	Verifies the Encryption key.
Verify Feature Rows	Verifies the contents of the devices feature row.
Verify ID	Verifies the ID of the device.
Verify Only	Verifies the new configuration memory.

Table 68: Operation (Continued)

Operation	Description
Verify UFM	Verify the contents of User Fuse Memory (UFM).
Verify USERCODE	Verifies the USERCODE of the device.
Verify with Encryption Option	Verifies the new configuration memory and program the encryption key into the device. This operation mostly used in production programming.
Verify Only with Password	Verifies the new configuration memory after the device programmed with the password keys. The password key is required to shift in first to un-lock the device for re-configuration.
XFLASH Bypass	Same as “Bypass”
XFLASH CFG Erase Only	Same as “Erase CFG”
XFLASH CFG Erase, Program, Verify	Erases, programs, and verifies the CFG arrays in background mode. The device is still operating during the process.
XFLASH CFG Erase, Program, Verify, Secure	Erases, programs, and verifies the CFG arrays. Lock the local “read back” and/or “program” of the Flash sectors in background mode. It will not lock the “erase” of the sectors. The device is still operating during the process.
XFLASH CFG Verify Only	Verify the content of the CFG arrays in background mode. Leave all other memory arrays alone. The device is still operating during the process.
XFLASH Display ID	Same as “Display ID”
XFLASH Display USERCODE	Same as “Display USERCODE”
XFLASH Dry Run	Trigger the downloading the bitstream from CFG array to check internally without actually writing the configuration SRAM in background mode. The device is still operating during the process.
XFLASH Erase Only	Same as “Flash Erase Only”
XFLASH Erase, Program, Verify	Same as “Erase, Program, Verify”
XFLASH Erase, Program, Verify, Secure	Erases, programs, and verifies the CFG arrays. Lock the local “read back” and/or “program” of the Flash sectors in background mode. It will not lock the “erase” of the sectors. The device is still operating during the process.
XFLASH Program and TransFR	Same as “Program Verify and TransFR”
XFLASH Read and Save	Same as “Read and Save”
XFLASH Read CFG Locks Policies	Reads and Displays the content of the central security lock policies (CSEC) of the configuration sectors in background mode.
XFLASH Read Status Register	Same as “Read Status Register”
XFLASH Read UFM Locks Policies	Reads and Displays the content of the central security lock policies (USEC) of the Flash user memory sectors in background mode.
XFLASH Refresh	Same as “Refresh”
XFLASH Secure CFG Plus	Lock the central “read back” and/or “erase” and /or “wishbone port access” of all the configuration sectors (SRAM, CFG0, CFG1, FEA, AESKEY, PUBKEY and CSEC) inn background mode. The device is still operating during the process.

Table 68: Operation (Continued)

Operation	Description
XFLASH Secure UFM Plus	Lock the central “read back” and/or “erase” and /or “wishbone port access” of the Flash user memory (UFM) sectors (UFM0/UFM1/UFM2/UFM3/USEC) in background mode. The device is still operating during the process.
XFLASH TransFR	Freezes IO pins and transfers configuration from Flash to SRAM.
XFLASH UFM Erase Only	Erases the User Flash Memory (UFM) arrays in background mode. Leaves all other memory arrays alone. The device is still operating during the process.
XFLASH UFM Erase, Program, Verify	Erases, programs, and verifies the User Flash Memory (UFM) arrays in background mode. The device is still operating during the process.
XFLASH UFM Erase, Program, Verify, Secure	Erases, programs, and verifies the User Flash Memory (UFM). Lock the local “read back” and/or the “program” of the Flash sectors in background mode. It will not lock the “erase” of the sectors. The device is still operating during the process.
XFLASH UFM Verify Only	Same as “Verify UFM”
XFLASH Verify ID	Same as “Verify ID”
XFLASH Verify Only	Same as “Verify Only”
XSRAM Bypass	Same as “Bypass”
XSRAM Display Control Register0	Same as “Display Control Register0”
XSRAM Display Control Register1	Reads and Displays the content of Control Register 1 in background mode.
XSRAM Display ID	Same as “Display ID”
XSRAM Display USERCODE	Same as “Display USERCODE”
XSRAM Read and Save	Same as “RAM Read and Save”
XSRAM Read Status Register	Same as “Read Status Register”
XSRAM Refresh	Same as “Refresh”
XSRAM SEI Fast Program	Same as “SEI Fast Program”
XSRAM Verify ID	Same as “Verify ID”

Programming File Selects the data file for programming or verify.

Use I2C Interface of the Lattice HE-USBN-2B Download Cable Check this option to program the device using the I2C port with the Lattice USB-2B download cable.

I2C Slave Address Enter I2C slave address in binary.

Reinitialize Part on Program Error Reinitializes the part to its blank, or erased, state when a programming error occurs.

TCK Frequency Specifies the TCK clock frequency for the chosen device. This value is used to determine the TCK clock period and the length of the delay times.

SVF Vendor Select the SVF vendor for the chosen device.

Instruction Register Length Specify the instruction register length for putting the device into BYPASS during programming. The software automatically fills in this box when you select a BSDL file. You must enter the instruction register length for a JTAG-NOP device if a BSDL file is not selected.

Load from File Import the IR length from a BSDL or SVF file.

Reinitialize Part on Program Error Reinitializes the device to its blank, or erased, state when a programming error occurs.

Verify Readback Bitstream File Select a custom verify mask file.

Family Select an external memory family from the drop-down list.

Vendor Select an external memory vendor from the drop-down list.

Device Select an external memory device from the drop-down list.

Package Select an external memory package from the drop-down list..

Data File Size Displays the full file size. You can change this size by typing a different file size. This feature is useful if you only want to use a portion of the file for the operation. If you change the file size, it must be no larger than the full file size or the device size.

Start Address Displays the start address of the flash device. For the AMD parallel flash, the starting address is automatically selected and cannot be changed.

End Address Displays the end address of the flash.

Erase SPI on Programming Error Erases the flash device if a verify error occurs.

Secure SPI Flash Golden Pattern Sectors Allows user to secure second half of SPI Flash to secure golden pattern. Available only on devices that support this secure feature.

Enter Key Enter encryption key.

Confirm Key Confirm encryption key.

Load Key Load an encryption key from an external file.

Save Key Save encryption key to external file.

Format Choose between ASCII or Hex key display.

Show Key Toggles display of key.

Password Protection Options (Provide key file if password protection enabled.) If device password protection is enabled, User must provide password key file.

Flash-A Programming Options Allows user to select A target flash block.

Flash-B Programming Options Allows user to select B target flash block.

Flash-C Programming Options Allows user to select C target flash block. Flash C includes UFM2 and UFM3 flash blocks which require programming files.

Configuration Sectors Central Locks Options Options for SRAM Sector, Flash-A Sector, Flash-B Sector, Feature Row Sector, Encryption Key Sector, Public Key Sector, and CSEC Sector.

UFM Sectors Central Locks Options Options for UFM0 Sector, UFM1 Sector, UFM2 Sector, UFM3 Sector, USEC Sector.

Port Interface Locks Options Options for JTAG Port Interface, Slave SPI Port Interface, I2C Port Interface

Device Information Tab

The Device Information tab displays information on the device selected. The content can vary depending upon the device selected, and can include:

- Family Name
- Device Name
- VCC Voltage Supply
- VCCJ Voltage Supply
- Address Register Length
- Data Register Length
- JTAG IDCODE
- JTAG IDCODE MASK
- IDCODE Length
- SOFT IDCODE
- Instruction Register Length
- USERCODE Register Length
- Boundary Scan Register Length
- Support External ASC Device
- Support FPGA Loader
- Maximum Erase Pulse Width (ms)
- Maximum Program Pulse Width (ms)

See Also ▶"Programmer Options" on page 857

- "Device Properties Dialog Box - Device, Access Mode, and Operation Options" on page 858
- Programming Tools User Guide

Edit Custom Device Dialog Box

The following options are available in the Edit Custom Device dialog box:

Device Family Dropdown list of custom device families.

Device The name that was assigned to the device.

Package The name that was assigned to the package.

Device Description The description that was assigned to the device.

See Also ▶"Programmer Options" on page 857

- Programming Tools User Guide

Custom SPI Flash Dialog Box

The following options are available in the Custom SPI Flash dialog box:

Device Family Dropdown list of custom device families.

Device Description The name that was assigned to the device.

Device Name This can be any alpha-numeric string that describes the device name (for example: SPI-M25P32).

Package This can be any alpha-numeric string that describes the package (for example: 16-pin SOIC).

Device Vendor The vendor of the custom SPI Flash device.

Device ID This can be any alpha-numeric string that describes the device ID (for example: 0x15).

Byte Per Sector Allows you to choose desired bytes per sector value from dropdown.

Protection Options ON If the SPI Flash device supports sector protection, check this box to enable protection options. This will allow you to select **Secure SPI Flash Golden Pattern Sectors** in the "Device Properties Dialog Box" on page 926.

See Also ▶"Programmer Options" on page 857

- Programming Tools User Guide

BSCAN Configuration Dialog Box

The following options are available in the BSCAN Configuration dialog box:

BSCAN Configuration Type Allows you to choose one of five BSCANs configuration types: BSCAN2 4 Port, BSCAN2 8 Port Asset Model, BSCAN2 8 Port JTAG/Corelis Model, BSCAN2 12 Port JTAG/Corelis Model, or BSCAN2 16 Port JTAG/Corelis Model.

Select Ports Select the scan ports for the chains you want to access.

Leave Selected Ports In Select RTI, run test idle, to configure the BSCAN2. Selecting TLR, test logic rest, will remove the selected ports from the configuration.

Reset All Ports Resets all ports to the TLR state and the interface to the default state. Select this button to begin another configuration session.

Reset Selected Ports Resets the selected ports to the TLR state.

Configure Selected Ports Scans the selected ports and displays the chains and devices for programming.

See Also ▶"Programmer Options" on page 857

▶ Programming Tools User Guide

Settings Dialog Box

The following options are available in the Settings dialog box:

General Tab

At Programmer Start-Up Allows you to select between showing the Programmer Getting Started dialog box at start-up, or opening the last Programmer project at start-up.

USERCODE Display Allows the user to choose in which format the USERCODE will be displayed. Choices are Hex, ASCII, and Decimal.

Device Family Selection List Order Allows the user to display the Device Family drop-down list in the Programmer main window in either chronological or alphabetical order. The default is chronological order.

Log File Path Shows the location of the Programmer log file, and allows you to browse to and set a new location for the Programmer.log file.

Clear Log File Each Time Application Starts Clears log file each time the applcation starts: If the box is unchecked, the log file will continue increase in size until the file is manually erased.

Programming Tab

Turbo Mode Programs all the devices on the board in parallel. If an Operation Override is selected, all Operation descriptions in the chain file are temporarily changed to the override setting.

Sequential Mode Programs all the devices on the board one at a time. If an Operation Override is selected, all Operation descriptions in the chain file are temporarily changed to the override setting.

Use Default JTAG States (TLR/TLR) Uses Test-Logic-Reset (TLR) as the starting and ending JTAG state of the JTAG State Machine for download.

Avoid Test Logic Reset (TLR) State Avoids the Test Logic Reset State of the JTAG State Machine during download.

Use Custom JTAG States Specify Test-Logic-Reset (TLR) or Run-Test/Idle (RTI) as the starting and ending JTAG state of the JTAG State Machine for download.

Initial TAP State Specify TLR or RTI as the starting JTAG state of the JTAG State Machine for download.

Final TAP State Specify TLR or RTI as the ending JTAG state of the JTAG State Machine for download.

Check Cable Setup Before Programming Confirms that the cable signals are correctly connected to the board and devices in the JTAG chain on the board match the devices selected in the .xcf file.

Continue Download on Error Ignores any errors while downloading and continues running.

See Also ▶"Programmer Options" on page 857

- Programming Tools User Guide

Cable Settings Tab

The following options are available in the Cable Settings tab:

Detect Cable Automatically detects the parallel port to which the download cable is connected.

Cable Specifies the download cable type:

- **HW-USBN-2A -** (Lattice HW-USBN-2A USB port programming cable)
- **HW-USBN-2B (FTDI)** - (Lattice HW-USBN-2B (FTDI) USB programming cable)
- **HW-DLN-3C (Parallel)** - (Lattice HW-DLN-3C parallel programming cable)

Port Specifies the serial port to which the download cable is connected. Select the port from the list or click Detect Cable.

Custom Port (Hex) Specifies a custom parallel port to which the download cable is connected. Use hexadecimal format to type the port name.

Use Default Clock Divider Uses the fastest TCK clock speed.

Use Custom Clock Divider Enables the Use Custom Clock Divider feature.

TCK Divider Setting (0 - 10x) Allows you to slow down the TCK clock. This is done by extending the low period of the clock. Refer the following tables for specific frequency settings for USB-2B (2232H FTDI USB host chip), USB-2B (2232D FTDI USB host chip), and USB-2A and Parallel port cables.

Table 69: USB-2B (2232H FTDI USB host chip)

Divider	Clock Frequency[1]	Divider	Clock Frequency[1]
0	30 MHz	5	5 MHz
1	15 MHz (Default)	6	4.2 MHz
2	10 MHz	7	3.7 MHz
3	7.5 MHz	8	3.1 MHz
4	6 MHz	9	3 MHz
		10	2.7 MHz

[1]Calculation formula for USB-2B (2232H FTDI USB host chip):

Frequency = 60 MHz / (1 + ClockDivider) *2

Table 70: USB-2B (2232D FTDI USB host chip)

Divider	Clock Frequency[2]	Divider	Clock Frequency[2]
0	6 MHz	5	1 MHz
1	3 MHz (Default)	6	0.8 MHz
2	2 MHz	7	0.7 MHz
3	1.5 MHz	8	0.65 MHz
4	1.2 MHz	9	0.6 MHz
		10	0.5 MHz

[2]Calculation formula for USB-2B (2232D FTDI USB host chip):

Frequency = 12 MHz / (1 + ClockDivider) *2

Table 71: USB-2A and Parallel port

Divider	Low Pulse Width delay[3]	Divider	Low Pulse Width delay[3]
0	NA	5	5x
1	1x	6	6x
2	2x	7	7x
3	3x	8	8x
4	4x	9	9x
		10	10x

[3]The USB-2A frequency fixed at 1.5 MHz and Parallel Port frequency fixed at 500 KHz

Use Default I/O Settings Only use the four JTAG signals.

Use Custom I/O Settings Specify additional non-JTAG signals connected to the board.

INITN Pin Connected Select this option if you connect the INIT pin to the download cable. This option is only available with the Lattice HW-USBN-2A USB port programming cable.

Done Pin Connected Select this option if you connect the DONE pin to the download cable. This option is not available for the Lattice HW-DLN-3C parallel programming cable.

TRST Pin Connected Select this option if you connect the TRST pin to the download cable. Specify active high or active low.

PROGRAMN Pin Connected Select this option if you connect the PROGRAMN pin to the download cable.

ispEN Pin Connected Select this option if you connect the ispEN pin to the download cable. Specify active high or active low.

See Also ▶"Programmer Options" on page 857

▶ Programming Tools User Guide

Firmware Tab

The following options are available in the Firmware tab.

MachXO2 firmware Select a file to update the firmware on the FTDI cable's MachXO2.

POWR607 firmware Select a file to update the firmware on the FTDI cable's POWR607.

Update Firmware Reprograms the firmware of the device/devices on cable.

Save Existing Firmware Users can save current cable's firmware on a file.

Cable's Firmware Version Shows the cable's firmware version number.

See Also ▶"Programmer Options" on page 857

▶ Programming Tools User Guide

Edit I/O State Dialog Box

The following options are available in the Edit I/O State dialog box:

I/O State The state of the I/O pin (input or output, high or low).

BSDL File A BSDL file, which is the acronym for Boundary Scan Description Language file, is a subset of Very High Speed IC Hardware Description Language (VHDL) that describes the boundary scan device package, pin description and boundary scan cell of the input and output pins. The BSDL file is very important in generating a boundary scan test. Without a BSDL file, it is impossible to generate any boundary scan test.

Package The target device package.

See Also ▶"Programmer Options" on page 857

▶ Programming Tools User Guide

Display Status Register Dialog Box

The following options are available in the Display Status Register dialog box:

Refresh Refreshes the status of the device.

See Also ▶"Programmer Options" on page 857

▶ Programming Tools User Guide

Custom Device Information Dialog Box

The following options are available in the Custom Device Information dialog box:

Device Name Edit box limited to 12 characters maximum. Valid characters are alphanumeric and a dash.

Device Full Name Edit box limited to 12 characters maximum. Valid characters are alphanumeric and a dash.

Package This can be any alpha-numeric string that describes the package (for example: 16-pin SOIC).

ID Length ID length equal to 32, per IEEE 1149.1 Std. This box is not editable.

Device ID (Hex) Limited to four hexadecimal characters. Valid characters are "Ox" followed by two hexadecimal characters. Default value is "OxFFFFFFFF".

Instruction Register Length Select any number ranging from 2 to 32.

Read ID Instruction Must be entered in binary only (0 or 1). The number of characters entered is limited to the Instruction Register Length.

Instruction Bypass Pattern Must be entered in binary only (0 or 1). The number of characters entered is limited to the Instruction Register Length.

BSDL File Browse to the desired bsm file. A BSDL file, which is the acronym for Boundary Scan Description Language file, is a subset of Very High Speed IC Hardware Description Language (VHDL) that describes the boundary scan device package, pin description and boundary scan cell of the input and output pins. The BSDL file is very important in generating a boundary scan test. Without a BSDL file, it is impossible to generate any boundary scan test.

Cable Signal Tests Dialog Box

The following options are available in the Cable Signal Tests dialog box:

Toggle Alternates between log 1, logic 0, and logic 1.

Hold High Holds at logic 1.

Hold Low Holds at logic 0.

Test Applies the selected settings to the selected pin connections. This causes the pins that have a toggle setting to toggle once from logic 1 to logic 0 to logic 1.

Loop Test Performs continuous testing, causing the pins that have a toggle setting to toggle continuously until you click ESC.

View Log Opens the log file, an ASCII text file that summarizes the results of the Cable Signal Test operations.

Power Check Tests the cable and power connections, causing the VCC Status LED to blink green or red to indicate that cable and power are detected or not detected.

VCC Status Shows the status of the cable and power connection. The LED blinks green when the cable and power are detected. It blinks red and produces an error message when cable or power is not detected.

Toggle Delay Sets the delay after each operation. Default is 0.

Number of Bytes Sets the number of bytes read by each operation. Default is 0.

Deploying the Design with the Deployment Tool

The Deployment Tool allows you to generate files for deployment for single devices, a chain of devices, and can also convert data files to other formats and use the data files it produces to generate other data file formats.

Deployment Tool is a stand-alone tool available from the Diamond Accessories. The Deployment Tool graphical user interface (GUI) is separate from the Diamond design environment.

A four-step wizard allows you to select deployment type, input file type, and output file type.

Deployment Function Types

This section provides tables that list device family, input file types, output file extensions, and options for each available deployment function type.

There are four types of deployments available. Click on the list items below to jump to topics that contain lists of device family, input file types, output file type/extensions, and options for each deployment function type.

- "File Conversion Deployment Function Type" on page 952
- "Tester Deployment Function Type" on page 959
- "Embedded System Deployment Function Type" on page 965

▶ “External Memory Deployment Type” on page 977

File Conversion Deployment Function Type

This topic provides tables that list device family, input file types, output file extensions, and options for File Conversion deployment function type.

IEEE 1532 ISC Data File - Device Family, Input File 1, and Output File

The following table lists device family, input file types, and output file extensions for IEEE 1532 ISC data file conversion deployment.

Table 72:

Device Family	Input File 1	Output File
spMACH4000/ ZE ispXPGA Mature	JEDEC (.jed)	ISC Data (.isc)

IEEE 1532 ISC Data File - Options

The following table lists Options for IEEE 1532 ISC data file conversion deployment.

Table 73:

Device Family	Overwrite USERCODE		
ispMACH4000/ ZE ispXPGA Mature	**Off (Default)**	**On**	**Checksum**
	Input File USERCODE.	User specified value.	JEDEC checksum.

Application Specific BSDL File - Device Family, Input File 1, Input File 2, and Output File

The following table lists device family, input file types, and output file extensions for Application Specific BSDL data file conversion deployment.

Table 74:

Device Family	Input File 1	Input File 2	Output File
Lattice	JEDEC (.jed) Argument File (.alt)	Generic BSDL (.bsm)	BSDL File (.bsm)

Application Specific BSDL File - Options

The following table lists options for Application Specific BSDL data file conversion deployment.

Table 75:

Device Family	Convert Bi-directional I/O's to Input and Output	
Lattice	**Off (Default)**	**On**
	Do not convert.	Convert.

JEDEC File - Device Family, Input File 1, and Output File

The following table lists device family, input file types, and output file extensions for JEDEC file conversion deployment.

Table 76:

Device Family	Input File 1	Output File
LIFMD MachXO2 MachXO3D MachXO3L Platform Manager Platform Manager 2	JEDEC (.jed)	JEDEC (.jed)
LatticeXP2 LatticeXP MachXO	JEDEC (.jed) Bitstream (.bit, .rbt)	
ispXPGA Mature	JEDEC (.jed) ISC Data (.isc)	

JEDEC File - Options - Overwrite USERCODE

The following table lists options -- Overwrite USERCODE -- for JEDEC file conversion deployment.

Table 77:

Device Family	Overwrite USERCODE			
	Off (Default)	**On**	**Checksum**	**Disable (Internal Command Line Only)**
Platform Manager 2, Platform Manager LatticeXP2 LatticeXP LIFMD MachXO2 MachXO3D MachXO3L MachXO ispXPGA Mature	Input File USERCODE.	User specified value.	JEDEC checksum.	Omit USERCODE from JEDEC.

JEDEC File - Options - Program Security Bit

The following table lists options -- Program Security Bit -- for JEDEC file conversion deployment.

Table 78:

Device Family	Program Security Bit		
	Default (Default)	**Off**	**On**
Platform Manager 2 Platform Manager LatticeXP LIFMD MachXO2 MachXO3D MachXO3L ispXPGA Mature	Use setting from input file.	Do not program security fuses.	Program security fuses.

JEDEC File - Options - Encryption

The following table lists options -- Encryption-- for JEDEC file conversion deployment.

Table 79:

Device Family	Encryption
MachXO3D	**Encryption Key**
LatticeXP2	Load from BEK file.

Bitstream - Device Family, Input File 1, Format, and Output File

The following table lists device family, input file types, format, and output file extensions for bitstream conversion deployment.

Table 80:

Device Family	Input File 1	Format	Output File
MachXO3D ECP5 LatticeECP3 LatticeECP2/MS LatticeECP2/M LatticeECP LatticeSC/M ORCA Unknown or Non-Lattice	Bitstream (.bit, .rbt).	Binary Bitstream	Bitstream (.bit)
		ASCII Bitstream	Bitstream (.rbt)
		Intel Hex	Hex (.mcs)
		Motorola Hex	Hex (.exo)
		Extended Tektronix Hex	Hex (.xtek)
MachXO3D LatticeXP2 LatticeXP MachXO2	JEDEC (.jed) Bitstream (.bit, .rbt)	Binary Bitstream	Bitstream (.bit)
		ASCII Bitstream	Bitstream (.rbt)
		Intel Hex	Hex (.mcs)
		Motorola Hex	Hex (.exo)
		Extended Tektronix Hex	Hex (.xtek)

Bitstream- Options - Encryption

The following table lists options -- Encryption-- for bitstream conversion deployment..

Table 81:

Device Family	Encryption	
	Configuration Mode	**Encryption Key**
		Load from BEK File
LatticeECP3 LatticeECP2S/MS	Selects the appropriate configuration mode for the bitstream encryption.	Load from BEK file.

Bitstream- Options - Encryption

The following table lists options -- Encryption-- for bitstream conversion deployment..

Table 82:

Device Family	Encryption
ECP5 MachXO3D	Encryption Key
	Load from BEK File

Bitstream- Options - Authentication

The following table lists options -- Authentication-- for bitstream conversion deployment..

Table 83:

Device Family	Authentication
MachXO3D	Public Key and Private Key or Signature Key
	Load from GUI and load Public Key (.pub) File and Private File (.prv).

Bitstream Options -- Verify ID Code, Frequency, Compression

The following table lists options -- Verify ID Code, Frequency, and Compression-- for bitstream conversion deployment.

Figure 9:

Device Family	Verify ID Code			Frequency		Compression		
	Default (Default)	**On**	**Off**	**Default (Default)**	**Frequency Selection**	**Default (Default)**	**On**	**Off**
ECP5 MachXO2 MachXO3D MachXO3L	Use setting from input file.	Include verify ID in bitstream.	Do not verify ID code.	Use setting from input file.	Valid frequency device dependent.	Use setting from input file.	Compress bistream data.	Do not compress.
LatticeECP3 LatticeXP LatticeXP2	Use setting from input file.	Include verify ID in bitstream.	Do not verify ID code.	Use setting from input file.	Valid frequency device dependent.	-	-	-
LatticeSC/M	-	-	-	-	-	Use setting from input file.	Compress bistream data.	Do not compress.

Bitstream Options -- CRC Calculation, Overwrite USERCODE, Byte Wide Bit Mirror, and Retain Bitstream Header

The following table lists options -- CRC Calculation, Overwrite USERCODE, Byte Wide Bit Mirror, and Retain Bitstream Header -- for bitstream conversion deployment.

Figure 10:

Device Family	CRC Calculator			Overwrite USERCODE		Byte Wide Bit Mirror (Intel Hex (.mcs), Motorola Hex (.exo), and Extended Tektronix Hex (.xtek) only)		Retain Bitstream Header (Intel Hex (.mcs), Motorola Hex (.exo), and Extended Tektronix Hex (.xtek) only)	
	Default (Default)	**On**	**Global CRC Only**	**Off (Default**	**On**	**Off (Default)**	**On**	**Off (Default)**	**On**
ECP5 LatticeECP3 LatticeXP2 MachXO2\ MachXO3D MachXO3L	Use setting from input file.	Include CRC for each data frame.	Include global CRC only.	Input File USERCODE.	User specified value.	No change to bit order.	Flips each byte.	Replace bitstream header.	Retain bitstream header.
LatticeECP2S/MS LatticeECP2/M	Use setting from input file.	Include CRC for each data frame.	Include global CRC only.	Input File USERCODE.	User specified value.	No change to bit order.	Flips each byte.	-	-
LatticeEC/P LatticeSC/M LatticeXP	-	-	-	Input File USERCODE.	User specified value.	No change to bit order.	Flips each byte.	Replace bitstream header.	Retain bitstream header.
ORCA	-	-	-	-	-	No change to bit order.	Flips each byte.	Replace bitstream header.	Retain bitstream header.
Unknown or Non-Lattice	-	-	-	-	-	No change to bit order.	Flips each byte.	-	-

JEDEC to Hex File Conversion

The following table lists device family, input file types, format, and output file extensions for JEDEC to Hex deployment.

Table 84:

Device Family	Input File 1	Format	Output File
Lattice	JEDEC (.jed)	ASCII Raw Hex	ASCII Hex (.hex)
		Binary Raw Hex	Binary Hex (.bin)

Tester Deployment Function Type

This topic provides tables that list device family, input file types, output file extensions, and options for Tester deployment function type.

SVF Single Device - Device Family, Input File 1, and Output File

The following table lists device family, input file types, and output file extensions for SVF single device deployment.

Table 85:

Device Family	Input File 1	Output File
Lattice Single Device	JEDEC (.jed)	SVF File (.svf)
	ISC Data (.isc)	
	Bitstream (.bit, .rbt)	

SVF Single Device - Options - Operation

The following table lists options -- Operation -- for SVF single device deployment.

Table 86:

Device Family	Operation
Lattice Single Device	Device dependent list.

SVF Single Device - Options - Write Header and Comments, Write Rev D Standard SVF File

The following table lists options -- Write Header and Comments, Write Rev D Standard SVF File -- for SVF single device deployment.

Table 87:

Device Family	Write Header and Comments		Write Rev D Standard SVF File	
Lattice Single Device	**On (Default)**	**Off**	**Off (Default)**	**On**
	Write headers and comments.	Omit header and comments.	Rev E Standard SVF For Flash based FPGA's, Lattice Extended SVF.	Rev D Standard SVF.

SVF Single Device - Options - Use RUNTEST from Rev C; For Erase, Program, and Verify Operations, Skip Verify

The following table lists options -- Use RUNTEST from Rev C; For Erase, Program, and Verify Operations, Skip Verify -- for SVF single device deployment.

Table 88:

Device Family	Use RUNTEST from Rev C		For Erase, Program, and Verify Operations, Skip Verify	
Lattice Single Device	**Off (Default)**	**On**	**Off (Default)**	**On**
	Standard RUNTEST.	Rev C RUNTEST.	Include verify in EPV operations.	Omit verify in EPV operations.

SVF Single Device - Options - Include RESET at the End of the SVF File; Set Maximum Data Size per Row (Kbits)

The following table lists options -- Include RESET at the End of the SVF File; Set Maximum Data Size per Row (Kbits) -- for SVF single device deployment

Table 89:

Device Family	Include RESET at the End of the SVF File		Set Maximum Data Size per Row (Kbits)	
Lattice Single Device	**Off (Default)**	**On**	**Off (Default)**	**On**
	Do not write RESET at the end of the SVF file.	Write RESET at the end of the SVF file.	-	8/16/32/64/128/256

SVF JTAG Chain - Device Family, Input File 1, and Output File

The following table lists device family, input file types, and output file extensions for SVF JTAG chain deployment.

Table 90:

Device Family	Input File 1	Output File
Lattice Chain	XCF File (.xcf)	SVF File (.svf)

SVF JTAG Chain - Options - Operation

The following table lists options -- Operation -- for SVF JTAG chain deployment.

Table 91:

Device Family	Operation
Lattice Single Device.	Contained in XCF file.

SVF JTAG Chain - Options - Write Header and Comments, Write Rev D Standard SVF File

The following table lists options -- Write Header and Comments, Write Rev D Standard SVF File -- for SVF JTAG chain deployment.

Table 92:

Device Family	Write Header and Comments		Write Rev D Standard SVF File	
Lattice Single Device	**On (Default)**	**Off**	**Off (Default)**	**On**
	Write headers and comments.	Omit header and comments.	Rev E Standard SVF. For Flash based FPGA's, Lattice Extended SVF.	Rev D Standard SVF.

SVF JTAG Chain - Options - Use RUNTEST from Rev C; For Erase, Program, and Verify Operations, Skip Verify

The following table lists options -- Use RUNTEST from Rev C; For Erase, Program, and Verify Operations, Skip Verify -- for SVF JTAG chain deployment.

Table 93:

Device Family	Use RUNTEST from Rev C		For Erase, Program, and Verify Operations, Skip Verify	
Lattice Single Device	**Off (Default)**	**On**	**Off (Default)**	**On**
	Standard RUNTEST.	Rev C RUNTEST.	Include verify in EPV operations.	Omit verify in EPV operations.

SVF JTAG Chain - Options - Include RESET at the End of the SVF File; Set Maximum Data Size per Row (Kbits)

The following table lists options -- Include RESET at the End of the SVF File; Set Maximum Data Size per Row (Kbits) -- for SVF JTAG Chain deployment

Table 94:

Device Family	Include RESET at the End of the SVF File		Set Maximum Data Size per Row (Kbits)	
Lattice Single Device	**Off (Default)**	**On**	**Off (Default)**	**On**
	Do not write RESET at the end of the SVF file.	Write RESET at the end of the SVF file.	-	64/8/16/32/128/256

STAPL Single Device - Device Family, Input File 1, and Output File

The following table lists device family, input file types, and output file extensions for STAPL single device deployment.

Table 95:

Device Family	Input File 1	Output File
Lattice Single Device.	JEDEC (.jed)	STAPL File (.stp)
	ISC Data (.isc)	

STAPL Single Device - Options - ACA Compression; Include Print Statements; For Erase, Program, and Verify Operations, Skip Verify

The following table lists options -- ACA Compression; Include Print Statements; For Erase, Program, and Verify Operations, Skip Verify -- for STAPL single device deployment.

Table 96:

Device Family	ACA Compression		Include Print Statements		For Erase, Program, and Verify Operations, Skip Verify	
Lattice Single Device	**On (Default)**	**Off**	**Off (Default)**	**On**	**Off (Default)**	**On**
	Compress data.	Uncompressed data.	Print statements as comments.	Include print statements.	Include verify in EPV operations.	Omit verify in EPV operations.

STAPL JTAG Chain - Device Family, Input File 1, and Output File

The following table lists device family, input file types, and output file extensions for STAPL JTAG chain deployment.

Table 97:

Device Family	Input File	Output File
Lattice Chain	XCF File (.xcf)	STAPL File (.stp)

STAPL JTAG Chain - Options - ACA Compression; Include Print Statements; For Erase, Program, and Verify Operations, Skip Verify

The following table lists options -- ACA Compression; Include Print Statements; For Erase, Program, and Verify Operations, Skip Verify -- for STAPL single device deployment.

Table 98:

Device Family	ACA Compression		Include Print Statements		For Erase, Program, and Verify Operations, Skip Verify	
Lattice Single Device	**On (Default)**	**Off**	**Off (Default)**	**On**	**Off (Default)**	**On**
	Compress data.	Uncompressed data.	Print statements as comments.	Include print statements.	Include verify in EPV operations.	Omit verify in EPV operations.

ATE - Device Family, Input File 1, and Output File

The following table lists device family, input file types, and output file extensions for ATE deployment.

Note

The HP3070 and HP3065 output files are Agilent Pattern Capture Format File (.pcf) format.

Table 99:

Device Family	Input File 1	Output File
Lattice Chain	XCF File (.xcf)	Generic Vector Format (.tst) GenRad (.gr) HP3070 (.pcf) HP3065 (.pcf) Teradyne 1800 (.asc) Teradyne L200/300 (.asc)

ATE - Options - Tester Type

The following table lists options -- Tester Type-- for ATE deployment.

Table 100:

Device Family	Operation
Lattice Chain	Generic Vector Format
	GenRad
	HP3070
	HP3065
	Teradyne 1800
	Teradyne L200/300

ATE - Options - ACA Compression; Include Print Statements; For Erase, Program, and Verify Operations, Skip Verify

The following table lists options -- Vector in ispDCD Format; For Erase, Program, and Verify Operations, Skip Verify; Header file -- for ATE deployment.

Table 101:

Device Family	Vector in ispDCD Format		For Erase, Program, and Verify Operations, Skip Verify		Header File (HP3070, HP3065, Teradyne 1800, and Teradyne L200/ 300 only)	
Lattice Chain	**Off (Default)**	**On**	**Off (Default)**	**On**	**Blank (Default)**	**User Selected Header File**
	Standard format.	ispDCD format.	Include verify in EVP operations.	Omit verify in EVP operations.	Use default header file.	User customer header file.

ATE - Options - Split File

The following table lists options -- Split File -- for ATE deployment.

Table 102:

Device Family	Split File							
Lattice Chain	**Off (Default)**	**On**	**Initialize Each Split File**		**Max Number of Vectors per File**		**Split File At (HP3070 and HP3065 only)**	
	No Split	Split	**Off (Default)**	**On**	**1000 (Default)**	**Enter Value from GUI**	**Active High (Default)**	**Active Low**
			Split without initialization.	Initialize each time after split.	1000 vectors per file.	Enter value from GUI.	Split at active high.	Split at active low.

See Also ▶"Input File Descriptions" on page 992

Embedded System Deployment Function Type

This topic provides tables that list device family, input file types, output file extensions, and options for Embedded System deployment function type.

JTAG Full VME Embedded -- Device Family, Input XCF Fle, and Output File

The following table lists device family, input file types, and output file extensions for JTAG Full VME embedded deployment

Table 103:

Device Family	Input XCF File	Output File
ECP5 LatticeECP3 LatticeECP2S/MS LatticeECP2/M LatticeEC/P LatticeSC/M Platform Manager Platform Manager 2 LatticeXP2 LatticeXP MachXO3D MachXO3L MachXO2 MachXO ispXPGA ORCA ispMACH4000 / ZE ispPAC-CLK5300 ispPAC-CLK5400 ispPAC-POWR605 ispPAC-POWR607 ispPAC-POWR6AT6 ispPAC-POWR1014 / A ispPAC-POWR1220AT8 Mature SVF	XCF File (.xcf) -Programmer Project file. XCF files can be used to save the setup of a Programmer Project. XCF files can either be loaded back into Programmer to work on a previous project or loaded into deployment tool for file conversions, generate a tester file, generate an embedded system file, or generate an external memory file.	VME File (.vme)

JTAG Full VME Embedded Options -- Compress VME File, Convert VME Files to HEX (c.) File-Based Embedded VME

The following table lists options -- Compress VME File, Convert VME Files to HEX (c.) File-Based Embedded VME -- for JTAG Full VME embedded deployment.

Table 104:

Device Family	Compress VME		Convert VME Files to HEX (c.) File-Based Embedded VME	
ECP5	**On (Default)**	**Off**	**Off (Default)**	**On**
LatticeECP3 LatticeECP2S/MS LatticeECP2/M LatticeEC/P LatticeSC/M Platform Manager Platform Manager 2 LatticeXP2 LatticeXP MachXO3D MachXO3L MachXO2 MachXO ispXPGA ORCA ispMACH4000 / ZE ispPAC-CLK5300 ispPAC-CLK5400 ispPAC-POWR605 ispPAC-POWR607 ispPAC-POWR6AT6 ispPAC-POWR1014 / A ispPAC-POWR1220AT8 Mature SVF	Compress data. This option reduces the file size of the VME file through compression, using less memory space. Unchecking this option generates an uncompressed VME, which is useful for debugging. Compressed and uncompressed VME have the same level of performance.	Uncompressed data.	By default this operation is turned off, this will create a VME file that will be used in file based embedded programming where the programming of the device is based on the input file. When this option is turned on then it will create a .c file which will be used in EPROM base programming to create a single complied image that will be loaded in to the CPU. An then the CPU will use this image to then program the device.	Generate Hex (.c) file.

JTAG Full VME Embedded Options -- Compact VME File, Fixed Pulse Width (Rev. D)

The following table lists options -- Compact VME File, Fixed Pulse Width (Rev. D) -- for JTAG Full VME embedded deployment.

Table 105:

Device Family	Compact VME File		Fixed Pulse Width (Rev. D)	
Platform Manager	**Off (Default)**	**On**	**Off (Default)**	**On**
Platform Manager 2 LatticeXP2 LatticeXP MachXO3D MachXO3L MachXO2 MachXOF	By default this operation is turned off. When this option is turned on it will split the VME data file into two different sections. An algorithm section and a data section. Whenever there is data needed in the algorithm section it will get it from the data section. This option is useful to turn on when the VME file is repeating the same operation even with different data. The operation will be in a loop and will reference the data section. This option will reduce the file size of the VME file.	Compact VME file.	By default this setting is off enabling looping (status polling algorithm) in the VME file. When it is turned on then there will be no looping (status polling algorithm) and instead commands in loops will be repeated for as many times as the loop iterated for. Status polling algorithm is a Lattice specific command in VME files, turning this option on makes the VME file generic and is useful when programming through a non-Lattice device, but increases file size.	Fixed Pulse Width VME file.

JTAG Full VME Embedded Options -- Verify USERCODE, Program Device if Fails

The following table lists options -- Verify USERCODE, Program Device if Fails -- for JTAG Full VME embedded deployment.

Table 106:

Device Family	Verify USERCODE, Program Device if Fails	
ECP5	**Off (Default)**	**On**
LatticeECP3	By default this operation is turn off and preforms the standard erase, program, verify flow. When this option is turned on then before attempting to program a device it will check to see if the USERCODE of the device is the same as the file to be programmed. If the USERCODEs are the same then that device will be skipped and will not be reprogrammed, otherwise if the USERCODEs do not match then the device will be programmed.	Verify USERCODE, Program device if USERCODE Verify Fails.

JTAG Full VME Embedded Options -- Include Header, Include Comment, Maximum Memory Allocation Size Per Row of Data (Kbytes)

The following table lists options -- Maximum Memory Allocation Size Per Row of Data (Kbytes) -- for JTAG Full VME embedded deployment.

Table 107:

Device Family	Include Header		Include Comment		Maximum Memory Aloocation Size Per Row of Data (Kbytes)
ECP5 LatticeECP3 LatticeECP2S/MS LatticeECP2/M LatticeEC/P LatticeSC/M Platform Manager Platform Manager 2 LatticeXP2 LatticeXP MachXO3D MachXO3L MachXO2 MachXO ispXPGA ORCA ispMACH4000 / ZE ispPAC-CLK5300 ispPAC-CLK5400 ispPAC-POWR605 ispPAC-POWR607 ispPAC-POWR6AT6 ispPAC-POWR1014 / A ispPAC-POWR1220AT8 Mature SVF	**Off (Default)**	**On**	**Off (Default)**	**On**	Set the Maximum buffer size. By default this size of the buffer is 64k, but if a system has a limitation on the max buffer size only being 16k then this option can be set to 16k to compensate for that limitation. Or if the system can support buffers of more than 64k than the setting can be increase to 128k or 256k. Valid values for this operation are 8, 16, 32, 64, 128, 256.
	By default the header is included in the VME file otherwise the header file is omitted from the VME file. The header contains information on the version and is useful in debugging. Turning the header off can be used to reduce the file size of the VME file size.	Omit header from VME file.	The default is off which does not include comments in the VME file, if turned on then comments will appear for the operations. Turning comments on is useful for debugging the VME file, but will increase file size.	Include comments in VME file.	

JTAG Slim VME Embedded -- Device Family, Input File 1, Output File 1, and Output File 2

The following table lists device family, input file types, and output file. extensions for JTAG Slim VME embedded deployment.

Table 108:

Device Family	Input File	Output File 1	Output File 2
Lattice Chain	XCF File (.xcf)	Algorithm VME File (*_algo.vme) - This is the algorithm file that specifies which operations will be executed must be used with a VME data file. This file is used in device programming or in field upgrading.	Data VME File (*_data.vme) - This is the data file that provides the data that the algorithm file will use to preforms executed operations must be used with a VME algorithm file. This file is used in device programming or in field upgrading.

JTAG Slim VME Embedded Options -- Compressed VME Data File, Convert VME files to HEX (c.) File-Based Embedded VME

The following table lists options -- Compressed Embedded Files, onvert VME files to HEX (c.) File-Based Embedded VME -- for JTAG Slim VME embedded deployment.

Table 109:

Device Family	Compress VME Data File		Convert VME files to HEX (c.) File-Based Embedded VME	
Lattice	**On (Default)**	**Off**	**Off (Default)**	**On**
	Compress data. This option reduces the file size of the VME file through compression, using less memory space. Unchecking this option generates an uncompressed VME, which is useful for debugging. Compressed and uncompressed VME have the same level of performance.	Do not compress.	By default this operation is turned off, this will create a VME file that will be used in file based embedded programming where the programming of the device is based on the input file. When this option is turned on then it will create a .c file which will be used in EPROM base programming to create a single complied image that will be loaded in to the CPU. An then the CPU will use this image to then program the device.	Generate Hex (.c) file.

Slave SPI Embedded -- Device Family, Input File 1, Output File 1, and Output File 2

The following table lists device family, input file types, and output file extensions for Slave SPI embedded deployment.

Table 110:

Device Family	Input File	Output File 1	Output File 2
MachXO3D ECP5 LatticeECP3 LIFMD	XCF File (.xcf) Bitstream (.bit)	Algorithm VME File (*_algo.vme) - This is the algorithm file that specifies which operations will be executed must be used with a VME data file. This file is used in device programming or in field upgrading.	Data File (*_data.sed)
LatticeXP2	XCF File (.xcf) JEDEC (.jed)		

Slave SPI Embedded Options -- Compress Embedded Files, Convert VME files to HEX (c.) File-Based Embedded VME

The following table lists options -- Compress Embedded Files, Convert VME files to HEX (c.) File-Based Embedded VME -- for Slave SPI embedded deployment.

Table 111:

Device Family	Convert VME files to HEX (c.) File-Based Embedded VME		Generate Hex (.c) File		Operation (.xcf and .jed files only)
MachXO3D ECP5 LatticeECP3 LatticeXP2 LIFMD	**On (Default)** By default this operation is turned off, this will create a VME file that will be used in file based embedded programming where the programming of the device is based on the input file. When this option is turned on then it will create a .c file which will be used in EPROM base programming to create a single complied image that will be loaded in to the CPU. An then the CPU will use this image to then program the device.	**Off** Do not compress	**Off (Default)** Do not generate Hex (.c) file	**On** Generate Hex (.c) file.	The list of options and operation is dependent on which device is selected.

I2C Embedded -- Device Family, Input File 1, Output File 1, and Output File 2

The following table lists device family, input file types, and output file extensions for I2C embedded deployment.

Table 112:

Device Family	Input File	Output File 1	Output File 2
MachXO2 MachXO3D MachXO3L Platform Manager 2	XCF File (.xcf) JEDEC (.jed)	Algorithm File (*_algo.sea)	Data File (*_data.sed)

I2C Embedded Options -- Compress Embedded Files, Convert VME files to HEX (c.) File-Based Embedded VME, Operation (.xcf and .jed files only), I2C Slave Address

The following table lists options -- Compress Embedded Files, Convert VME files to HEX (c.) File-Based Embedded VME, Operation (.xcf and .jed files only), I2C Slave Address -- for I2C embedded deployment.

Table 113:

Device Family	Compressed Embedded Files		Convert VME files to HEX (c.) File-Based Embedded VME		Operation (.jed files only)	I2C Slave Address
LIFMD MachXO2 MachXO3D MachXO3L Platform Manager 2	**On (Default)**	**Off**	**Off (Default)**	**On**	The list of options and operation is dependent on which device is selected.	Used to set the I2C Slave address. By default the value is 0b1000000. The user can modify this value if the value of the I2C Slave Address if there project calls for it.
	Compress embedded files.	Do not compress.	By default this operation is turned off, this will create a VME file that will be used in file based embedded programming where the programming of the device is based on the input file. When this option is turned on then it will create a .c file which will be used in EPROM base programming to create a single complied image that will be loaded in to the CPU. An then the CPU will use this image to then program the device.	Generate Hex (.c) file.		

I2C Embedded Options -- Include Comments

The following table lists options -- Include Comments for I2C embedded deployment.

Table 114:

Device Family	Include Comments	
LIFMD	**Off (Default)**	**On**
MachXO2 MachXO3D MachXO3L Platform Manager 2	The default is off which does not include comments in the VME file, if turned on then comments will appear for the operations. Turning comments on is useful for debugging the VME file, but will increase file size.	Include comments.

I2C Embedded Options -- Fixed Pulse Width

The following table lists options -- Fixed Pulse Width for I2C embedded deployment.

Table 115:

Device Family	Fixed Pulse Width	
MachXO2	**Off (Default)**	**On**
MachXO3D MachXO3L Platform Manager 2	By default this setting is off enabling looping (status polling algorithm) in the VME file. When it is turned on then there will be no looping (status polling algorithm) and instead commands in loops will be repeated for as many times as the loop iterated for. Status polling algorithm is a Lattice specific command in VME files, turning this option on makes the VME file generic and is useful when programming through a non-Lattice device, but increases file size.	Used fixed pulse width.

sysCONFIG (CPU) Embedded -- Device Family, Input File 1, Format, and Output File 1

The following table lists device family, input file types, and output file extensions for I2C embedded deployment

Table 116:

Device Family	Input File 1	Format	Output File
ECP5 LatticeECP3 LatticeECP2S/MS LatticeECP2/M LatticeEC/P LatticeXP ispXPGA	XCF File (.xcf)	Binary	Embedded Bitstream (.cpu)
		C-Code	Embedded Bitstream (.c)
		Intel Hex	Embedded Bitstream (.hex)
		Text (Debug Only)	Embedded Bitstream (.txt)

sysCONFIG (CPU) Embedded - Options - For Erase, Program, and Verify Operations, Skip Verify; Include Comments

The following table lists options -- For Erase, Program, and Verify Operations, Skip Verify; Include Comments -- for sysCONFIG (CPU) embedded deployment.

Table 117:

Device Family	For Erase, Program, and Verify Operations, Skip Verify		Include Comments	
ECP5 LatticeECP3 LatticeECP2S/MS LatticeECP2/M LatticeEC/P LatticeXP ispXPGA	**On (Default)**	**Off**	**Off (Default)**	**On**
	By default this option is turned on, leave this option on if the user wishes to not verify the CPU file programmed in. By turning this option off this will perform the Erase, Program, Verify operations which will reprogram the device and verify the contents of the device. If the user wants to verify that the Contents of CPU file they should turn this option off.	Include verify.	Include comments in CPU file.	Do not include comments in CPU file.

sysCONFIG (CPU) Embedded - Options - Compress Embedded Files, Byte Wide Bit Mirror

The following table lists options -- Compress Embedded Files, Byte Wide Bit Mirror -- for sysCONFIG (CPU) embedded deployment.

Table 118:

Device Family	Compress Embedded Files (Binary, C-code, and Intel Hex only)		Byte Wide Bit Mirror (Intel Hex and Text - Debug Only)	
ECP5	**On (Default)**	**Off**	**Off (Default)**	**On**
LatticeECP3 LatticeECP2S/MS LatticeECP2/M LatticeEC/P LatticeXP ispXPGA	By default the this operation is off. When this operation is off it includes comments in the CPU file, this is useful for debugging to see which operations are being performed. Turning this option off cause the CPU file to not include the comments. This is useful in reducing the file size if there is a memory constraint.	Do not compress.	By default this is turned off. When this is turned on each byte of data will be flipped. This can be used if the pin mapping on the device is the mirror of the Lattice devices, instead of remapping the pins the user can just select this option.	Flip each byte of data.

External Memory Deployment Type

This topic provides tables that list device family, input file types, output file extensions, and options for File Conversion deployment function type.

Hex Conversion

The following table lists device family, input file types, and output file extensions for each External Memory file type.

Table 119:

Device Family	Input File	Output File 1	Output File 2
ECP5 LatticeECP3 LatticeECP2S/MS LatticeECP2/M LatticeEC/P LatticeSC/M ORCA Unknown or Non-Lattice	Bitstream (.bit, .rbt)	Intel Hex	Hex (.mcs)
		Motorola Hex	Hex (.exo)
		Extended Tektronix Hex	Hex (.xtek)
LatticeXP2 LatticeXP LIFMD MachXO2 MachXO3D MachXO3L	JEDEC (.jed) Bitstream (.bit, .rbt)	Intel Hex	Hex (.mcs)
		Motorola Hex	Hex (.exo)
		Extended Tektronix Hex	Hex (.xtek)

Hex Conversion Options - Program Security Bit

The following table lists options -- Program Security Bit -- for Hex conversion deployment.

Table 120:

Device Family	Program Security Bit		
ECP5 LatticeECP3 LatticeECP2S/MS LatticeECP2/M LatticECP LatticeXP2 LatticeXP LIFMD	**Default (Default)**	**Off**	**On**
	Use setting from input file.	Do not program security fuses.	Program security fuses.

Hex Conversion Options - Encryption

The following table lists options -- Encryption-- for Hex conversion deployment.

Table 121:

Device Family	Encryption	
	Configuration Mode	**Encryption Key**
		Load from BEK File
MachXO3D ECP5 LatticeECP3 LatticeECP2S/MS	Selects the appropriate configuration mode for the bitstream encryption.	Load from BEK file.

Hex Conversion Options - Authentication

The following table lists options -- Encryption-- for Hex conversion deployment.

Table 122:

Device Family	Authentication
MachXO3D	**Public Key and Private Key or Signature Key**
	Load from GUI and load Public Key file (.pub) and Private File (.prv).

Hex Conversion Options -- Verify ID Code, Frequency, Compression

The following table lists options -- Verify ID Code, Frequency, and Compression-- for hex conversion deployment.

Figure 11:

Device Family	Verify ID Code			Frequency		Compression		
ECP5 MachXO2 MachXO3D MachXO3L	**Default (Default)**	**On**	**Off**	**Default (Deafault)**	**Frequency Selection**	**Default (Default)**	**On**	**Off**
	Use setting from input file.	Include verify ID in bitstream .	Do not verify ID code.	Use setting from input file.	Valid frequency device dependent.	Use setting from input file.	Compress bistream data.	Do not compress .

Figure 11:

Device Family	Verify ID Code			Frequency		Compression		
LatticeECP3, LatticeXP, LatticeXP2	Use setting from input file.	Include verify ID in bitstream .	Do not verify ID code.	Use setting from input file.	Valid frequency device dependent.	-	-	-
LatticeSC/M	-	-	-	-	-	Use setting from input file.	Compress bistream data.	Do not compress .

Hex Conversion Options -- CRC Calculation

The following table lists options -- CRC Calculation -- for hex conversion deployment.

Figure 12:

Device Family	CRC Calculation		
	Default (Default)	**On**	**Global CRC Only**
ECP5 LatticeECP2S/MS LatticeECP2/M LatticeXP2 LatticeXP MachXO2 MachXO3D MachXO3L	Use setting from input file.	Include CRC for each Data Frame.	Include Global CRC Only.

Hex Conversion Options -- Byte Wide Mirror

The following table lists options -- Byte Wide Mirror -- for hex conversion deployment.

Figure 13:

Device Family	Off (Default)	On
ECP5	No change to bit order.	No change to bit order.

Hex Conversion Options -- SPI Flash Read Mode and Starting Address (ECP5 only)

The following table lists options -- SPI Flash Read Mode and Starting Address -- for hex conversion deployment.

Figure 16:

Device Family	SPI Flash Mode		Starting Address	
ECP5	**Off (Default)**	**Fast Read**	**Off (Default)**	**Starting Address**
	Standard Read Opcode.	Fast Read Opcode.	No address offset.	Starting address in 0x010000 increments.

Dual Boot

The following table lists device family, input file types, format, and output file extensions for dual boot deployment

Table 123:

Device Family	Golden Pattern Input File 1	Primary Pattern Input File 2	Format	Output File
ECP5 LatticeECP3 LatticeECP2S/MS LatticeECP2/M LIFMD	Bitstream (.bit, .rbt)	Bitstream (.bit, .rbt)	Intel Hex	Hex (.mcs)
			Motorola Hex	Hex (.exo)
			Extended Tektronix Hex	Hex (.xtek)
MachXO2 Platform Manager 2	ASC File(s) (.hex)	-	Intel Hex	Hex (.mcs)
			Motorola Hex	Hex (.exo)
			Extended Tektronix Hex	Hex (.xtek)
MachXO3L MachXO3D		-	Intel Hex	Hex (.mcs)
			Motorola Hex	Hex (.exo)
			Extended Tektronix Hex	Hex (.xtek)

Dual Boot Options -- SPI Flash Size

The following table lists options -- SPI Flash Size -- for dual boot deployment.

Figure 17:

Device Family	SPI Flash Size
ECP5 LatticeECP3 LatticeECP2S/MS LatticeECP2/M LIFMD MachXO2 MachXO3D MachXO3L Platform Manager 2	1/2/4/8/16/32/64/128/256/513 (512 Mb)

Dual Boot Options -- Protect Golden Sector

The following table lists options -- Protect Golden Sector -- for dual boot deployment.

Table 124:

Device Family	Protect Golden Sector	
MachXO3D	**Off (Default)**	**On**
ECP5 LatticeECP3 LatticeECP2S/MS LatticeECP2/M	Locate golden in next available sector.	Locate Golden at the beginning of the upper half.

Dual Boot Options -- Bye Wide Mirror and Retain Bitsteam Header

The following table lists options -- Bye Wide Mirror and Retain Bitsteam Header -- for dual boot deployment.

Figure 18:

Device Family	Byte Wide Mirror		Retain Bitstream Header	
ECP5	**Off (Default)**	**On**	**Off (Default)**	**On**
LatticeECP3 LatticeECP2S/MS LatticeECP2/M MachXO2 MachXO3D MachXO3L Platform Manager 2	No change to bit order.	Flip each byte of data.	Replace Bitstream Header.	Retain Bitstream Header.

Dual Boot Options -- External ASC Devices

The following table lists options -- External ASC Devices-- for dual boot deployment.

Figure 19:

Device Family	External ASC Devices					
	Off (Default)	**On**				
			Number of External ASC Devices	**Select External ASC Data File 1**	**External ASC 2-6**	**Select Last External ASC Data File**
MachXO2	No External ASC.	External ASC.	1/2/3/4/5/6/7/8	Select External ASC Data File 1.	External ASC 2-7.	Select External ASC Data File 8.
Platform Manager 2	No External ASC.	External ASC.	1/2/3/4/5/6/7	Select External ASC Data File 1.	External ASC 2-6.	Select External ASC Data File 7.

Dual Boot Options -- SPI Flash Read Mode

The following table lists options -- SPI Flash Read Mode-- for dual boot deployment.

Figure 20:

Device Family	SPI Flash Mode			
ECP5	**Off (Default)**	**Fast Read**	**Dual I/O**	**Quad I/O**
	Standard Read Opcode.	Fast Read Opcode.	Dual I/O Read Opcode.	Quad I/O Read Opcode.

Dual Boot Options -- Optimize Memory Space

The following table lists options -- Optimize Memory Space -- for dual boot deployment.

Figure 21:

Device Family	SPI Flash Mode	
	Off (Default)	**On**
MachXO3D ECP5 LatticeECP3 LatticeECP2S/MS LatticeECP2/M LIFMD	Use worst case bitstream size.	Use file size.

Dual Boot Options -- Encryption

The following table lists options -- Encryption-- for dual boot deployment..

Table 125:

Device Family	Off (Default)	On
ECP5 LatticeECP3 LatticeECP2/MS LatticeECP2/M LatticeECP MachXO3D	Normal bitstream.	Primary encrypted bitstream.

Table 125:

Device Family	Off (Default)	On
LatticeXP2	Binary Bitstream	Bitstream (.bit)
LatticeXP	ASCII Bitstream	Bitstream (.rbt)
MachXO2	Intel Hex	Hex (.mcs)
	Motorola Hex	Hex (.exo)
	Extended Tektronix Hex	Hex (.xtek)

Dual Boot Options -- Authentication

The following table lists options -- Authentication-- for dual boot deployment.

Figure 22:

Device Family	Off (Default)	On
MachXO3D	Normal bitstream.	Primary authentication bitstream.

Advanced SPI Flash

The following table lists device family, input file types, format, and output file extensions for external SPI Flash deployment.

Table 126:

Device Family	Input File 1	Format	Output File
ECP5	Bitstream (.bit, .rbt)	Intel Hex	Hex (.mcs)
LatticeECP3		Motorola Hex	Hex (.exo)
LatticeECP2S/MS		Extended Tektronix Hex	Hex (.xtek)
LatticeECP2/M			
LatticeEC/P			
LatticeSC/M			
LIFMD			
MachXO2			
MachXO3D			
MachXO3L			

Advanced SPI Flash Options -- SPI Flash Size

The following table lists options -- SPI Flash Size -- for advanced SPI Flash deployment.

Figure 23:

Device Family	SPI Flash Size
ECP5 LatticeECP3 LatticeECP2S/MS LatticeECP2/M LatticeEC/P LatticeSC/M MachXO2 MachXO3D MachXO3L	512 (512Kb)/1/2/4/8/ 16/32/64/128/256/ 513 (512Mb)

Advanced SPI Flash Options -- Bye Wide Mirror

The following table lists options -- Bye Wide Mirror and Retain Bitsteam Header -- for advanced SPI Flash deployment.

Figure 24:

Device Family	Byte Wide Mirror	
ECP5 LatticeECP3 LatticeECP2S/MS LatticeECP2/M LatticeEC/P LatticeSC/M MachXO2 MachXO3L	**Off (Default)**	**On**
	No change to bit order.	Flip each byte of data.

Advanced SPI Flash Options -- Retain Bitstream Header

The following table lists options -- Bye Wide Mirror and Retain Bitsteam Header -- for advanced SPI Flash deployment.

Figure 25:

Device Family	Retain Bitstream Header	
ECP5	**Off (Default)**	**On**
LatticeECP3	Replace Bitstream Header.	Retain Bitstream Header.
LatticeECP2S/MS		
LatticeECP2/M		
LatticeEC/P		
LatticeSC/M		
MachXO2		
MachXO3D		
MachXO3L		

Advanced SPI Flash Options -- User Hex Files

The following table lists options -- User Hex Files-- for advanced SPI Flash deployment.

Figure 26:

Device Family								
ECP5	**Off (Default)**	**On**						
LatticeECP3								
LatticeECP2S/MS	Off	User data	**Number of User Hex Files**	**Select User Hex File 1**	**Select Starting Address 1**	**User Data 2-3**	**Select User Hex File 4**	**Select Starting Address 4**
LatticeECP2/M								
LatticeEC/P								
LatticeSC/M			1/2/3/4/5/6/7/8/9/10/11/12/13/14/15/16	Select User Hex File	0x010000 Sectors	User Data 2 - 3	Select User Hex File	0x010000 Sectors
MachXO2								
MachXO3D								
MachXO3L								

Advanced SPI Flash Options -- SPI Flash Read Mode

The following table lists options -- SPI Flash Read Mode -- for advanced SPI Flash deployment.

Figure 27:

Device Family				
ECP5 MachXO2 MachXO3D MachXO3L	**Off (Default)**	**Fast Reset**	**Dual I/O**	**Quad I/O**
	Off	Fast Read Opcode.	Dual I/O Read Opcode.	Quad I/O Read Opcode.

Advanced SPI Flash Options -- Multiple Boot

The following table lists options -- SPI Flash Read Mode-- for advanced SPI Flash deployment.

Figure 28:

Device Family	**Multiple Boot**												
ECP5 MachXO2 MachXO3D MachXO3L	**Off (Default)**	**On**										**Optimize Memory Space**	
	No Multiboot	Multiboot	**Number of Alternate Data Files**	**Select Golden Data File**	**Select Alternate Data File 1**	**Select Starting Address 1**	**Next Pattern**	**Alternates 2 - 3**	**Select Alternate Data File 4**	**Select Starting Address 4**	**Next Pattern**	**Off (Default)**	**On**
			1/2/3/4	Select Golden Data File.	Select Alternate Data File.	0x010000 Sectors.	<prim|alt1|alt2|alt3|alt4>.	Alternates 2 - 3.	Select Alternate Data File.	0x010000 Sectors.	<prim|alt1|alt2|alt3|alt4>.	Use worst case bitstream size.	Use file size.

sysCONFIG Daisy Chain

The following table lists device family, input file types, format, and output file extensions for sysCONFIG daisy chain deployment

Table 127:

Device Family	Input File 1	Input File 2	Format	Output File
ECP5 LatticeECP3 LatticeECP2S/MS LatticeECP2/M LatticeEC/P LatticeXP LatticeSC/M ORCA Unknown or Non-Lattice	Bitstream (.bit, .rbt)	Bitstream (.bit, .rbt)	Intel Hex	Hex (.mcs)
			Motorola Hex	Hex (.exo)
			Extended Tektronix Hex	Hex (.xtek)

sysCONFIG Daisy Chain Options -- Merge Format

The following table lists options -- Merge Format -- for sysCONFIG daisy chain deployment.

Table 128:

Device Family	Merge Format			
	Intelligent (Default)	Intelligent Merge		Combine
		Frequency	Slayer Output	
ECP5 LatticeECP3 LatticeECP2S/MS LatticeECP2/M LatticeECP	Intelligent Merge.	Default/(Device Specific Selections).	-	Combine Merge.
Lattice XP	Intelligent Merge.	-	-	Combine Merge.
LatticeSC/M ORCA	Intelligent Merge.	-	LatticeSC/M Output Pin.	Combine Merge.
Unknown or Non-Lattice	-	-	-	Combine Merge.

sysCONFIG Daisy Chain- Options - Byte Wide Bit Mirror and Retain Bitstream Header

The following table lists options -- Byte Wide Bit Mirror and Retain Bitstream Header -- for sysCONFIG Daisy Chain deployment.

Table 129:

Device Family	Byte Wide Bit Mirror		Retain Bitstream Header	
ECP5	**Off (Default)**	**On**	**Off (Default)**	**On**
LatticeECP3 LatticeEC/P LatticeXP LatticeSC/M ORCA	No change to bit order.	Flip each byte of data.	Replace Bitstream Header.	Retain Bitstream Header.
LatticeECP2S/MS LatticeECP2/M Unknown or Non-Lattice	No change to bit order.	Flip each byte of data.	-	-

See Also ▶Input File Descriptions

Input File Descriptions

The following table shows how files produced by Diamond (and ispLEVER for mature devices) and the Deployment Tool can be used as input files to generate other data file formats. For example, the Deployment Tool uses a binary bitstream generated by Diamond for a LatticeEC device to output an ISC file. This ISC file can then be used to generate a bitstream ASCII readback file.

The Deployment Tool can read customized bitstreams with various commands and options, such as CRC calculation and comparison.

Table 130:

Input File	Description	Output
.jed	Joint Electronic Design Engineering Council standard data file (JEDEC) generated from an ISC, BIT, or RBT	Bitstream, SVF, ISC, STAPL, Intel, Motorola, and Extended Tektronix Hex
.isc	In-System Configurable file (ISC) generated from a JEDEC, BIT, RBT, RBK, RBKA, MSK, or MSKA	Bitstream, SVF, JED, STAPL
.bit	Bitstream binary file (BIT) generated from a JEDEC (ispXPLD devices only), ISC, BIT, or RBT	Bitstream, ISC, JED, Intel, Motorola, and Extended Tektronix Hex

Table 130:

Input File	Description	Output
.rbt	Bitstream ASCII file (RBT) generated from a JEDEC (ispXPLD devices only), ISC, BIT, or RBT	Bitstream, ISC, JED, Intel, Motorola, and Extended Tektronix Hex
.rbk	Bitstream binary readback file (RBK) generated from an ISC when the READ option is selected for bitstream binary output.	ISC
.rbka	Bitstream ASCII readback file (RBKA) generated from an ISC when the READ option is selected for bitstream ASCII output.	ISC
.xcf	An .xcf file is a configuration file used by the Diamond Programmer and by ispVM System for programming devices in a JTAG daisy chain. The XCF file contains information about each device, the data files targeted, and the operations to be performed.	STAPL File (.stp), SVF File (.svf), Generic Vector Format (.tst), GenRad (.gr), HP3070 (.pcf), HP3065 (.pcf), Teradyne 1800 (.asc), Teradyne L200/ 300 (.asc), ME File (.vme), Data VME File (*_data.vme), Data File (*_data.sed), Embedded Bitstream (.cpu), Embedded Bitstream (.c), Embedded Bitstream (.txt), Embedded Bitstream (.hex)

See Also ▶"Input File Formats" on page 993

Input File Formats

The input file format used with the Deployment Tool depends on the device and the selected output format. The following table shows the data files for Lattice devices that can be used as input files to generate bitstream, serial vector format, or in-system configuration data files.

Table 131:

Input for Bitstream Output	Multiple Input/ Output	Input for SVF Output	Input for ISC Output	Input for JEDEC Output
LatticeECP/EC, LatticeECP2, LatticeECP3, LatticeSCM/SC, ECP5U/UM				
.bit, .rbt	.bit, .rbt	.bit, .rbt	Not available	Not available
LatticeXP				
.bit, .isc, .jed, .rbt	Not available	.jed	Not available	.bit, .rbt, .jed
MachXO, MachXO2				
Not available	Not available	.jed	Not available	Not available

Table 131:

Input for Bitstream Output	Multiple Input/ Output	Input for SVF Output	Input for ISC Output	Input for JEDEC Output
ORCA Series 2, 3, 4, ORCA FPSC				
.bit, .rbt	Not available	.bit, .rbt	Not available	Not available
ispXPGA				
.jed, .isc	.isc	.jed, .isc	.jed	.isc, .jed
ispXPLD				
.jed, .isc	.jed	.jed, .isc	.jed	.isc
CPLD				
Not available	Not available	.jed, .isc	.jed	.isc, .jed

See Also ▶"Input File Descriptions" on page 992

Bitstream Output File Descriptions

The output file format generated by the Deployment Tool depends on the device and the selected format options. To see a list of all the output formats by device family, see "Bitstream Output Formats" on page 995.

Table 132:

File Extension	Description
.bit	Binary bitstream.
.rbt	ASCII bitstream.
.msk	Binary bitstream mask file generated from an In-System Configurable (ISC) file when the READ_MASK option is selected for bitstream binary output.
.mska	ASCII bitstream mask file generated from an In-System Configurable (ISC) file when the READ_MASK option is selected for ASCII output.
.rbk	Binary readback bitstream file generated from an ISC file when the READ option is selected for binary output.
.rbka	ASCII readback bitstream file generated from an ISC file when the READ option is selected for ASCII output.
.exo	A Motorola hexadecimal output data file.
.mcs	An Intel hexadecimal output data file.
.xtek	An Extended Tektronix hexadecimal output data file.

Bitstream Output Formats

The Deployment Tool generates bitstream data files for the following Lattice device families: LatticeECP/EC, LatticeECP2 LatticeECP3, LatticeXP, and LatticeSCM/SC; ORCA Series 2, 3, 4; ORCA FPSC; ispXPGA; ispXPLD. The table below shows the types of bitstreams and output formats that can be generated for each of these families.

Table 133:

ECP5 LatticeECP/EC, LatticeECP2, LatticeECP3, LatticeXP, LatticeSCM/SC	**ORCA2, 3, 4, ORCA FPSC**	**ispXPGA**	**ispXPLD**
Single Bitstream

SVF, ISC, JEDEC, and STAPL Output Formats

The Deployment Tool generates Serial Vector Format (SVF), In-System Configuration (ISC), Joint Electronic Design Engineering Council (JEDEC), and Standard Test and Programming Language (STAPL) data files for Lattice devices.

SVF Output Files

SVF files are generated from JEDEC, ISC, binary bitstream (BIT), or ASCII bitstream (RBT) input files.

ISC Output Files

ISC files are generated from JEDEC, binary bitstream (BIT), ASCII bitstream (RBT), binary readback (RBK), ASCII readback (RBKA), binary mask (MSK), and ASCII mask (MSKA) input files.

JEDEC Output Files

JEDEC files are generated from ISC, BIT, and RBT input files.

STAPL Output Files

STAPL files are generated from JEDEC input files.

See Also ▶"Input File Descriptions" on page 992

Output Options Descriptions

The following describes each of the options provided by the Deployment Tool for outputting data files. The number and types of options depend on the type of device that you are programming and the output format. For options available by device type, refer to the device-specific options.

Verify ID Code – Generates the bitstream which verifies the ID code.

Program Secure – Generates the data file which secures the device.

Compression – Compresses the bitstream.

Frequency – Generates the bitstream using the specified frequency.

Byte Wide Bit Mirroring – Flips each byte in Intel, Extended Tektronix, and Motorola hexadecimal data files.

RUNTEST from REV C – Generates the serial vector format file using the format specified in the SVF file specification, revision C or earlier.

For Erase, Program, and Verify Operations, Skip Verify – Globally skips the verification step of the Erase, Program, and Verify operation.

Creating a New Deployment

Deployment Tool has a wizard interface that allows you step through the process of creating a deployment for the various function types and output file types.

To create a new Deployment:

1. Issue the start command.
   - In Linux, from the from the <*Programmer install path*>/bin/lin directory, enter the following on a command line:

     ```
     ./deployment
     ```
2. In the Getting Started dialog box, choose **Create a New Deployment.**
3. In the Function Type dropdown menu, choose from one of the following options:
   - File Conversion
   - Tester
   - Embedded System
   - External Memory
4. In the Output File Type box, choose an output file type.
5. Click **OK**. The Deployment Tool loads the device database.
6. If you are creating a deployment from an .xcf file, in the Step 1 of 4 dialog box, use the ... **(Browse)** button to browse to the project's .xcf file.

   If you are creating a deployment from a data file, in the Step 1 of 4 dialog box, select Input File(s) window, click **... (Browse)** in the File Name box. The Device Family and Device boxes are automatically populated by the Deployment Tool.
7. Click **Next**.
8. In the Step 2 of 4 Options dialog box, select the desired options for your output file type.
9. Click **Next**.
10. In the Step 3 of 4 Select Output File(s) dialog box, select the desired output file type from the dropdown menu, and using the using the ... button, browse to the desired location of the output file(s).
11. Click **Next**.
12. In the Step 4 of 4 Generate Deployment dialog box, review Deployment Tool Summary and Command Line Information.
13. Choose **File > Generate**, or click the button, to perform the Deployment. The Deployment Generate Result are available for review.
14. If you wish to save the deployment, choose **File > Save**, or click the button, to save the deployment (.ddt) file in your desired location.

- "Output Options Descriptions" on page 996
- "Bitstream Output Formats" on page 995
- "Bitstream Output File Descriptions" on page 994

Opening an Existing Deployment

If a deployment was saved as a deployment (.ddt) file, the deployment can be opened in Deployment Tool and regenerated using the same deployment options, or by applying different deployment options.

To open an existing deployment:

1. Issue the start command.
   - In Linux, from the from the <*install path*>/bin/lin directory, enter the following on a command line:

     ```
     ./deployment
     ```
2. In the Getting Started dialog box, choose **Open an Existing Deployment.**
3. Click **OK**. The Deployment Tool loads the device database.
4. If you are creating a deployment from a .ddt file, in the Step 1. of 4 dialog box, using the ... button, browse to the and select the project's .ddt file.

   If you are creating a deployment from a data file, in the Step 1. of 4 dialog box, select Input File(s) window, click **... (Browse)** in the File Name box. The Device Family and Device boxes are automatically populated by the Deployment Tool.
5. Click **Next**.
6. In the Step 2 of 4 Options dialog box, select the desired options for your output file type.
7. Click **Next**.
8. In the Step 3 of 4 Select Output File(s) dialog box, select the desired output file type from the dropdown menu, and using the using the ... button, browse to the desired location of the output file(s).
9. Click **Next**.
10. In the Step 4 of 4 Generate Deployment dialog box, review Deployment Tool Summary and Command Line Information.
11. Choose **File > Generate**, or click the  button, to perform the Deployment. The Deployment Generate Result are available for review.
12. If you wish to save the deployment, choose **File > Save**, or click the  button, to save the deployment (.ddt) file in your desired location.

Encrypting a JEDEC with Deployment Tool

Encryption settings are initially set in the Diamond software using the Security Setting Tool. Refer to “Setting Security Options” on page 75.

Deployment Tool allows you to encrypt an existing unencrypted JEDEC (.jed) file it has not already been encrypted, and output an encrypted .jed file.

Note

LatticeXP2 familyand MachXO3D family supports encrypted JEDEC files.

IMPORTANT!

To turn on this security feature, you need to install the Encryption Control Pack.

To encrypt an unencrypted .jed file with Deployment Tool:

1. Issue the start command.
   - In Linux, from the <*install_path*>/bin/lin directory, enter the following on a command line:

     ```
     ./deployment
     ```
2. In the Getting Started dialog box, choose **Create a New Deployment.**
3. In the Function Type dropdown menu, choose **File Conversion**.
4. In the Output File Type box, choose **JEDEC File**.
5. Click **OK**. The Deployment Tool loads the device database.
6. In the Step 1 of 4 dialog box, select Input File(s) window, click **... (Browse)** in the File Name box, and browse to and open the .bit, .isc., .jed, or .rbt file you wish to encrypt, click **Open**, then click **Next**.
7. In the Step 2 of 4 Options dialog box,click the **Encryption** box.
8. To edit the encryption key, click **Edit Key** to display the Encryption Key dialog box. Edit the encryption key as desired, or load an Encryption Key Format file (.bek or .BEK) from file, and click **OK**.

   Note

   If the encryption key was entered manually, you must save the key to a .BEK file.
9. Click **Next**.
10. In the Step 3 of 4 Select Output File(s) dialog box, select the desired output file type from the dropdown menu, and using the ... button, browse to the desired location of the output file(s).
11. Click **Next**.

12. In the Step 4 of 4 Generate Deployment dialog box, review Deployment Tool Summary and Command Line Information.
13. Choose **File > Generate**, or click the button, to perform the Deployment. The Deployment Generate Result are available for review.
14. If you wish to save the deployment, choose **File > Save**, or click the button, to save the deployment (.ddt) file in your desired location.

For more information about setting security options for Lattice FPGA devices, refer to the following Lattice Technical Notes:

- TN1212, LatticeXP2 Advanced Security Programming Usage Guide
- TN1215, Advanced Security Encryption Key Programming Guide for ECP5, LatticeECP3, and LatticeECP2/MS Devices

See Also "Setting Security Options" on page 75

- "Encrypting a Bitstream with Deployment Tool" on page 1000

Encrypting a Bitstream with Deployment Tool

Encryption settings are initially set in the the Diamond software using the Security Setting Tool. Refer to "Setting Security Options" on page 75.

Deployment Tool allows you to encrypt an existing unencrypted bitstream (.bit or .rbt) file if it was not already encrypted, and output an encrypted .bit file.

Note

Only the ECP5, LatticeECP2S/MS, MachXO3D, and LatticeECP3 devices support encrypted bitstreams.

IMPORTANT!

To turn on this security feature, you need to install the Encryption Security Control Pack.

To encrypt an unencrypted .bit or .rbt file with Deployment Tool:

1. Issue the start command.
   - In Linux, from the <*install_path*>/bin/lin directory, enter the following on a command line:

     ```
     ./deployment
     ```
2. In the Getting Started dialog box, choose **Create a New Deployment.**
3. In the Function Type dropdown menu, choose **File Conversion**.
4. In the Output File Type box, choose **Bitstream**.

5. Click **OK**. The Deployment Tool loads the device database.
6. In the Step 1 of 4 dialog box, select Input File(s) window, click **... (Browse)** in the File Name box, and browse to and open the .bit you wish to encrypt, then click **Next**.
7. In the Step 2 of 4 Options dialog box, select a USERCODE format (Hex, ASCII, or Binary) from the USERCODE Format drop-down list, then type alphanumeric values using up to 16 characters
   - For the default ASCII format, type alphanumeric values using up to 16 characters.
   - For hex format, type values of 0 through F, using up to 32 characters.
   - For binary format, type 0 and 1 values, using up to 128 characters.
8. Alternately, you can choose to overwrite USERCODE with JEDEC checksum by checking the box.
9. Click the **Encryption** box.
10. To edit the encryption key, click **Edit Key** to display the Encryption Key dialog box. Edit the encryption key as desired, or load an Encryption Key Format file (.bek or .BEK) from file, and click **OK**..

    Note

    If the encryption key was entered manually, you must save the key to a .BEK file.

11. Click **Next**.
12. In the Step 3 of 4 Select Output File(s) dialog box, select the desired output file type from the dropdown menu, and using the ... button, browse to the desired location of the output file(s).
13. Click **Next**.
14. In the Step 4 of 4 Generate Deployment dialog box, review Deployment Tool Summary and Command Line Information.
15. Choose **File > Generate**, or click the button, to perform the Deployment. The Deployment Generate Result are available for review.
16. If you wish to save the deployment, choose **File > Save**, or click the button, to save the deployment (.ddt) file in your desired location.

For more information about setting security options for Lattice FPGA devices, refer to the following Lattice Technical Notes:

- TN1212, LatticeXP2 Advanced Security Programming Usage Guide
- TN1215, Advanced Security Encryption Key Programming Guide for ECP5, LatticeECP3, and LatticeECP2/MS Devices

See Also ▶"Setting Security Options" on page 75

- "Encrypting a JEDEC with Deployment Tool" on page 999

Authenticating a Bitstream with Deployment Tool (MachXO3D Only)

Authentication settings are initially set in the Diamond software using the Security Setting Tool. Refer to "Setting Security Options" on page 75.

Deployment Tool allows you to convert an existing normal bitstream (.bit or .rbt) to an authentication output bitstream.

IMPORTANT!

To turn on this security feature, you need to install the Encryption Security Control Pack.

To convert a normal .bit or .rbt file to an authenticated output bitstream with Deployment Tool:

1. Issue the start command.
   - In Windows choose **Programs > Lattice Diamond > Accessories > Deployment Tool**.
   - In Linux, from the <*install_path*>/bin/lin directory, enter the following on a command line:

     ```
     ./deployment
     ```
2. In the Getting Started dialog box, choose **Create a New Deployment.**
3. In the Function Type dropdown menu, choose **File Conversion**.
4. In the Output File Type box, choose **Bitstream**.
5. Click **OK**. The Deployment Tool loads the device database.
6. In the Step 1 of 4 dialog box, select Input File(s) window, click **... (Browse)** in the File Name box, and browse to the file you wish to authenticate, then click **Next**.
7. In the Step 2 of 4 Options dialog box, select a USERCODE format (Hex, ASCII, or Binary) from the USERCODE Format drop-down list, then type alphanumeric values using up to 16 characters.
   - For the default ASCII format, type alphanumeric values using up to 16 characters.
   - For hex format, type values of 0 through F, using up to 32 characters.
   - For binary format, type 0 and 1 values, using up to 128 characters.
8. Alternately, you can choose to overwrite USERCODE with JEDEC checksum by checking the box.
9. Click the **Authentication** box.
10. To load the public key, under Public Key, click **Load,** and in the security_setting directory, browse to desired public key (.pub) file.
11. Depending on which type of authentication method was selected in the Security Setting tool:

- For Private Key, click **Load**, and in the security_setting directory, browse to desired Private Key (.prv) file. In the Encryption File Password dialog box, provide a password to open the file, and click **OK**.
- For ECDSA Signature, click **Load**, and in the security_setting directory, browse to desired Private Key (.prv) file. In the Encryption File Password dialog box, provide a password to open the file, and click **OK**.

12. Click **Next**.
13. In the Step 3 of 4 Select Output File(s) dialog box, select the desired output file type from the dropdown menu, and using the ... button, browse to the desired location of the output file(s).
14. Click **Next**.
15. In the Step 4 of 4 Generate Deployment dialog box, review Deployment Tool Summary and Command Line Information.
16. Choose **File > Generate**, or click the button, to perform the Deployment. The Deployment Generate Result are available for review.
17. If you wish to save the deployment, choose **File > Save**, or click the button, to save the deployment (.ddt) file in your desired location.

See Also ▶"Setting Security Options" on page 75

Opening an Existing Deployment While Running the Deployment Tool

You can open a different existing deployment while running the Deployment Tool, and save the deployment you are currently working on.

To open an existing deployment while running the Deployment Tool:

1. Choose **File > Open**, or click the button, and browse to the deployment (.ddt) file that you wish to open.
2. Deployment Tool prompts you to save the .ddt file for the project you are currently working on. If you wish to save the deployment you are currently working on, click **Yes**, and in the Save As dialog box, create a name for the .ddt file and save in the desired location.
3. In the Open dialog box, choose the .ddt file you wish to open.
4. Click **Open**.

See Also ▶"Creating a New Deployment" on page 996

- "Input File Descriptions" on page 992
- "Output Options Descriptions" on page 996
- "Bitstream Output Formats" on page 995

- “Bitstream Output File Descriptions” on page 994

Creating a New Deployment While Running the Deployment Tool

You can create a new deployment while running the Deployment Tool.

To create a new deployment while running the Deployment Tool:

1. Choose **File > New**, or click the  button.
2. Deployment Tool prompts you to save the .ddt file for the project you are currently working on. If you wish to save the deployment you are currently working on, click **Yes**, and in the Save As dialog box, create a name for the .ddt file and save in the desired location.
3. In the Getting Started dialog box, choose **Create a New Deployment.**
4. In the Function Type dropdown menu, choose from one of the following options:
   - File Conversion
   - Tester
   - Embedded System
   - External Memory
5. In the Output File Type box, choose an output file type.
6. Click **OK**. The Deployment Tool loads the device database.

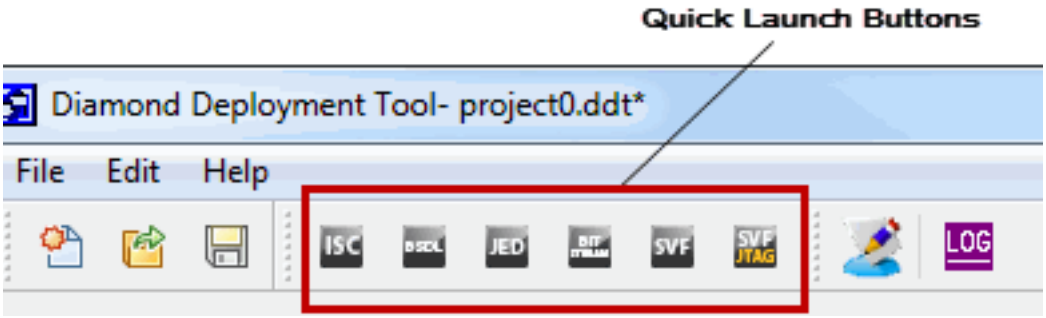
See Also ▶“Creating a New Deployment” on page 996

- “Using Quick Launch Button to Create a New Deployment” on page 1004
- “Input File Descriptions” on page 992
- “Output Options Descriptions” on page 996
- “Bitstream Output Formats” on page 995
- “Bitstream Output File Descriptions” on page 994

Using Quick Launch Button to Create a New Deployment

Quick launch buttons allow you to create a new Deployment while running the Deployment Tool without having to use the Getting Started dialog box. The toolbar supports up to six quick launch buttons.

You can customize which quick launch buttons appear in the toolbar. Choices of quick launch buttons include:



- IEEE 1532 ISC Data File
- Application Specific BSDL File
- JEDEC File
- Bitstream
- SVF - Single Device
- SVF - JTAG Chain
- STAPL - Single Device
- STAPL - JTAG Chain
- ATE
- JTAG Full VME Embedded
- JTAG Slim VME Embedded
- Slave SPI Embedded
- I2C Embedded
- sysCONFIG Embedded
- Hex Conversion
- Dual Boot
- Advanced SPI Flash
- sysCONFIG Daisy Chain

To customize which quick launch buttons appear in the Deployment Tool toolbar:

1. Place cursor in the toolbar, and right-click.
2. In the drop-down menu, check the box of the quick start button that you want to display in the toolbar. A maximum of six buttons may be selected.

See Also ▶"Creating a New Deployment" on page 996

- "Creating a New Deployment While Running the Deployment Tool" on page 1004

- "Bitstream Output File Descriptions" on page 994

Viewing the Deployment Tool Log File

The log file shows recent actions in a text editor.

To view the log file:

Click  button on the toolbar.

See Also "Deploying the Design with the Deployment Tool" on page 951

Changing the Deployment Tool Log File Settings

The log file shows recent actions in a text editor. You can change settings to clear log file path each time the application starts, and you can also change where the log file is saved.

To change where the log file is saved:

1. Choose **Edit > Settings**.
2. In the Settings dialog box, browse to the folder where you wish to save the deployment_tool.log file.

To clear log file each time the application starts:

1. Choose **Edit > Settings**.
2. In the Settings dialog box, check the **Clear Log File Each Time Application Starts** box.

If the **Clear Log File Each Time Application Starts** box is unchecked, the log file will continue increase in size until the file is manually erased.

See Also "Deploying the Design with the Deployment Tool" on page 951

Debugging SVF, STAPL, and VME Files

Download Debugger is a stand-alone software tool for debugging Serial Vector Format (SVF) files, Standard Test And Programming Language (STAPL) files, and Lattice Embedded (VME) files. Download Debugger allows you to program a device, and edit, debug, and trace the process of SVF, STAPL, and VME files.

Download Debugger also allows you to create, edit, or view a VME file in hexadecimal format.

This section provides procedures for using Download Debugger. Topics include:

▶ “Setting Windows Options in Download Debugger” on page 1018

Understanding SVF Files

The Serial Vector Format file (.svf) is the medium for exchanging descriptions of high-level 1149.1 bus operations. The SVF file is defined as an ASCII file that consists of a set of SVF statements. The 1149.1 bus operations consist of scan operations and movements between deferent stable states. Refer to the Serial Vector Format Specification Rev E for detailed definitions of SVF statement formats. Current SVF specifications are available from Asset-Intertech website at www.asset-intertech.com.

See Also “Debugging SVF, STAPL, and VME Files” on page 1007

Download Debugger Software Support of SVF Operations

The Download Debugger supports a selective set of SVF operations. The following table lists SVF operations supported by the Download Debugger.

SVF Operation	Description	Support Status
ENDDR	Specifies default end state for DR scan operations.	Full support
ENDIR	Specifies default end state for IR scan operations.	Full support
HDR	(Header Data Register) Specifies a header pattern, which is placed at the beginning of subsequent DR, scan operations.	Supports TDI keyword only. SMASK, TDO and MASK are not supported.
HIR	(Header Instruction Register) Specifies a header pattern, which is placed at the beginning of subsequent IR, scan operations.	Supports TDI keyword only. SMASK, TDO and MASK are not supported.
RUNTEST	Forces the 1149.1 bus to the RUN_TEST/IDLE state for a specified number of clocks.	Full support
SDR	(Scan data register) Performs an 1149.1 data register scan.	Supports TDI, TDO, and MASK keywords. SMASK is ignored.
SIR	(Scan Instruction Register) Performs an 1149.1 instruction register scan.	Supports TDI, TDO, and MASK keywords. SMASK is ignored.
STATE	Forces the 1149.1 bus to a specified stable state.	Supports only single target state. The Download Debugger does not allow you to specify custom traverse path.

SVF Operation	Description	Support Status
TDR	(Trailer Data Register) Specifies a trailer pattern, which is appended to the end of subsequent DR scan operations.	Supports TDI keyword only. SMASK, TDO, and MASK are not supported.
TIR	(Trailer Data Register) Specifies a trailer pattern which is appended to the end of subsequent IR scan operations	Supports TDI keyword only. SMASK, TDO, and MASK are not supported.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Running Download Debugger

Download Debugger runs separately from the Diamond software environment.

To start the Download Debugger:

1. Issue the start command.
   - In Windows choose **Programs > Lattice Diamond > Accessories > Download Debugger**.
   - In Linux, from the <*install_path*>/bin/lin directory, enter the following on a command line:

     ```
     ./debugger
     ```

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Opening an Existing SVF File

The Download Debugger Edit Window allows you to perform various editing functions on your SVF file. You can check the SVF file for errors line by line when you program your device.

To open an existing SVF file:

1. In Download Debugger, choose **File > Open** to open the dialog box.
2. Locate and select the desired SVF file, and then click **Open**.

   The selected SVF file opens in the Download Debugger Edit Window.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Creating a New SVF File

To create a new empty SVF file:

- In Download Debugger, choose **File > New** to open the SVF Debugger Edit Window and create a new empty SVF file. The Options Dialog Box also opens.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Setting Device Programming Options in Download Debugger

To set SVF options:

1. In Download Debugger, choose **Configuration > Options**.

   The "Options Dialog Box" on page 1019 opens.

2. Select the options that you want and click **OK**.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Setting Port Assignments and Options in Download Debugger

Use the "Cable and I/O Port Settings Dialog Box" on page 1018 to specify the preferred parallel port for download, select the port address, and select the download cable type.

To set port assignments and options:

1. In Download Debugger, choose **Configuration > Cable and I/O Port Setup**.

   The "Cable and I/O Port Settings Dialog Box" on page 1018 opens.

2. Select the options that you want and click **OK**.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Viewing SVF Processing

To view the progress of SVF processing, you need to open the Output dialog box before processing the SVF file.

To view the progress of SVF processing:

- In Download Debugger, choose **Configuration > SVF Output** before processing the SVF file.

  The Output Dialog Box opens, displaying the programming pin values, clock pulses, data register, and JTAG state. Keep the dialog box open. The display will be refreshed in real time during SVF processing.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Setting and Removing Breakpoints in an SVF File

By using the Download Debugger, you can set a breakpoint in your SVF file before processing it. The process stops at the line that you specify, and a dialog box notifies you that the breakpoint has been reached. After clicking OK in the dialog box, you can resume the process.

To set a breakpoint in an SVF File:

1. Select a line in your SVF file.
2. Choose **Command > Breakpoint > Set Breakpoint**.

To select the next breakpoint:

1. Select a line in your SVF file.
2. Choose **Command > Breakpoint > Next Breakpoint**.

To select the previous breakpoint:

1. Select a line in your SVF file.
2. Choose **Command > Breakpoint > Previous Breakpoint**.

To clear all breakpoints:

1. In your SVF file, select the breakpoint you want to remove.
2. Choose **Command > Breakpoint > Clear All Breakpoints**.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Processing an SVF File

After setting device programming options and port assignments, you can process your SVF file with the Download Debugger and examine it in the SVF Output box. You can program a device with a download cable, step through each line of the process, reset it and begin again.

Note

To view the SVF Output box, you must choose Configuration > SVF Output before processing the SVF file.

To process an SVF file:

- Choose **Command > Go**.

To step through a process, line by line:

- Choose **Command > Step**.

  The process will step through the SVF file line by line.

To step the state machine and toggle the programming signal:

1. Choose **Command > Mini Step**.
2. In the Manual TAP Operations Dialog Box, select state path as you wish, and step through the TAP controller.

To reset a process and start a process from the beginning:

- Choose **Command > Reset**.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Viewing the Download Debugger Log File

The Download Debugger generates a log file of the process and reports any errors encountered. When you select **Continue on Error** in the "Options Dialog Box" on page 1019, the log file also reports state machine transitions and delay time for debug.

To view a log file:

- In Download Debugger, choose **View > View Log File**.

  The log file is displayed in a text editor.

See Also "Clearing the Contents of a Log File in Download Debugger" on page 1013

- "Debugging SVF, STAPL, and VME Files" on page 1007

Saving a Log File in Download Debugger

To save a log file:

1. In Download Debugger, choose **Configuration > Options**.
2. The "Options Dialog Box" on page 1019 opens.
3. Specify the path to the directory that you wish to save your log file. You can use the Browse button to navigate to the directory where you would like to save the log file.
4. Click **OK**.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Clearing the Contents of a Log File in Download Debugger

To clear the contents of the log file:

- In Download Debugger, choose **Edit > Clear Log File**.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Editing an SVF File

Use the Edit menu commands in the Download Debugger to edit an SVF file.

To edit an SVF file:

1. In Download Debugger, select a line in your SVF file.
2. Make the edits using commands in the Edit menu, and click **File > Save**.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Setting Windows Options in Download Debugger

Use the Windows options to change the way the Download Debugger software is displayed.

To cascade open windows:

- Choose **Window > Cascade**.

To tile open windows:

- Choose **Window > Tile**.

To arrange minimized open windows:

- Choose **Window > Arrange Icons**.

  Minimized open windows in Download Debugger will be arranged along the bottom of your computer screen.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Opening an Existing STAPL File

The Download Debugger allows you to perform various editing functions on your STAPL file. You can check the STAPL file for errors line by line when you program your device.

To open an existing STAPL file:

1. In Download Debugger, choose **File > Open** to open the dialog box.
2. Locate and select the desired STAPL (.stp or .jam) file, and then click **Open**.

   The selected STAPL file opens in the Download Debugger.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Creating a New STAPL File

To create a new empty STAPL file:

- In Download Debugger, choose **File > New**.

  A blank edit window opens. You can start entering contents for your new STAPL file, and save the file when you finish.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Viewing STAPL Processing

To view the output information during STAPL processing, you should open the Output Information dialog box before processing the STAPL file.

To view the progress of STAPL processing:

- In Download Debugger, choose **Configuration > STAPL Output** before processing the STAPL file.

The Output Information Dialog Box opens, displaying the programming pin values, clock pulses, data register, JTAG state, and variables values. Keep the dialog box open. The display will be refreshed in real time during STAPL processing.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Setting and Removing Breakpoints in a STAPL File

By using the Download Debugger, you can set a breakpoint in your STAPL file before processing it. The process stops at the line that you specify, and a dialog box notifies you that the breakpoint has been reached. After clicking OK in the dialog box, you can resume the process.

To set a breakpoint in a STAPL file:

1. Select a line in your STAPL file.
2. Choose **Command > Breakpoint > Set Breakpoint**.

To select the next breakpoint:

1. Select a line in your STAPL file.
2. Choose **Command > Breakpoint > Next Breakpoint**.

To select the previous breakpoint:

1. Select a line in your STAPL file.
2. Choose **Command > Breakpoint > Previous Breakpoint**.

To clear all breakpoints:

1. In your STAPL file, select the breakpoint you want to remove.
2. Choose **Command > Breakpoint > Clear All Breakpoints**.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Processing a STAPL File in Download Debugger

After setting device programming options and port assignments, you can process your STAPL file with the Download Debugger and examine the progress in the Output Information dialog box.You can program a device with a download cable, step through each line of the process, reset it and begin again.

Note

To view the Output Information dialog box, you must choose **Configuration > STAPL Output** before processing the STAPL file.

To process a STAPL file:

- Choose **Command > Go**.

To step through a process, line by line:

- Choose **Command > Step**.

  The process will step through the STAPL file line by line.

To step the state machine and toggle the programming signal:

1. Choose **Command > Mini Step**.
2. In the Manual TAP Operations Dialog Box, select state path as you like, and step through the TAP controller.

To reset a process and start a process from the beginning:

- Choose **Command > Reset**.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Viewing the Download Debugger Log File

The Download Debugger generates a log file that tracks the process and reports any errors encountered. The log file contains all the information displayed in the Status window and also the status of the cable. When you select **Continue on Verification Failure** in the "Options Dialog Box" on page 1019, the log file also reports state machine transitions and delay time for debug.

To view a log file:

- In Download Debugger, choose **View > View Log File**.

  The log file is displayed in a text editor.

See Also “Saving a Log File in Download Debugger” on page 1013

- “Clearing the Contents of a Log File in Download Debugger” on page 1017
- “Debugging SVF, STAPL, and VME Files” on page 1007

Saving a Log File in Download Debugger

To save a log file:

1. In Download Debugger, choose **Configuration > Options**.

   The “Options Dialog Box” on page 1019 opens.
2. Specify the path to the directory that you want to save your log file. You can use the Browse button to navigate to that directory.
3. Click **OK**.

See Also “Debugging SVF, STAPL, and VME Files” on page 1007

Clearing the Contents of a Log File in Download Debugger

To clear the contents of the log file:

- In Download Debugger, choose **Edit > Clear Log File**.

See Also “Debugging SVF, STAPL, and VME Files” on page 1007

Editing a STAPL File

Use the Edit menu commands in the Download Debugger to edit a STAPL file.

To edit a STAPL file:

1. In Download Debugger, select a line in your STAPL file.
2. Make the edits using commands in the Edit menu, and click **File > Save**.

See Also “Debugging SVF, STAPL, and VME Files” on page 1007

Setting Windows Options in Download Debugger

Use the Windows options to change the way how multiple windows are displayed in Download Debugger.

To cascade open windows:

- Choose **Window > Cascade**.

To tile open windows:

- Choose **Window > Tile**.

To arrange minimized open windows:

- Choose **Window > Arrange Icons**.

  Minimized open windows in Download Debugger will be arranged along the bottom of your computer screen.

See Also "Debugging SVF, STAPL, and VME Files" on page 1007

Download Debugger Options

This section lists the options available in Download Debugger.

Topics include:

Cable and I/O Port Settings Dialog Box

The following options are available in the Cable and I/O Port Settings dialog box.

Cable Description This option is displayed when multiple cables are detected. When enabled, this option allows you to select the desired cable.

Cable Specifies the download cable type: Lattice (parallel port), USB (LSC USB cable), or USB2 (FTDI USB2 cable)

Port Specifies the port to which the download cable is connected.

Custom Port Specifies a custom parallel port to which the download cable is connected. Use hexadecimal format to type the port name.

Using Slave SPI Interface Connection This option allows you to target the slave SPI port of the selected device. This allows you to debug slave SPI device programming

Use Default I/O Settings Only use the four JTAG signals.

Use Custom I/O Settings .Specify additional non-JTAG signals connected to the board.

INITN Pin Connected Select this option if you connect the INIT pin to the download cable. This option is only available with the ispDOWNLOAD USB cable.

DONE Pin Connected Select this option if you connect the DONE pin to the download cable. This option is only available with the ispDOWNLOAD USB cable.

TRST Pin Connected Select this option if you connect the TRST pin to the download cable. Specify active high or active low.

PROGRAM Pin Connected Select this option if you connect the PROGRAMN pin to the download cable.

ispEN Pin Connected Select this option if you connect the ispEN pin to the download cable. Specify active high or active low.

See Also "Download Debugger Options" on page 1018

Options Dialog Box

The following options are available in the Options dialog box.

Log Allows you to specify name and location of log file.

Clear Log File Each Time Start Application A Check to clear the log file each time Download Debugger is started.

Source Editor Allows you to specify font, size, tab size, of Source Editor.

Show The Number Toggles display of line numbers in left margin of Source Editor.

Show Indicator Margin Toggles display of indicator margin in left side of Source Editor.

Disable SVF Syntax Checker Disables the tool that checks the syntax of the SVF file.

Ignore IR and DR Header Trailer in SVF Ignores the HIR, TIR, HDR, and TDR information in SVF file. If you set up HIR, TIR, HDR, or TDR in this dialog box, this option must be selected.

Continue on Error Continues processing the file even if there is an error. You can look at the log file for the errors encountered. When this option is selected, the log file also reports state machine transitions and delay time for debug.

Mixed Chain Tells the Download Debugger that the hardware configuration is a mixed chain, therefore disabling the ISP chain when processing the SVF file.

SVF TCK Frequency Specifies the TCK clock frequency for the chosen SVF file. This value is used to determine the TCK clock period and the length of the delay times.

SVF Vendor Allows you select from the following SVF vendors for the selected device: JTAG STANDARD, LATTICE, ALTERA, and XILINX. This option is available for JTAG devices only.

Instruction Register Header Sets the IR header length in number of bits (0-100).

Instruction Register Trailer Sets the IR trailer length in number of bits (0-100).

Data Register Header Sets the HDR in number of bits (0-100).

Data Register Trailer Sets the TDR in number of bits (0-100).

Ignore IR and DR Header Trailer in STAPL Ignores the HIR, TIR, HDR and TDR information in STAPL file. If you set up HIR, TIR, HDR, or TDR in this dialog box, this option must be selected.

Starting TAP State Select the starting JTAG state of the JTAG State Machine for download. Only two states are available: TLR (Test-Logic-Reset) and RTI (Run-Test/Idle).

See Also “Download Debugger Options” on page 1018

Using the Model 300 Programmer

The Model 300 Programmer is a simple engineering device programmer that allows you to perform single-device programming directly from a PC or Linux environment. The Model 300 Programmer software and hardware support all JTAG devices produced by Lattice, with device Vcc of 1.8, 2.5, 3.3, and 5.0V.

Programming Software Support

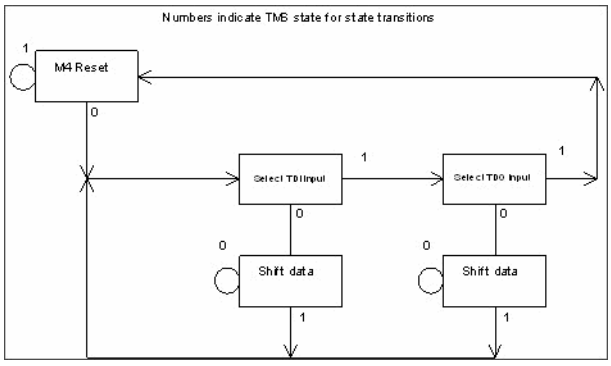
The Model 300 Programmer software controls the programming process. When you select a device, the programming adapter configuration and the correct device Vcc is automatically set up. LEDs indicate the power status and the selected Vcc level.

Software Control

The Model 300 programmer is controlled by the TRST, ENABLE (ispEN), TMS, TDI, and TCK signals from the download cable. When in normal operation mode, the Model 300 programmer controls IC channels TMS, TDI, TCK, and TDO to/from the programming adapter socket. TRST and ENABLE control the programmer's operation mode.

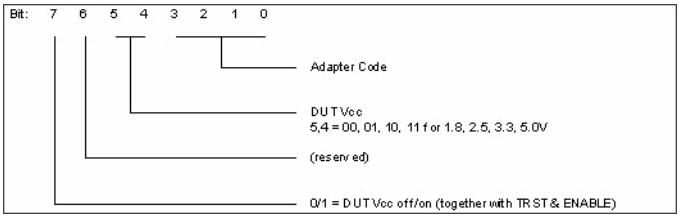
TRST	ENABLE	Description
0	0	DUT is target of JTAG signals, DUT Vcc is off
0	1	DUT is target of JTAG signals, DUT Vcc is on if Control Bit 7 = 1
1	0	Control IC TAP is target of JTAG signals, DUT Vcc is off
1	1	Control IC State Machine is target of JTAG signals, DUT Vcc is off when State Machine is not in M4 Reset state

When TRST and ENABLE are high and LOCAL is Off, JTAG signals interact with the State Machine programmed into the M4A5-64/32 Control IC. Use this State Machine to write or read Control Register bits for routing the JTAG signals to the appropriate pins for the selected adapter and for controlling DUT Vcc.



When TDI input is selected, data is shifted into the State Machine from TDI, to write new data into the Control Register. When TDO input is selected, data is rotated through the Control Register to read it out on TDO. It must be shifted eight times to return the Control Register to its original pattern.

Control Register



Valid Adapter Code values are 0000, 0001, 0010, 0011, 0100, and 1100.

Device Support

All Lattice products that feature non-volatile configuration elements are supported. This includes devices with a VCC of 1.2V, 1.8V, 2.5V, 3.3V and 5V.

Socket Support

Individual devices are supported via device/package-specific socket adapters, which interface to the 28-pin DIP on the Model 300. For a complete list of supported devices and socket adapters, see the Socket Adapter list on the Lattice web site.

Connector Support

The interface connection from the controlling PC is through a 10-pin JTAG connector on the Model 300. This is the standard configuration for Lattice's ispDOWNLOAD 10-pin JTAG connector cable.

Power Supply Support

The Model 300 programmer requires 9V DC at 1A minimum, to provide power for the programmer itself and for programming the target device. A 9V power adapter is included with each kit. This power adapter accepts 110V to 220V inputs, and includes interchangeable physical plugs for use worldwide.

Setting Up the Hardware

Before you can use the Model 300 programmer, you must connect a download cable to your PC and insert the socket adapter.

To set up your Model 300 programmer:

1. Turn on and boot up the PC, if you have not already done so.
2. With the Model 300 programmer in the power off position, connect the download cable between the PC parallel port and the Model 300 programmer.
3. Connect the power supply to a properly grounded AC outlet and to the AC plug at the rear of the Model 300 programmer.
4. Make sure that the PC has booted up completely, and then turn on the Model 300 programmer.
5. Place the device in the programming adapter socket. The 1.8V and PWRRDY LED indicators illuminate, indicating that the Model 300 is ready for programming.

- “Checking the Model 300 Project” on page 1029
- “Model 300 Options” on page 1030

Running the Model 300 Software

To run the Model 300 programmer:

1. Make sure that the Model 300 programmer is turned on and connected to the PC by the appropriate download cable.

2. Issue the start command.

   - In Windows choose **Programs > Lattice Diamond > Accessories > Model 300 Programmer**.
   - In Linux, from the <*install_path*>/bin/lin directory, enter the following on a command line:

     ```
     ./model300
     ```

   The Model 300 Programmer Window opens.

Programming a Device

To program a device:

1. If you are using a 28-pin socket adapter, insert the socket adapter into the 40-pin ZIF socket of the Model 300. Make sure that the socket adapter is bottom-justified.

   Note

   If the socket adapter is not bottom-justified, Model 300 will not read or program the device.

   If you are using a Lattice socket adapter board, insert the socket adapter board pins into the appropriate connector on both sides of the 40-pin ZIF socket of the Model 300. Make sure that all of the pins are installed correctly.
2. Using proper ESD handling procedures, place the device in the programming adapter socket and ensure the correct alignment of the device.
3. In the Model 300 main window, select the appropriate device, device family, package, Model 300 adapter, and Operation.
4. Under File Name, browse select the required data file.

5. Choose **Design > Program, or** click  on the toolbar, to download the program to the device.

   The Vcc ON indicator on the Model 300 Programmer turns red during the download process. It turns off when the operation is completed. The Output Pane of the Model 300 software indicates the progress of the operation and reports any errors. A green "Pass" message in the Status field shows whether the operation was successful.

6. When the process has finished, remove the device from the adapter socket and, optionally, turn off the Model 300 Programmer.

Programming a JTAG-SVF or JTAG-NOP Device

You can program any JTAG-SVF or JTAG-NOP with the Model 300 Programmer and software.

To program a JTAG-SVF or JTAG NOP device:

1. Make sure that the 28-pin socket adapter has been correctly inserted into the Model 300 Programmer and that the device has been placed into the adapter socket with the correct alignment.
2. In the Model 300 main window, under Device Family, select **Generic JTAG Device**.
3. Under Device, select **JTAG-SVF** or **JTAG-NOP**.
4. Select the appropriate device package, Model 300 adapter, and Operation.
5. Under File Name, browse select the required SVF file.
6. Choose **Design > Program**, or click  , to download the program to the device.

The Vcc ON indicator on the Model 300 Programmer turns red during the download process. It turns off when the operation is completed. The Output Pane of the Model 300 software indicates the progress of the operation and reports any errors. A green "Pass" message in the Status field shows whether the operation was successful.

When the process has finished, remove the device from the adapter socket and, optionally, turn off the Model 300 Programmer.

Saving a Model 300 Project

When you set up a Model 300 project for programming, you can save the Model 300 project as a .job file.

To save a Model 300 project:

1. Choose **File > Save Untitled**, or click  , and in the Save Model 300 File As dialog box, navigate to the desired directory.
2. Type a name in the file name box and click Save. The information entered in your project is saved in the .job file.

Editing Device Properties

To edit device properties:

1. In the Model 300 software main window, select the device that you want to edit.
2. Choose **Edit > Device Properties**, click  on the toolbar, or right-click and choose **Device Properties**.
3. In the Device Properties Dialog Box, edit the device properties.
4. Click **OK** to close the Device Properties Dialog Box.

- “Checking the Model 300 Project” on page 1029
- “Model 300 Options” on page 1030

Selecting Project Settings

Use the Project Settings command to specify how the software will download the program to the target device.

To select project settings:

1. In Model 300 Programmer, choose **Edit > Settings**.

   The “Settings Dialog Box” on page 1030 opens.
2. Select the appropriate check boxes for the specifications you want to include.
3. Choose between TLR and RTI for the starting and stopping TAP states.

4. To change the TCK clock pulse for an optional JTAG signal, click **Use Custom Pulse Width Delay**, and then type a different level in the TCK Low Pulse Width Delay box.
5. Click **OK**.

Model 300 Options

This section lists the options available in Model 300. Topics include:

Device Properties Dialog Box

The following options are available in the Device Properties dialog box:

Access Mode Selects the mode for programming the device.

Operation Lists the available operation modes for the device. Select one from the drop-down list.

Programming File Selects the data file for programming or verify.

Reinitialize Part on Program Error Reinitializes the part to its blank, or erased, state when a programming error occurs.

- “Selecting Project Settings” on page 1028
- “Checking the Model 300 Project” on page 1029
- “Model 300 Options” on page 1030

Settings Dialog Box

The following options are available in the Settings dialog box:

USERCODE Display Allows the user to choose in which format the USERCODE will be displayed. Choices are Hex, ASCII, and Decimal.

Log File Path Shows the location of the Programmer log file.

Use Default JTAG States (TLR/TLR) Uses Test-Logic-Reset (TLR) as the starting and ending JTAG state of the JTAG State Machine for download.

Avoid Test Logi Reset (TLR) State Avoids the Test Logic Reset State of the JTAG State Machine during download.

Use Custom JTAG States Specify Test-Logic-Reset (TLR) or Run-Test/Idle (RTI) as the starting and ending JTAG state of the JTAG State Machine for download.

Initial TAP State Specify TLR or RTI as the starting JTAG state of the JTAG State Machine for download.

Final TAP State Specify TLR or RTI as the ending JTAG state of the JTAG State Machine for download.

Use Default Pulse Width Delay Uses the fastest TCK clock speed.

Use Custom Pulse Width Delay Enables the Use Custome Pulse Width Delay feature.

TCK Low Pulse Width Delay (1 - 10x) Allows you to slow down the TCK clock. This is done by extending the low period of the clock.

Check Cable Setup Before Programming Confirms that the cable signals are correctly connected to the board and devices in the JTAG chain on the board match the devices selected in the .xcf file.

Continue Download on Error Ignores any errors while downloading and continues running.

Using Programming File Utility

The Programming File Utility is a stand-alone tool that allows you to view, compare, and edit data files. When comparing two data files, the software generates an output (.out) file with the differences highlighted in red.

See Also ▶"Running Programming File Utility" on page 1032

- "Viewing Data Files" on page 1032
- "Comparing Two Data Files" on page 1033
- "Editing Feature Row Values" on page 1034
- "Editing Control Register0 Values" on page 1034
- "Editing the USERCODE in the Data File" on page 1035
- "Securing the Device and Setting the Persistent Bit" on page 1036

Running Programming File Utility

To Run the Programming File Utility:

1. Issue the start command.
   - In Windows choose **Programs > Lattice Diamond > Accessories > Programming File Utility**.
   - In Linux, from the <*install_path*>/bin/lin directory, enter the following on a command line:

     ```
     ./fileutility
     ```

     The Programming File Utility window opens.

See Also ▶"Using Programming File Utility" on page 1032

Viewing Data Files

To view a data file:

- In the Programming File Utility, choose **File > Open** and select the data file you want to view.

  Note

  The data file can be in any of the following formats: .jed, .isc, .rbt, .bit, .rbk, .rbka, .msk, .mska.

Use the **Edit > Find** and **Edit > Find Again** commands to search for text in the file. Choose **File > Save As** to save the file with another file name.

Change file appearance such as font and font size by choosing **Configuration > Options** and changing settings in the Options dialog box.

See Also ▶"Using Programming File Utility" on page 1032

Comparing Two Data Files

You can use the Programming File Utility application to compare two data files. After creating the output file, the software displays the output file and highlights the differences between the two files.

To compare two data files:

1. Choose **Command > Data File Comparison** or click  on the toolbar.

   The Data Files Comparison Dialog Box opens.
2. Click the Browse buttons under First Data and Second Data to select the two data files you want to compare.
3. Optionally, if you are comparing two readback files (.rbk), browse for the mask file (.msc) to include masked bits in the comparison.
4. If desired, type a different name for the output file or browse to a file name that you want to overwrite. By default, the software uses the first data file name and appends the extension .out.
5. Click **OK**.

   The software compares the files and displays a message indicating whether the two files are identical or contain differences.
6. Click **OK** to close the message box and display the output file in the Programming File Utility window.
7. If the files contain differences, the Next  and Previous  arrows will become enabled on the toolbar. Use these buttons to examine each difference in the output file.

Viewing the Output File

The output file displays lines of data from the first file. Each of these lines is followed by a comparison line. The comparison line shows dots where the files are the same; where different, the line is highlighted in red and the data from the second file is displayed.

An output file that uses a mask file to compare two readback files displays each line of data from the first readback file in black, followed by a line of data in green from the mask file, followed by a comparison line. The comparison line shows dots where the two readback files are the same; where different, the line is highlighted in red and the data from the second readback file is displayed.

See Also ▶"Using Programming File Utility" on page 1032

Editing Feature Row Values

You can use the Feature Row Editor to enable or disable silicon features in the MachXO2, MachXO3L, and Platform Manager 2 devices by editing the Feature Row fuse settings in the data file.

To edit control register values:

1. Choose **Tools > Feature Row Editor**.

   The "Feature Row Editor Dialgog Box" on page 1037 opens.

2. Using the **(Browse)** button, browse to the data (.jed) file you want to edit.

3. Click **Read** to display current data file settings.

   The software displays the default values in the top row. On the second row, it displays in block the values that can be modified, and in red the values that cannot be modified.

4. Click the cell of a value displayed in black to change it.

   - To change the value in Feature Row, click the value cell and toggle the value from 1 to 0 or from 0 to 1.

5. To overwrite the existing data file, choose **Save**.

6. To create a new data file with a different name, choose **Save As** and save as a different file name.

See Also "Using Programming File Utility" on page 1032

Editing Control Register0 Values

You can use Control Register Editor0 to read the control registers of a bitstream file, modify the settings, and save them.

To edit control register values:

1. Choose **Tools > Control Register0 Editor**.

   The "Control Register0 Editor Dialog Box" on page 1037 opens.

2. Using the **(Browse)** button, browse to the .jed, .isc, .rbt, or .bit file that you want to edit, select the file, and then click **Open**.

   The editor opens with the selected file.

3. Click **Read** to display the values of the control register.

   The software displays the default values in the top row. On the second row, it displays in block the values that can be modified, and in red the values that cannot be modified.

4. Click the cell of a value displayed in black to change it.

- To change a value, click the value cell and toggle the value from 1 to 0 or from 0 to 1.
- To change the frequency in Control Register 0, click the Frequency value cell and select a frequency from the drop-down list.

5. To overwrite the existing data file, choose **Save.**
6. To create a new data file with a different name, choose **Save As** and save as a different file name.
7. A message box pops up, displaying the new control register value. Click **OK**.
8. Another message box tells you that Write to file was successful. Click **OK**.
9. Click **Close** to exit the Control Register.

See Also ▶"Using Programming File Utility" on page 1032

Editing the USERCODE in the Data File

The USERCODE Editor allows you to add information, such as serial code number, design code, or lot number, to the .jed, .isc, .rbt, or .bit file. This information is written to the USERCODE after the fuse map data in a JEDEC file. The signature must be in either decimal (0-9), ASCII, or hexadecimal (0-F) characters. In an ISC data file, this information is written in the user code data record in hexadecimal.

To use the USERCODE Editor:

1. Choose **Tools > USERCODE Editor**.

   The "USERCODE Editor Dialog Box" on page 1037 opens.

2. Using the  **(Browse)** button, browse to the .jed, .isc, .rbt, or .bit file that you want to edit, select the file, and then click **Open**.

   The editor opens with the selected file.

3. Click **Read**.

   If there is no data in the field, you will see a string of 8 Fs (Hexadecimal).

4. Edit the string as required. The USERCODE edit box displays the current bit position as you type. The signature must be stated in decimal (0-9), ASCII, or hexadecimal (0-F) characters.
5. When you have finished, click **Save** or **Save As** to save the USERCODE data.
6. A message box asks you if you want to overwrite the data file? Click **Yes**.
7. Another message box tells you that the USERCODE write to file was successful. Click **OK**.

If you open the .jed file in a text editor, you will see the new USERCODE data added to the bottom of the file, as shown in the example below:

```
N User Electronic Signature
Data*U00000000000000000000000010011110011001100*
```

If you open the .isc data file in a text editor, you will see the new USERCODE data added to the end of the bottom of the file, as shown in the example below:

```
data usercode (initialize --LATTICE_NOTEDATA_WIDTH = 32--
LATTICE_NOTEADDRESS_WIDTH = 1(97D84A22) ),
```

Securing the Device and Setting the Persistent Bit

The Security and Persistent Fields Editor allows you to read the settings of the security and the persistent bit of the bitstream file and change the setting to ON or OFF.

To read the settings of the security and persistent fields:

1. Choose **Tools > Security and Persistent Fields Editor.**
2. Click the **Browse** button and select the bitstream data file.
3. Click **Read** to read the settings for Security and Persistent Bit.

   The editor reads the settings and displays them in the Status cells.
4. To change a setting from OFF to ON or vice versa, click the status cell.
5. Do either of the following to save the changes:
   - To save the changes to the current data file, click **Write** (or click the arrow beside **Write** and then choose **Overwrite**). In the pop-up dialog box, click **Yes** to confirm that you want to overwrite the data file.
   - To save the changed data file to a different location or with a different file name, click the arrow beside **Write** and then choose **Save As**. In the Save As Data File dialog box, specify file name and location, and click **Save**.
6. A message box tells you that Write to file was successful. Click **OK**.
7. Click **Close** to exit the Security and Persistent Fields Editor.

Programming File Utility Options

This section lists the options available in Programming File Utility. Topics include:

Feature Row Editor Dialgog Box

The following options are available in the Feature Row Editor dialog box:

Device Lists the project’s device. If a device is not displayed, use the browse button to locate the correct data file. Once a device is displayed, click **Read** to get the correct Max Bits/Digits information.

Read Reads the data file values and displays it in the display field.

Save Saves the data file.

Save As saves the data file with another file name.

Close Closes this dialog box.

See Also ▶“Programming File Utility Options” on page 1037

Control Register0 Editor Dialog Box

The following options are available in the Control Register0 Editor dialog box:

Device Lists the project’s device. If a device is not displayed, use the browse button to locate the correct data file. Once a device is displayed, click **Read** to get the correct Max Bits/Digits information.

Read Reads the data file values and displays it in the display field.

Save Saves the data file.

Save As saves the data file with another file name.

Close Closes this dialog box.

See Also ▶“Programming File Utility Options” on page 1037

USERCODE Editor Dialog Box

The following options are available in the USERCODE Editor dialog box:

Device Lists the project's device. If a device is not displayed, use the browse button to locate the correct data file. Once a device is displayed, click **Read** to get the correct Max Bits/Digits information.

USERCODE Format Allows you to display the USERCODE field in hexadecimal, decimal, or ASCII format.

Usercode Allows you to specify a USERCODE value to override the current value in the data file.

Read Reads the USERCODE field in the data file and displays it in the display field.

Save Writes the value in the USERCODE display field and saves the data file.

Save As Writes the value in the USERCODE display field allows you to save the data file with another file name.

Close Closes this dialog box.

See Also ▶"Programming File Utility Options" on page 1037

Chapter 13

Testing and Debugging On-Chip

The final stage of developing a design is testing it on the actual FPGA on either a test board or in your system. Lattice Semiconductor offers two tools for debugging both the hardware aspect of the design and—if you are using the LatticeMico32 microprocessor—the software aspect:

- Reveal Analyzer to check for and to analyze specific events on signals
- LatticeMico Debugger to debug LatticeMico32 microprocessor software

Note

LatticeMico Debugger does not support the LatticeMico8 microcontroller.

While Reveal Analyzer and LatticeMico Debugger work independently, they can run at the same time.

Before you start debugging, each tool requires that a special interface module be added to the design. Then you rerun the design implementation process (Synthesize Design, Translate Design, Map Design, Place & Route Design) and generate bitstream data or a JEDEC file (depending on the device family) to program the FPGA. The tools can share the same ispDOWNLOAD cable and JTAG port that Programmer uses to download the design.

About Reveal Logic Analysis

One of the most common activities in debugging is logic analysis. To do this, use Reveal Inserter and Reveal Analyzer. You can use Reveal Inserter and Analyzer with all FPGAs and with MachXO and MachXO2 devices of 1200 or more LUTs.

Reveal continuously monitors signals within the FPGA for specific conditions, which can range from simple to quite complex. When the trigger condition occurs, Reveal can save signal values preceding, during, and following the event for analysis, including a waveform presentation. The data can be saved to a value change dump file (.vcd), which can be used with tools such as ModelSim, or to an ASCII tabular format that can be used with tools such as Excel.

To use Reveal Analyzer, first use Reveal Inserter to add Reveal modules to your design. In these modules, you specify the signals to monitor, define the trigger conditions, and other options. You can have up to 15 modules, typically one for each clock region of interest. When the modules are set up, regenerate the bitstream data or JEDEC file to program the FPGA.

Before starting a test run, set up Reveal Analyzer. It includes a number of options, including modifying trigger conditions and customizing the waveform display. You can save these settings for later use. During and after a test run, view the incoming data in Reveal's LA Waveform view. You can also save the data to a .vcd or .txt file to analyze with other tools.

Using the Reveal Example Project

If you want to get some hands-on experience with the Reveal tools, try using the example project while studying the online help.

The example is a simple 3-bit counter coded in Verilog. It already has a Reveal module inserted. It also already has trace data that can be viewed in Reveal Analyzer. A test board is not required to open the Reveal tools or to view the existing trace data. But, to actually run Reveal Analyzer to collect new data, you need a test board.

To start the Reveal example project:

1. Choose **File > Open > Design Example**.

   The Open Example dialog box opens.
2. Double-click **counta_reveal_XP2**.
3. Choose **count.ldf**.
4. Click **Open**.

The count design project opens. At this point, you can open Reveal Inserter.

Note

If you want to preserve the original example for future experiments, choose **File > Archive Project** now.

5. In the Processes view, double-click **Export Files** to implement the design.

   At this point, you can open Reveal Analyzer.

If you want to use the example project with a test board, change the device type to match the board by double-clicking the device in the File List view. Then run the design implementation process. See “Targeting a Device” on page 27.

Using the Reveal Debug Projects

If you are having trouble running Reveal with your design, Lattice provides the following pre-verified Reveal Debug Projects to allow you to verify that Reveal is working correctly on your computer.

- counter_impl_ECP2M
- counter_reveal_ECP2
- counter_reveal_ECP3
- counter_reveal_ECP5
- counter_reveal_LIFMD
- counter_reveal_MACHXO2
- counter_reveal_XO
- counter_reveal_XP2

The Reveal Debug Projects are located in a folder in the examples directory:

<diamond_install_path>\examples\reveal_debugger\

Your computer must be connected to a board with the appropriate Lattice device.

The reference design is a 32-bit counter which includes one input reset and 4 outputs LEDPIO_OUT0, LEDPIO_OUT1, LEDPIO_OUT2 and LEDPIO_OUT3.

Choose the appropriate device package and locate the output ports to see if the counter is toggling with the LED.

The clock signal is driven by internal oscillator and the OUTPOT_OUT3 to OUTPUTPIO_OUT0 are connecting to the most significant bit cnt[31:28]. This reference design has a Reveal module inserted and has trace signal TU1 that monitoring cnt[5:0] equal to 6b'100000 as trigger condition.

To start the Reveal example project:

1. Choose **File > Open > Project**.

   The Open Example dialog box opens.

2. Browse to the desired Reveal Debug Project folder, and choose the apppropriate **.ldf** file.
3. Click **Open**.
4. Ensure that the Diamond project settings match the device on your board.
5. Follow the steps outlined in “Performing Logic Analysis” on page 1024.
   - If you are able to run the Reveal Debug Project successfully in Reveal, then the problem may be with your design or in the clock source.
   - If you are unable to run the Reveal Debug Project successfully in Reveal, contact Lattice Technical Support as described in “Contacting Technical Support” on page 16, and send the project with the log files.

Debugging Software

If you include the LatticeMico32 microprocessor in your design, you will almost certainly be doing some on-chip software debugging. For this, use LatticeMico Debugger. With LatticeMico Debugger you can set breakpoints in the code, set watchpoints in the memory, inspect processor registers, and view many other aspects of the software and the processor.

When you’re not sure if the problem is in the software or the hardware, use LatticeMico Debugger along with Reveal Analyzer.

To use LatticeMico Debugger, first use Mico System Builder (MSB) to add the debug module to the LatticeMico32 instance in your design. Then regenerate the bitstream data or JEDEC file to program the FPGA.

In C/C++ Software Project Environment (SPE), compile your software with debug symbols enabled. Then switch to the Debug perspective.

Creating Reveal Modules

Create the modules for Reveal logic analysis with Reveal Inserter. The process basically consists of identifying trace signals, which are the signals that you want to analyze, defining a trigger signal, which is the event you want to analyze, and setting a few options. Then you insert the modules into your design and implement it.

With Reveal Inserter, it is easy to set up simple triggering conditions, as well as extremely complex ones. Triggering in Reveal is based on the trigger unit and the trigger expression. A trigger unit is used to compare signals to a value, and a trigger expression is used to combine trigger units to form a trigger signal.

Each Reveal Inserter project can include up to 15 modules. Each module has its own settings, trace signals, and trigger signal. In many cases, a single module is all that is required to debug a design. However, in designs with multiple clock regions, it may be necessary to sample different clock regions at the same time. For those types of designs, it is recommended that you use multiple modules, one for each clock region.

You can also set up modules that allow you to adjust and monitor serdes functions in ECP5UM designs.

Take some time to plan the logic analysis. Reveal modules can take a considerable amount of FPGA resources and creating the modules can take a significant amount of time. Find out how many EBRs and slices are still available. Consider adding all the trace signals and trigger events that you might want to analyze. The trigger signals can be modified in Reveal Analyzer while you're running tests if the necessary signals and capacity have been specified in the modules.

Note

Interactive and stand-alone synthesis are not compatible with Reveal modules. Reveal Inserter automatically uses the integrated synthesis option. Make sure your design project is set up for integrated synthesis. See "Pre-Synthesis Check List" on page 576.

About Reveal Inserter

Reveal Inserter has several views to help you manage the Reveal modules, find signals, and set up trace and trigger signals.

Dataset Dataset provides a list of all the modules in the Reveal project. To work on the trace and trigger signals of a module, select the module in the Dataset view. You can also add, remove, or rename modules by right-clicking a module name and choosing from the drop-down menu. See “Managing the Modules in a Project” on page 1045.

Design Tree Design Tree provides a list of all the buses and signals in the design. You can select signals to trace and to trigger on by dragging them from the Design Tree view. To find signals, use the Signal Search function. See “Searching for Signals” on page 1046.

Design Tree also keeps track of how signals are being used. See “Viewing Signals in Design Tree” on page 1045.

Trigger Output Trigger Output provides a list of trigger signals available from other modules. These signals can also be traced and triggered on by the current logic analyzer module. Select these signals by dragging them from the Trigger Output view. To make a trigger available in the Trigger Output view, see “Trigger Out” on page 1067.

Trace Signal Setup Trace Signal Setup is where you assemble and organize the list of signals to be traced by the current logic analyzer module. Select signals by dragging them from the Design Tree and Trigger Output views. You can rearrange the signals in the list and organize them into groups. This view also provides several options for the trace operation. See “Setting Up Trace Signals” on page 1050.

Trigger Signal Setup Trigger Signal Setup is where you assemble the trigger for the current logic analyzer module. The trigger is the event that tells the module to save the data from the trace signals. Triggers are built up from “trigger units,” collections of signals compared to specific values, and “trigger expressions,” logical and sequential combinations of trigger units. See:

- “About Trigger Signals” on page 1055
- “Setting Up Trigger Units” on page 1056
- “Setting Up Trigger Expressions” on page 1059
- “Setting Trigger Options” on page 1066

Serdes Debug Setup Serdes Debug Setup is where you specify signals to control the current SERDES Debug module. Select signals by dragging them from the Design Tree view. See See “Creating SERDES Debug Modules” on page 1067.

Note

The Serdes Debug Setup tab is only visible when you select a Serdes Debug module in the Dataset pane.

Managing the Modules in a Project

Each Reveal Inserter project can include up to 15 modules. They are listed in the Dataset view. Working in the Dataset view or with the Debug menu, you can add, rename, and remove modules.

To add a module:

1. Choose **Debug > Add New Core**.
2. From the submenu, choose a module type.

   Reveal Inserter adds a new module in the Dataset pane.

To rename a module:

1. Double-click the module in the Dataset pane.
2. Type the new name of the module over the old name. The module name must:
   - Begin with a letter.
   - Consist of letters, numbers, and underscores (_).
   - Be different from all other modules in the Reveal project.
   - Be different from all other modules and instances in the design.
3. Press **Enter**.

To remove a module:

1. Select the module in the Dataset pane.
2. Press **Delete**.

Viewing Signals in Design Tree

The Design Tree pane shows the hierarchy of the whole design with all of the signals and buses. From the Design Tree pane, you can select signals and drag them to the Trace Signal Setup and Trigger Signal Setup views. To help you find signals, Design Tree has a search function, explained in “Searching for Signals” on page 1046.

The Design Tree pane also gives some information about the signals and how they are being used in the Reveal module. If you select a signal in the hierarchy, the Output tab displays information about it. If a signal is being used in the Reveal module, its name in the Design Tree pane is shown in bold type and followed by a symbol showing how the signal is being used:

- @Tc: trace signal
- @Tg: trigger unit signal
- @C: control signal (sample clock or sample enable)
- @Mx: mixed bus. Some of the signals are being used one way and some are not or are being used in another way.

To view all signals in the design hierarchy:

- Right-click on the design name in the Design Tree pane and choose **Expand All** from the pop-up menu.

To view the buses, ports, top-level signals, and top level of the hierarchy:

- Right-click on the design name in the Design Tree pane and choose **Collapse All** from the pop-up menu.

Searching for Signals

You can find signals in the Design Tree pane with a text search including wildcard characters.

To search for signals:

1. In the Signal Search box in the Design Tree pane, type the full name of the signal or a part of the name with wildcards (see the following table). The search is case-insensitive. The bit range of a bus, such as the "[7:0]" in cout[7:0] is not part of the name and should not be included in the search. Instead, just search on "cout".

Wildcard	Finds	Example
?	Any single character	"?out" finds aout, bout, and cout.
*	A sequence of any number of characters	"c*" finds cin and cout.
[<*string*>]	Any character in the string	"[ab]out" finds aout and bout.
[^<*string*>]	Any character except those in the string	"[^ab]out" finds cout but not aout or bout.
[<*c1*>-<*c2*>]	Any character in the range from <*c1*> through <*c2*>	"[a-c]out" finds aout, bout, and cout. "cout:[4-6]" finds cout:4, cout:5, and cout:6.
[^<*c1*>-<*c2*>]	Any character except those in the range from <*c1*> through <*c2*>	"cout:[^3-7]" finds cout:0, cout:1, and cout:2.

2. Click **Search**.

   If only one signal is found, it is highlighted it in the Design Tree pane.

   If more than one signal is found, the Search Result dialog box opens with a list of the signals.

3. If the Search Result dialog box opens, select the desired signals and click **OK**.

To select one signal or bus, click on it. To select more than one, Control-click on each one. To select all signals and buses in a range, click on one end of the range and Shift-click the other end.

The selected signals are highlighted in the Design Tree pane.

See Also "Viewing Signals in Design Tree" on page 1045

Checking the Design Rules

At any time you can check that your Reveal project is not violating any design rules such as proper module names, number of signals used, and required options set. The design rule check also tells you the total number of EBRs and slices needed for the project.

To check the Reveal module settings:

- Choose **Debug > Design Rule Check**.

  The results of the check are displayed in the Output tab.

Saving a Project

At any time you can save your Reveal project. Reveal Inserter automatically performs a design rule check when it saves a project. The results are shown in the Output tab.

Note

Reveal Inserter generates a new "signature," or tracking mechanism, whenever a Reveal project is saved. Reveal Analyzer reads this signature to ensure that the FPGA has been programmed with the latest Reveal project. If you save the project without re-programming the FPGA, Reveal Analyzer will issue an error message, even if the Reveal project was not changed.

To save the project settings in the current directory:

- Choose **File > Save** <*filename*>.

To save the project settings in another directory:

- Choose **File > Save** <*filename*> **As**. In the Save Reveal Project dialog box, browse to the desired directory, enter the name of the .rvl file in the File Name box, and click **Save**.

See Also

- "Inserting the Reveal Modules" on page 1068

Logical Preference File Changes

Reveal Inserter modifies the logical preference (.lpf) file. These changes are handled automatically.

In the .lpf, Reveal:

- Modifies the timing settings needed for the debug logic.
- Adds an RVL_ALIAS preference, which maps clock names generated by Reveal to the clock names used in the original design. So you do not need to change your preferences that refer to those clock signals.

You may need to manually change preferences on some signals that Reveal Inserter is using. See “Preferences Not Recognized” on page 1069.

Limitations

Reveal Inserter has the following limitations:

Unsupported VHDL and Verilog Features in Reveal Inserter The following features that are valid in the VHDL and Verilog languages are not supported in Reveal Inserter:

- Array types of two dimensions or more are not shown in the port or node section.
- Undeclared wires attached to instantiated component instances are not shown in the hierarchical design tree. You must declare these wires explicitly if you want to trace or trigger with them.
- Variables used in conditional statements like if-then-else statements are not available for tracing and triggering.
- Variables used in selection statements like the case statement are not available for tracing and triggering.
- If function calls are used in the array declaration, the actual size of the array is unknown to Reveal Inserter.
- Entity and architecture of the same design cannot be in different files.
- In Verilog, you must explicitly declare variables at the very beginning of a module body to avoid obtaining different results from various synthesis tools.
- In VHDL, you must declare synthesis attributes within an entity, not within an architecture, to avoid obtaining different results from various synthesis tools.
- Signals used in VHDL “generate” statements are not available for tracing and triggering.
- Signals that are VHDL user-defined enumerated types, integer type, or Boolean type are not available for tracing and triggering.

Syn_keep and Preserve_signal Attributes In VHDL, always define the syn_keep and preserve_signal attributes as Boolean types when you declare them in your design. Synplify defines them as Boolean types, and Reveal Inserter will issue an error message if you define them as strings.

Signals Implemented as Hard Routes Signals that are implemented as hard routes in the FPGA instead of using the routing fabric are not available for tracing or triggering. Examples are connections to IB and OB components.

Many common hard routes are automatically shown as unavailable in Reveal Inserter, but some are not. If you select a signal for tracing or triggering that is implemented as a hard route, an error will occur during the synthesis, mapping, placement, or routing steps.

Dangling or Unconnected Nets Dangling, or unconnected, nets in Verilog or VHDL code are available for use with Reveal Inserter. However, if you are using EDIF files as your source, dangling nets are probably not available because synthesis tools, which produce EDIF files, normally optimize out dangling logic.

Using Unlicensed IP

If your design contains an unlicensed IP block, the Hardtimer mechanism enables you to evaluate the IP. You can control this mechanism by choosing **Project > Active Strategy > Translate Design**, and setting the Hardware Evaluation option to Enable.

If you use the Reveal tools on a design that includes an unlicensed IP block, you cannot disable the Hardtimer mechanism. It is required to generate the bitstream data or JEDEC file for Reveal Analyzer. If you set the Hardware Evaluation option to Disable, the Reveal flow overwrites the Hardtimer mechanism. However, the option automatically reverts to Disable when you exit the Reveal flow.

Creating Logic Analysis Modules

Following are the major steps in creating a Logic Analysis module.

Before running Reveal Inserter the design must have been successfully synthesized.

Note

Reveal Inserter has limitations and requirements in how it works with the design. See “Limitations” on page 1048 and “Using Unlicensed IP” on page 1049.

To create a Logic Analyzer module:

1. After opening the design project, choose **Tools >**  **Reveal Inserter**.

   Reveal Inserter opens with the active Reveal project (.rvl) file. If there are no existing projects, Reveal Inserter creates one.

   Reveal Inserter also parses and statically elaborates the design. In some cases, code that was successfully synthesized is flagged as having an error. In these cases, Reveal Inserter is interpreting the HDL code more strictly than the chosen synthesis tool. It is likely that the code would not synthesize with a different synthesis tool or would have other compliance issues.

To correct this problem, see the reveal_error.log file in the implementation directory. With the help of this file, locate and correct the problem in the code. Then synthesize the design and open Reveal Inserter again.

2. Select a module in the Dataset view. If you want to add another module to the project, choose **Debug > Add New Core > Add Logic Analyzer**. See also “Managing the Modules in a Project” on page 1045.
3. Set up the trace signals as desired. See “Setting Up Trace Signals” on page 1050.
4. Create trigger units, which are collections of signals and the values that will be part of causing a trigger signal. See “Setting Up Trigger Units” on page 1056.
5. Create trigger expressions, which are logical combinations of trigger units. See “Setting Up Trigger Expressions” on page 1059.
6. Select trigger options. See “Event Counter” on page 1066 and “Trigger Out” on page 1067.
7. When you have set up all your modules, add them to the design project by choosing **Debug > Insert Debug** and running the design implementation process. See “Inserting the Reveal Modules” on page 1068.

Setting Up Trace Signals

Setting up the trace signals for a module is mostly a matter of selecting the signals and buses that you want to watch and dragging them into the Trace Signal Setup tab. You can have up to 512 trace signals in a module.

The organization of the signals is up to you. Organize the signals according to how you want to view the data. Order them from top to bottom and organize them into buses. You are not limited to the bus organization of the design. You can completely rearrange the signals into your own organization of trace buses. You can manage the trace signals using the Debug menu or by right-clicking selected signals.

To set up trace signals:

1. Click the **Trace Signal Setup** tab.
2. Select a module in the Dataset view.
3. Select signals in the Design Tree and Trigger Output views and drag the signals to the desired position in the Trace Signal Setup tab. For help finding signals, see “Searching for Signals” on page 1046.

   Check the value to the right of the Implementation box to see how adding trace signals affects the consumption of FPGA resources.
4. You can further organize the signals in the Trace Signal Setup tab by ungrouping buses into individual signals and grouping signals into new buses.

   - To break a bus into individual signals, select the bus and choose **Debug > UnGroup Trace Bus**.

- To create a new trace bus, select the desired signals and buses and choose **Debug > Group Trace Data**. Double-click the new bus and type in the desired name.

You can also drag signals and buses into and out of other buses.

5. If you want to see what happens in the signals that define the trigger units, select **Include trigger signals in trace data** at the bottom of the Trace Signal Setup tab.

   A bus named “Trigger Signals” appears at the top of your list of trace signals. For details, see “Include trigger signals in trace data” on page 1051.

6. Set the trace options. There are several options that enhance the trace signals or control how data is sampled:

   - “Sample Clock” on page 1051
   - “Sample Enable” on page 1052
   - “Buffer Depth” on page 1053
   - “Timestamp” on page 1053
   - “Implementation” on page 1054
   - “Data Capture Mode” on page 1054
   - “POR Debug” on page 1054

See Also “Viewing Signals in Design Tree” on page 1045

Include trigger signals in trace data

You can add all the signals used in the trigger units to the trace signals. This allows you to see what happens on the signals that make up the trigger.

This option creates a bus named “Trigger Signals” at the top of your list of trace signals. Trigger Signals contains buses named for each trigger unit and containing the buses and signals used in the trigger units. The Trigger Signals bus cannot be moved or modified in any way.

To add the trigger signals to the trace signals:

- Select **Include trigger signals in trace data**.

Sample Clock

The sample clock determines when the trace signals are sampled. Reveal Analyzer samples the trace signals once every clock cycle on the clock’s rising edge.

To set the sample clock signal:

- Find the signal in the Design Tree view and drag it to the Sample Clock box of the Trace Signal Setup tab.

Note

On the board, make sure that the sample clock frequency is at least that of the JTAG clock. If the sample clock speed is too slow, you will be unable to complete capturing data with Reveal Analyzer.

The sample clock frequency should be no more than 200 MHz.

See Also ▶"Searching for Signals" on page 1046

Sample Enable

The sample enable is a signal that can be used to turn data capture on and off. Normally, data is captured for every sample clock cycle for a specified number of cycles. With sample enable, data capture only happens when the sample enable signal is active. Use sample enable to reduce the size of the trace buffer when there are stretches of data of no interest and these stretches are associated with a single signal.

An example is a design that contains many different sections but some sections only work during certain clock phases. The design uses a master clock and generates different signals for the phases. You could use one of the phase signals as the sample enable.

If the trigger occurs while the sample enable is inactive, Reveal Analyzer cannot accurately calculate the trigger point. Instead of showing the precise trigger point, Reveal Analyzer shows a trigger region that spans five clock cycles. Reveal Analyzer can guarantee that the trigger occurred in this region, but it cannot determine during which clock cycle the trigger occurred.

To set the sample enable:

1. Select **Sample Enable**.
2. Find the signal in the Design Tree view and drag it to the box in the Sample Enable section of the Trace Signal Setup tab.
3. In the box to the right of the signal name box, choose whether the signal is:

- **Active High**. Data can be captured when the sample enable is high.
- **Active Low**. Data can be captured when the sample enable is low.

See Also ▶"Searching for Signals" on page 1046

Buffer Depth

The buffer depth specifies the size of the trace memory buffer as the maximum number of samples that can be stored. The buffer should be deep enough to hold enough samples, before and after the trigger, for your analysis multiplied by the number of trigger events that you want to see in one test run. Available values are powers of two from 16 to 65,536.

For example, if you want 20 samples from each of five events, choose a buffer depth of at least 128.

To set the buffer depth:

1. Determine the maximum number of samples that you might want from a test run. Be generous to avoid re-implementing the design just to get a bigger buffer.
2. In the Buffer Depth box, choose a value that is at least as large as the desired number of samples.

Check the value to the right of the Implementation box to see how changing the buffer depth affects the consumption of FPGA resources.

Timestamp

The timestamp is a count of sample clock cycles from the beginning of a test run. This is different from the sample index that Reveal Analyzer automatically supplies. The sample index only provides a count of samples within each trigger's data set. The timestamp continues counting between triggers and when the sample enable signal blocks data capture.

However, unlike the sample index, the timestamp is extra data in each sample and so requires a larger trace buffer.

Use the timestamp when you want to know how long the test ran before triggering or how long the sample enable signal blocked data capture. The timestamp can also help associate triggers with external events or with data from another Reveal module using the same sample clock.

To add timestamps to the trace samples:

1. Select **Timestamp**.
2. Determine the number of sample clock cycles in the longest test run you might want to do.
3. In the drop-down menu to the right of "Timestamp," choose the size of the timestamp in bits. Choose the smallest value that can hold the count for the desired number of sample clock cycles.

   For example, if you might want to run a test for 50 thousand cycles, choose 16 bits.

Check the value to the right of the Implementation box to see how changing the timestamp size affects the consumption of FPGA resources.

Implementation

The implementation specifies what kind of RAM to use for the Reveal module. Normally you should choose EBR. But if you are short of EBR, choose distributed RAM.

To set the implementation:

- In the Implementation box, choose a kind of RAM:
  - **EBR** (embedded block RAM)
  - **DistRAM** (distributed RAM)

The number of EBR or slices needed is shown to the right. This value changes as you add or remove trace signals, or change the buffer depth or timestamp size.

Data Capture Mode

The data capture mode specifies whether Reveal Analyzer can look for one trigger or multiple triggers in a test run. Multiple Trigger Capture mode provides the greatest flexibility during test runs. Single Trigger Capture mode slightly reduces the amount of FPGA resources needed.

To set the data capture mode:

1. In the Data Capture Mode section, select one of the following:
   - **Single Trigger Capture**. Reveal Analyzer captures the data for only one trigger.
   - **Multiple Trigger Capture**. Reveal Analyzer captures the data for multiple triggers. The number of triggers is specified in Reveal Analyzer unless you are creating a module to monitor the power-on reset (POR) functions (see below).
2. If you select Multiple Trigger Capture, choose the “Minimum samples per trigger.” The number of samples collected for each trigger is set in Reveal Analyzer but cannot be smaller than this value.
3. If you select Multiple Trigger Capture and are creating a POR module, choose the “Number of triggers for POR.” For an explanation of POR modules, see “POR Debug” on page 1054.

POR Debug

To monitor power-on reset (POR) functions an automatic “trigger enable” signal must be built into the Reveal module. This is because POR functions happen immediately after power-on of the test board, before Reveal Analyzer can be started. When the trigger enable signal transitions to active, the module will watch for the trigger and collect samples. This is similar to clicking the Run  button in Reveal Analyzer. When Reveal Analyzer starts, it loads and displays any data collected by the POR modules.

POR modules are only supported with ECP5, LatticeECP3, LatticeSC, LatticeXP2, MachXO2, MachXO3D, and MachXO3L.

To set a POR trigger enable:

1. In the POR Debug section, select **Trigger Enable**.
2. Find the POR trigger signal in the Design Tree view and drag it to the text box in the POR Debug section.
3. Choose whether the signal is **Active High** or **Active Low**.

About Trigger Signals

Most of the trigger features need to be set up initially in Reveal Inserter but many of them can be modified in Reveal Analyzer while testing the design. See Table 134. Changes in Reveal Inserter mean the design has to be re-implemented (synthesis, map, place, and route) and reloaded into the FPGA. So it is worthwhile to be generous in defining your trigger units, trigger expressions, and other options. Think of setting up a trigger signal as creating capacity: access to signals and memory. Try to give yourself capacity to define all the triggering events that you might want to analyze later.

Table 134: Where Trigger Features Can Be Changed

Feature		Reveal Inserter	Reveal Analyzer
Trigger Units	Add	✔

- “Setting Up the Trigger Signals” on page 1080

Setting Up Trigger Units

The trigger unit is used to compare a number of signals to a value. A number of different operators are available for comparison and can be dynamically changed during analysis, along with the comparison value and the trigger unit name.

Each trigger unit can have up to 256 signals. Since there are 16 allowable trigger units, each module can have a maximum of 4096 trigger signals.

Try to minimize the number of trigger units in a module. The more trigger units there are, the longer it takes for Reveal Analyzer to configure the module at the beginning of a test run. More than eight trigger units may cause a delay of 30 seconds or more; 16 trigger units many cause a delay of 5 minutes.

Before you start setting up the trigger units, set the **Default Trigger Radix**. This option is in the Trigger Unit section of the Trigger Signal Setup tab. The default trigger radix is applied automatically to any new trigger units that you create but does not affect the radix of any existing trigger units. You can always change the radix of any trigger unit at any time.

To set up a trigger unit:

1. If you want to add a new trigger unit, click **Add** in the Trigger Unit section of the Trigger Signal Setup tab.
2. Specify the signals in the trigger unit by one of following methods:
   - Drag and drop signals from the Design Tree and Trigger Output views to the Signals column. For more information on using the Design Tree view, see “Viewing Signals in Design Tree” on page 1045 and “Searching for Signals” on page 1046.

- Double-click in the Signals column to open the TU Signals dialog box. See “Selecting and Ordering Trigger Signals” on page 1057.

3. If you want to change the order of the signals or remove any, double-click in the **Signals** column.

   The TU Signals dialog box opens. See “Selecting and Ordering Trigger Signals” on page 1057.

4. Click in the **Operator** column, and choose an operator from the drop-down menu. See “About Trigger Unit Operators” on page 1058.

   Both the operator type and the trigger unit value can be changed in Reveal Analyzer during hardware debugging.

5. If you want to change the radix of the Value column, click in the **Radix** column and choose a radix from the drop-down menu. The menu includes token sets whose bit width matches the trigger unit’s signals.

   Token sets are text labels for values that might appear on trace buses. You can create and apply token sets in Reveal Analyzer. See “Creating Token Sets” on page 1088.

6. Enter the comparison value in the **Value** column. The form of the value must match the specified radix. If you selected a token set in the Radix column, a drop-down menu opens in the Value column listing the tokens in the token set.

   You can use “x” for a don’t-care value if you selected binary, octal, or hexadecimal in the Radix column and if you selected ==, !=, or serial compare in the Operator column.

Selecting and Ordering Trigger Signals

In the Trigger Unit section of the Trigger Signal Setup view, double-click in the Signals column. The TU Signals dialog box opens.

To select and order trigger unit signals:

1. In the left box of the TU Signals dialog box, select signals that you want to use in the trigger unit. To select one signal or bus, click on it; to select more than one, Control-click on each one; to select all signals and buses in a range, click on one end of the range and Shift-click the other end.
2. Click **>** to add them to the box on the right.
3. To remove signals from the trigger unit, select them in the right box and click **<**.
4. Organize the signals by selecting one and clicking the up or down arrow until the signal is in its desired position. Continue until all the signals are in the desired order from least significant bit (LSB) down to the most significant bit (MSB).
5. Click **OK**.

About Trigger Unit Operators

Most of the trigger unit operators use standard logical comparisons between the current value of the combined signals of the trigger unit and a specified value. But some of the operators are unusual and need some explanation.

With the exception of “serial compare,” the operators can be changed in Reveal Analyzer.

Standard Logical Operators Reveal includes the following operators:

- == equal to
- != not equal to
- > greater than
- >= greater than or equal to
- < less than
- <= less than or equal to

Rising Edge and Falling Edge The “rising edge” and “falling edge” operators check for change in the signal value, not the value itself. So the trigger unit’s specified value is a bit mask showing which signals should have a rising or falling edge. A 1 means “look for the edge;” a 0 means “ignore this bit.” A multiple-bit value is true if any of the specified bits has the edge.

For example, consider a trigger unit defined as cout[3:0], rising edge, 1110. This trigger unit will be true only when cout[3], cout[2], or cout[1] have a rising edge. What happens on cout[0] does not matter.

- 0000 > 1110

  True because cout[3], cout[2], and cout[1] rose.

- 0000 > 1111

  True for the same reason. It does not matter whether cout[0] rises or not.

- 0000 > 0100

  True because a rising edge on any of the specified bits is sufficient.

- 1000 > 1000

  False because cout[3] did not rise. It just stayed high.

Serial Compare The “serial compare” operator checks for a series of values on a single signal. For example, if a trigger unit’s specified value is 1011, the “serial compare” operator looks for a 1 on the first clock, a 0 on the next clock, a 1 on the next clock, and a 1 on the last clock. Only after those four conditions are met in those four clock cycles is the trigger unit true.

Serial compare is available only when a single signal is listed in the trigger unit’s signal list. The radix is automatically binary.

You can only set the serial compare operator in Reveal Inserter. You cannot change it or select it in Reveal Analyzer as you can the other operators.

Managing Trigger Units

You can add and remove trigger units only in Reveal Inserter. You cannot add them in Reveal Analyzer.

To add a trigger unit:

- To add a new trigger unit, click **Add** in the Trigger Unit section of the Trigger Signal Setup tab.

To rename a trigger unit:

- Click in the Name column of the Trigger Unit section of the Trigger Signal Setup tab, and type in the new name. The name can consist of letters, numbers, and underscores. The first character must be either an underscore or a letter.

To remove a trigger unit:

1. In the Trigger Unit section of the Trigger Signal Setup tab, click in any box in the line representing the trigger unit that you want to remove.
2. Click **Remove**.

See Also ▶"Setting Up Trigger Units" on page 1056

Setting Up Trigger Expressions

You set up the initial trigger expressions in Reveal Inserter, but you can change them and their names in Reveal Analyzer. You can also enable or disable trigger expressions in Reveal Analyzer. However, you cannot change the maximum sequence depth or the maximum event counter of the trigger expressions in Reveal Analyzer.

To set up a trigger expression:

1. If you want to add a new trigger expression, click **Add** in the Trigger Expression section of the Trigger Signal Setup tab.
2. In the **Expression** column, enter the trigger expression. See "Trigger Expression Syntax" on page 1060.

   Reveal Inserter checks the syntax and displays the syntax in red font if it is erroneous.

   Both the trigger units and operators associated with a trigger expression can be changed in Reveal Analyzer during hardware debugging.
3. Click in the **Ram Type** column and choose whether the trigger expression is to be implemented with EBR (embedded block RAM) or slices (distributed RAM). The menu also shows how many of each resource would be needed. Normally you should choose EBR. But if you are short of EBR, choose slices.

4. Click in the **Max Sequence Depth** column and choose the maximum number of sequences, or trigger units connected by THEN operators, that can be used in the trigger expression.

   The maximum sequence depth must be at least as large as the number in the Sequence Depth column, which shows the number of sequences currently used by the trigger expression. Increasing the maximum sequence depth allows you to use more sequences if you change the trigger expression in Reveal Analyzer, but increasing the value also uses more FPGA resources. Consider the largest chain of sequences you might want to use in your test and choose a value at least that large. Reveal supports up to 16 sequence levels.

   The Max Sequence Depth value is set statically in Reveal Inserter and cannot be changed in Reveal Analyzer.

5. Click in the **Max Event Counter** box and choose the maximum size of the count in the trigger expression (the count is how many times a sequence must occur before a THEN statement).

   The Max Event Counter value must be at least as large as the largest counter value used in the trigger expression. Increasing the size of the event counter allows you to use larger counts if you change the trigger expression in Reveal Analyzer, but increasing the value also uses more FPGA resources. Consider the largest count you might want to use in your test and choose a value at least that large. The maximum is 65,536.

   You cannot change the Max Event Counter setting in Reveal Analyzer. You can only change it in Reveal Inserter.

See Also ▶"Example Trigger Expressions" on page 1064

Trigger Expression Syntax

Trigger expressions are combinations of trigger units. Trigger units can be combined in combinatorial, sequential, and mixed combinatorial and sequential patterns. A trigger expression can be dynamically changed at any time. Each module supports up to 16 trigger expressions that can be dynamically enabled or disabled in Reveal Analyzer. Trigger expressions support AND, OR, XOR, NOT, parentheses (for grouping), THEN, NEXT, # (count), and ## (consecutive count) operators. Each part of a trigger expression, called a sequence, can also be required to be valid a number of times before continuing to the next sequence in the trigger expression.

Detailed Trigger Expression Syntax Trigger expressions in both Reveal Inserter and Reveal Analyzer use the same syntax.

Operators You can use the following operators to connect trigger units:

- & (AND) – Combines trigger units using an AND operator.
- | (OR) – Combines trigger units using an OR operator.
- ^ (XOR) – Combines trigger units using a XOR operator.
- ! (NOT) – Combines a trigger unit with a NOT operator.
- Parentheses – Groups and orders trigger units.

- THEN – Creates a sequence of wait conditions. For example, the following statement:

  ```
  TU1 THEN TU2
  ```

  means “wait for TU1 to be true, then wait for TU2 to be true.”

  The following expression:

  ```
  (TU1 & TU2) THEN TU3
  ```

  means “wait for TU1 and TU2 to be true, then wait for TU3 to be true.”

  Reveal supports up to 16 sequence levels.

  See “Sequences and Counters” on page 1061 for more information on THEN statements.

- NEXT – Creates a sequence of wait conditions, like THEN, except the second trigger unit must come immediately after the first. That is, the second trigger unit must occur in the next clock cycle after the first trigger unit. See “Sequences and Counters” on page 1061 for more information on NEXT statements.
- # (count) – Inserts a counter into a sequence. See “Sequences and Counters” on page 1061 for information on counters.
- ## (consecutive count) – Inserts a counter into a sequence. Like # (count) except that the trigger units must come in consecutive clock cycles. That is, one trigger unit immediately after another with no delay between them. See “Sequences and Counters” on page 1061 for information on counters.

Case Sensitivity Trigger expressions are case-insensitive.

Spaces You can use spaces anywhere in a trigger expression.

Sequences and Counters Sequences are sequential states connected by THEN or NEXT operators. A counter counts how many times a state must occur before a THEN or NEXT statement or the end of the sequence. The maximum value of this count is determined by the Max Event Counter value. This value must be specified in Reveal Inserter and cannot be changed in Reveal Analyzer.

Here is an example of a trigger expression with a THEN operator:

```
TU1 THEN TU2
```

This trigger expression is interpreted as “wait for TU1 to be true, then wait for TU2 to be true.”

If the same example were written with a NEXT operator:

```
TU1 NEXT TU2
```

it is interpreted as “wait for TU1 to be true, then wait *one clock cycle* for TU2 to be true.” If TU2 is not true in the next clock cycle, the sequence fails and starts over, waiting for TU1 again.

The next trigger expression:

```
TU1 THEN TU2 #2
```

is interpreted as “wait for TU1 to be true, then wait for TU2 to be true for two sample clocks.” TU2 may be true on consecutive or non-consecutive sample clocks and still meet this condition.

The following statement:

```
TU1 ##5 THEN TU2
```

means that TU1 must occur for five consecutive sample clocks before TU2 is evaluated. If there are any extra delays between any of the five occurrences of TU1, the sequence fails and starts over.

The next expression:

```
(TU1 & TU2)#2 THEN TU3
```

means “wait for the second occurrence of TU1 and TU2 to be true, then wait for TU3.”

The last expression:

```
TU1 THEN (1)#200
```

means “wait for TU1 to be true, then wait for 200 sample clocks.” This expression is useful if you know that an event occurs a certain time after a condition.

You can only use one count (# or ##) operator per sequence. For example, the following statement is not valid, because it uses two counts in a sequence:

```
TU1 #5 & TU2 #2
```

Multiple count values are allowed for a single trigger expression, but only one per sequence. For two count operators to be valid in a trigger expression, the expression must contain at least one THEN or NEXT operator, as in the following example:

```
(TU1 & TU2) #5 THEN TU2 #2
```

This expression means “wait for TU1 and TU2 to be true for five sample clocks, then wait for TU2 to be true for two sample clocks.”

Also, the count operator must be applied to the entire sequence expression, as indicated by parentheses in the expression just given. The following is not allowed:

```
TU1 #5 & TU2 THEN TU2 #2
```

The count (#) operator cannot be used as part of a sequence following a NEXT operator. A consecutive count (##) operator may be used after a NEXT operator. The following is not allowed:

```
TU1 NEXT TU2 #2
```

The count (# or ##) operators can only be used in one of two areas:

- Immediately after a trigger unit or parentheses (). However, if the trigger unit is combined with another trigger unit without parentheses, a # cannot be used.
- After a closing parenthesis.

Precedence The symbols used in trigger expression syntax take the following precedence:

- Because it inserts a sequence, the THEN and NEXT operators always take the highest precedence in trigger expressions.
- Between THEN or NEXT statements, the order is defined by parentheses that you insert. For example, the following trigger expression:

  ```
  TU1 & (TU2|TU3)
  ```

  means “wait for either TU1 and TU2 or TU1 and TU3 to be true.”

  If you do not place any parentheses in the trigger expression, precedence is left to right until a THEN or NEXT statement is reached.

  For example, the following trigger expression:

  ```
  TU1 & TU2|TU3
  ```

  is interpreted as “wait for TU1 & TU2 to be true or wait for TU3 to be true.”
- The precedence of the ^ operator is same as that of the & operator and the | operator.
- The logic negation operator (!) has a higher precedence than the ^ operator, & operator, or | operator, for example:

  ```
  !TU1 & TU2
  ```

  means “not TU1 and TU2.”
- The # and ## operators have the same precedence as the ^ operator, & operator, or | operator. However, they can only be used in one of two areas:
  - Immediately after a trigger unit or trigger units combined in parentheses. However, if the trigger unit is combined with another trigger unit without parentheses, a # or ## operator cannot be used.

    Here is an example of correct syntax using the count (#) operator:

    ```
    TU1 #2 THEN TU3
    ```

    This statement means “wait for TU1 to be true for two sample clocks, then wait for TU3.”

    However, the following syntax is incorrect, because the count operator is applied to multiple trigger units combined without parentheses:

    ```
    TU1 & TU2#2 THEN TU3
    ```
  - After a closing parenthesis. Use parentheses to combine multiple trigger units and then apply a count, as in the following example:

    ```
    (TU1 & TU2)#2 THEN TU3
    ```

    This statement means “wait for the combination of TU1 and TU2 to be true for two sample clocks, then wait for TU3.”

See Also ▶"Example Trigger Expressions" on page 1064

Example Trigger Expressions

Following is a series of examples that demonstrate the flexibility of trigger expressions.

Example 1: Simplest Trigger Expression Following is the simplest trigger expression:

TU1

This trigger expression is true, causing a trigger to occur when the TU1 trigger unit is matched. The value and operator for the trigger unit is defined in the trigger unit, not in the trigger expression.

Example 2: Combinatorial Trigger Expression An example of a combinatorial trigger expression is as follows:

TU1 & TU2 | TU3

This trigger expression is true when (TU1 and TU2) or TU3 are matched. If no precedence ordering is specified, the order is left to right.

Example 3: Combinatorial Trigger Expression with Precedence Ordering In the following example of a combinatorial trigger expression, precedence makes a difference:

TU1 & (TU2 | TU3)

This trigger expression gives different results than the previous one. In this case, the trigger expression is true if (TU1 and TU2) or (TU1 and TU3) are matched.

Example 4: Simple Sequential Trigger Expression Following is an example of a simple sequential trigger expression:

TU1 THEN TU2

This trigger expression looks for a match of TU1, then waits for a match on TU2 a minimum of one sample clock later. Since this expression uses a THEN statement, it is considered to have multiple sequences. The first sequence is "TU1," since it must be matched first. The second sequence is "TU2," because it is only checked for a match after the first sequence has been found. The "sequence depth" is therefore 2.

The sequence depth is an important concept to understand for trigger expressions. Since the debug logic is inserted into the design, logic must be used to support the required sequence depth. Matching the depth to the entered expression can be used to minimize the logic. However, if you try to define a trigger expression that has a greater sequence depth than is available in the FPGA, an error will prevent the trigger expression from running. The dynamic capabilities of the trigger expression can therefore be

limited. To allow more flexibility, you can specify the maximum sequence depth when you set up the debug logic in Reveal Inserter. You can reserve more room for the trigger expression than is required for the trigger expression currently entered. If you specify multiple trigger expressions, each trigger expression can have its own maximum sequence depth.

Example 5: Mixed Combinatorial and Sequential Trigger Expression Here is an example showing how you can mix combinatorial and sequential elements in a trigger expression:

TU1 & TU2 THEN TU3 THEN TU4 | TU5

This trigger expression only generates a trigger if (TU1 AND TU2) match, then TU3 matches, then (TU4 or TU5) match. You can set precedence for any sequence, but not across sequences. The expression (TU1 & TU2) | TU3 THEN TU4 is correct. The expression (TU1 & TU2 THEN TU3) | TU4 is invalid and is not allowed.

Example 6: Sequential Trigger Expression with Sequence Counts The next trigger expression shows two new features, the sequence count and a true operator to count sample clocks:

(TU1 & TU2)#2 THEN TU3 THEN TU4#5 THEN (1)#200

This trigger expression means wait for (TU1 and TU2) to be true two times, then wait for TU3 to be true, then wait for TU4 to be true five times, then wait 200 sample clocks. The count (# followed by number) operator can only be applied to a whole sequence, not part of a sequence. When the count operator is used in a sequence, the count may or may not be contiguous. The always true operator (1) can be used to wait or delay for a number of contiguous sample clocks. It is useful if you knew that an event that you wanted to capture occurred a certain time after a condition but you did not know the state of the trigger signals at that time.

However, there is a limitation on the maximum size of the counter. This depends on how much hardware is reserved for the sequence counter. When you define a trigger expression, the Max Event Counter setting in the Trigger Expression section of Reveal Inserter and Reveal Analyzer specifies how large a count value is allowed in the trigger expression. Each trigger expression can have a unique Max Event Counter setting.

See Also ►"Trigger Expression Syntax" on page 1060

Managing Trigger Expressions

Trigger expressions are combinatorial or sequential equations of trigger units or both. Trigger expressions can be defined during insertion and changed in Reveal Analyzer. You can add up to 16 trigger expressions.

You can add trigger expressions only in Reveal Inserter. You cannot add them in Reveal Analyzer. You can dynamically enable or disable individual trigger expressions before triggering is activated during hardware debugging.

To add a trigger expression:

- In the Trigger Expression section of the Trigger Signal Setup tab, click **Add**.

To rename a trigger expression:

- Click in the Name column of the Trigger Expression section of the Trigger Signal Setup tab, and type in the new name. The name can consist of letters, numbers, and underscores. The first character must be either an underscore or a letter.

To remove a trigger expression:

1. Click in any box in the line representing the expression that you want to remove.
2. Click **Remove**.

See Also ▶Setting Up Trigger Expressions

Setting Trigger Options

In addition to the trigger units and trigger expressions, there are two other aspects of triggers: the final event counter and enabling the trigger signal for other Reveal modules.

Event Counter

The final event counter allows a counter to be added to the final trigger of one or more trigger expressions. In order to use the final event counter during logic analysis, you must specify it during insertion, along with the maximum count allowed. The actual count used by the counter during triggering can be dynamically changed during logic analysis.

To add a counter to the output of the final trigger:

1. Select **Enable final trigger counter** in the lower left portion of the Trigger Signal Setup tab.
2. In the **Event Counter Value** drop-down menu, choose the maximum size of the count of all the trigger expression outputs combined. You can choose powers of 2 between 2 and 65536.

   Clearing the “Enable final trigger counter” option is equivalent to setting the counter to a value of 1.

   You can change the value of this parameter in Reveal Analyzer, but you cannot make the value bigger, so be sure to reserve enough space for the count that you think you will need.

Trigger Out

To support triggers based on multiple sample clocks, cross-triggering is available between different debug modules. Reveal provides an optional trigger-out signal in the triggering section for every module.

If a design has multiple modules, trigger-out signals from other modules are listed as an available signal. To use a trigger-out signal as an input to another module, you must specify it as a NET or BOTH type. The IO type is only used for connecting the trigger-out to an external I/O. Trigger-out signals are listed in the Trigger Output view.

To create a trigger output signal:

1. Select **Enable Trigger Out**, at the bottom of the Trigger Signal Setup view.
2. In the Net drop-down menu, choose one of the following:
   - **IO** – Creates an I/O signal that can connect to an I/O pin.
   - **NET** – Creates a net signal that can be used in another module.
   - **BOTH** – Creates a signal that can be used another module and can connect to an I/O pin.
3. If you want to change the signal's name, double-click the name next to the Net menu and type in the new name.
4. In the Polarity menu, choose whether the signal is **Active High** or **Active Low**.
5. In the "Minimum pulse width" box, enter the minimum pulse width of the trigger output signal, measured in cycles of the sample clock. You can input any value of 0 or greater as the minimum pulse.
6. If you chose IO or BOTH for the Net type, go into the .lpf file and add a LOCATE preference to specify which pin the trigger-out should go to. See Applying Design Constraints. For example:

   LOCATE COMP "reveal_debug_count_LA0_net" SITE "J2" ;

Creating SERDES Debug Modules

SERDES Debug modules help in debugging the serdes function by giving you read and write access to control registers. In Reveal Analyzer you can monitor what is happening in the serdes and experiment with different control settings. These modules are only available with ECP5UM designs that use the DCU block.

To add a SERDES Debug module:

1. Choose **Debug > Add New Core > Add SERDES Debug**. See also "Managing the Modules in a Project" on page 1045.

   A new module appears in the Dataset view and the Serdes Debub Setup tab appears.

2. Select the sample clock in the Design Tree view and drag it to the Serdes Debug Setup tab. For help finding signals, see “Searching for Signals” on page 1046. For more about sample clocks, see “Sample Clock” on page 1051.
3. Select the serdes reset signal in the Design Tree view and drag it to the Serdes Debug Setup tab.
4. When you have set up all your modules, add them to the design project by choosing **Debug >** **Insert Debug** and running the design implementation process. See “Inserting the Reveal Modules” on page 1068.

Inserting the Reveal Modules

When you finish setting up the trace and trigger signals, you can insert the Reveal modules into the design.

Note

Interactive and stand-alone synthesis are not compatible with Reveal modules. Reveal Inserter automatically uses the integrated synthesis option. If you have not already, make sure your design project is set up for integrated synthesis. See Pre-Synthesis Check List.

To insert the debug logic modules into the design:

1. Choose **Debug >** **Insert Debug**.
2. In the Insert Debug to Design dialog box, select the modules to insert.
3. Select **Activate Reveal file in design project**.

   You should usually select this option. If the .rvl file is not active in the design project, the Reveal modules will not be included during synthesis.
4. Click **OK**.

   Reveal Inserter performs a design rule check and saves the Reveal (.rvl) file. The Output view shows resource requirements and the DRC report for the modules. The .rvl file is listed in the File List pane under Debug Files.
5. Implement the design in the usual way. See “Implementing the Design” on page 570.

   Adding Reveal modules can sometimes cause design implementation to fail. If you have problems, see “Troubleshooting Design Implementation Errors” on page 1068 and “Limitations” on page 1048.

Troubleshooting Design Implementation Errors

If the design implementation process fails after inserting Reveal modules, check this section for solutions. Some possible problems are preferences not being recognized and signals not being physically available for tracing or triggering.

Preferences Not Recognized When Reveal Inserter adds modules to a design, it must connect to the signals being used for triggers, traces, and the sample clock. If any of these signals have preferences on them, there is a chance that the preference may no longer be recognized. This only occurs on signals that do not go to the top level of the design when the Reveal module is not present. When the signal connects to a top-level Reveal module, the name on the net segment attached to the Reveal module is used for assigning preferences instead of the original name.

This problem occurs most often on the sample clock but other clocks may also be renamed. Check the clock section of the mapping report file (.mrp) for clock names. Being a clock signal, it is likely there is a preference already assigned to this signal. If the clock was not originally present in the top level of the design, the original preference is not recognized. This results in one or more warnings of the following form when Spreadsheet View is opened:

WARNING - baspe: Semantic Error: clocksig_200 matches no nets in the design. Occurred in "USE PRIMARY PURE NET "clocksig_200" ; ". Disabled this preference.

The solution is to copy the preference for the original signal and make a new preference for the net name that is now being used. Reveal Inserter always generates a name in the format of reveal_ist_<*number*>.

In the case of the above warning, the Period/Frequency sheet of Spreadsheet View shows a clknet named reveal_ist_67 instead of clocksig_200. In the preference file (.lpf), this can be corrected by copying the existing preference line ‘USE PRIMARY PURE NET “clocksig_200” ;’ and adding the line ‘USE PRIMARY PURE NET “reveal_ist_67” ;’.

By copying the preference instead of just changing it, the same preference file can be used both with and without the Reveal modules. If the debug connections are changed in Reveal Inserter, it may be necessary to change the preference due to Reveal Inserter generating a slightly different name.

Signals Implemented as Hard Routes Some signals that are implemented as hard routes in the FPGA instead of using the routing fabric are not available for tracing or triggering. Examples are connections to IB and OB components. If you select a signal for tracing or triggering that is implemented as a hard route, an error will occur during the synthesis, mapping, placement, or routing steps. However, the error can take many forms. Following are a couple of examples.

Here is an example error from the synthesis log file, <*cktname*>.log:

@E:"f:\cws\bugs\cr37986\reveal_workspace\tmprveal\rx_ddr_rvl.vhd":648:8:648:12|Port 'serin' on Chip 'RX_DDR' drives 1 PAD loads and 1 non PAD loads

In this example error message, the serin signal is a hard route, and serin is not the name of the original signal that was traced. The hierarchical path shown is for the Reveal module that was generated. It is not part of the original design and is not displayed during the debug module insertion. The

error message does not specify which trace or trigger signal is causing the problem.

To manually determine which signal is causing this error, you can use two approaches:

- Remove signals one by one in Reveal Inserter to see which caused the error. If you have only a few signals, this would be the best approach.
- Manually look through the design to determine the problem. If you have many signals, this approach would be the best.

  However, the error message refers to the temporary HDL design that is generated during debug logic insertion. Normally this HDL source is deleted after the database is built. To save this temporary HDL source in the case of errors in mapping, you must set an environment variable.

  a. In the System control panel, click on the Advanced tab, then click on the environment variable button at the bottom of the window.

  b. Create a new environment variable named KEEP_REVEAL_TEMP. The value can be anything, but it is normally set to TRUE.

  c. Once this variable is set, exit Diamond.

  d. Open Diamond and synthesize the design.

  You can now open the generated HDL to determine which signal caused the error. You can open this file with a text editor, or use HDL Explorer to open and explore the design. The top-level generated file is located at <*project_directory*>/reveal_workspace/tmpreveal/<*project_name*>_rvl.<*v or vhd*>.

Following is another example of an error generated during mapping:

ERROR - map: IO register/latch FF_inst cannot be implemented in PIC.

In this case, the input of a register is being traced. But the register is being implemented as an input flip-flop because of a preference, USE DIN. Allowing the register to be implemented as an internal flip-flop by removing the preference resolves the issue.

See Also ▶"Limitations" on page 1048

Removing Reveal Modules from the Design

When you want to remove the Reveal modules from your design, you can either remove the .rvl file from the design project or set it as inactive, leaving it easily available for future use. Otherwise, the modules will continue to be inserted.

To remove the Reveal modules from the design:

1. In the File List view, right-click the .rvl file.
2. Do one of the following:

- To remove the Reveal modules but keep the project, choose **Set as Inactive**.
- To delete the Reveal project, choose **Remove**.

3. Implement the design in the usual way. See Implementing the Design.

Performing Logic Analysis

Once you have created one or more Reveal modules in Reveal Inserter, you can use Reveal Analyzer to capture the trace signal data from your evaluation board and view that data as waveforms. As you run your tests and start getting results, you can modify the trigger units and expressions and the use of the trace buffer to test other conditions.

With ECP5UM designs you can also adjust serdes register settings and monitor serdes operation. See “Controlling Serdes” on page 1097.

To perform logic analysis:

1. If you will be working in a secured lab (without a network connection to the design project files), make a copy of the required files and install them in the lab computer. See “Working in a Secured Lab” on page 1073.
2. Connect your evaluation board and program the FPGA. See “Programming the FPGA” on page 1075.
3. Start Reveal Analyzer by selecting **Create a new file** in the Reveal Analyzer Startup Wizard. See “Starting Reveal Analyzer” on page 1076.
4. Set up the trigger signals for each module that you want to use. See “Setting Up the Trigger Signals” on page 1080.
5. Capture data. See “Capturing Data” on page 1089.
6. View the resulting waveforms for each module. See “Viewing Waveforms” on page 1091.
7. Optionally, you can save the data in a Reveal Analyzer (.rva) file, a value change dump (.vcd) file for use in third-party tools, or in an ASCII text (.txt) file. See “Saving the Reveal Analyzer Settings and Data” on page 1099.

To just view waveforms captured earlier:

1. Start Reveal Analyzer by selecting **Open an existing file** in the Reveal Analyzer Startup Wizard. See “Starting Reveal Analyzer” on page 1076.
2. View the waveforms. See “Viewing Waveforms” on page 1091.
3. Optionally, you can save the data in a Reveal Analyzer (.rva) file, a value change dump (.vcd) file for use in third-party tools, or in an ASCII text (.txt) file. See “Saving the Reveal Analyzer Settings and Data” on page 1099.

Working in a Secured Lab

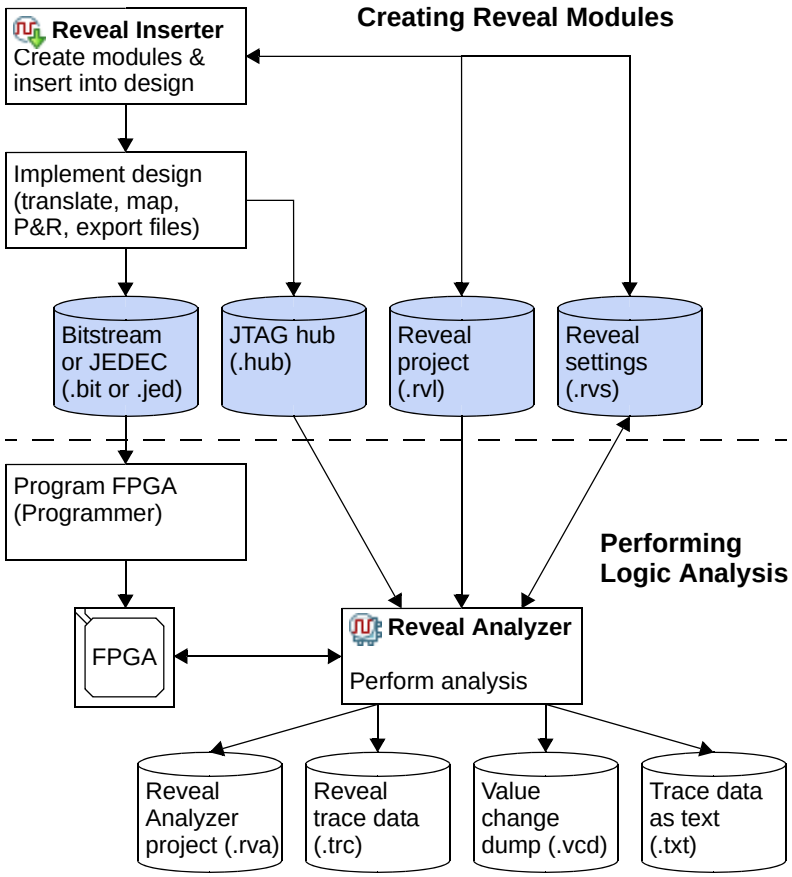
The usual process of Reveal logic analysis assumes that you are performing logic analysis on the same computer on which you created the Reveal modules, or that you are using a computer on the same network with easy access to the files. But sometimes your evaluation system is in a secured lab that is off the network.

In this situation use the stand-alone Reveal Analyzer and the stand-alone Programmer in the lab. To perform logic analysis, copy the files needed to

program the FPGA and to run Reveal Analyzer over to the lab computer. After you finish collecting trace data, you may want to copy settings or the trace data to bring them out of the lab.

The following figure shows the files needed by such a lab system and their sources. It also shows the files produced by Reveal Analyzer that you might want to bring out of the lab. See the following sections for more information about the files and how they are used.

Figure 29: Reveal Data Flow



Files to Bring into the Lab

The files you need to run Reveal Analyzer in the lab are:

- Bitstream (.bit) or JEDEC (.jed) file produced by the Export Files stage of the design implementation process. This file is required to program the FPGA.
- JTAG hub (.hub) file produced by the Translate Design stage of the design implementation process. This file is used by Reveal Analyzer to sort the data coming from the different Reveal modules.
- Reveal project (.rvl) file produced by Reveal Inserter. This is the defining file for a Reveal project and its modules. The .rvl file identifies the trace and trigger signals, and stores the trace and trigger options.

- Reveal settings (.rvs) file produced by Reveal Inserter. This file contains settings that can be changed in Reveal Analyzer while running tests. These settings include important parts of trigger units and trigger expressions.

Files to Bring Back

After collecting data with Reveal Analyzer, you may want to bring one or more files back from the lab either to update the Reveal project or to analyze the data somewhere else. See Figure 29 on page 1074.

If you made changes to the settings for trigger units or trigger expressions in Reveal Analyzer and want to update the project in Reveal Inserter with them, copy the .rvs file.

If you want to analyze the trace data outside the lab using Reveal Analyzer's LA Waveform view, choose **File >**  **Save** <*file*> and copy the following two files:

- Reveal Analyzer (.rva) file defines the Reveal Analyzer project. This file also contains data about the display of signals in the LA Waveform view.
- Reveal trace (.trc) file contains data recorded from the last test run. This file loads Reveal Analyzer's LA Waveform view.

If you want to analyze the trace data outside the lab using another tool, save the data as either a value change dump (.vcd) or text (.txt) file and copy that file. See "Saving to Other Formats" on page 1099.

Programming the FPGA

For an evaluation board using a single FPGA, program the FPGA in the usual way.

For an evaluation board using multiple FPGAs in a JTAG daisy chain, Reveal Analyzer has the following requirements:

- Only one device can be debugged at a time.
- The .xcf file must be in the design project directory.

To program an FPGA with a Reveal module in a daisy chain:

1. In Programmer, uncheck the Process column of the devices that do not get the Reveal module. This sets the operation of these devices to Bypass mode.
2. Ensure that the Process column of the device that does get the Reveal module is checked.
3. Double-click in the row of the device that does get the Reveal module.

   The Device Properties dialog box opens.

4. In the Device Properties dialog box, choose **Fast Program** from the drop-down menu.
5. Click **OK**.

For an FPGA that contains its own SPI flash, flash programming is also an option.

- "Programming the FPGA" on page 799

Starting Reveal Analyzer

Before starting Reveal Analyzer you need to decide if you want to work with a new Reveal Analyzer (.rva) file or an existing one. The .rva file defines the Reveal Analyzer project and contains data about the display of signals in the LA Waveform view. You may want to start Reveal Analyzer with a new file to set up a new test. Start with an existing file to rerun a test, to set up a new test based on existing settings, or to just view the waveforms from an earlier test.

How you start Reveal Analyzer also depends on whether you are using it integrated with Diamond or using the stand-alone version, and on your operating system.

Starting with a New File

Before you can start Reveal Analyzer with a new .rva file, you need to be connected to your evaluation board with a download cable and have the board's power turned on.

To start Reveal Analyzer with a new file:

1. Issue the start command. To start:
   - For integrated with Diamond, go to the Diamond main window and choose **Tools >** **Reveal Analyzer**.
   - For stand-alone in Windows, go to the Windows Start menu and choose **Programs > Lattice Diamond Reveal >** **Reveal Logic Analyzer**.
   - For stand-alone in Linux, go to a command line and enter the following:

     <*Reveal install path*>/bin/lin/**rvamain**

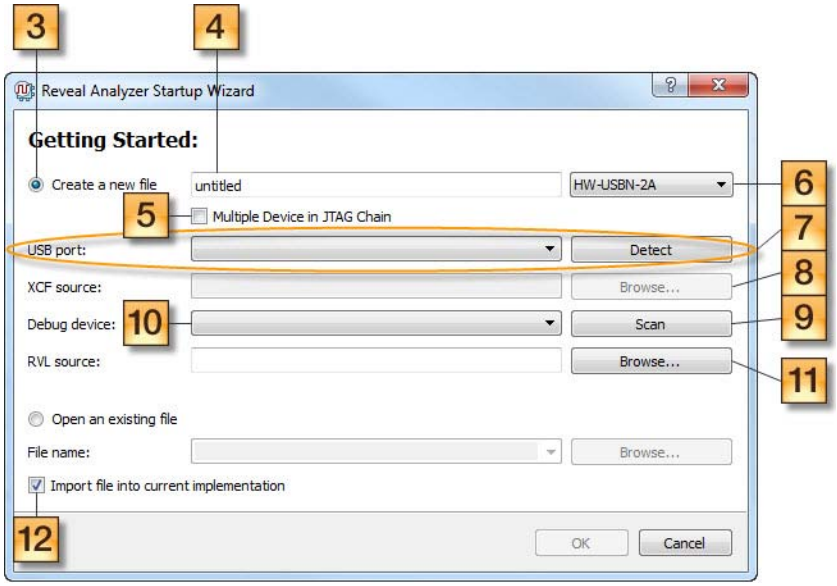
   If Reveal Analyzer finds just one .rva file in the active implementation, Reveal Analyzer opens with the data from that file. Otherwise, the Reveal Analyzer Startup Wizard dialog box appears.
2. If Reveal Analyzer opens with an existing file, choose **File > Save** <*file*> **As**.

The Save Reveal Analyzer File dialog box opens. Change the filename and click **Save**. You now have a new .rva file ready to work with.

3. In the Reveal Analyzer Startup Wizard dialog box, select **Create a new file** (at the upper-left of the dialog box).

   The dialog box presents a few rows of boxes that need to be filled in. In the figure below, the numbers match up with the steps in this procedure and show where the boxes, buttons, and menus are for each step.

Figure 30: Startup Wizard with Steps for a New File



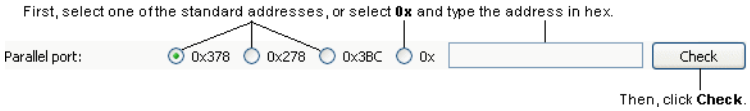
4. In the first row, type in the base name of the file. The extension is added automatically.
5. If there are daisy-chained devices, select **Multiple Device in JTAG Chain**.
6. To the right of this row is a drop-down menu. Choose the type of cable that your board is connected to.

   Another row in the dialog box (circled in the figure above) changes to select the port.
7. Select the port. The method depends on the cable type:

   - If USB, click **Detect**. Then choose from the active ports found. The following figure shows the row after choosing a USB type.

   - If parallel, select the port address. If it's not one of the standard addresses given, select **0x** and type in the hexadecimal address.

Then click **Check** to verify that the connection is working. The following figure shows the row after choosing a parallel type.



8. If there are daisy-chained devices, click **Browse** in the XCF source row to find the XCF source file.
9. Click **Scan** to find the FPGA.
10. If there is more than one FPGA on your board, go to the “Debug device” menu and choose one that has a Reveal icon. The icon indicates the presence of a Reveal module.
11. Click **Browse** in the RVL source row to find the Reveal Inserter project (.rvl) file.
12. To add the new .rva file to the File List view, select **Import file into current implementation**. The .rva file works the same either way.
13. Click **OK**.

See Also

- “Creating a New Source File” on page 35

Starting with an Existing File

If you want to start with an existing file, you just need to have that .rva file in the design project. You need to be connected to the evaluation board only if you want to run a test and capture data.

To start Reveal Analyzer with an existing file:

1. Issue the start command. To start:
   - In the Diamond main window, choose **Tools > Reveal Analyzer**.
   - The stand-alone Reveal Analyzer in Windows, go to the Windows Start menu and choose **Programs > Lattice Diamond Reveal > Reveal Logic Analyzer**.
   - The stand-alone Reveal Analyzer in Linux, enter the following on a command line:

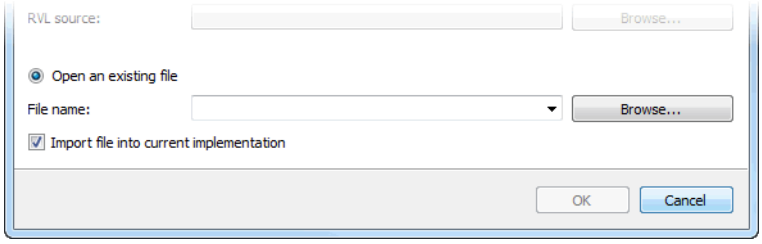
     <*Reveal install path*>/bin/lin/**rvamain**

   If Reveal Analyzer finds just one .rva file in the active implementation, Reveal Analyzer opens with the data from that file. Otherwise, the Reveal Analyzer Startup Wizard dialog box appears.

   If Reveal Analyzer opens with the .rva file you want to use, you’re ready to go. Otherwise continue with the following steps.

2. In the Reveal Analyzer Startup Wizard dialog box, select **Open an existing file** (in the lower part of the dialog box). See following figure.

Figure 31: Existing File Part of Startup Wizard



3. In the “File name” box, choose one of the available .rva files.
4. If the file you want is not in the menu, click **Browse** and browse to the desired .rva file.
5. To add the .rva file to the File List view, select **Import file into current implementation**. The .rva file works the same either way.
6. Click **OK**.

If the connection to your evaluation board has changed, either in the cable type or the computer port used, you need to tell Reveal Analyzer about the new connection. See “Changing the Cable Connection” on page 1079.

Changing the Cable Connection

If you need to change how your evaluation board is connected to your computer, go ahead and make the change. Then go through the following procedure to change the Reveal Analyzer project.

To change the cable setting in a Reveal Analyzer project:

1. Make sure your evaluation board is connected and that its power is on.
2. If Reveal Analyzer is not already open, start it as described in “Starting with an Existing File” on page 1078.
3. Choose **Design > Cable Connection Manager**.

   The Cable Connection Manager dialog box opens.
4. In the dialog box, choose the cable type.

   The second row in the dialog box changes to select the specific port.
5. Select the specific port. The method depends on the port type:
   - If USB, click **Detect**. Then choose from the active ports found.
   - If parallel, select the port address. If it’s not one of the standard addresses given, select **0x** and type in the hexadecimal address. Then click **Check** to verify that the connection is working.
6. To change the clock speed of the cable connection, adjust the value of TCK Low Pulse Width Delay.

7. Click **OK**.

Setting Up the Trigger Signals

In Reveal Analyzer, you cannot create new trigger units or trigger expressions, but you can change how they are named and defined. In trigger units, you can change the operators, radices, and values. In trigger expressions, you can change the expression including the operators and which trigger units are used. You can also modify some of the trigger options and the trigger position.

To modify the trigger of a module.

1. Click on the **LA Trigger** tab.
2. Choose the module from the drop-down menu in the Reveal Analyzer toolbar.

   The definition of the module's trigger units and trigger expressions appear. Grayed out cells and options cannot be changed in Reveal Analyzer. To change them, you must go back to Reveal Inserter.
3. Modify the trigger units as desired. If you want to change:
   - Operator: Choose an operator from the drop-down menu. You cannot change or select serial compare in Reveal Analyzer. See "About Trigger Unit Operators" on page 1081.
   - Radix of the value: Choose a radix from the drop-down menu. The menu includes token sets whose bit width matches the trigger unit's signals.
   - Value: Select it and type in a new comparison value. The form of the value must match the specified radix. If you selected a token set in the Radix column, a drop-down menu opens in the Value column listing the tokens in the token set.

     You can use "x" for a don't-care value if you selected binary, octal, or hexadecimal in the Radix column and if you selected ==, !=, or serial compare in the Operator column.
4. Modify the trigger expressions as desired. Trigger expressions can be completely rewritten provided that you do not exceed the maximum sequence depth or the maximum event counter. See "Trigger Expression Syntax" on page 1082.
5. In the Trigger Expression Name column, select the trigger expressions that you want to use in the next test.
6. In the Trigger Options section, at Enable TE, choose how to combine the selected trigger expressions to form the trigger event:
   - **AND All** means that all of the trigger expressions must be satisfied to form the trigger event.
   - **OR All** means that only one of the trigger expressions must be satisfied to form the trigger event.

7. If you want the trigger event, as specified in the Enable TE option, to happen more than once before capturing trace data, select **Final Event Counter**, in the Trigger Position section. Then specify the number of times the event is to happen to produce the actual trigger on the trigger signal. This option is available only if the event counter was enabled for the module in Reveal Inserter.
8. In the Trigger Options section, specify the number of samples per trigger and the number of triggers you want to record. The number of samples multiplied by the number of triggers cannot be greater than the trace buffer depth that was specified in Reveal Inserter. Reveal Analyzer adjusts the values when needed.
9. In the Trigger Position section, specify the trigger position relative to the trace data. The numbers in the section title show the current position. For example, “8/128” means the trigger happens on sample 8 out of the 128 samples per trigger. Select either:
   - **Pre-selected** and choose one of the standard positions:
     - Pre-Trigger: 1/16 of the way from the beginning of the samples.
     - Center-Trigger: 1/2 of the way from the beginning of the samples.
     - Post-Trigger: 15/16 of the way from the beginning of the samples.
   - **User-selected** and choose a position with the slider.

About Trigger Unit Operators

Most of the trigger unit operators use standard logical comparisons between the current value of the combined signals of the trigger unit and a specified value. But some of the operators are unusual and need some explanation.

With the exception of “serial compare,” the operators can be changed in Reveal Analyzer.

Standard Logical Operators Reveal includes the following operators:

- == equal to
- != not equal to
- > greater than
- >= greater than or equal to
- < less than
- <= less than or equal to

Rising Edge and Falling Edge The “rising edge” and “falling edge” operators check for change in the signal value, not the value itself. So the trigger unit’s specified value is a bit mask showing which signals should have a rising or falling edge. A 1 means “look for the edge;” a 0 means “ignore this bit.” A multiple-bit value is true if any of the specified bits has the edge.

For example, consider a trigger unit defined as cout[3:0], rising edge, 1110. This trigger unit will be true only when cout[3], cout[2], or cout[1] have a rising edge. What happens on cout[0] does not matter.

- 0000 > 1110

  True because cout[3], cout[2], and cout[1] rose.

- 0000 > 1111

  True for the same reason. It does not matter whether cout[0] rises or not.

- 0000 > 0100

  True because a rising edge on any of the specified bits is sufficient.

- 1000 > 1000

  False because cout[3] did not rise. It just stayed high.

Serial Compare The “serial compare” operator checks for a series of values on a single signal. For example, if a trigger unit’s specified value is 1011, the “serial compare” operator looks for a 1 on the first clock, a 0 on the next clock, a 1 on the next clock, and a 1 on the last clock. Only after those four conditions are met in those four clock cycles is the trigger unit true.

Serial compare is available only when a single signal is listed in the trigger unit’s signal list. The radix is automatically binary.

You can only set the serial compare operator in Reveal Inserter. You cannot change it or select it in Reveal Analyzer as you can the other operators.

Trigger Expression Syntax

Trigger expressions are combinations of trigger units. Trigger units can be combined in combinatorial, sequential, and mixed combinatorial and sequential patterns. A trigger expression can be dynamically changed at any time. Each module supports up to 16 trigger expressions that can be dynamically enabled or disabled in Reveal Analyzer. Trigger expressions support AND, OR, XOR, NOT, parentheses (for grouping), THEN, NEXT, # (count), and ## (consecutive count) operators. Each part of a trigger expression, called a sequence, can also be required to be valid a number of times before continuing to the next sequence in the trigger expression.

Detailed Trigger Expression Syntax Trigger expressions in both Reveal Inserter and Reveal Analyzer use the same syntax.

Operators You can use the following operators to connect trigger units:

- & (AND) – Combines trigger units using an AND operator.
- | (OR) – Combines trigger units using an OR operator.
- ^ (XOR) – Combines trigger units using a XOR operator.
- ! (NOT) – Combines a trigger unit with a NOT operator.
- Parentheses – Groups and orders trigger units.

- THEN – Creates a sequence of wait conditions. For example, the following statement:

  ```
  TU1 THEN TU2
  ```

  means “wait for TU1 to be true, then wait for TU2 to be true.”

  The following expression:

  ```
  (TU1 & TU2) THEN TU3
  ```

  means “wait for TU1 and TU2 to be true, then wait for TU3 to be true.”

  Reveal supports up to 16 sequence levels.

  See “Sequences and Counters” on page 1083 for more information on THEN statements.

- NEXT – Creates a sequence of wait conditions, like THEN, except the second trigger unit must come immediately after the first. That is, the second trigger unit must occur in the next clock cycle after the first trigger unit. See “Sequences and Counters” on page 1083 for more information on NEXT statements.

- # (count) – Inserts a counter into a sequence. See “Sequences and Counters” on page 1083 for information on counters.

- ## (consecutive count) – Inserts a counter into a sequence. Like # (count) except that the trigger units must come in consecutive clock cycles. That is, one trigger unit immediately after another with no delay between them. See “Sequences and Counters” on page 1083 for information on counters.

Case Sensitivity Trigger expressions are case-insensitive.

Spaces You can use spaces anywhere in a trigger expression.

Sequences and Counters Sequences are sequential states connected by THEN or NEXT operators. A counter counts how many times a state must occur before a THEN or NEXT statement or the end of the sequence. The maximum value of this count is determined by the Max Event Counter value. This value must be specified in Reveal Inserter and cannot be changed in Reveal Analyzer.

Here is an example of a trigger expression with a THEN operator:

```
TU1 THEN TU2
```

This trigger expression is interpreted as “wait for TU1 to be true, then wait for TU2 to be true.”

If the same example were written with a NEXT operator:

```
TU1 NEXT TU2
```

it is interpreted as “wait for TU1 to be true, then wait *one clock cycle* for TU2 to be true.” If TU2 is not true in the next clock cycle, the sequence fails and starts over, waiting for TU1 again.

The next trigger expression:

```
TU1 THEN TU2 #2
```

is interpreted as “wait for TU1 to be true, then wait for TU2 to be true for two sample clocks.” TU2 may be true on consecutive or non-consecutive sample clocks and still meet this condition.

The following statement:

```
TU1 ##5 THEN TU2
```

means that TU1 must occur for five consecutive sample clocks before TU2 is evaluated. If there are any extra delays between any of the five occurrences of TU1, the sequence fails and starts over.

The next expression:

```
(TU1 & TU2)#2 THEN TU3
```

means “wait for the second occurrence of TU1 and TU2 to be true, then wait for TU3.”

The last expression:

```
TU1 THEN (1)#200
```

means “wait for TU1 to be true, then wait for 200 sample clocks.” This expression is useful if you know that an event occurs a certain time after a condition.

You can only use one count (# or ##) operator per sequence. For example, the following statement is not valid, because it uses two counts in a sequence:

```
TU1 #5 & TU2 #2
```

Multiple count values are allowed for a single trigger expression, but only one per sequence. For two count operators to be valid in a trigger expression, the expression must contain at least one THEN or NEXT operator, as in the following example:

```
(TU1 & TU2) #5 THEN TU2 #2
```

This expression means “wait for TU1 and TU2 to be true for five sample clocks, then wait for TU2 to be true for two sample clocks.”

Also, the count operator must be applied to the entire sequence expression, as indicated by parentheses in the expression just given. The following is not allowed:

```
TU1 #5 & TU2 THEN TU2 #2
```

The count (#) operator cannot be used as part of a sequence following a NEXT operator. A consecutive count (##) operator may be used after a NEXT operator. The following is not allowed:

```
TU1 NEXT TU2 #2
```

The count (# or ##) operators can only be used in one of two areas:

- Immediately after a trigger unit or parentheses (). However, if the trigger unit is combined with another trigger unit without parentheses, a # cannot be used.
- After a closing parenthesis.

Precedence The symbols used in trigger expression syntax take the following precedence:

- Because it inserts a sequence, the THEN and NEXT operators always take the highest precedence in trigger expressions.
- Between THEN or NEXT statements, the order is defined by parentheses that you insert. For example, the following trigger expression:

  ```
  TU1 & (TU2|TU3)
  ```

  means “wait for either TU1 and TU2 or TU1 and TU3 to be true.”

  If you do not place any parentheses in the trigger expression, precedence is left to right until a THEN or NEXT statement is reached.

  For example, the following trigger expression:

  ```
  TU1 & TU2|TU3
  ```

  is interpreted as “wait for TU1 & TU2 to be true or wait for TU3 to be true.”
- The precedence of the ^ operator is same as that of the & operator and the | operator.
- The logic negation operator (!) has a higher precedence than the ^ operator, & operator, or | operator, for example:

  ```
  !TU1 & TU2
  ```

  means “not TU1 and TU2.”
- The # and ## operators have the same precedence as the ^ operator, & operator, or | operator. However, they can only be used in one of two areas:
  - Immediately after a trigger unit or trigger units combined in parentheses. However, if the trigger unit is combined with another trigger unit without parentheses, a # or ## operator cannot be used.

    Here is an example of correct syntax using the count (#) operator:

    ```
    TU1 #2 THEN TU3
    ```

    This statement means “wait for TU1 to be true for two sample clocks, then wait for TU3.”

    However, the following syntax is incorrect, because the count operator is applied to multiple trigger units combined without parentheses:

    ```
    TU1 & TU2#2 THEN TU3
    ```
  - After a closing parenthesis. Use parentheses to combine multiple trigger units and then apply a count, as in the following example:

    ```
    (TU1 & TU2)#2 THEN TU3
    ```

    This statement means “wait for the combination of TU1 and TU2 to be true for two sample clocks, then wait for TU3.”

See Also ▶"Example Trigger Expressions" on page 1086

Example Trigger Expressions

Following is a series of examples that demonstrate the flexibility of trigger expressions.

Example 1: Simplest Trigger Expression Following is the simplest trigger expression:

TU1

This trigger expression is true, causing a trigger to occur when the TU1 trigger unit is matched. The value and operator for the trigger unit is defined in the trigger unit, not in the trigger expression.

Example 2: Combinatorial Trigger Expression An example of a combinatorial trigger expression is as follows:

TU1 & TU2 | TU3

This trigger expression is true when (TU1 and TU2) or TU3 are matched. If no precedence ordering is specified, the order is left to right.

Example 3: Combinatorial Trigger Expression with Precedence Ordering In the following example of a combinatorial trigger expression, precedence makes a difference:

TU1 & (TU2 | TU3)

This trigger expression gives different results than the previous one. In this case, the trigger expression is true if (TU1 and TU2) or (TU1 and TU3) are matched.

Example 4: Simple Sequential Trigger Expression Following is an example of a simple sequential trigger expression:

TU1 THEN TU2

This trigger expression looks for a match of TU1, then waits for a match on TU2 a minimum of one sample clock later. Since this expression uses a THEN statement, it is considered to have multiple sequences. The first sequence is "TU1," since it must be matched first. The second sequence is "TU2," because it is only checked for a match after the first sequence has been found. The "sequence depth" is therefore 2.

The sequence depth is an important concept to understand for trigger expressions. Since the debug logic is inserted into the design, logic must be used to support the required sequence depth. Matching the depth to the entered expression can be used to minimize the logic. However, if you try to define a trigger expression that has a greater sequence depth than is available in the FPGA, an error will prevent the trigger expression from running. The dynamic capabilities of the trigger expression can therefore be

limited. To allow more flexibility, you can specify the maximum sequence depth when you set up the debug logic in Reveal Inserter. You can reserve more room for the trigger expression than is required for the trigger expression currently entered. If you specify multiple trigger expressions, each trigger expression can have its own maximum sequence depth.

Example 5: Mixed Combinatorial and Sequential Trigger Expression
Here is an example showing how you can mix combinatorial and sequential elements in a trigger expression:

TU1 & TU2 THEN TU3 THEN TU4 | TU5

This trigger expression only generates a trigger if (TU1 AND TU2) match, then TU3 matches, then (TU4 or TU5) match. You can set precedence for any sequence, but not across sequences. The expression (TU1 & TU2) | TU3 THEN TU4 is correct. The expression (TU1 & TU2 THEN TU3) | TU4 is invalid and is not allowed.

Example 6: Sequential Trigger Expression with Sequence Counts The next trigger expression shows two new features, the sequence count and a true operator to count sample clocks:

(TU1 & TU2)#2 THEN TU3 THEN TU4#5 THEN (1)#200

This trigger expression means wait for (TU1 and TU2) to be true two times, then wait for TU3 to be true, then wait for TU4 to be true five times, then wait 200 sample clocks. The count (# followed by number) operator can only be applied to a whole sequence, not part of a sequence. When the count operator is used in a sequence, the count may or may not be contiguous. The always true operator (1) can be used to wait or delay for a number of contiguous sample clocks. It is useful if you knew that an event that you wanted to capture occurred a certain time after a condition but you did not know the state of the trigger signals at that time.

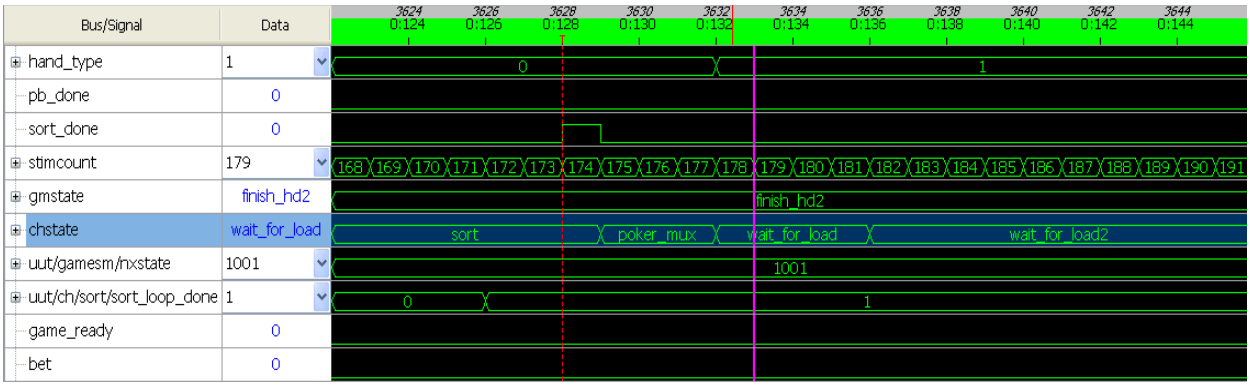
However, there is a limitation on the maximum size of the counter. This depends on how much hardware is reserved for the sequence counter. When you define a trigger expression, the Max Event Counter setting in the Trigger Expression section of Reveal Inserter and Reveal Analyzer specifies how large a count value is allowed in the trigger expression. Each trigger expression can have a unique Max Event Counter setting.

See Also ▶"Trigger Expression Syntax" on page 1082

Creating Token Sets

You can create sets of “tokens,” or text labels, for values that might appear on trace buses. You can create tokens such as ONE, TWO, THREE, or Reset, Boot, Load. Tokens can make reading the waveforms in Reveal Analyzer easier and can highlight the occurrence of key values. See the following figure for an example. The row for the chstate bus uses tokens.

Figure 32: LA Waveform View Using Tokens



To create or modify a token set:

1. Choose **Design > Token Set Manager**.

   The Token Manager dialog box opens. If the Reveal project already has token sets defined, they are listed in the dialog box.

2. If you want to use token sets that were previously saved to a separate file, right-click in the dialog box and choose **Import**. In the Import Tokens dialog box, browse to the token (.rvt) file and click **Open**.

   The token sets in the .rvt file are added to the list in Token Manager.

3. To create a new token set, click **Add Set**.

   A new token set is started with default values. But it has no tokens defined yet.

4. To change the size of the token values, double-click the value in the Num. of Bits column and type in the new width, in bits. The width can be up to 256. The width must be the same as the bus that the token set will be used with.

   The Num. of Bits value can only be changed when the token set is empty. If there are any tokens, you will get an error message.

5. To create a new token, select a token set. Then click **Add Token**.

   A new token is created with default values. Repeat for as many new tokens needed.

6. You can modify token sets by doing any of the following:

   - To change the name of a token or token set, double-click the name and type a new name. The name can consist of letters, numbers, and underscores (_). It must start with a letter.

- To change the value of a token, double-click the value and type in a new value. Token values must be prefixed by one of the radix indicators shown in the following table:

Radix	Prefix	Example
Binary	b’	b’110x0
Octal	o’	o’53
Decimal	d’	d’123
Hexadecimal	h’	x’0F2

  If a value does not have a prefix, its radix is assumed to be binary. You can use an “x” in binary numbers as a don’t-care value.

- To remove a token or token set, select it. Then click **Remove**.

7. You can save the collection of token sets showing in the dialog box to a separate file for use in another project. To save the token sets, right-click and choose **Export**. In the Export Tokens dialog box, browse to the desired location and type in the name of the new token (.rvt) file. Click **Save**.
8. When you are done, click **Close** to close the dialog box. The token sets are automatically applied to the current Reveal project.

Capturing Data

After you have configured trigger settings in the LA Trigger tab, you can capture data.

Before capturing data, your evaluation board must be connected and the design downloaded. See “Programming the FPGA” on page 1075.

To capture data:

1. In the Reveal Analyzer toolbar, select the modules you want to use.
2. Click the Run button in the Reveal Analyzer toolbar.

   The Run button changes into the Stop button and the status bar next to the button shows the progress.

Reveal Analyzer first configures the modules selected for the correct trigger condition, then waits for the trigger conditions to occur. When a trigger occurs, the data is uploaded to your computer. The resulting waveforms appear in the LA Waveform tab.

If the trigger condition is not met, Reveal Analyzer continues running. In that case, you can use manual triggering, described in “Using Manual Triggering” on page 1090.

See Also ▶"Stopping Data Capture" on page 1090

Stopping Data Capture

You can stop capturing data at any time.

To stop data capture:

1. Choose a module from the drop-down menu in the Reveal Analyzer tool bar.
2. Click the Stop button in the Reveal Analyzer toolbar.

This command only stops the data capture for the current module. You must stop each module separately.

Using Manual Triggering

If triggering fails to occur or you want to trigger manually instead of triggering when a signal condition occurs, you can use manual triggering to collect data. The data may then help you find out why triggering did not occur as you originally intended.

When you select manual triggering, Reveal Analyzer fills the buffer with data captured from that moment. In single-trigger capture mode, it fills the buffer and stops. In multiple-trigger capture mode, it captures one trigger and data. You can then continue to manually trigger as many times as the original triggering setup specified. If you want to capture fewer triggers, you can manually trigger the desired number of times, then click the Stop button. Then the buffer starts uploading the data.

To use manual triggering:

1. After you start capturing data with the Run button, choose a module from the drop-down menu in the Reveal Analyzer tool bar.
2. Click the Manual Trigger button.

   This command only applies to the data capture on the current module. You must start each module separately.
3. When you have captured the desired number of triggers in multiple trigger capture mode, click the Stop button.

Common Error Conditions

Reveal Analyzer may fail to generate waveforms and instead issue an error message because of problems with the inserted modules.

Clock Causes Module to Malfunction If Reveal Analyzer issues the following error message, the module may not be functional because of a clock problem:

```
Incorrect HUB ID. Check the clock or cable setup.
```

In this case, be sure the clock is running on the target hardware.

Signature in .rvl File Does Not Match Signature in Bitstream If Reveal Analyzer issues an error message similar to the following, the module may be functional, but the signature in the .rvl file does not match the signature in the bitstream:

ERROR: core0 incorrect signature
Problem cause is device programmed with incorrect (older) bitstream.

This problem can be caused by saving the Reveal Inserter project file, even if you have made no changes, without re-implementing the design.

If you receive this message, regenerate the bitstream or JEDEC file, including running all implementation stages, or download another file whose signature matches that of the .rvl file.

Sample Clock Runs Too Slowly The following module signature error message indicates that the sample clock is running too slowly:

ERROR: core0 incorrect signature
Problem cause is sample clock not running or running too slow.

On the board, make sure that the minimum sample clock frequency is at least three times (and preferably four times) that of the JTAG clock. If the sample clock speed is too slow, you will not be able to complete capturing data.

If the device signature is all ones:

ERROR: core0 incorrect signature (RVL File [1906089203] does not match Device [1111111111]).

there may have been a problem during implementation. The post-map netlist needs to be viewed directly to determine the root cause. Contact Lattice Technical Support.

Viewing Waveforms

After capturing data, you can view the trace data in waveform format in the LA Waveform tab. Whenever the trace stops, Reveal Analyzer reads the trace samples and automatically updates the signal waveforms.

To view a waveform:

1. Click the **LA Waveform** tab.
2. Choose a module from the drop-down menu in the Reveal Analyzer tool bar.

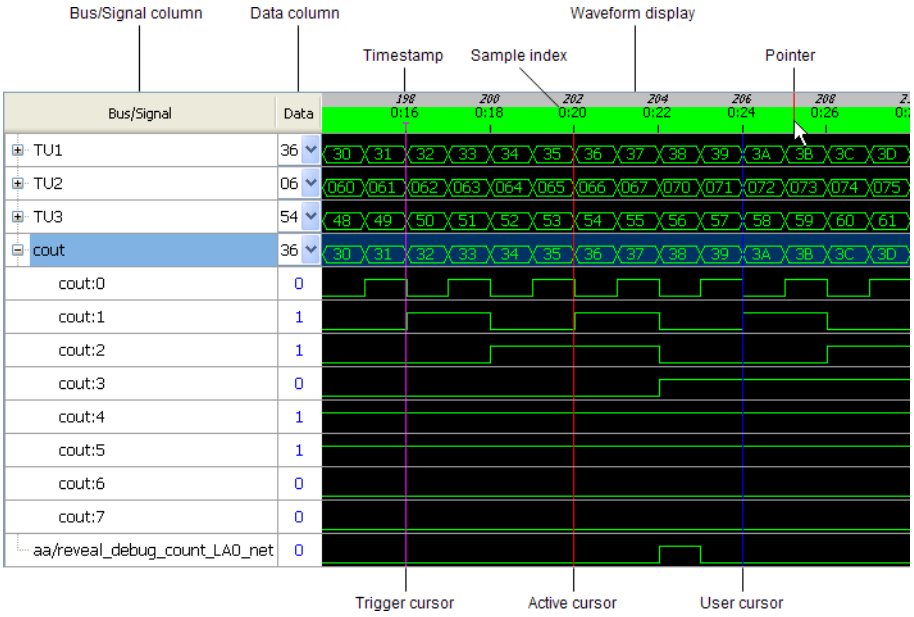
Sometimes the waveform includes fewer clock cycles than you expect; in particular, fewer before the trigger. This happens if the trigger occurs so

quickly after the test starts that there are not enough clock cycles before the trigger to fill that part of the trace buffer.

About the LA Waveform View

Waveforms are presented in a grid layout as shown in Figure 33 along with several features to help you find and analyze the data.

Figure 33: Elements of the LA Waveform View



Bus/Signal Column Displays the names of the trace buses and signals in the selected module.

Data Column Displays the value of the bus or signal at the active cursor (a solid, red line that you can set in the waveform display). Buses also have a drop-down menu for setting the radix used in the Data column and in the waveform display. The menu includes token sets whose bit width matches the bus. See “Setting a Trace Bus Radix” on page 1095.

Waveform Display Displays the trace data in waveform format. When there is room, bus values are included the display using the radix set in the Data column. You can zoom in and out, pan, and jump to various points.

The waveform display includes several other elements to help you read the display and analyze the data:

- Timestamp. The gray bar at the top of the display shows “timestamps” of the trace frames (actually, a simple count of the clock cycles). Timestamps are shown only if the Timestamp trace option was selected for the module in Reveal Inserter. See “Timestamp” on page 1053.
- Sample Index. The green bar near the top of the display shows a count of triggers and trace samples within each trigger’s data set. The sample indexes have the form <*trigger*>:<*sample*>. For example, 0:2 indicates the

first trigger and the third trace sample for that trigger (the counts are zero-based). 2:10 indicates the third trigger and the eleventh trace sample for that trigger.

- Pointer. A red line that cuts across the timestamp and sample index bars, the pointer follows the horizontal movement of the mouse pointer across the waveform display. Use the pointer to see where you are in time as you examine the waveform.
- Cursors. Vertical lines cutting through all the signals, cursors mark moments in the waveform. See “About Cursors” on page 1093.

See Also

- “Zooming In and Out” on page 1094
- “Moving around the Waveform” on page 1095

About Cursors

The LA Waveform view comes with three types of “cursors” to highlight moments in the waveform. The cursors are vertical lines cutting through all the signals at the leading edge of a clock cycle. See Figure 33 on page 1092. The three types are:

- Trigger. A purple line with a “T” at the top, trigger cursors are automatically placed at the moment of each final trigger event. If the module used a sample enable signal and the exact moment of the trigger is unknown, the waveform shows a trigger cursor five clock cycles before the sample enable signal turned inactive and sampling stopped.
- Active. A red line appears wherever you click in the waveform. The Data column shows the values of the signals and buses at the moment highlighted by the active cursor.
- User. A blue line can be placed anywhere you want. Use these cursors to mark moments of interest. You can also use these cursors to maneuver about a long waveform with the Go to Cursor command. See “Working with User Cursors” on page 1093.

Working with User Cursors

You can create any number of user cursors. They can be moved or deleted. You can also jump the display to any one of them.

Most cursor functions require that the LA Waveform view be in Select mode: right-click in the LA Waveform view and choose **Select Mode**.

To create a user cursor:

1. Click in the desired clock cycle.

   The active cursor appears. Make sure it is where you want the user cursor to be.

2. Right-click and choose **Add Cursor**.

To move a user cursor:

1. Zoom in so you can easily see and click in individual samples.
2. Click in the desired location.

   The active cursor appears. Make sure it is where you want the user cursor to be.
3. Carefully click in the sample to the right of the user cursor.

   You must click on or to the right of the user cursor. Otherwise you are just moving the active cursor to a neighboring sample.

   The user cursor and the active cursor exchange locations.

To jump to a user cursor:

- Right-click in the waveform and choose **Go to Cursor >** <*cursor*>. Cursors are identified by the sample index as shown in the green bar at the top of the waveform display.

To remove a user cursor:

1. Click on or near the cursor.

   The active cursor appears. Make sure it is on or next to the user cursor you want to remove.
2. Right-click and choose **Remove Cursor**.

To remove all user cursors:

- Right-click in the waveform and choose **Clear All Cursor**.

See Also "Moving around the Waveform" on page 1095

Zooming In and Out

You can zoom in, to expand the waveform and see more detail, and zoom out, to see more of the waveform.

To zoom in on a waveform:

- Choose **View > Zoom In**.

To zoom in on a specified area:

1. Right-click the waveform and choose **Zoom Mode**.

   The pointer changes to a cross: +.
2. Hold down the left mouse button and drag the pointer across the area you want to zoom in on.

   A shaded area appears on the waveform display.
3. Release the mouse button.

The shaded area expands to fill the display.

To zoom out on a waveform:

- Choose **View >**  **Zoom Out**.

To show the entire waveform in the window:

- Choose **View >**  **Zoom Fit**.

See Also ▶"Moving around the Waveform" on page 1095

Moving around the Waveform

The waveform is usually much wider than the display, especially if you zoom in enough to see individual trace samples. To see nearby sections of the waveform, you can slide it left and right by panning (described below) or by using the horizontal scroll bar at the bottom of the LA Waveform view. You can also jump to various points in the waveform including any cursors you've placed, the trigger point, the start of the display, and the end.

To pan the waveform display:

1. Right-click in the waveform and choose **Pan Mode**.
2. Press the left mouse button and drag to the left or the right.

To jump to a location in the waveform:

- Right-click in the waveform and choose from the menu. To jump to the:
  - User cursor, choose **Go to Cursor >** <*cursor*>. Cursors are identified by the sample index as shown in the green bar at the top of the waveform display.
  - Trigger point, choose **Zoom > Zoom Trigger**
  - Start of the display, choose **Zoom > Zoom Start**
  - End of the display, choose **Zoom > Zoom End**

  The display changes to show the selection. The zoom level may change to keep the display filled.

- "Working with User Cursors" on page 1093
- "Zooming In and Out" on page 1094

Setting a Trace Bus Radix

You can set the radix of a trace bus displayed in the LA Waveform tab. You can choose a binary, octal, decimal, or hexadecimal radix. You can also use any token set whose bit width matches the bus.

To set the bus radix of a signal or bus:

1. In the LA Waveform tab, click in the Data cell of the signal or bus.

   A menu appears showing the different radices and any token sets that fit.

2. Choose the desired radix or token set.

To set the bus radix of multiple signals and buses:

This method can set several signals to the same radix but cannot use tokens.

1. In the LA Waveform tab, select one or more buses.

   To select one bus, click on it. To select more than one, Control-click on each one. To select all buses in a range, click on one end of the range and Shift-click the other end. If you want to change all the signals in the waveform to the same radix, you do not need to select anything.

2. Right-click in one of the selected waveforms and choose **Set Bus Radix**. Be careful to click in the same row as one of your selections, or you will change the selection.

   The Set Bus Radix dialog box opens.

3. In the drop-down menu, choose the radix.
4. In the Range drop-down menu, choose **Selected signals** or, if you want to change all the signals in the waveform to the same radix, choose **All signals**.
5. Click **OK**.

Changing LA Waveform Colors

You can change the colors used by the LA Waveform view.

To change the colors:

1. Choose **Tools > Options**.
2. In the Options dialog box, choose **Reveal Analyzer > Colors**.
3. Click on the color sample for the desired part of the LA Waveform view.

   The Select Color dialog box opens.

4. Select a color.
5. In the Select Color dialog box, click **OK**.
6. To see the effect of the change, click **Apply**.
7. Change other colors if desired.
8. Click **OK**.

Counting Samples

You can easily count the number of samples in a range on the display.

To count samples:

- Click where you want to start counting and drag to the end of the range.

  While you're dragging, the LA Waveform view shows two red lines and the number of samples between the lines.

Controlling Serdes

Reveal Analyzer provides two methods for controlling serdes functions in an ECP5UM device. You can use:

- A Serdes Debug module created with Reveal Inserter to experiment with control registers and monitor system status
- A Wishbone bus in the design to set and monitor register values

Setting Serdes Debug Registers

You can adjust a large variety of serdes settings while running tests. Settings can be changed individually or by importing previously saved settings. You can also restore the design's original values from the configuration SRAM.

You can also monitor the following items in the Serdes Debug tab (green for good, red for bad):

- PLL lock status
- Receive input signal status
- CDR loss status

To set the serdes registers:

1. Click the **Serdes Debug** tab.
2. Click the DCUA drop-down menu and choose the block.
3. Click the Channel drop-down menu and choose the channel.
4. Change settings as desired.
5. Click **Apply**.

   The new values are immediately written to the FPGA.

To use previously saved settings:

1. Click the **Serdes Debug** tab.
2. Click the DCUA drop-down menu and choose the block.
3. Click the Channel drop-down menu and choose the channel.
4. Click **Import**.
5. In the Import SERDES File dialog box, browse to the desired serdes register (.srv) file.
6. Click **Open**.

The file's settings are appear in the Serdes Debug tab.

7. Click **Apply**.

   The new values are immediately written to the FPGA.

To restore the design's original values:

1. Click the **Serdes Debug** tab.
2. Click the DCUA drop-down menu and choose the block.
3. Click the Channel drop-down menu and choose the channel.
4. Click **Config SRAM Reload**.

   The original settings appear in the Serdes Debug tab.

5. Click **Apply**.

   The new values are immediately written to the FPGA.

See Also ▶"Saving Serdes Debug Settings" on page 1100

Reading and Writing with a Wishbone Bus

If you have a Wishbone bus in your design, you can write directly into the serdes registers, manually or using a file, and read values from them.

To write to a serdes register:

1. Click the **Wishbone Debug** tab.
2. Enter the address of the register.
3. In the Data box, type a 1-byte value.
4. Click **Write**.

   The value in the Data box is written to the register.

To write to several serdes registers from a file:

1. Click the **Wishbone Debug** tab.
2. Click **Load**.

   The Load SERDES File dialog box opens.

3. Browse to the desired Tcl file.
4. Click **Open**.

   The addresses and values defined in the file are written to the FPGA.

To read a serdes register:

1. Click the **Wishbone Debug** tab.
2. Enter the address of the register.

3. If you want to monitor the value in the register continuously, select **Continuous**.
4. Click **Read**.

   The value in the register appears in the Data box. If you selected Continuous, the value changes as the register changes.

Saving the Reveal Analyzer Settings and Data

You can save the waveform data in different formats:

- Reveal Analyzer (.rva) file, which will also include the trigger settings and waveform setup for future use
- Value change dump (.vcd) file, which can be imported by third-party tools such as ModelSim or Active-HDL
- Text (.txt) file

Save to an .rva file if you want to see the data in the LA Waveform view again or if you want to use the trigger settings again. See “Saving a Reveal Analyzer File” on page 1099. To save to a different format, see “Saving to Other Formats” on page 1099.

Saving a Reveal Analyzer File

You can save the waveform along with the trigger settings and waveform setup in a Reveal Analyzer (.rva) file that you can use in the future. You can also save an existing .rva file in a file with a different name.

To save changes in the current file:

- Choose **File >**  **Save** <*file*>.

To save the file with a different name:

1. Choose **File > Save** <*file*> **As**.

   The Save Reveal Analyzer File dialog box appears.
2. Browse to the directory in which you want to save the project.
3. In the File name box, type the file name.
4. Click **Save**.

Saving to Other Formats

You can export the data captured for individual modules to a value change dump (.vcd) file, which can be imported by third-party tools such as ModelSim or Active-HDL, or to an ASCII text (.txt) file.

To export data:

1. Choose the module from the drop-down menu in the Reveal Analyzer tool bar.
2. If you want the data to include an approximate measure of time instead of a simple count of clock cycles, right-click the waveform and choose **Set Clock Period**. See “Specifying the Clock Period” on page 1100.
3. If you want to export only some of the signals, select them in the waveform. You can only export whole buses. If you select only some of the signals in a bus, you get the whole bus.
4. Right-click in the waveform and choose **Export Waveform**.

   The Export Waveform dialog box opens.
5. Browse to the location where you want to export the file.
6. Type in a name in the **File name** box.
7. Choose a file type.
8. If you are exporting only some of the signals, choose **Selected signals** in the Range box.
9. If you are exporting to .vcd, type in a module name. This will form the title in the .vcd file. If you leave the field empty, the module name will be “<unknown>”.
10. Click **Save**.

Saving Serdes Debug Settings

You can save your Serdes Debug settings for later use.

To save the Serdes Debug settings:

1. In the Serdes Debug tab, click **Export**.

   The Export SERDES Register File dialog box opens.
2. Browse to where you want to save the file.
3. Type in a name in the **File name** box.
4. Click **Save**.

Specifying the Clock Period

By default, Reveal Analyzer refers to time by a count of the sample clock cycles. You can convert this to an approximate measure of time, in nanoseconds or picoseconds, by specifying the length of the clock period. When the waveform is exported, this measure of time is shown instead of a simple count of cycles.

To set the clock period:

1. Right-click the waveform and choose **Set Clock Period**.

2. Specify the scale by choosing a unit for the period in the drop-down menu on the right side of the dialog box. If you are specifying a frequency in the megahertz range, choose **ns**. If you are specifying a frequency in the gigahertz range, choose **ps**.
3. Place the cursor in either the Period or Frequency text box and type in the desired value. The other text box fills in automatically.

   Only integers are allowed. If you try to specify a frequency that would require a non-integer period, the period is truncated to an integer and the frequency is automatically adjusted. For example, typing 150 in the Frequency text box gives you a period of 6 and a frequency of 166.
4. Click **OK**.

Chapter 14

Applying Engineering Change Orders

Engineering Change Orders, or ECOs, are requests to make changes to your design after it has been placed and routed. The changes are written into the Native Circuit Description (.ncd) database file without requiring you to repeat the entire design implementation process. After applying ECOs, you can continue to generate bitstream/JEDEC files for your design.

ECOs are mainly used to correct errors found in the hardware model during debugging, or to facilitate design specification changes when problems are introduced with the integration of other FPGAs or components in your PC board design.

The Diamond design flow supports interactive ECO editing with the ECO Editor, which is a tabular user interface similar to Spreadsheet View. The ECO Editor includes sheets for editing I/O preferences, PLL preferences, and memory initialization values. These features enable you to edit the Native Circuit Description (.ncd) database file created by the Place & Route Design process. You can also sort the sysIO or PLL preference list and save the sorting order. The ECO Editor provides a Change Log window that enables you to track the changes between the modified .ncd file and the post-PAR .ncd file.

Note

After you have edited your post-PAR NCD file, your functional simulation and timing simulation will no longer match.

Editing sysIO and PLL Preferences in ECO Editor

The ECO Editor provides separate sheets for editing sysIO and PLL preferences. After a design is placed and routed, you can open the ECO Editor to edit these preferences. The changes you make in the ECO Editor are written into the Native Circuit Description (.ncd) database file without requiring you to go through the entire design implementation process.

To edit sysIO and PLL preferences, click the sysIO Setting tab or the PLL Programming tab at the bottom of the ECO Editor window.

Editing sysIO Preferences

You can use the ECO Editor to edit sysIO preferences after the design has been placed and routed.

To edit sysIO preferences:

1. In Diamond, make sure that you have already run the Place & Route Design process, and then choose **Tools > ECO Editor** .
2. At the bottom of the ECO Editor, click the **sysIO Setting** tab.

   In the sysIO Setting window, default values are shown in blue, values from design sources are shown in green, and modified values are shown in black. You can customize the color and font settings by choosing **Tools > Options** from the Diamond menu bar.

   You can only edit the values of cells that have white backgrounds.
3. In the sysIO Setting window, double-click the preference that you want to modify. Select a value from the drop-down menu or type a new value.
4. When you have finished, choose **File > Save <file_name>.ncd** to save the changes to the current .ncd file.

   After you save the file, you can select the **NCD Change Log** tab to view a summary of the changes.

Editing PLL Preferences

You can use the ECO Editor to edit PLL preferences after the design has been placed and routed.

To edit PLL preferences:

1. In the Diamond main window, make sure you have already run the Place & Route Design process, and then choose **Tools > ECO Editor**.
2. At the bottom of the ECO Editor, click the **PLL Programming** tab.

   In the PLL Programming window, you can edit the values of cells that have white backgrounds.
3. Double-click the PLL preference cell that you want to modify. Select a value from the drop-down menu or type a new value.
4. When you have finished, choose **File > Save <file_name>.ncd** to save the changes to the current .ncd file.

   After you save the file, you can select the **NCD Change Log** tab to view a summary of the changes.

Sorting a Preference List

In the sysIO Setting or PLL Programming window, you can sort the preference list by one or more columns. The sorting order is automatically saved. When you close and re-open ECO Editor, you will see the same sort order displayed.

To sort a list by one column:

1. Select the **sysIO Setting** or **PLL Programming** tab at the bottom of the ECO Editor window to display the preference list you want to sort.
2. In the preference list, click the heading of the column you want to sort.

   An up arrow is displayed in the heading, indicating that the list has been sorted by the column in ascending order. Click the heading again to sort the list in descending order.

To sort a list by more than one column:

1. Click the **sysIO Setting** or **PLL Programming** tab at the bottom of the ECO Editor window to display the preference list you want to sort.
2. Choose **View > Sort**  .
3. In the Sort dialog box, select the first column to sort by from the “Sort By” drop-down menu. Click **Ascending** or **Descending** to control the order of the sorted list.
4. Use the “Then by” boxes to select additional columns, as well as the Ascending/Descending option for each column.

   The list will be sorted first by the column specified in the “Sort By” box and then by the additional columns in the “Then By” boxes in sequence.
5. Click **OK**.

Setting Memory Initialization Values in ECO Editor

Memory Initialization is a feature that allows you to change initial values to EBRs (Embedded Block RAM) and User Flash Memory (UFM) for device configuration after the design has been placed and routed. It saves you time by allowing you to fix a few incorrect initialization values in your post-PAR Native Circuit Description (.ncd) file without having to repeat the entire flow.

Note

User Flash Memory (UFM) is only available for MachXO2-640 and higher density devices.

Changing initial memory values might become necessary, for example, if incorrect values were assigned during synthesis or if there is some off-chip device that your FPGA is communicating with that requires a different value than the one that was initially set.

You use the ECO Editor's Memory Initialization window to update initial memory values.

See Also "Memory Initialization Input Files" on page 1106

- "Updating Initial Values for EBRs" on page 1106
- "Updating Initial Values for User Flash Memory" on page 1108

Memory Initialization Input Files

Setting initial memory values actually writes the initial values directly into your post-PAR Native Circuit Description (.ncd) file. For this to be accomplished, you need to provide the following information:

- Native Circuit Description file (.ncd) – the <*design_name*>.ncd file that is updated by the Place & Route Design process.
- Memory initialization file (.mem) – an ASCII-based text file that contains initial data values on various address locations in the memory module. This file should be in the same format that was used in module creation.

  Note

  You must create .mem files for ROMs. Memory Initialization files are optional for RAM modules.

  To learn more about how to create a memory initialization file, see "Creating a Memory Initialization File" on page 202
- Memory block parameters – information on the memory block such as module name, memory mode, depth, width, and format.

  If the memory module is created by IPexpress, the software can read the parameters from the Lattice parameter configuration file (.lpc). If your design utilizes PMI (Parameterized Module Instantiation) to generate memory modules, the software gets the parameters from the PMI module.
- Instance name (not a file) – the name that was given to the memory module in your top-level EDIF netlist.

Updating Initial Values for EBRs

Before updating memory values in ECO Editor, you need to add the memory module to your design and run the Place & Route Design process. The memory modules can be PMI modules or modules created by IPexpress.

For memory modules created by IPexpress, an LPC file is needed for memory initialization. PMI modules do not require an LPC file to re-initialize the memory.

Note

Once you edit initial memory values in the post-PAR NCD file, your functional simulation and timing simulation results will no longer match. You might need to preserve an original version of your NCD file.

To update memory initialization values:

1. Customize a memory initialization (.mem) file in any ASCII text editor or use the Memory Generator, the recommended method (see"Creating a Memory Initialization File" on page 202). In this step, you should change the values of the INITVALs in your .mem file as necessary and save the file in your project directory. You might also want to create a copy of the original .mem file.

   Note

   You must create a .mem file for ROM instances in your design. RAM instances may or may not need .mem files associated with them.

   For example, there might be a ROM memory instance in your design; so you create a .mem file called romb.mem in your project directory. These updated INITVALs will be used to override present ones that were auto-generated through the flow. Although the .mem file can be located anywhere on your system, it is recommended that you place them in your project directory.

2. In the Diamond main window, make sure that you have already successfully run the Place & Route Design process, and then choose **Tools > ECO Editor**.
3. Select the **Memory Initialization** tab at the bottom of the ECO Editor window.

   The Memory Initialization window displays the memory instances, memory file, and any LPC parameters for memory modules that were created by IPexpress.
4. Right-click a memory instance, and choose **Update Initial Memory** from the pop-up menu. You can also choose **Update Initial Memory** from the Edit menu.

   The Update Initial Memory dialog box opens, displaying the information about the currently selected memory block.
5. To change the format of the memory file, select a format from the File Format menu.
6. Click the **...** button next to the Memory File box to browse to the .mem file that you previously edited, as suggested in Step 1. Make sure that the File Format is correct.

   If your design targets a MachXO2 device and uses EBR blocks, you can use the .mem file or one of two other initialization options, as follows:

- Initialize to all 1s – fills the EBR memory with all 1s instead of the values in the .mem file.
- Initialize to all 0s – fills the EBR memory with all 0s instead of the values in the .mem file.
- Memory File – uses the values in the .mem file for initialization.

Note

The MacXO2 EBR cannot be initialized when the INIT_DATA attribute has been set to STATIC.

7. If the memory module is created by IPexpress, specify LPC parameters as follows. (This step is not required for PMI module.)
   - If the current design directory includes a .lpc file that is specified in the selected memory block, or if the parameters have been correctly written in the design source, the memory parameters from the .lpc file or the design source will be displayed in the dialog box.
   - If the associated .lpc file is stored outside the design directory, click the **...** button next to the LPC File box to browse to the file. The memory parameters included in the .lpc file will be displayed.
8. Click **Update**.

   The ECO Editor attempts to update the current memory block's initial memory values. A message will appear telling you whether the initialization succeeds or not.
9. Click **OK**.

   The Update Initial Memory dialog box closes after a successful initialization. If the initialization fails, the dialog box will stay open.
10. After the initialization succeeds, choose **File > Save File** to save the memory initialization changes to the current NCD file.

Updating Initial Values for User Flash Memory

The UFM (User Flash Memory) component is available in MachXO2-640 and higher density devices.
