Before updating UFM initial values in ECO Editor, you need to use IPexpress to generate an EFB module with access to the user flash memory, add the module to your design, and run the Place & Route Design process.

To update UFM initialization values:

1. Customize a UFM memory initialization (.mem) file in any ASCII text editor or use the Memory Generator, the recommended method (see "Creating a Memory Initialization File" on page 202).

The UFM initialization file has the following properties and format:

Extension: .mem

Format: Binary, Hexadecimal

Data Width: 1 page (128 bits in one row of the file)

Number of Rows: less than or equal to the number of available pages

Example (Binary):

1010...1010 (Placed at the starting page of the UFM initialization data, address = N)
1010...1010 (Page address = N + 1)
1010...1010 (Page address = N + 2)
...
1010...1010 (Placed at the highest UFM page address)

Example (Hexadecimal):

A...B (Placed at the starting page of the UFM initialization data, address = N)
C...D (Page address = N + 1)
E...F (Page address = N +2)
...
A...F (Placed at the highest UFM page address)

The most significant byte (byte 15) of the page is on the left side of the row. The least significant byte of the page (byte 0) is on the right side of the row.

2. In the Diamond main window, make that sure you have already successfully run the Place & Route Design process, and then choose **Tools > ECO Editor** .

3. Select the **Memory Initialization** tab at the bottom of the ECO Editor window.

   The Memory Initialization window displays the UFM component in a tree view format. The window displays the UFM's number of pages and page range, as well as its initialization file name and format.

4. Right-click the UFM component, and choose **Edit UFM Parameters** from the pop-up menu. You can also choose **Edit UFM Parameters** from the Edit menu.

   The Update UFM Parameters dialog box opens, displaying the UFM information.

5. In the Update UFM Parameters dialog box, do one of the following:

   - If you want to initialize the UFM to all zeros, select **Enabled** for the Initialized with All Zeroes option.
   - If you want to change the UFM's initialization file, clear the Initialized with All Zeroes option, and then click the **...** button next to the UFM

Initialization Data File box to browse to the .mem file that you edited in Step 1. Make sure that the Initialization Data Format is correct.

Note

The default location where Lattice Diamond searches for the UFM initialization file is the project implementation directory. If the initialization file you specify is not in the implementation directory, ECO Editor will copy it to the implementation directory and inform you that the file is copied.

6. Click **Update**.

   The ECO Editor attempts to update the UFM's initial memory values. A message will appear telling you whether the initialization succeeds or not.

7. Click **OK**.

   The Edit UFM Parameters dialog box closes after a successful initialization. If the initialization fails, the dialog box will stay open.

8. After the initialization succeeds, choose **File > Save File** to save the memory initialization changes to the current NCD file.

Modifying SerDes Settings

For ECP5 devices, ECO Editor enables you to modify the SerDes settings for the PCS modules in your design after placement and routing.

To modify SerDes settings:

1. In ECO Editor, select the **SERDES Settings** tab.

   The SERDES page shows each PCS module in the design, with a tree view of the instance setup and each SerDes channel.

2. Double-click the name of the PCS module that you would like to modify to open the tree view.

   The tree view displays the attributes for the Instance Setup and for the Control and SerDes Setup for each channel.

3. Select the desired setting from the Attributes column for each attribute that you want to modify.

4. Save your changes.

See Also ▶"PCS Options (ECP5UM)" on page 1555

Adding Signal Probes

Lattice Diamond enables you to use the ecoeditor_probe attribute in your HDL code to mark signals as possible probe points. The attribute for each signal is then passed to the .ncd file when you process the design. You can then use the ECO Editor to assign these signals to external pins as test probes for

debugging. You do not need to open EPIC to configure the signal probes. The ECO Editor automatically gathers these signals from the .ncd file and adds them to the top of the list in the Signal Probes sheet.

Marking Signals as Possible Probe Points

In order to use the ECO Editor for configuring signal probes, you must edit the HDL source. Add the ecoeditor_probe attribute to each signal that you want to specify as a possible probe point, and add the syn_keep attribute to keep the specified net intact during optimization and synthesis.

To mark signals as possible probe points:

1. Open the HDL source and add the ecoeditor_probe attribute, using the appropriate VHDL or Verilog syntax, as shown in the following examples.

   Using VHDL:

   ```
   attribute ecoeditor_probe : string;
   attribute ecoeditor_probe of countai: signal is
   "my_vhdl_signal";
   attribute syn_keep : boolean;
   attribute syn_keep of countai: signal is true;
   ```

   Using Verilog:

   ```
   reg ack_err; /* synthesis syn_keep = 1 ecoeditor_probe =
   "my_verilog_signal2" */;
   ```

2. Save the HDL file, and then process the design through Place & Route.

See Also ▶"Assigning Signals to Pins as Test Probes" on page 1111

Assigning Signals to Pins as Test Probes

The Signal Probes sheet in the ECO Editor lists all of the signal names. Those that were marked with the ecoeditor_probe attribute in the HDL are placed at the top of the list. An Available IO column is provided that enables you to assign pins to these signals and use them as test probes for debugging.

To assign signals to pins for use as test probes:

1. Select the Signal Probes tab.
2. For each signal that you want to assign, do the following:
   a. Double-click the cell in the Available IO column.

b. Select a pin for the signal from the drop-down list.

3. When you have finished making your selections, click the **Apply Signal Probes** button (**SP**) on the ECO Editor vertical toolbar.

   The ECO Editor routes the signals to the pins that you selected.

After applying the signal probes, you can view the routing in Physical View.

Tracking NCD Changes

All ECO changes that have been saved to the NCD file are recorded in the ECO Editor Change Log in the Reports view. Each time the NCD is modified and saved, a new change entry is added to the change log. All changes remain in the log even when the ECO Editor is closed.

To view the change log, select **ECO Editor Change Log** in the Tool Reports section of the Reports view.

Exporting sysIO Preferences

You can export the sysIO preferences currently displayed in the ECO Editor to a preference file (.lpf).

To export the current sysIO preferences:

1. In the ECO Editor, choose **File > Export > Preferences**.

   By default, the ECO Editor uses <project name>_eco to prevent the original .lpf file from being overwritten.

2. In the Save Preference File dialog box, accept the default file name or specify a different .lpf file name and location, and then click **Save**.

Running Design Rule Check

When you edit preferences in the ECO Editor, the software automatically runs design rule check and reports errors, if any, in the Diamond Output view.

You can also manually run the design rule check by choosing **View > Run DRC**  .

Chapter 15

Strategy Reference Guide

A strategy provides a unified view of all the options related to implementation tools such as synthesis, map, and place and route. Strategy options are listed in the Strategy dialog box. Open the dialog box by double-clicking a strategy name in the File List view.

For information about an option, select it. A brief description appears at the bottom of the dialog box. Press **F1** to open this guide and see the full description.

The descriptions of the strategy options are grouped by their processes (such as Synplify Pro, Translate Design, or Map Trace). Below is an alphabetical list of all the options.

For detailed information on how to apply strategies to your project, see "Using Strategies" on page 47.

A

B

C

- Carry Chain Length
- Chain Mode
- Check Unconstrained Connections (for Map Trace)
- Check Unconstrained Connections (for Place & Route Trace)
- Check Unconstrained Paths (for Map Trace)
- Check Unconstrained Paths (for Place & Route Trace)
- Clock Conversion
- Clock Skew Minimization
- Command Line Options (for LSE)
- Command Line Options (for Map Design)
- Command Line Options (for Place & Route Design)
- Command Line Options (for Precision)
- Command Line Options (for Synplify Pro)
- Command Line Options (for Synplify Pro Translate Design)
- Congestion-Driven Placement
- Congestion-Driven Routing
- Consistent Bus Name Conversion
- Convert Gated Clock
- Create Bit File
- Create Delay Statistic File

D

- Decode Unreachable States
- Default Clock Frequency
- Default Enum Encoding
- Disable Distributed RAM
- Disable I/O Insertion (for Precision)
- Disable IO Insertion (for Synplify Pro)
- Disable Timing Driven
- Disable UES
- DSP Style
- DSP Utilization

E

- EBR Utilization
- EDIF Names
- Enable I/O in Re-configuration
- Enable Timing Check
- Export Diamond Settings to Synplify Pro GUI
- External Clock

F

- Fanout Limit
- Fix Gated Clocks
- Force GSR (for LSE)
- Force GSR (for Precision)
- Force GSR (for Synplify Pro)
- Frequency (for Precision)
- Frequency (for Synplify Pro)
- FSM Encoding (for Precision)
- FSM Encoding (for Synplify Pro)
- FSM Encoding Style
- Full Case
- Full Name (for Map Trace)
- Full Name (for Place & Route Trace)

G

- Generate PUR in the Netlist
- Generate TRACE Report for Each Iteration
- Generate X for Setup/Hold Violation
- Grant Timeout

H

- Hardware Evaluation (for LSE)
- Hardware Evaluation (for Translate Design)
- Hold Check Min Speed Grade

I

- Ignore Preference Errors (for Map Design)
- Ignore Preference Errors (for Place & Route Design)
- Ignore RAM Read/Write Collision
- Infer DSPs Across Hierarchy
- Infer GSR
- Input Delay (ns)
- Intermediate File Dump
- IO Registering

L

- LengthBits
- Library Directories
- Loop Limit

M

- Macro Search Path (for LSE)
- Macro Search Path (for Translate Design)
- Max Fanout Limit
- Memory Initial Value File Search Path (for LSE)
- Memory Initial Value File Search Path (for Translate Design)
- Multichip Module Prefix
- Multi-Tasking Node List
- MUX Style

N

- Negative Setup-Hold Times
- No Header
- Number of Critical Paths (for LSE)
- Number of Critical Paths (for Precision)
- Number of Critical Paths (for Synplify Pro)
- Number of Start/End Points
- Number of Timing Summary Paths
- Number of Unconstrained Paths (for Map Trace)
- Number of Unconstrained Paths (for Place & Route Trace)

O

- Optimization Goal
- Output Delay (ns)
- Output Format
- Output Netlist Format (for Precision)
- Output Netlist Format (for Synplify Pro)
- Output Preference File
- Output Zero Frames
- Overmap Device if Design Does Not Fit

P

- Pack Logic Block Util.
- Parallel Case
- Partition Search Path
- Path-based Placement
- Pipelining and Retiming
- Placement Effort Level
- Placement Iteration Start Pt
- Placement Iterations
- Placement Save Best Run
- Placement Sort Best Run
- PROM Data Output Format
- Propagate Constants
- Push Tristates

R

- RAM Style
- ReadBack
- ReadCapture
- Reencode FSM Outputs
- Register Configuration
- Register Retiming
- Remove Duplicate Registers
- Remove LOC Properties (for LSE)
- Remove LOC Properties (for Translate Design)
- Remove Previous Design Directory
- Report Asynchronous Timing Loops (for Map Trace)
- Report Asynchronous Timing Loops (for Place & Route Trace)
- Report Clock Frequencies
- Report Missing Constraints
- Report Signal Cross Reference
- Report Style (for Map Trace)
- Report Style (for Place & Route Trace)
- Report Symbol Cross Reference
- Report Timing Violations
- Reset Config RAM in Re-configuration
- Resolved Mixed Drivers (for Synplify Pro)
- Resolved Mixed Drivers (for LSE)
- Resource Sharing (for LSE)
- Resource Sharing (for Precision)
- Resource Sharing (for Synplify Pro)
- Retarget Speed Grade
- ROM Style
- Route Estimation Algorithm (%)
- Routing Delay Reduction Passes
- Routing Method
- Routing Passes
- Routing Resource Optimization
- Run DRC
- Run Placement Only
- Run Retiming

S

- Search Path
- Show Clock Domain Crossing
- Show Net Fanout
- SLVS MIPI LVCMOS Output
- Speed for Hold Analysis
- Speed for Setup Analysis
- SPI Start Address
- Startup Clock
- Stop Once Timing is Met
- Sysbus Clock Config
- Sysbus Config

Synplify Pro Options

This page lists all the strategy options associated with the Synplify Pro Synthesis process.

For information on their use in Synplify Pro, see the Synopsis Synplify Pro for Lattice Reference Manual.

- Default Enum Encoding
- Disable IO Insertion
- EDIF Names
- Export Diamond Settings to Synplify Pro GUI
- Fanout Limit
- Force GSR
- Frequency
- FSM Encoding
- Library Directories
- Number of Critical Paths
- Number of Start/End Points
- Output Netlist Format
- Pipelining and Retiming
- Push Tristates
- Resolved Mixed Drivers (for Synplify Pro)
- Resource Sharing
- Update Compile Point Timing Data
- Use Clock Period for Unconstrained I/O
- Use LPF Created from SDC in Project (for Synplify Pro)
- Verilog Input
- VHDL 2008 (for Synplify Pro)

Allow Duplicate Modules (for Synplify Pro) Allows the use of duplicate modules in your design.

When it is set to True, the last definition of the module is used by the software and any previous definitions are ignored. The default is False.

Area (for Synplify Pro) Specifies optimization preference for area reduction over timing delay reduction.

The True option specifies the area reduction mode. When set to True, this setting overrides the setting in Frequency (for Synplify Pro).

The default is False for all devices.

This option is equivalent to the “set_option -frequency 1” command in Synplify Pro.

Arrange VHDL Files Allows Synplify Pro to reorder the VHDL source files for synthesis.

The default is True for VHDL or Schematic/VHDL design entry type projects, and False for other projects. When this is set to False, Synplify Pro will use the file order in the Diamond File List view.

Clock Conversion Controls gated and generated clock conversion.

Values are:

- 0 – does not convert
- 1 (default) – converts; does not report
- 2 – converts; reports only sequential elements that could not be converted
- 3 – converts; reports all sequential elements

This option is equivalent to the “set_option -fix_gated_and_generated_clocks 0 | 1 | 2 | 3” command in Synplify Pro.

Command Line Options (for Synplify Pro) Enables additional command line options for the Synplify Pro Synthesis process.

To enter a command line option:

1. In the Strategy dialog box, select **Synplify Pro** in the Process list.
2. Double-click the Value column for the Command Line Options option.
3. Type in the option and its value (if any) in the text box.
4. Click **Apply**.

For example:

```
set_option -library_path c:/source
```

Default Enum Encoding (For VHDL designs) Defines how enumerated data types are implemented.

The type of implementation affects the performance and device utilization. Available options are:

- Default – Automatically assigns an encoding style based on the number of states:
  - Sequential: 0-4 enumerated types
  - Onehot: 5-40 enumerated types
  - Gray: more than 40 enumerated types
- Gray – Only one bit of the state register changes at a time, but because more than one bit can be hot, the value must be decoded to determine the state. For example: 000, 001, 011, 010, 110
- Onehot – Only two bits of the state register change (one goes to 0; one goes to 1) and only one of the state registers is hot (driven by a 1) at a time. For example: 0000, 0001, 0010, 0100, 1000

- Sequential – More than one bit of the state register can change at a time, but because more than one bit can be hot, the value must be decoded to determine the state. For example: 000, 001, 010, 011, 100

This option is equivalent to the “set_option -default_enum_encoding default | onehot | gray | sequential” command in Synplify Pro.

Disable IO Insertion (for Synplify Pro) Controls whether the synthesis tool will add I/O buffers into your design.

If this is set to True, Synplify Pro will not add I/O buffers into your design. If it is set to False (default), the synthesis tool will insert I/O buffers into your design.

This option is equivalent to the “set_option -disable_io_insertion 1 | 0” command in Synplify Pro.

EDIF Names Controls the format of bus names in the EDIF file. Select Standard to use brackets in the names of bus signals as in "bus[1]", which is the current standard for Synplify Pro. Select Legacy to use the older format as in "bus_1".

Standard is required to use Synplify Pro to cross-probe from the Place & Route TRACE Report to a schematic view. See “Cross-Probing to Synplify Pro HDL Analyst” on page 715.

Export Diamond Settings to Synplify Pro GUI Controls whether the strategy settings are exported to Synplify Pro during interactive synthesis (opening Synplify Pro through the Tools menu). After opening Synplify Pro, you can change settings in Synplify Pro's interface. This option has no effect with integrated or stand-alone synthesis.

Available options are:

- No (default) – Synplify Pro opens with its own defaults, ignoring the strategy settings.
- Yes – Synplify Pro opens with the strategy settings every time. Options set and saved in a previous Synplify Pro session are ignored.
- Only on First Launch – Synplify Pro opens with the strategy settings the first time only. After that, Synplify Pro opens with settings saved in a previous session or with its own defaults. After the first time, the strategy settings are ignored.

For more information, see “Interactive Synthesis” on page 583.

Fanout Limit Controls fanout during synthesis. When the specified fanout limit is achieved, logic will be duplicated.

The default is 1000.

This option is equivalent to the “set_option -maxfan <*number*>” command in Synplify Pro.

Force GSR (for Synplify Pro) Forces Global Set/Reset Pin usage.

Available options are:

- Auto – Allows the software to decide whether to infer Global Set/Reset in your design.
- False (default) – Does not infer Global Set/Reset in your design.
- True – Always infers Global Set/Reset in your design.

This option is equivalent to the “set_option -force_gsr auto | yes | no” command in Synplify Pro.

Frequency (for Synplify Pro) Specifies the global design frequency (in MHz). Nothing in the Value column means "auto" (the default) and Synplify Pro will try to maximize the frequency of the clocks.

The setting is ignored when Area (for Synplify Pro) is set to True.

This option is equivalent to the “set_option -frequency <*number*> | auto” command in Synplify Pro.

FSM Encoding (for Synplify Pro) Enables or disables the FSM Compiler and controls the use of FSM synthesis for state machines.

When Synplify Pro is selected as the synthesis tool, it enables or disables the FSM Compiler and controls the use of FSM synthesis for state machines. When this is set to True (default), the FSM Compiler automatically recognizes and optimizes state machines in the design. The FSM Compiler extracts the state machines as symbolic graphs, and then optimizes them by re-encoding the state representations and generating a better logic optimization starting point for the state machines.

This option is equivalent to the “set_option -symbolic_fsm_compiler 1 | 0” command in Synplify Pro.

Library Directories Specifies all the paths to the directories which contain the Verilog library files to be included in your design for the project.

You can also add custom library files with module definitions for the design in a single file. The names of files read from the library path must match module names. Mismatches result in error messages.

Number of Critical Paths (for Synplify Pro) Specifies the number of critical timing paths to be reported in the timing report.

This option is equivalent to the “set_option -num_critical_paths <*number*>” command in Synplify Pro.

Number of Start/End Points Specifies the number of start and end points you want the software to report in the critical path section of the timing report.

This option is equivalent to the “set_option -num_startend_points <*number*>” command in Synplify Pro.

Output Netlist Format (for Synplify Pro) Outputs a mapped Verilog or VHDL netlist for post-synthesis simulation.

Available options are: None (default), VHDL, and Verilog.

This option is equivalent to the “set_option -write_verilog 1 | 0 -write_vhdl 1 | 0” command in Synplify Pro.

Pipelining and Retiming Enables the pipelining and retiming features to improve design performance.

Values are:

- None – Disables the pipelining and retiming features.
- Pipelining Only (default) – Runs the design at a faster frequency by moving registers into the multiplier, creating pipeline stages.
- Pipelining and Retiming – When enabled, registers may be moved into combinational logic to improve performance.

This option is equivalent to the “setup_option -pipe 1 | 0 -retiming 1 | 0” command in Synplify Pro.

Push Tristates When this is set to True, the Synplify Pro compiler pushes tristates through objects such as muxes, registers, latches, buffers, nets, and tristate buffers, and propagates the high impedance state.

The high-impedance states are not pushed through combinational gates such as ANDs or ORs.

The default is False.

This option is equivalent to the “set_option -compiler_compatible 1 | 0” command in Synplify Pro.

Resolved Mixed Drivers (for Synplify Pro) If a net is driven by a VCC or GND and active drivers, setting this option to True (default) will connect the net to the VCC or GND driver.

This option is equivalent to the “set_option -resolve_multiple_driver 1 | 0” command in Synplify Pro.

Resource Sharing (for Synplify Pro) When this is set to True (default), the synthesis tool uses resource sharing techniques to optimize area.

With resource sharing, synthesis uses the same arithmetic operators for mutually exclusive statements; for example, with the branches of a case statement. Conversely, you can improve timing by disabling resource sharing, but at the expense of increased area.

This option is equivalent to the “set_option -resource_sharing 1 | 0” command in Synplify Pro.

Update Compile Point Timing Data Determines whether (True) or not (False) changes inside a compile point can cause the compile point (or top-level) containing it to change accordingly.

When this is set to False (default), Synplify Pro keeps the top level module the same, which is desired by incremental flow.

When this is set to True, changes in low level partitions will be propagated to top partitions up to top module. Synplify Pro will possibly optimize timing data and certainly will write a new timestamp onto the partition for the top level module.

This option is equivalent to the “set_option -update_models_cp 1 | 0” command in Synplify Pro.

Use Clock Period for Unconstrained I/O Controls whether to forward annotate constraints for I/O ports without explicit user-defined constraints.

When this is set to True, only explicit I/O port constraints are forward annotated. When it is set to False (the default), all I/O port constraints are forward annotated.

This option is equivalent to the “set_option -auto_constraint_io 1 | 0” command in Synplify Pro.

Use LPF Created from SDC in Project (for Synplify Pro) When this is set to True (default), Synplify Pro creates a preference (.lpf) file based on the Synopsys Design Constraint (.sdc) file. With this .lpf file, the synthesis constraints will also be applied to the Map Design stage of implementation.

This option is equivalent to the “set_option -write_apr_constraint 1 | 0” command in Synplify Pro.

Verilog Input Specifies the Verilog standard used for the project.

The default is System Verilog.

This option is equivalent to the “set_option -vlog_std v2001 | v95 | sysv” command in Synplify Pro.

For information about Verilog 2001, refer to the Synplify and Synplify Pro for Lattice Reference Manual. Go to the “Verilog 2001 Support” section in the “Verilog Language Support” chapter.

VHDL 2008 (for Synplify Pro) When this is set to True, VHDL 2008 is selected as the VHDL standard for the project.

Precision Options

This page lists all the strategy options associated with the Precision Synthesis process.

- Area
- Array Bounds Case
- Auto Resource Allocation of RAM
- Command Line Options
- Convert Gated Clock
- Disable I/O Insertion
- Force GSR
- Frequency
- FSM Encoding
- Full Case
- Ignore RAM Read/Write Collision
- Infer DSPs Across Hierarchy
- Input Delay (ns)
- Number of Critical Paths
- Number of Timing Summary Paths
- Output Delay (ns)
- Output Netlist Format
- Output Preference File
- Parallel Case
- Reencode FSM Outputs
- Report Clock Frequencies
- Report Missing Constraints
- Report Timing Violations
- Resource Sharing
- Run Retiming
- Show Clock Domain Crossing
- Show Net Fanout
- Transform Set/Reset on DFFs to Latches
- Use Safe FSM
- Verilog Standard V2001

Area (for Precision) Specifies optimization preference for area reduction over timing delay reduction.

The True option specifies the area reduction mode. When set to True, this option overrides the setting in Frequency (for Precision).

The default is True for MachXO, and False for the other devices.

This option is equivalent to the “setup_design -compile_for_area” command in Precision RTL Synthesis.

Array Bounds Case Enables or disables the Precision tool to check array bounds for Verilog input files.

The default is False.

This option is equivalent to the “setup_design –array_bounds_check” command in Precision RTL Synthesis.

Auto Resource Allocation of RAM Enables or disables the automatic resource allocation of RAMs.

When set to False, it stops the synthesis step when the number of inferred RAMs exceeds the block-RAM resources on the target device. To map RAMs to block-RAM resources first and then map remaining RAM structures into logic resources, set this to True.

This option is equivalent to the “setup_design -auto_resource_allocation_ram” command in Precision RTL Synthesis.

Command Line Options (for Precision) Enables additional command line options for the Precision Synthesis process.

To enter a command line option:

1. In the Strategy dialog box, select **Precision** in the Process list.
2. Double-click the Value column for the Command Line Options option.
3. Type in the option and its value (if any) in the text box.
4. Click **Apply**.

Convert Gated Clock Controls the gated-clock conversion by Precision RTL Synthesis during the synthesis phase.

Options are:

- True – Converts gated-clock flip-flops to equivalent enable flip-flops.
- False (default) – Does not convert gated-clock flip-flops to equivalent enable flip-flops.

This option is equivalent to the “setup_design -gated_clock” command in Precision RTL Synthesis.

Disable I/O Insertion (for Precision) Controls whether the synthesis tool will add I/O buffers into your design.

If this is set to True, Precision RTL Synthesis will not add I/O buffers into your design. If it is set to False (default), the synthesis tool will insert I/O buffers into your design.

This option is equivalent to the “setup_design -addio” command in Precision RTL Synthesis.

Force GSR (for Precision) Forces Global Set/Reset Pin usage.

Available options are:

- Auto – Allows the software to decide whether to infer Global Set/Reset in your design.
- True – Always infers Global Set/Reset in your design.
- False (default) – Does not infer Global Set/Reset in your design.

This option is equivalent to the “setup_design -infer_gsr” command in Precision RTL Synthesis.

Frequency (for Precision) Specifies the global design frequency (in MHz).

The default is 200 for both Precision RTL Synthesis and Synplify Pro. The option is ignored when Area (for Precision) is set to True.

This option is equivalent to the “setup_design -frequency=<*number*>” command in Precision RTL Synthesis.

FSM Encoding (for Precision) Specifies the encoding style to use with the design.

When Precision RTL Synthesis is selected as the synthesis tool, it specifies the encoding style to use with the design. Valid values are: Auto (default), Binary, One Hot, Two Hot, Random, and Gray.

This option is equivalent to the “setup_design -encoding=auto | binary | onehot | twohot | random | gray” command in Precision RTL Synthesis.

Full Case When set to True, tells Precision that for all case statements throughout your design, all relevant conditions are specified. If the default assignment is not used then this option prevents the inference of latches.

The default is False.

This option is equivalent to the “setup_design –variable_full_case=TRUE” command in Precision RTL Synthesis.

Ignore RAM Read/Write Collision Controls whether to ignore RAM read/write collision.

If the dual-port RAMs in your design do not require simultaneous read and write of the same address, you can set this to True to prevent inference of glue-logic and save logic resources. The default is False.

This option is equivalent to the “setup_design -ignore_ram_rw_collision” command in Precision RTL Synthesis.

Infer DSPs Across Hierarchy When this is set to True, Precision Synthesis will optimize pipeline registers across hierarchical boundaries.

The True option performs one or more of the following actions:

- Absorb all necessary pipe registers
- Rearrange arithmetic operators where necessary
- Other optimization techniques

The default is False.

This option is equivalent to the “setup_design -dsp_across_hier” command in Precision RTL Synthesis.

Input Delay (ns) Specifies the global input delay (in ns) for use with the frequency switch.

This option is equivalent to the “setup_design -input_delay=<*number*>” command in Precision RTL Synthesis.

Number of Critical Paths (for Precision) Specifies the number of critical timing paths to be reported in the timing report.

The default is 3.

This option is equivalent to the “setup_analysis -critical_paths -num_critical_paths=<*number*>” command in Precision RTL Synthesis.

Number of Timing Summary Paths Specifies the number of timing paths to be reported in the timing report.

The default is 10.

This option is equivalent to the “setup_analysis -summary -num_summary_paths=<*number*>” command in Precision RTL Synthesis.

Output Delay (ns) Specifies the global output delay (in ns) for use with the frequency switch.

This option is equivalent to the “setup_design -output_delay=<*number*>” command in Precision RTL Synthesis.

Output Netlist Format (for Precision) Outputs a mapped Verilog or VHDL netlist for post-synthesis simulation.

Available options are: None (default), Verilog, and VHDL.

For Precision RTL Synthesis, setting this to Verilog will create a .vm file. Setting it to VHDL creates a .vhm file.

This option is equivalent to the “setup_design [-verilog | -vhdl]” command in Precision RTL Synthesis.

Output Preference File When this is set to True (default), Precision RTL Synthesis creates a preference file and gives it the same name as the module: module_name.prf.

This option is equivalent to the “setup_design -vendor_constraint_file=false | true” command in Precision RTL Synthesis.

Parallel Case When set to True, tells Precision that for all case statements throughout your design, case conditions are mutually exclusive. This results in a multiplexer implementation instead of a priority encoder.

The default is False.

This option is equivalent to the “setup_design –variable_parallel_case=TRUE” command in Precision RTL Synthesis.

Reencode FSM Outputs Controls Precision FSM extraction and re-encoding when Precision needs to create decoding logic.

The default state is True. To stop Precision from extracting, re-encoding, and creating decode logic, set this to False.

This option is equivalent to the “setup_design -reencode_fsm_outputs” command in Precision RTL Synthesis.

Report Clock Frequencies Setting this to True (default) lets the software report all clock frequencies.

This option is equivalent to the “setup_analysis -clock_frequency” command in Precision RTL Synthesis.

Report Missing Constraints When this is set to True, the timing report will report missing constraints.

The default is False.

This option is equivalent to the “setup_analysis -missing_constraints” command in Precision RTL Synthesis.

Report Timing Violations When this is set to True (default), the timing report will include timing violations.

This option is equivalent to the “setup_analysis -timing_violations” command in Precision RTL Synthesis.

Resource Sharing (for Precision) When this is set to True (default), the synthesis tool uses resource sharing techniques to optimize area.

With resource sharing, synthesis uses the same arithmetic operators for mutually exclusive statements; for example, with the branches of a case statement. Conversely, you can improve timing by disabling resource sharing, but at the expense of increased area.

This option is equivalent to the “setup_design -resource_sharing” command in Precision RTL Synthesis.

Run Retiming Setting this to True (default) causes the advanced retiming algorithms to be run.

This option is equivalent to the “setup_design -retiming” command in Precision RTL Synthesis.

Show Clock Domain Crossing When this is set to True, the timing report will show clock domain crossings.

The default is False.

This option is equivalent to the “setup_analysis -clock_domain_crossing” command in Precision RTL Synthesis.

Show Net Fanout When this is set to True (default), the timing report will show net fanout.

This option is equivalent to the “setup_analysis -net_fanout” command in Precision RTL Synthesis.

Transform Set/Reset on DFFs to Latches Setting this to True transforms Set/Reset on DFFs to Latches.

The default is True.

This option is equivalent to the “setup_design -transformations” command in Precision RTL Synthesis.

Use Safe FSM Enables or disables the use of safe FSMs.

Safe FSMs are FSMs that have no illegal states. The default is False.

This option is equivalent to the “setup_design -use_safe_fsm” command in Precision RTL Synthesis.

Verilog Standard V2001 When this is set to True, Verilog 2001 is selected as the Verilog standard for the project. Otherwise, Verilog 95 will be used.

This option is equivalent to the “setup_design -language_syntax_verilog” command in Precision RTL Synthesis.

LSE Options

This page lists all the strategy options associated with the Lattice Synthesis Engine (LSE) synthesis process.

- EBR Utilization
- Fix Gated Clocks
- Force GSR
- FSM Encoding Style
- Hardware Evaluation
- Intermediate File Dump
- Loop Limit
- Macro Search Path
- Max Fanout Limit
- Memory Initial Value File Search Path
- MUX Style
- Number of Critical Paths
- Optimization Goal
- Propagate Constants
- RAM Style
- Remove Duplicate Registers
- Remove LOC Properties
- Resolved Mixed Drivers (for LSE)
- Resource Sharing
- ROM Style
- Target Frequency
- Use Carry Chain
- Use IO Insertion
- Use IO Registers
- Use LPF Created from SDC in Project (for LSE)
- VHDL 2008 (for LSE)

Allow Duplicate Modules (for LSE)

When set to True, allows the design to keep duplicate modules. LSE issues a warning and uses the last definition of the module. Any previous definitions are ignored. The default is False, which causes an error if there are duplicate modules.

This option is equivalent to the “-allow_duplicate_modules” option in the SYNTHESIS command.

Carry Chain Length Specifies the maximum number of carry chain cells (CCUs) that get mapped to a single carry chain. Default is 0, which is interpreted as infinite length.

This option is equivalent to the “-carry_chain_length” option in the SYNTHESIS command.

Command Line Options (for LSE) Enables additional command line options for the LSE Synthesis process.

To enter a command line option:

1. In the Strategy dialog box, select **LSE** in the Process list.
2. Double-click the Value column for the Command Line Options option.
3. Type in the option and its value (if any) in the text box.
4. Click **Apply**.

For detailed descriptions of LSE command line options, see “Running SYNTHESIS from the Command Line” on page 2448.

Decode Unreachable States When set to True, synthesis infers safe recovery logic from unreachable states in all the state machines of the design.

This option is equivalent to the “-decode_unreachable_states” option in the SYNTHESIS command.

Disable Distributed RAM When set to True, inferred memory will not use the distributed RAM of the PFUs.

DSP Style Specifies how DSP modules should be implemented: with DSP resources or with Logic (LUTs).

This option is equivalent to the “-use_dsp” option in the SYNTHESIS command.

DSP Utilization Specifies the percentage of DSP sites that LSE should try to use.

This option is equivalent to the “-dsp_utilization” option in the SYNTHESIS command.

EBR Utilization Specifies EBR utilization target setting in percent of total vacant sites. LSE will honor the setting and do the resource computation accordingly. Default is 100 (in percentage).

This option is equivalent to the “-bram_utilization” option in the SYNTHESIS command.

Fix Gated Clocks When set to True, LSE changes standard gated clocks to forms more effective for FPGAs. Clocks are gated with AND or OR gates to conserve power, but in FPGAs such clocks cause skew and prevent global clock resources from being used. The Fix Gated Clocks option is ignored if the Optimization Goal option is set to Area.

The gated clocks must be specified in the .ldc file with create_clock constraints. For help writing the constraints, see “Defining Clocks Using LDC

Editor" on page 367 or "create_clock" on page 1340. All inputs of the gating logic must be driven by primary inputs and the gating logic must be decomposable. Instantiated primitives and black boxes are not affected.

Converted clocks and the associated registers are reported in the synthesis.log file.

Force GSR (for LSE) Enables (True) or disables (False) forced use of the global set/reset routing resources. When the value is Auto, the synthesis tool decides whether to use the global set/reset resources.

This option is equivalent to the "-force_gsr" option in the SYNTHESIS command.

FSM Encoding Style Specifies the encoding style to use with the design.

This option is equivalent to the "-fsm_encoding_style" option in the SYNTHESIS command. Valid options are auto, one-hot, gray, and binary. The default value is auto, meaning that the tool looks for the best iimplementation.

Note

The encoding type "gray" only works with less than or equal to four machine states. When the number of machine states is large than four, LSE will use other encoding styles and issue the following warning message:

WARNING - Gray encoding is not supported for state machines with more than four states.

Hardware Evaluation (for LSE) Enables or disables the ability to temporarily test IP in a device without an IP license. If enabled, a timer is added to the design that allows unlicensed IP to function for about 4 hours in a device. If disabled, you cannot generate a bitstream if there are any unlicensed IP in the design.

You might want to disable this option to refine your design while waiting for the license. You will not be able to generate a bitstream, but you will be able to see how resources are used (without the timer) and close timing. When you get the license, you can then generate the bitstream.

Regardless of how this option is set, if there are any unlicensed IP in the design, some features of Diamond, such as gate level simulation and EPIC, are blocked.

This option is equivalent to the "-dt" option in the SYNTHESIS command.

Intermediate File Dump If you set this to True, LSE will produce intermediate encrypted Verilog files. If you supply Lattice with these files, they can be decrypted and analyzed for problems. This option is good for analyzing simulation issues.

This option is equivalent to the "-ifd" option in the SYNTHESIS command.

Loop Limit Specifies the maximum number of iterations of "for" and "while" loops in the source code. The limit is applied when the loop index is a variable, not when it is a constant. The higher the loop_limit, the longer the run time. The default value is 1950. Setting a higher value may cause stack overflow during some of the optimizations during synthesis. A lower value will be ignored and the default used instead.

This option is equivalent to the “-loop_limit” option in the SYNTHESIS command.

Macro Search Path (for LSE) Allows you to specify a path (or paths) to locate physical macro files used in a given design. The software will add the specified paths to the list of directories to search when resolving file references. The option can also be used for indicating the directories containing include files that are specified in the RTL design files.

You don’t need to specify a search path if the necessary .ngo or .nmc file is in the directory containing the top-level .ngo file or if the FILE attribute in the design gives a complete path name for the file (instead of a relative path name).

The software follows the following order to search for .ngo files:

1. Current implementation directory
2. Project directory
3. Directories where the LPC or IPX source files reside
4. User-specified macro search paths

To specify a macro search path, double-click the Value box, and directly enter the path or click the **...** button to browse for one or more paths.

This option is equivalent to the “-p” option in the SYNTHESIS command.

Max Fanout Limit Specifies the maximum fanout setting. LSE will make sure that any net in the design is not exceeding this limit. Default is 1000 fanouts.

This option is equivalent to the “-max_fanout” option in the SYNTHESIS command.

Memory Initial Value File Search Path (for LSE) Allows you to specify a path (or paths) to locate memory initialization file (.mem) used in a given design. The software will add the specified path(s) to the list of directories to search when resolving file references.

To specify a search path, double-click the Value box, and directly enter the path or click the **...** button to browse for one or more paths.

This option is equivalent to the “-p” option in the SYNTHESIS command.

MUX Style Specifies the MUX style setting, which controls the way the macrogenerator implements the multiplexer macros.

Valid options are:

- Auto (default) - LSE looks for the best implementation for each considered macro.
- L6Mux Multiple - Generates multiplexers allowing for multiple L6Mux resources.
- L6Mux Single - Generates multiplexers allowing for the use of a single L6Mux resource.
- PFU Mux - Generates multiplexers using only PFUMux and LUT4 resources.

Note

L6Mux resources will only be inferred when driven by four LUT4 and two PFUMux devices.

This option is equivalent to the “-mux_style” option in the SYNTHESIS command.

Number of Critical Paths (for LSE) Specifies the number of critical timing paths to be reported in the timing report.

This option is equivalent to the “-twr_paths” option in the SYNTHESIS command.

Optimization Goal Enables LSE to optimize the design for area, speed, or balanced.

Valid options are:

- Area – Optimizes the design for area by reducing the total amount of logic used for design implementation.

  When Optimization Goal is set to Area, LSE honors the LDC constraints if there are any. If Use IO Registers is set to Auto, LSE packs input and output registers into I/O pad cells.

  Note

  With the Area setting, LSE also ignores all SDC constraints. These constraints are not used by LSE and are not added to an .lpf file for use by the later stages of implementation.

- Timing – Optimizes the design for speed by reducing the levels of logic.

  When Optimization Goal is set to Timing and a create_clock constraint is available in an .ldc file, LSE ignores the Target Frequency setting and uses the value from the create_clock constraint instead.

  If there are multiple clocks, and if not all the clocks use create_clock constraint, then LSE will asssign 200 MHz constraint on the remaining clocks in Timing Mode.

  If Use IO Registers is set to Auto, LSE does not pack input and output registers into I/O pad cells.

- Balanced – Optimizes the design for both area and timing.

  When Optimization Goal is set to Balanced, all timing driven optimizations based on static timing analysis will run depending on LDC constraints. If Use IO Registers is set to Auto, LSE does not pack input and output registers into I/O pad cells.

The default setting depends on the device type. Smaller devices, such as MachXO and Platform Manager, default to Balanced. Larger devices—ECP5U, LatticeECP2, LatticeECP3, and LatticeXP2—default to Timing.

For more information, see "Optimizing LSE for Area and Speed" on page 579.

This option is equivalent to the "-optimization_goal" option in the SYNTHESIS command.

Propagate Constants When set to True (default), enables constant propagation to reduce area, where possible. LSE will then eliminate the logic used when constant inputs to logic cause their outputs to be constant.

You can turn off the operation by setting this option to False.

This option is equivalent to the "-propagate_constants" option in the SYNTHESIS command.

RAM Style Sets the type of random access memory globally to distributed, embedded block RAM, or registers.

The default is Auto which attempts to determine the best implementation, that is, the synthesis tool will map to technology RAM resources (EBR/Distributed) based on the resource availability.

This option will apply a syn_ramstyle attribute globally in the source to a module or to a RAM instance. To turn off RAM inference, set its value to Registers.

- Registers – Causes an inferred RAM to be mapped to registers (flip-flops and logic) rather than the technology-specific RAM resources.
- Distributed – Causes the RAM to be implemented using the distributed RAM or PFU resources.
- Block_RAM – Causes the RAM to be implemented using the dedicated RAM resources. If your RAM resources are limited, for whatever reason, you can map additional RAMs to registers instead of the dedicated or distributed RAM resources using this attribute.

This option is equivalent to the "-ramstyle" option in the SYNTHESIS command.

Remove Duplicate Registers Specifies the removal of duplicate registers.

When set to True (default), LSE removes a register if it is identical to another register. If two registers generate the same logic, the second one will be deleted and the first one will be made to fan out to the second one's

destinations. LSE will not remove duplicate registers if this option is set to False.

This option is equivalent to the “-remove_duplicate_regs” option in the SYNTHESIS command.

Remove LOC Properties (for LSE) Setting this to On removes LOC properties in the synthesized design before building the Native Generic Database (.ngd) file.

Resolved Mixed Drivers (for LSE) If a net is driven by a VCC or GND and active drivers, setting this option to True connects the net to the VCC or GND driver.

Resource Sharing (for LSE) When this is set to True (default), the synthesis tool uses resource sharing techniques to optimize area.

With resource sharing, synthesis uses the same arithmetic operators for mutually exclusive statements; for example, with the branches of a case statement. Conversely, you can improve timing by disabling resource sharing, but at the expense of increased area.

This option is equivalent to the “-resource_sharing” option in the SYNTHESIS command.

ROM Style Allows you to globally implement ROM architectures using dedicated, distributed ROM, or a combination of the two (Auto).

This applies the syn_romstyle attribute globally to the design by adding the attribute to the module or entity. You can also specify this attribute on a single module or ROM instance.

Specifying a syn_romstyle attribute globally or on a module or ROM instance with a value of:

- Auto (default) – Allows the synthesis tool to choose the best implementation to meet the design requirements for speed, size, and so on.
- Logic – Causes the ROM to be implemented using the distributed ROM or PFU resources. Specifically, the logic value will implement ROM to logic (LUT4) or ROM technology primitives (such as ROM16X1, ROM32X1, ROM64X1, and so on).
- EBR – Causes the ROM to be mapped to dedicated EBR block resources. ROM address or data should be registered to map it to an EBR block. If your ROM resources are limited, for whatever reason, you can map additional ROM to registers instead of the dedicated or distributed RAM resources using this attribute.

Infer ROM architectures using a CASE statement in your code. For the synthesis tool to implement a ROM, at least half of the available addresses in the CASE statement must be assigned a value. For example, consider a ROM with six address bits (64 unique addresses). The CASE statement for this ROM must specify values for at least 32 of the available addresses.

This option is equivalent to the “-romstyle” option in the SYNTHESIS command.

Target Frequency Specifies the target frequency setting. This frequency applies to all the clocks in the design. If there are some clocks defined in an .ldc file, the remaining clocks will get this frequency setting. When a create_clock constraint is available in an .ldc file, LSE ignores the Target Frequency setting for that clock and uses the value from the create_clock constraint instead.

This option is equivalent to the “-frequency” option in the SYNTHESIS command.

Use Carry Chain Turns on (True) or off (False) carry chain implementation for adders. Default is True.

This option is equivalent to the “-use_carry_chain” option in the SYNTHESIS command.

Use IO Insertion When set to True, LSE uses I/O insertion and GSR.

This option is equivalent to the “-use_io_insertion” option in the SYNTHESIS command.

Use IO Registers When True, this option forces the synthesis tool to pack all input and output registers into I/O pad cells based on the timing requirements for the target device family. Auto, the default setting, enables this register packing if Optimization Goal is set to Area. If Optimization Goal is Timing or Balanced, Auto disables register packing.

This option is equivalent to the “-use_io_reg” option in the SYNTHESIS command.

You can also control packing on individual registers and ports. See “syn_useioff” on page 1397.

Use LPF Created from SDC in Project (for LSE) LSE creates a preference (.lpf) file based on the Synopsys Design Constraint (.sdc) file. (When you use LSE, SDC constraints must be in a Lattice Design Constraints (.ldc) file.) When this option is set to True, the synthesis constraints are also applied to the Map Design stage of implementation.

VHDL 2008 (for LSE) When this is set to True, VHDL 2008 is selected as the VHDL standard for the project.

Translate Design Options

This page lists all the strategy options associated with the Translate Design process.

- Command Line Options (for Synplify Pro Translate Design)
- Consistent Bus Name Conversion

- Hardware Evaluation
- Macro Search Path
- Memory Initial Value File Search Path
- “Partition Search Path” on page 1140
- Remove LOC Properties

Command Line Options (for Synplify Pro Translate Design) Enables EDIF2NGD command line options for the Synplify Translate Design process.

To enter a command line option:

1. In the Strategy dialog box, select **Translate Design** in the Process list.
2. Double-click the Value column for the Command Line Options option.
3. Type in the option and its value (if any) in the text box.
4. Click **Apply**.

For detailed descriptions of EDIF2NGD netlist translation command line options, see “Running EDIF2NGD from the Command Line” on page 2455.

Consistent Bus Name Conversion Allows you to set preferences for bus signals in Verilog and VHDL designs that can be honored by LSE, Synopsys Synplify Pro, and Mentor Graphics Precision synthesis tools.

Four options are available.

- Synplify – Converts the bus signal names to match the Synplify Pro format. The Verilog or VHDL bus signal preferences will then be honored by Synplify Pro.
- Precision – Converts the bus signal names to match the Precision format. The Verilog or VHDL bus signal preferences will then be honored by Precision RTL Synthesis.
- Lattice – Converts “( )”, “[ ]”, “< >”, “{ }” in the bus signal names to underscores “_”. For example, the bus name aq[i] is converted to aq_i_, bq(i) is converted to bq_i_, cq<i> is converted to cq_i_, dq{i} is converted to dq_i_, and eq_i to eq_i_.
- None (default) – Does not convert the bus signal names. The Verilog or VHDL bus signal preferences set for Synplify Pro will not be honored by Precision, and vice versa.

Hardware Evaluation (for Translate Design) Enables or disables the ability to temporarily test IP in a device without an IP license. If enabled, a timer is added to the design that allows unlicensed IP to function for about 4 hours in a device. If disabled, you cannot generate a bitstream if there are any unlicensed IP in the design.

You might want to disable this option to refine your design while waiting for the license. You will not be able to generate a bitstream, but you will be able to see how resources are used (without the timer) and close timing. When you get the license, you can then generate the bitstream.

Regardless of how this option is set, if there are any unlicensed IP in the design, some features of Diamond, such as gate level simulation and EPIC, are blocked.

Macro Search Path (for Translate Design) Allows you to specify a path (or paths) to locate physical macro files used in a given design. The software will add the specified paths to the list of directories to search when resolving file references.

You don't need to specify a search path if the necessary .ngo or .nmc file is in the directory containing the top-level .ngo file or if the FILE attribute in the design gives a complete path name for the file (instead of a relative path name).

The software follows the below order to search for .ngo files.

1. Current implementation directory
2. Project directory
3. Directories where the LPC or IPX source files reside
4. User-specified macro search paths

To specify a macro search path, double-click the Value box, and directly enter the path or click the **...** button to browse for one or more paths.

Memory Initial Value File Search Path (for Translate Design) Allows you to specify paths to locate memory initialization files (.mem) used in a given design. Diamond will add the specified paths to the list of directories to search when resolving file references.

To specify a search path, double-click the Value box and directly enter the path or click the **...** button to browse for the path.

Partition Search Path Allows you to specify paths to locate native generic object files (.ngo) that define partitions used in the design. Diamond will add the specified paths to the list of directories to search when resolving file references. The partition .ngo files will be loaded and used for replacing the original partition.

To specify a search path, double-click the Value box and directly enter the path or click the **...** button to browse for the path.

Remove LOC Properties (for Translate Design) Setting this to On removes LOC properties in the synthesized design before building the Native Generic Database (.ngd) file.

Map Design Options

This page lists all strategy options associated with the Map Design process. The options available for user setting are dependent on the target device of your project.

- Command Line Options
- Ignore Preference Errors
- Infer GSR
- IO Registering
- Overmap Device if Design Does Not Fit
- Pack Logic Block Util.
- Register Retiming
- Report Signal Cross Reference
- Report Symbol Cross Reference
- Timing Driven Mapping
- Timing Driven Node Replication
- Timing Driven Packing

Command Line Options (for Map Design) Enables additional command line options for the associated process.

To enter a command line option:

1. In the Strategy dialog box, select the associated process in the Process list.
2. Double-click the Value column for the Command Line Options option.
3. Type in the option and its value (if any) in the text box. For example: -exp parPathBased=ON
4. Click **Apply**.

To reference more information about command line options for the Map Design process, type map -h <architecture> in a command line window. For detailed options description, refer to Running MAP from the Command Line.

Ignore Preference Errors (for Map Design) Enables or disables the Map Design process to ignore errors in the preference file.

With the default setting of True, Map Design ignores errors in the preference file and continues processing. When you set it to False, Map Design terminates processing and issues an error message.

The Map report includes the setting of this option and the preference errors found.

Infer GSR Enables or disables the GSR inferencing.

The default is True. By default, if the input design (NGD) does not include a GSR buffer, MAP will infer one based on the signal that drives the most set/reset loads.

If this is set to False, all the GSR_NET preferences in the logical preference file (LPF) will be ignored.

IO Registering Directs the I/O register packing.

Valid options are:

- Input – Packs the input registers only.
- Output – Packs the output registers only.
- Both – Packs both the input and output registers whenever possible.
- None – Does not pack the IO registers but uses PFF/PFU resources only.
- Auto (default) – Allows the software to decide whether to pack IO registers or not.

This option overrides the register types of the native generic database (NGD). The USE DIN or USE DOUT preference in the logical preference file (LPF) overrides this option.

Overmap Device if Design Does Not Fit When this is set to True, the Map Design process will write a Native Circuit Description (.ncd) file even if the device is too small for the design. This .ncd file cannot be used for Place and Route Design, just for you to observe mapping results.

Pack Logic Block Util. Sets the relative density (of available slices) at which the slices within a device are to be packed, in terms of a percentage of the available slices in the device.

This option has great control of the packing density. The value range is 0-100 percent (100 = minimum packing; 0 = maximum density).

If this option is not specified (blank), it defaults to 97 percent. The result will be a less dense packing, depending on the size of the design relative to the number of available slices in the device. If the design is large compared with the number of available slices in the device, the mapper will make a reasonable effort to pack the design so that it fits in the device.

If you specify a density value for this option, the mapper will attempt to pack the device to that density. The “0” setting results in the densest mapping. If the design is large compared with the target density, the mapper will make an aggressive packing effort to meet your target. However, this may adversely impact the design’s f_{MAX} performance.

Register Retiming Moves registers across combinational logic to balance timing according to the constraints t_{SU} (INPUT_SETUP), t_{CO} (CLOCK_TO_OUT), and f_{MAX} (FREQUENCY).

This is a typical logic optimization technique to balance combinational logic across register-pairs to allow you to maximize clock frequency. However, there is no guarantee that a better f_{MAX} can be achieved. The f_{MAX} constraint activates re-timing around all registers. The t_{SU} and t_{CO} constraints may de-activate re-timing on I/O registers depending on the balancing of t_{SU} versus f_{MAX} and t_{CO} versus f_{MAX}. The re-timing process stops when it estimates that the constraints have been met.

Register Retiming is turned off by default and should not be used on the initial run until you have determined whether or not it could be used to optimize your design to meet timing.

For more information, see Map Register Retiming.

Report Signal Cross Reference When this is set to True, the map report (.mrp) will show where nets in the logical design were mapped in the physical design (NCD).

The default is False.

Report Symbol Cross Reference When this is set to True, the map report (.mrp) will show where symbols in the logical design were mapped in the physical design (NCD).

The default is False.

Timing Driven Mapping Allows you to apply timing-driven logic collapsing and optimization to further optimize the critical paths.

Timing Driven Mapping reads the preference file and calculates the slacks for all constrained paths. The mapping optimizes the critical paths based on the slack distributions. Options are True and False (default).

Timing Driven Node Replication Allows you to activate timing driven logic replication.

When this is set to True, the software replicates a LUT-4 that has multiple fanouts to flip-flops (FFs), adding LUT for each FF if the LUT belongs to the timing path. This allows packing LUT/FF in the same slice for all FFs. Default is False.

Timing Driven Packing Allows you to activate timing driven packing of LUT/FF, FF/LUT, and LUT/LUT in the same slice.

Options are True and False (default).

Map Trace Options

This page lists all strategy options associated with the Map Trace process.

- Analysis Options
- Auto Timing
- Check Unconstrained Connections (for Map Trace)
- Check Unconstrained Paths
- Full Name
- Number of Unconstrained Paths (for Map Trace)
- Report Asynchronous Timing Loops
- Report Style

- Route Estimation Algorithm (%)
- Worst-Case Paths (0-4096)

Analysis Options (for Map Trace) Specifies the analysis type.

- Hold Analysis – Performs hold analysis.
- Standard Setup Analysis (default) – Performs setup time checks on the following preferences: FREQUENCY, CLOCK_TO_OUT, and INPUT_SETUP.
- Standard Setup with Hold Analysis on IOs – Performs standard setup analysis and a hold time analysis on I/Os in the same report file. Applies to INPUT_SETUP and CLOCK_TO_OUT timing preferences.
- Standard Setup and Hold Analysis – Performs both the Standard Setup Analysis and the Hold Analysis.

Auto Timing (for Map Trace) Lists the auto-generated timing preferences in the TRACE report.

If you do not define any timing preference for your FPGA design, Lattice Diamond will automatically generate timing preferences for you. Set this to True (default) if you want your TRACE report to list the auto-generated timing preferences.

Check Unconstrained Connections (for Map Trace) Reports connections not covered by a timing preference.

Check Unconstrained Paths (for Map Trace) Reports paths not covered by a timing preference.

Full Name (for Map Trace) When this is set to True, the TRACE report will show full-length component names instead of the truncated names.

Number of Unconstrained Paths (for Map Trace) Sets the maximum number of unconstrained paths that will be reported. "Unconstrained paths" are those not covered by a timing preference.

Report Asynchronous Timing Loops (for Map Trace) Produces a report of paths that could not be analyzed because they are asynchronous loop.

Report Style (for Map Trace) Specifies the type of the timing report.

- Verbose Timing Report (default) – Lists detailed logic and route delays for all constrained paths and nets in the design.
- Error Timing Report – Lists logic and route delays for each path and net that causes a timing error.

Route Estimation Algorithm (%) Configures the route estimation algorithm for pre-route static timing analysis.

- 0 (default) – Enables route delay estimation based on a suite of Lattice benchmark designs. Note that delay estimates are based on the default performance grade of the target device.

- 1~100 – Specifies logic delay as a percentage of the overall path delay where the total delay is the sum of logic and route delays.

Worst-Case Paths (0-4096) (for Map Trace) Specifies the number of paths to be reported for each timing preference. Enter zero or a grater value.

- When **Verbose Timing Report** is selected, the value you specify limits the number of paths reported for each timing preference (0 = no limit). There is no practical limit, although unlimited reporting may exhaust available memory and disk space.

  Scoring a path refers to the timing extraction performed by the static timing analysis engine. TRACE will always extract the worst case paths, however, you can choose to analyze and score more than the system default.

  Given a large design with many paths to examine, you may wish to limit the report size by using more specific preferences or BLOCK type exceptions temporarily to mask paths that are not of interest.
- When **Error Timing Report** is selected, the specified number of paths with timing error will be printed out. If you enter **0**, no path will be reported.

Place & Route Design Options

This page lists all strategy options associated with the Place & Route Design process. The options available for user setting are dependent on the target device of your project.

- Remove Previous Design Directory
- Routing Delay Reduction Passes
- Routing Method
- Routing Passes
- Routing Resource Optimization
- Run Placement Only
- SLVS MIPI LVCMOS Output
- Stop Once Timing is Met

Auto Hold-Time Correction Controls whether the router will automatically insert extra wires to compensate for hold-time violations on affected registers. Auto hold-time correction has a negative impact on your setup time. If the setup time is more design critical, turn off this option. The default is On.

Note

If there is a setup timing error, auto hold-time correction will not be done. If you want the correction to be done anyway, add the following option to “Command Line Options” (see below) in the Place & Route Design strategy:

```
-exp parHold=1
```

See parHold for more information.

There are several `par -exp` command line options that affect auto hold-time correction. All of these options can be added to “Command Line Options” (see below) in the Place & Route Design strategy.

- `parHold=1` forces correction to run.
- `parHoldIter=<value>` sets the maximum number of iterations to run.
- `parHoldLimit=<value>` sets the maximum number of hold time violations to be processed.
- `parHoldOnly=1` causes place and route to be run for auto hold time correction only. Use with parHold.
- `parHoldSpeedGrade=<value>` sets the performance grade to be used.

For details, see Running PAR from the Command Line.

For more about using this option, see:

- “Hold-Time Error Correction” on page 603
- “Changing Temperature and Voltage for Auto Hold-Time Correction” on page 606.

Clock Skew Minimization Balances routing to reduce skews for clock signals that are not assigned to the global clock tree.

Options are Off (default), 1, and 2.

- The 1 setting routes from driver pins to each clock load with pre-computed delay lower bound for balanced routing. This setting may help when the candidate net has a very small span (for example, the bounding box span is within 2 to 3 PLCs) and possesses small skew.
- The 2 setting routes a clock trunk first and then routes from the trunk to each clock load with pre-computed delay lower bound for balanced routing. This setting usually creates better results with less time and memory use.

Command Line Options (for Place & Route Design) Allows you to specify options from the par command without directly using the command line. Type in a string of options without the par command. For example: `-exp parPathBased=ON:parHold=1`

For detailed descriptions of placement, routing, and PAR explorer (-exp) command line options, see Running PAR from the Command Line.

Congestion-Driven Placement Enables or disables the congestion-driven placement algorithm.

The available options are:

- 1 – Enables the congestion-driven placement algorithm.
- 0 – Disables the congestion-driven placement algorithm.
- Auto – Automatically turns on or off the congestion-driven placement based on the device size and design parameters.

The default is Auto for LatticeECP2/M, LatticeECP3, and LatticeXP2 devices, and 0 for other devices.

Congestion-driven placement is compatible with all Lattice FPGA device families. It is most beneficial for designs targeted to LatticeSC/M, LatticeECP2/M, LatticeECP3, and LatticeXP2 device families.

See Routing Method and Congestion-Driven Routing for more congestion-driven options.

Congestion-Driven Routing Enables or disables the congestion-driven routing algorithm.

The available options are:

- 1 – Enables the congestion-driven routing algorithm.
- 0 – Disables the congestion-driven routing algorithm.
- Auto – Automatically turns on or off the congestion-driven routing based on the device size and design parameters.

The default is 1 for LatticeECP2/M, LatticeECP3, and LatticeXP2 devices, and 0 for other devices.

Congestion-driven options like Congestion-Driven Placement and Congestion-Driven Routing can improve performance given a design with

multiple congestion “hotspots.” The Layer > Congestion command of the Floorplan View can help visualize routing congestion. Large congested areas may prevent the options from finding a successful solution.

Congestion-driven routing is compatible with all Lattice FPGA device families. It is most beneficial for designs targeted to LatticeECP2/M, LatticeECP3, and LatticeXP2 device families.

See Routing Method and Congestion-Driven Placement for more congestion-driven options.

Create Delay Statistic File When set to True, outputs a delay report file (.dly) on each PAR run.

The delay report file contains delay information for each net in the design for each run. You can generate this file when you use the -y option in the command line.

Default Clock Frequency (MachXO3L/LF 9400C/E devices only.) The proper Default Clock Frequency (MHz) must be set before running the Thermal Analysis process. Default setting of 0 will cause an error.

Disable Timing Driven Enables or disables the timing-driven option for the PAR run.

When this is set to True, the timing-driven option for the PAR run will not be used. If this is set to False, PAR automatically uses the timing-driven option if the Timing Wizard is present and if any timing preferences are found in the preference file. If selected, the timing-driven option is not invoked in any case and cost-based placement and routing are done instead.

Two examples of situations in which you might disable this option are:

- You have timing preferences specified in your preference file, but you want to execute a quick PAR run without using the timing-driven option to give you a rough idea of how difficult the design is to place and route.
- You only have a single license for the timing-driven option but you want to use this license for another application (for example, to perform timing-driven routing within EPIC) that will run at the same time as PAR. This option keeps the license free for the other application.

Generate TRACE Report for Each Iteration Generates a post-PAR TRACE report (.twr) for each intermediate NCD created by multi-PAR.

Ignore Preference Errors (for Place & Route Design) Enables or disables the Place and Route Design process to ignore errors in the preference file.

With the default setting of True, the PAR process ignores errors in the preference file and continues processing. When you set it to False, the PAR process terminates processing and issues an error message.

The Place & Route report includes the setting of this option and the preference errors found.

Multi-Tasking Node List Allows you to specify the node file name for the multi-tasking PAR.

The multi-tasking PAR allows you to use multiple machines (nodes) that are networked together for a multi-run PAR job, significantly reducing the total amount of time for completion.

For more information on multi-tasking PAR, see Running Multiple PAR Jobs in Parallel.

Path-based Placement Allows you to apply path-based placement. Path-based placement gives better performance and more predictable results.

Options are Off (default) and On.

Placement Effort Level Specifies the effort level of the design from 1 (simplest designs) to 5 (most complex designs).

The level is not an absolute; it shows instead relative effort. After you use PLACE & ROUTE for a while, you will be better able to estimate whether a design is simple or complex. If you place and route a simple design at a complex level, the design will be placed and routed properly, but the process will take more time than placing and routing at a simpler level. If you place and route a complex design at a simple level, the design may not route to completion or may route less completely (or with worse delay characteristics) than at a more complex level.

Placement Iteration Start Pt Specifies the cost table to use (from 1-100) to begin the PAR run.

The default is 1. Cost tables are not an ordered set. There is no correlation between a cost table's number and its relative value. If cost table 100 is reached, placement does not begin at 1 again, even if command options specify that more placements should be performed.

Placement Iterations Specifies the maximum number of placement/routing passes (0-100, 0 = run until solved) to be run (regardless of whether they complete) at the Placement Effort Level.

Each iteration uses a different cost table when the design is placed and will produce a different Native Circuit Description (.ncd) file. If you specify a Starting Cost Table, the iterations begin at that table number.

Placement Save Best Run Determines the number (1-100) of best outputs of the Place and Route run to save (defaults to 1).

If no number is specified, all output designs produced by the PLACE & ROUTE run are saved. The best outputs are determined by a scoring system described in the section titled Scoring the Routed Design.

This option does not care how many iterations you performed or how many effort levels were used. It compares every result to every other result and leaves you with the best number of Native Circuit Description (.ncd) files.

Placement Sort Best Run Specifies how to sort the results of the Place and Route run in the PAR report. Results are sorted first by the number of unrouted connections. Then the results are ranked by timing. Choose whether you want to use the worst-slack value or the timing score to rank the results.

The default is Worst Slack.

Remove Previous Design Directory When this is set to True (default), the software removes the contents of the project design directory before Place and Route Design is rerun.

This prevents the accumulation of files from multiple Place & Route Design processes in the same directory.

Routing Delay Reduction Passes Determines the number of passes to be run for Routing Delay Reduction and Routing Resource Optimization properties. The first delay-based cleanup pass produces the greatest improvement.

The value range is 0 to 100.

Routing Method Specifies router algorithm.

Options are Default (rip-up-based routing) and NBR (negotiation-based routing).

NBR is supported by LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeXP2, and LatticeSC/M device families. The Routing Method option defaults to NBR for LatticeECP2, LatticeECP3, and LatticeXP2 devices, and Default for the other supported devices.

NBR involves an iterative routing algorithm that routes connections to achieve minimum delay cost. It does so by computing the demand on each routing resource and applying cost values per node. It will complete when an optimal solution is arrived at or the number of iterations is reached. Compared with the traditional rip-up-based routing, NBR can provide better results in performance (f_{MAX}), CPU time and completion rate.

A combination of this option and the Congestion-Driven Placement and Congestion-Driven Routing options can yield improved results. The relative runtime and quality by option is:

- Routing Method = Default, Congestion-Driven Placement = 0, Congestion-Driven Routing = 0: low congestion
- Routing Method = Default, Congestion-Driven Placement = 1, Congestion-Driven Routing = 1: moderate congestion
- Routing Method = NBR, Congestion-Driven Placement = 1: very congested

Routing Passes Determines the maximum number of routing passes the place and route tool takes.

One routing pass is an attempt to route each unrouted connection. While most designs route completely after a single routing pass, a design that is tightly packed or that has very tight timing requirements may require multiple routing passes to complete. If Routing Passes is not set, the router will intelligently decide the number of routing passes to make.

Routing Resource Optimization Determines the number of cost-based cleanup passes to run.

If not used, the router runs one cost-based cleanup pass. If you run both cost-based and delay-based cleanup passes, the cost-based passes run before the delay-based passes.

Run Placement Only Setting this to True prevents the design from being routed. PAR will output a placed, but not routed Native Circuit Description (.ncd) file.

This option defaults to False.

SLVS MIPI LVCMOS Output This option allows the user to select between LVCMO12_18 ONLY (default) or LVCMOS_NOT_PERMITTED.

LVCMO12_18 ONLY - LVCMOS output is limited to LVCMOS12 or LVCMOS18. I/O placement is limited by LCT plus.

- SLVS/MIPI bank: Only allows SLVS input, MIPI input/bidi, LVCMO12 output or LVDS output when bank VCCIO is 2.5 (if only using SLVS in the bank).
- Neighbor bank: Only allows LVCMOS12, LVCMOS18 or LVDS output.

LVCMOS_NOT_PERMITTED - No LVCMOS output is allowed. I/O placement is limited by LCT plus.

- SLVS/MIPI bank: Only supports either SLVS input or MIPI input/bidi; no any other IO_TYPE output is allowed.
- Neighbor bank: Only supports LVDS output.

Stop Once Timing is Met Setting this to True forces the Place and Route Design process to stop as soon as the timing requirement is satisfied. This option has no effect if the "Generate TRACE report for each iteration" option is set to True or if using Run Manager to produce multiple place-and-route runs.

Place & Route Trace Options

This page lists all strategy options associated with the Place & Route Trace process.

- Analysis Options
- Auto Timing

- "Check Unconstrained Connections (for Place & Route Trace)" on page 1152
- Check Unconstrained Paths
- Full Name
- "Number of Unconstrained Paths (for Place & Route Trace)" on page 1153
- Report Asynchronous Timing Loops
- Report Style
- Speed for Hold Analysis
- Speed for Setup Analysis
- Worst-Case Paths (0-4096)

Analysis Options (for Place & Route Trace) Specifies the analysis type.

- Hold Analysis – Performs hold analysis. For post-route analysis, you may override the default performance grade (the performance grade of the target device) using the Speed for Hold Analysis option.
- Standard Setup Analysis (default) – Performs setup time checks on the following preferences: FREQUENCY, CLOCK_TO_OUT, and INPUT_SETUP. For post-route analysis, you may override the default performance grade (the performance grade of the target device) using the Speed for Setup Analysis option.
- Standard Setup with Hold Analysis on IOs – Performs standard setup analysis and a hold time analysis on I/Os in the same report file. Applies to INPUT_SETUP and CLOCK_TO_OUT timing preferences. For post-route analysis, you may override the default performance grade (the performance grade of the target device) using the Speed for Setup Analysis option.
- Standard Setup and Hold Analysis – Performs both the Standard Setup Analysis and the Hold Analysis.

Auto Timing (for Place & Route Trace) Lists the auto-generated timing preferences in the TRACE report.

If you do not define any timing preference for your FPGA design, Lattice Diamond will automatically generate timing preferences for you. Set this to True (default) if you want your TRACE report to list the auto-generated timing preferences.

Check Unconstrained Connections (for Place & Route Trace) Reports connections not covered by a timing preference.

Check Unconstrained Paths (for Place & Route Trace) Reports paths not covered by a timing preference.

Full Name (for Place & Route Trace) When this is set to True, the TRACE report will show full-length component names instead of the truncated names.

Number of Unconstrained Paths (for Place & Route Trace) Sets the maximum number of unconstrained paths that will be reported. "Unconstrained paths" are those not covered by a timing preference.

Report Asynchronous Timing Loops (for Place & Route Trace) Produces a report of paths that could not be analyzed because they are asynchronous loop.

Report Style (for Place & Route Trace) Specifies the type of the timing report.

- Verbose Timing Report (default) – Lists detailed logic and route delays for all constrained paths and nets in the design.
- Error Timing Report – Lists logic and route delays for each path and net that causes a timing error.

Speed for Hold Analysis Specifies performance grade for hold analysis. This option allows you to override the default m (minimum) performance grade for hold time analysis, which represents faster silicon than the fastest performance grade of the device being targeted.

Speed for Setup Analysis Specifies performance grade for setup analysis. This option allows you to override the default performance grade which runs setup analysis against the performance grade of the device currently targeted by the project implementation.

Worst-Case Paths (0-4096) (for Place & Route Trace) Specifies the number of paths to be reported for each timing preference. Enter zero or a grater value.

- When **Verbose Timing Report** is selected, the value you specify limits the number of paths reported for each timing preference (0 = no limit). There is no practical limit, although unlimited reporting may exhaust available memory and disk space.

  Scoring a path refers to the timing extraction performed by the static timing analysis engine. TRACE will always extract the worst case paths, however, you can choose to analyze and score more than the system default.

  Given a large design with many paths to examine, you may wish to limit the report size by using more specific preferences or BLOCK type exceptions temporarily to mask paths that are not of interest.
- When **Error Timing Report** is selected, the specified number of paths with timing error will be printed out. If you enter 0, no path will be reported.

IO Timing Analysis Options

The following option is associated with the IO Timing Analysis process.

All Performance Grade Controls whether the I/O timing report (.ior) will give an in-depth analysis on all available performance grades or will just produce a summary report on the worst-case performance grade.

- True - The I/O Timing Report will summarize the worst-case scenario of all available performance grades.
- False (default) - The I/O Timing Report will only contain a summary of the worst-case performance grade for the given device.

Timing Simulation Options

This page lists all strategy options associated with the Timing Simulation process. The options available for user setting are dependent on the target device of your project.

Generate PUR in the Netlist When this is set to False, the timing simulation file generation process will not write PUR instance in the Verilog/ VHDL backannotation netlist. Then you have to instantiate PUR in the test bench.

Generate X for Setup/Hold Violation When this is set to True, the Timing Simulation process will place X notifiers in the output file on flip-flops with setup and/or hold time violations.

Hold Check Min Speed Grade Setting this to True replaces all timing information for back annotation with the minimum timing for all paths.

This option is used for simulation of hold time requirements. Separate simulations are required for hold time verification (-min switch) and delay time verification (normal output).

Timing Simulation Max Delay between Buffers (ps) Distributes routing delays by splitting the signal and inserting buffers. The delay value assigned represents the maximum delay number in picoseconds between each buffer (1000 ps by default).

Multichip Module Prefix Adds a prefix to module names to make them unique for multi-chip simulation.

Negative Setup-Hold Times Allows you to select negative setup time and negative hold time for better accuracy.

The default is True. You can set it to False for those simulators that might not be able to handle negative setup- hold times.

Retarget Speed Grade Retargets back annotation to a different performance grade than the one used to create the Native Circuit Description (.ncd) file.

You are limited to those performance grades available for the device used in the NCD file.

Transport Mode of Path Delay in VHDL When this is set to True, the VitalTransport glitch propagation type is used rather than the default OnDetect glitch propagation type. This selection should be used to prevent filtering of a glitch when an input pulse is shorter than the propagation delay..

The default is False. The option is only available for VHDL designs.

Verilog Hierarchy Separator Specifies the hierarchy separator character which will be used in name generation when the design hierarchy is flattened.

The default setting is “/”. You can specify an alpha-numeric character or special character as the hierarchy separator.

For alpha-numeric characters, just enter the character as is in the edit box. For special characters (such as +, -, and so on), encapsulate the character with double quotes, for example, “+”, “-”.

The option is only available for Verilog designs.

Write Verbose Netlist When this is set to False (default), a parameterized netlist will be generated. The parameterized format contains less details, but is more compact in size and memory efficient within the simulator.

Bitstream Options

This page lists all strategy options associated with the bitstream generation process. The options available for user setting are dependent on the target device of your project.

- Address
- Byte Wide Bit Mirror
- Chain Mode
- Create Bit File
- Disable UES
- Enable I/O in Re-configuration
- Enable Timing Check

- External Clock
- Grant Timeout
- LengthBits
- No Header
- Output Format
- Output Zero Frames
- PROM Data Output Format
- ReadBack
- ReadCapture
- Register Configuration
- Reset Config RAM in Re-configuration
- Run DRC
- Search Path
- SPI Start Address
- Startup Clock
- Sysbus Clock Config
- Sysbus Config
- UFM Initval Order
- Wait State Timeout
- XRES Calibration Control

Address Specifies the bitstream addressing mode.

- Increment (default) – For general use. Contains data information but no address information; each frame is loaded from lowest address to highest address.
- Explicit – For testing and debugging. Requires address information followed by data information, one address frame or more (depending on how many locations must be written).

Byte Wide Bit Mirror Reverses the order of the bits on a byte-by-byte basis.

Chain Mode When enabled, allows daisy chaining with other devices.

- Disabled – The device is not daisy chained with other devices.
- Flowthrough – This option, which can be implemented with either master or slave parallel configuration, pulls the CSON pin low when the device has completed its configuration. The Flowthrough option drives out a static low signal on the CSON pin. It then tristates the device D[0:7] and BUSY pins when configuration is completed so they will not interfere with the next daisy-chained device to be configured. Once Flowthrough mode starts, the device remains in Flowthrough mode until the wake-up

sequence is completed. One option for getting out of Flowthrough mode is to toggle CSN and CS1N, which act as reset signals.

- Bypass – This option is used in parallel and serial device daisy chains. When configuration of the device is completed, data coming into the device configuration port overflows serially out of DOUT to the DI of the next slave serial device. In serial configuration mode, the Bypass option connects DI to DOUT by means of a bypass register after configuration is completed. The bypass register is initialized with a 1 at the beginning of configuration. In parallel configuration mode, the Bypass option causes the data incoming from D[0:7] to be serially shifted to DOUT after completion of configuration. The serialized byte-wide register is shifted to DOUT through the bypass register. D0 of the byte wide data is shifted out first, followed by D1, D2, and so on. Once Bypass mode starts, the device remains in Bypass mode until the wake-up sequence finishes. One option for getting out of Bypass mode is to toggle CSN and CS1N, which act as reset signals.

Create Bit File When set to True, generates a bitstream file.

Disable UES Excludes or includes the "User Electronic Signature Data" field in the JEDEC file.

When this is set to True, the generated JEDEC will not contain the “User Electronic Signature Data” field, regardless of what the USERCODE preference is specified in the project preference (.lpf) file. When this is set to False, the “User Electronic Signature Data” field will be written into the JEDEC file.

Enable I/O in Re-configuration When enabled, programs the FPGA to drive outputs (not be tristated) during configuration/reconfiguration.

This option is disabled by default. The only time the “Enable IOs during reconfiguration” option should be used is for partial reconfiguration when it is desired to keep the part operational during reconfiguration, and then extreme care must be taken to ensure that no user outputs are placed at pins required for configuration.

Enable Timing Check When this is set to true and there is timing error in the Place and Route report file, a dialogue box will display before executing bitstream generation.

External Clock Used for testing Master configuration modes.

By default (option No), in Master configuration modes the configuration clock CCLK is an output driven by the internal oscillator (refer to the configuration section of the device data sheet for details). Setting this option to Yes makes CCLK an input.

Grant Timeout Controls an internal system bus grant counter that counts the number of HCLK (sysbus clk) cycles that go by before the grant signal is taken away from the master.

This prevents the system bus from locking up if anything goes wrong. Possible values are 0, 1, 2...15. See Wait State Timeout HCLK cycle values.

LengthBits Specifies bitstream length.

The default bitstream length field is 24 bits. For larger bitstreams, a 32-bit length field may be specified. Daisy chained bitstreams must all use the same size length field.

No Header When this is set to True, the header, or comment string, is not included in the bitstream.

By default, the header is included.

Output Format Specifies the type of bitstream to create for an FPGA device.

The following options are available:

- Bit File (Binary) – Generates a binary configuration file (.bit) that contains the default outputs of the Bit Generation process.
- Raw Bit File (ASCII) – Generates an ASCII raw bit text file (.rbt) of ASCII ones and zeros that represent the bits in the bitstream file. If you are using a microprocessor to configure a single FPGA, you can include the Raw Bit file in the source code as a text file to represent the configuration data. The sequence of characters in the Raw Bit file is the same as the bit sequence that will be written into the FPGA.
- Mask and Readback File (ASCII) – Generates an ASCII bitstream file that is used to compare bit locations and execute a readback of configuration data within an operating FPGA. When you select this option, BITGEN generates a an ASCII mask file (.mska) for the input design and an ASCII readback file (.rbka) for verifying the configuration data.
- Mask and Readback File (Binary) – The mask file is used to compare bit locations and execute a readback of configuration data within an operating FPGA. When you select this option, BITGEN generates a binary mask file (.msk) for the input design and a binary readback file (.rbk) for verifying the configuration data.

Output Zero Frames Controls whether zero frames are written to the output bitstream.

- If you set this option to False, the software skips zero frames and only writes non zero frames to the bitstream. This minimizes the size of the bitstream.

  For example,

  ```
  frame a 10011110011...
  frame c 01011101011...
  ```

  Note

  You don’t need to save the zero frames in the bitstream because RAM bits are zeros by default before configuration.

- If this option is set to True (default), the software writes all frames, including zero frames, to the bitstream.

For example,

```
frame a 10011110011...
frame b 00000000000...
frame c 01011101011...
```

PROM Data Output Format Specifies the type of PROM data to create for an FPGA device.

You can select Intel Hex 32-bit or Motorola Hex 32-bit as the PROM data format.

ReadBack Controls whether the sysCONFIG readback operation will read from FLASH or SRAM.

Options are FLASH or SRAM. The default is SRAM. If FLASH is selected, then control register 0 bit 31 is set to 1.

ReadCapture When this is enabled, the GLB is targeted during readback.

Register Configuration Controls whether the software will reset all flip-flops before reconfiguring the target FPGA.

If you are performing a partial reconfiguration and don't want to reset all flip-flops, set this option to NoResetDuringReConfig.

- ResetDuringReConfig – Resets all flip-flops before reconfiguration.
- NoResetDuringReConfig – Does not reset flip-flops before reconfiguration.

Reset Config RAM in Re-configuration The Reset option reinitializes the device when you download a bitstream or JEDEC file. The No Reset option retains the current configuration and allows additional bitstream or JEDEC configuration.

Run DRC When this is set to True, the software runs a physical design rule check and saves the output to the Bit Generation report file (.bgn).

Running DRC before a bitstream or JEDEC file is produced will detect any errors that could cause the FPGA to function improperly. If no fatal errors are detected, it will produce a bitstream or JEDEC file. Run DRC is the default.

Search Path Allows you to specify the search path of the auto-configuration file that is located in a directory other than the project directory.

For information on how to use the auto-configuration file, see the LatticeECP2M, LatticeECP3, and LatticeSC/M Data Sheets on the Lattice Web site.

To specify the search path, simply enter the path in the text box. A path that contains spaces should be enclosed in double quotes. If the required auto-configuration files are stored in multiple directories, use the following format.

- In Windows:

path1;*path2*;*path3*

- In Linux:

  path1:*path2*:*path3*

This option is equivalent to the command line: bitgen -path *path1* -path *path2* ...

SPI Start Address Specifies SPI start address.

The SPI start address is a 6 or 8 digit hex string prefixed with 0x. The default is 0x00000000.

When the device is initially configured using an external SPI Flash memory device, the start address is assumed to be 0x00000000. You can use this option to define an alternate start address that can be stored in a 32-bit register. If the device is re-configured without initialization, the start address specified by the prior bit stream will be used. This allows for multiple configuration images to be stored in the same SPI Flash memory or memories if multiple devices are used.

The user-defined address is latched upon the DONE signal going high so that it does not change during the re-configuration of the device. The memory cells storing the data can be re-written, providing a new start address, but the address used for the current configuration sequence would not change. This eliminates the need to preserve the memory contents by using the RAMCFG option.

Some Flash devices use 24-bit addressing. The software can interpret the 24-bit address and base address. For example, if you specify 24-bit address and base address 1, you should set this option to 0x000001.

Startup Clock Controls whether to use CCLK or a User clock during startup.

The default is CCLK. If a User clock is needed to synchronize startup to a system clock, it must be routed to the FPGA Macro Library element STRTUP.

Sysbus Clock Config Specifies either Reset or NoReset as the system bus clock at reconfiguration.

Sysbus Config Specifies either Reset or NoReset as the system bus at reconfiguration.

UFM Initval Order Sets the order of the TAG memory content of LatticeXP2 devices. Normal is for TAG memories created with Diamond 3.0 or later. Legacy is for TAG memories created with Diamond 2.2 or earlier.

Wait State Timeout Controls an internal system bus timeout counter. The counter counts the number of HCLK (sysbus clk) cycles that go by while the system bus is in wait states.

Valid values are integers from 0 to 15. The default is 5.

- 0 – Forever (never time out)
- 1 – 2^2 HCLK cycles
- 2 – 2^4 HCLK cycles
- 3 – 2^6 HCLK cycles
- 4 – 2^8 HCLK cycles
- 5 – 2^10 HCLK cycles
- 6 – 2^12 HCLK cycles
- 7 – 2^14 HCLK cycles
- 8 – 2^16 HCLK cycles
- 9 – 2^18 HCLK cycles
- 10 – 2^20 HCLK cycles
- 11 – 2^22 HCLK cycles
- 12 – 2^24 HCLK cycles
- 13 – 2^26 HCLK cycles
- 14 – 2^28 HCLK cycles
- 15 – 2^31 HCLK cycles

XRES Calibration Control Controls the calibration circuit connected to XRES pin.

The external resistor combined with an internal calibration control circuit is used to calibrate output drive strength and impedance. The calibration compensates for the effects of variations in process, voltage, and temperature (PVT). It is connected through a 1K+/-1% resistor to ground.

This option is available only for LatticeSC/M designs. Available values are:

- INIT (default) – Allows the calibration circuit to monitor PVT on power-up and during configuration. The circuit latches in the control value and does not allow changes after that. If voltage and temperature does not vary much during operation versus configuration time, INIT is the best choice.
- ON – Allows the calibration circuit to run all the time. If IOPVTCTRL is instantiated in the design, the XRES is controlled by the UPDATE signal. INIT and OFF options are disabled.
- OFF – Turns off the calibration circuit. The result is minimum drive on output buffer, maximum impedance, and maximum termination resistor. OFF is not recommended in most FPGA implementations.

Chapter 16

Hardware How-To

Each of the “How-To” topics that follow describe the high-level process you should follow to accomplish some aspect of creating your FPGA designs. These topics also provide a starting point for you to access all of the available material in the Help system and on the web for the subject matter.

Topics include:

How to Design with FPGA Memories

The Lattice FPGA memory technology helps you easily create and implement a variety of memory organizations including single-port, dual-port, pseudo dual-port RAMs, ROMs, or FIFOs. You can control what FPGA resources will be employed to implement the memory as either sysMEM embedded block RAM (EBR) or distributed RAM across programmable function units (PFUs). The Diamond software helps automate the implementation of memories from design entry through to creation of a programming file.

This How-to topic applies to all Lattice FPGA device families. For FPGA memory feature support by device family, see the references listed at the end of this topic.

Design Flow The following steps describe the typical flow for performing design entry, simulation, synthesis, and place and route of designs that incorporate embedded sysMEM or distributed RAM memories:

1. Open Diamond and choose **File > New > Project** to create a project that targets a supported device family.
2. Click **Tools > IPexpress** to generate a specific configuration of a memory module using the IPexpress module generator. Distributed RAM modules are located in the **Memory_Modules > Distributed_RAM** module folder and embedded sysMEM modules are located in the **Memory_Modules > EBR_Components** folder.
3. In the File List view, double click on your input HDL source file and instantiate one or more memory modules into your HDL design using Diamond's internal Source Editor tool.
4. In the File List view, right click on the Input Files folder. In the popup menu, choose **Add > Existing Source** and in the Add Design File dialog navigate to your <*module_name*>.ipx file to import it into your Diamond project. Alternately, you may import the defining module HDL file as your project source; however, future modifications to the module requires additional steps.

You may bypass IPexpress and directly instantiate memory library primitives into your HDL source as described below.

To instantiate memory library primitives into your HDL source:

1. In the Process view, double click the **Translate Design** process to create a Pre-Map version of the design. A green check mark will indicate if your NGD file was created successfully and the Output view will report results of the run.

   Note

   If you see a yellow triangular icon with an exclamation point, double click on the adjacent warning symbol to view the message in the Output view. Check the Error and Warning tabs in the Output view for potential issues. Generally, use this approach to investigate all warning and error messages in your design flow.

2. In the Process view, double click the **Map Design** process to create a post-map version of the design. Click on the Reports tab in the main view and in the Process Reports folder in the Design Summary list double click Map to open the MRP file. Use the MRP report file to confirm correct parameter usage and the specific device resources utilized.
3. In the Process view, double click the **Place & Route Design** process to create a post-PAR version of the design. Again, in the Process Reports folder in the Design Summary list, double click on Place & Route to open the PAR report file and review the final implementation.
4. You may simulate a project containing a memory module at all phases of the design flow, Functional, Post-Route Functional, or Post-Route Timing Simulation, using your third-party simulator of choice. Diamond allows you to export files for simulation. See applicable documentation in Diamond help for more information.
5. You may bypass IPexpress and directly instantiate memory macros into your HDL source. For more information see the "FPGA Libraries Reference Guide" on page 1664.

Modifying an Existing Memory Block If a configuration or port interface needs to be modified on an existing memory module of your project, use the following guidelines to make changes:

To modify an existing module:

If the <*module_name*>.ipx file is used as the project source in Diamond, double-click the file to open it in IPexpress.

If the HDL file of the module is used as the project source, use the following procedure:

1. In Diamond, choose **Tools > IPexpress** and select the module in the Module list on the left to populate the the macro type, module name, and other relevant text boxes in the module's Configuration tab view in the main area of the view.
2. After you type in the File name and select Module Output click the **Customize** button. A module dialog appears with a schematic block diagram of the module at left and various settings.
3. In the module's Customize dialog, check **Import IPX to Diamond Project** at the bottom left to include the <*module_name*>.ipx file. IPexpress loads the previous configuration.
4. Adjust the module configuration, then click **Generate**. IPexpress overwrites the prior version.

Optimizing Designs that Utilize FPGA Memory Placement of memories to specific physical locations may contribute to improved design performance and density. Design floorplanning of PFU-based memories is typically accomplished using region, bounding box, and HGROUP/UGROUP constraints whereas EBR-based memories are typically placed using simple LOCATE preferences. Using a combination of the Floorplanner and Logical and Physical Preferences with a design iteration strategy can produce a superior implementation.

For more information on design guidelines for optimal results, see the FPGA Design Guide.

How to Use Dedicated DDR Memory Support

This How-to topic applies to all Lattice FPGA device families. More detailed information is available in technical notes on the Lattice web site and in the online Help. These references are listed at the end of this topic.

LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeSC/M, and LatticeXP/2 devices all support various Double Data Rate (DDR) interfaces using the logic built into the Programmable I/O (PIO). The DDR interfaces capture data on both the rising and falling edges of the clock, thus doubling the performance.

The following steps briefly describe the typical flow for using the DDR I/O to interface to a DDR memory device.

1. Open Diamond and choose **File > New > Project** to create a project that targets a supported device family.
2. In the File List view, double click on your input HDL source file and instantiate the input and output DDR software primitives into your HDL design using Diamond's internal Source Editor tool.

   These primitives provide the 90-degree phase delay of the data strobe (DQS) with respect to the DDR data across process voltage temperature (PVT). They also implement the DDR I/O registers and adjust the system clock polarity to assure correct clock domain transfer in the I/O registers.
3. If you make pin assignments, make sure that the DQ-DQS group assignments are correct. You can use the Spreadsheet view or the HDL file to assign pins.

   Note

   When implementing an input DDR in the ECP/EC20 device family, a potential data corruption might occur in the last read cycle. Please refer to the DQS Postamble section of TN1050, LatticeECP/EC DDR Usage Guide, for a solution to this problem.
4. In the Process view, run the **Map Design** process. This process runs DRC checks to make sure that all the primitives are correctly instantiated.
5. In the Process view, run the **Place & Route Design** process. This process places all the DDR components and checks to see that all the connections made in the HDL are correct.

At any time during the flow you can run pre-route functions or post-route functions to verify the functionality of the DDR interface. You can also run

Timing Simulation after the Place and Route process to verify the interface timing and functionality.

How to Design with PCS/SERDES

The Diamond software allows you to design PCS/SERDES solutions for either LatticeSC, LatticeECP2M, and LatticeECP3 device families.

LatticeSC PCS/SERDES The LatticeSC family of FPGA devices combines a high-performance FPGA fabric, up to 32 channels of high-speed SERDES, high performance I/Os and large embedded RAM in a single industry leading architecture. The LatticeSC family of FPGA devices offers features to meet the needs of today's communication network systems. These features include an embedded PCS (Physical Coding Sublayer) supporting advanced system level standards including RapidIO, Sonet, Gigabit Ethernet, 10 Gb Ethernet, Fibre Channel, and PCI Express.

LatticeECP2M PCS/SERDES The LatticeECP2M family of FPGAs combines a high-performance FPGA fabric, high-performance I/Os and large embedded RAM in a single industry leading architecture. All LatticeECP2M devices also feature up to 16 channels of embedded SERDES with associated PCS logic. The PCS logic can be configured to support numerous industry standard high-speed data transfer protocols. Each channel of PCS logic contains dedicated transmit and receive SERDES for high-speed transfers at data rates up to 3.2 Gbps. The PCS logic in each channel can be configured data protocols including Ethernet (1GbE and SGMII), PCI Express, CPRI, and OBSAI.

LatticeECP3 PCS/SERDES The LatticeECP3 family of FPGA devices is optimized to deliver high performance features such as an enhanced DSP architecture, high speed SERDES and high speed source synchronous

interfaces in an economical FPGA fabric. This combination is achieved through advances in device architecture and the use of 65nm technology making the devices suitable for high-volume, high-speed, low-cost applications.

The architecture features high speed SERDES with dedicated PCS functions. High jitter tolerance and low transmit jitter allow the SERDES plus PCS blocks to be configured to support an array of popular data protocols including PCI Express, SMPTE, Ethernet (XAUI, GbE, and SGMII) and CPRI. Transmit Pre-emphasis and Receive Equalization settings make the SERDES suitable for transmission and reception over various forms of media.

Design Flow The Diamond design flow was designed to fuse the embedded portion of the device with the FPGA fabric in a seamless fashion.

The following lists the steps for designing with PCS/SERDES:

- Generate a netlist of the PCS with IPexpress.
- Merge the generated netlist with a supplied example reference design.
- Simulate the merged netlist.
- Synthesize the merged netlist.
- Map, place, and route the merged netlist.
- Perform full timing analysis including back annotated simulation.

Note

The basic design flow steps above will be covered in a tutorial being developed for this feature.

How to Design with sysCLOCK PLLs and DLLs

The Lattice sysCLOCK PLL (phase-locked loop) and DLL (delay-locked loop) technology helps you manage clock distribution and skew to improve overall system performance. PLLs are good for applications requiring the lowest output jitter or jitter filtering. DLLs are well suited to applications where the clock may be stopped or transferring jitter from input to output is important. The Diamond software helps automate the implementation of sysCLOCK PLL and DLL modules from design entry through creation of a programming file.

This How-to topic applies to all Lattice FPGA device families. For more sysCLOCK PLL information for these devices, see the references listed at the end of this topic.

Design Flow The following steps describe the typical flow for performing design entry, simulation, synthesis, and place and route of designs that incorporate sysCLOCK PLLs:

1. Open Diamond and choose **File > New > Project** to create a project that targets a supported device family.
2. Click **Tools > IPexpress** to generate a specific configuration of a sysCLOCK PLL or DLL module using the IPexpress module generator.
3. In the File List view, double click on your input HDL source file and instantiate one or more sysCLOCK PLL or DLL modules into your HDL design using Diamond's internal Source Editor tool.
4. Import the <*module_name*>.ipx file to your project's source list using Diamond. Alternatively, you may import the defining module HDL file as your project source; however, future modifications to the module require additional steps.
5. In the Process view, double click the **Translate Design** process to create a pre-map version of the design. A green check mark will indicate if your NGD file was created successfully and the Output view will report results of the run.

   Note

   If you see a yellow triangular icon with an exclamation point, double click on the adjacent warning symbol to view the message in the Output view. Check the Error and Warning tabs in the Output view for potential issues. Generally, use this approach to investigate all warning and error messages in your design flow.

6. In the Process view, double click the **Map Design** process to create a post-map version of the design. Click on the Reports tab in the main view and in the Process Reports folder in the Design Summary list double click Map to open the MRP file. Use the Map Report to confirm correct parameter usage and the specific device resources utilized.
7. In the Process view, double click the **Place & Route Design** process to create a Post-PAR version of the design. Double click Place & Route Report in the Design Summary view to open the PAR report file and review the final implementation.
8. Both phase-locked and delay-locked loops have analog behavior that can not be accurately modeled with most digital simulators, not all functionality

of sysCLOCK PLL hardware is supported in Functional, Post-Route Functional, or Post-Route Timing Simulation phases.

9. You may bypass IPexpress and directly instantiate PLL library primitives into your HDL source.

Important

Note that it may become necessary to regenerate a given PLL or DLL module with updated options because you edited a preference later in the flow (pre- or post-Map) that was a result of an attribute spawned from module generation and was present in the module output file. This will cause the design to become out of synch with the your project's source input module.

For example, it is possible to enhance a FREQUENCY preference in Spreadsheet view or manually in the LPF file in the Diamond flow that was initially auto-generated in the LPF because of clock divider options you selected for module generation in IPexpress. If you updated the FREQUENCY to a higher clock speed that is not in an allowable range for the clock divider options, you will encounter error messages during TRACE timing analysis.

Modifying an Existing sysCLOCK PLL or DLL If a configuration or port interface needs to be modified on an existing sysCLOCK PLL or DLL module of your project, use the following guidelines to make changes using IPexpress:

To modify an existing module:

- If the <*module_name*>.ipx file is used as the project source in Diamond, double-click the file to open it in IPexpress.

If the HDL file of the module is used as the project source, use the following procedure:

1. In Diamond, choose **Tools > IPexpress** and select the module in the Module list on the left to populate the the macro type, module name, and other relevant text boxes in the module's Configuration tab view in the main area of the view.
2. After you type in the File name and select Module Output click the **Customize** button. A module dialog appears with a schematic block diagram of the module at left and various settings.
3. In the module's Customize dialog, check **Import IPX to Diamond Project** at the bottom left to include the <*module_name*>.ipx file. IPexpress loads the previous configuration.
4. Adjust the module configuration, then click **Generate**. IPexpress overwrites the prior version.

Note on Using Tristate Internal Feedback Loops (LatticeECP/EC, LatticeECP2/M, LatticeXP, LatticeSC/M) In cases where you are using a tristate I/O buffer as an internal feedback loop, then the default capacitance

on that buffer should be set to zero. Use the OUTPUT LOAD preference to set this value. See the “Using Tristates as Internal Feedback Loops” section the OUTPUT LOAD preference topic for details.

Note on PLL Output Lock in LatticeSC/M The PLL Output Lock in LatticeSC/M designs requires added logic to prevent false out-of-lock signal.

Depending on certain input conditions of the clock frequency, the relative input clock edge and PLL update edge relationships may cause the digital detect logic of the PLL LOCK signal to transition low for several clock cycles. While the digitally produced lock signal may transition low for several clock cycles, the analog core of the PLL maintains operation within all of its specifications.

This LOCK signal transition may indicate a false out-of-lock occurrence if not properly filtered by the user design. The false out-of-lock signal is due to a synchronization state within the digital lock detect circuit itself and is not indicative of a true, analog out-of-lock condition of the PLL.

To compensate for this potential false indication, it is recommended that you implement a PLL LOCK mask circuit to filter out false PLL out-of-lock (low pulses). Follow the instructions and recommendations provided in the section on Lock Output in technical note, TN1098, “LatticeSC sysCLOCK PLL/DLL User’s Guide” to ensure that you can work around this issue.

How To Design with sysIO Buffers

The Lattice sysIO buffer technology helps you easily interface to a variety of advanced system I/O standards. The Diamond software helps automate the implementation of sysIO buffering from design entry through to creation of a programming file.

This How-to topic applies to all Lattice FPGA device families. For specific sysIO information on LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeSC/M, and LatticeXP/2 device families, see the references listed at the end of this topic.

Design Flow The following steps describe the typical flow for performing design entry, synthesis, and place and route of designs that incorporate sysIO buffers:

1. Open Diamond and create a project that targets a supported device family.
2. Specify sysIO attributes using HDL, the Spreadsheet view, or an ASCII preference file (.prf).
3. If you wish to use HDL-based sysIO attributes, add them to your source code. Then use the Translate Database process to create a Pre-Map version of the design; review the Output view and the Warning and Error tabs that are adjacent to it to confirm that syntax and usage are correct. HDL-based attributes have the advantage of being persistent from revision to revision of your source code; however, Lattice recommends that you avoid adding or modifying preferences with the Spreadsheet view process to avoid contention between preferences specified in both places.
4. If you wish to use the Spreadsheet view to specify sysIO attributes, click **Tools > Spreadsheet** view and use the Pin Attributes tab of the interface to specify each. You can confirm legal combinations sysIO configurations within device PIO by running a PIO DRC design rule check.
5. If you wish, edit the preference file (.prf) using a text editor or Diamond's internal Source Editor to directly to specify sysIO attributes. Double click on the file in the File List view.
6. In the Process view, double click the Map Design process to create a Post-Map version of the design. Double click Map Report in the Design Summary view to open the MRP file to confirm correct sysIO attribute usage and the specific device resources utilized.
7. In the Process view, double click the Place & Route Design process to create a Post-PAR version of the design. Double click Place & Route Report in the Design Summary view to open the PAR report file and review the final implementation.

Modifying a sysIO Buffer on an Existing PIO If a sysIO buffer needs to be modified on an existing PIO of your project, use the following guidelines to make changes:

To modify a sysIO buffer:

- If you defined sysIO preferences within your HDL source, use the internal Source Editor to modify the code and restart the Translate Database process.
- If you defined sysIO preferences using the Spreadsheet view, use it again to modify existing preferences. This bypasses the need to rerun the Translate Database phase of the design flow. Save the new preference file and rerun the Map Design process only.
- If you defined sysIO preferences in an LPF file directly using some text editor, double click the file in the File List view to further modify it using Diamond's internal Source Editor. Save the new preference file and rerun the Map Design process only.

How to Design with sysDSP

The Lattice sysDSP (digital signal processing) technology provides dedicated DSP hardware blocks that perform a variety of high-speed, fixed-point, multiply, sum, and accumulate functions. This technology is supported by the the LatticeECP, LatticeECP2/M, and LatticeXP2 Lattice FPGA device families.

The Diamond software helps automate the implementation of sysDSP block modules from design entry through creation of a programming file. Diamond software also includes Lattice-specific blockset functions for use with the MathWorks Simulink® products for algorithm development.

For more information on sysDSP and the Simulink design flow, see the references at the end of this topic.

Design Flow The following steps describe the typical flow for performing design entry, simulation, synthesis, and place and route of designs that incorporate sysDSP blocks:

1. (Optional) Capture system requirements, physical constraints, and model your sysDSP design using the Simulink design flow. RTL Verilog HDL or VHDL that is compatible with Diamond logic synthesis (Precision or Synplify) is produced by this tool set.
2. Open Diamond and create a project that targets a supported device family.
3. Enter the DSP functionality of your design with any of the following methods:
   - Import Verilog HDL or VHDL source files produced by the MATLAB/ Simulink design flow into your File List using Diamond. Right click on the Input Files folder and choose **Add > Existing Source** and navigate to the file using the Add Design File dialog.
   - Click **Tools > IPexpress** to generate a specific configuration of a sysDSP module using the IPexpress module generator. In the File List view, double click on your input HDL source file and instantiate one or more sysDSP modules into your HDL design using Diamond's internal Source Editor tool. Import the <*module_name*>.ipx file into your project's source list using Diamond. Alternately, you may import the defining module HDL file as your project source; however, modifications to the module requires additional steps.
   - Write HDL that will infer a sysDSP module.
4. In the Process view, double click the Translate Design process to create a Pre-Map version of the design. The Output view will show you if your NGD file was created successfully. Click the adjacent Error and Warning tabs to check for potential issues.
5. In the Process view, double click the Map Design process to create a Post-Map version of the design. Double click Map Report in the Design Summary view to review the DSP block summary section of the MRP file to confirm specific device resources utilized. The Map Design process will check for parameter usage and range violations and report errors in the Error tab adjacent to the Output view.
6. In the Process view, double click the Place & Route Design process to create a Post-PAR version of the design. Double click Place & Route Report in the Design Summary view the DSP block summary section of the PAR file to review the final implementation.
7. You may simulate a project that contains a sysDSP module at all phases of the design flow: Functional, Post-Route Functional, or Post-Route Timing Simulation.
8. You may bypass IPexpress and directly instantiate a sysDSP block library primitives into your HDL source.

See applicable technical notes listed in the References section of this topic for more information about connecting sysDSP software primitives, synthesis style guidelines, module types, modes, and configuration options.

Modifying an Existing ispDSP Module To modify an existing sysDSP module in your project (e.g. change module configuration or port interface), use the following guidelines to make changes:

To modify an existing module:

If the <*module_name*>.ipx file is used as the project source of Diamond, then double-click the file to open it into IPexpress.

If the HDL file of the module is used as the project source, use the following procedure:

1. In Diamond, choose **Tools > IPexpress** and select the module in the Module list on the left to populate the the macro type, module name, and other relevant text boxes in the module's Configuration tab view in the main area of the view.
2. After you type in the File name and select Module Output click the **Customize** button. A module dialog appears with a schematic block diagram of the module at left and various settings.
3. In the module's Customize dialog, check **Import IPX to Diamond Project** at the bottom left to include the <*module_name*>.ipx file. IPexpress loads the previous configuration.
4. Adjust the module configuration, then click **Generate**. IPexpress overwrites the prior version.

Note: If the port interface changes, the code using the module must be modified. If the port interface does not change, no additional modifications must be made, or steps taken once the module has been regenerated.

How to Use the Global Set/Reset (GSR) Signal

This topic provides guidelines and specific instructions for using the Global Set/Reset Interface (GSR) signal of a Lattice FPGA device simulation model for use with all Lattice FPGAs.

Details regarding the architecture of global signals are described in the data sheet for each device family on the Lattice Web site. For more information on the GSR library element, see "GSR" on page 2014.

The items presented in this topic are as follows:

- GSR Hardware Resource
- GSR Usage Cases
  - Inferred GSR
  - User Specified Inferred GSR
  - Global GSR
  - LSR (No GSR)
- Using the GSR Resource with Lattice IPs
- RTL Functional Simulation and the GSR Resource
- Mixed Language Simulation and the GSR Resource
- Using Attributes to Control GSR Resource Usage

GSR Hardware Resource Lattice FPGAs contain both GSR (Global Set Reset) and PUR (Power Up Reset) resources. The GSR hardware resource in Lattice FPGAs provides a convenient mechanism to allow design components to be reset without using any routing resources.

Note

The PUR resource is used to reset the device after configuration is complete when the device is powered on. A PUR component is provided to allow simulation testbenches to simulate this pulse, but this component is never used as part of the design. For more information on PUR, see the How to Use the Power Up Set/Reset (PUR) Global Signal topic.

There are two primary ways to take advantage of the GSR hardware resource in your design: *use the GSR to reset all components on your FPGA* or to *use the GSR to eliminate any routing resources needed for one reset in a multiple reset design*. If there is only one reset signal for the entire design, you would want to use the GSR in the first way, to reset all components on the FPGA. When using the GSR to eliminate any routing resources needed for one reset in a multiple reset design, typically the GSR would be used for the reset with the highest fan-out.

Note

The GSR should only be used for asynchronous active low resets since the hardware will always assert GSR asynchronously. The software will take this into account automatically and will not connect a synchronous reset to GSR when the Inferred GSR or User Specified Inferred GSR modes are used, However there are ways to override the software default behavior. You are responsible for ensuring correct functionality when overriding the normal software defaults or when using the Global GSR usage mode. The following sections of this document detail how to take advantage of this resource with the Lattice Diamond design software.

GSR Usage Cases In Diamond, there are four usage cases with respect to initialization set/resets:

- *Inferred GSR* – In this case the software automatically determines which reset signal has the highest fan-out (for either single or multiple reset designs) and uses the GSR resource as the routing for that reset signal. This usage case is the default condition in Diamond if there is no user-instantiated GSR component in the design.

  This usage case is the best choice for most applications. The software determines the reset with the most loads and uses the GSR resource for that signal which provides the largest reduction in needed routing resources. The Inferred GSR usage case can also be used whether the design has a single or multiple resets.
- *User-Specified Inferred GSR* – This is the same as the Inferred GSR usage except that the reset signal that is specified in the preference (.lpf) file determines which signal uses the GSR resource regardless of the fan-out of the signal.
- *Global GSR* – This case treats the GSR resource as a reset for all elements in the design.
- *LSR (No GSR)* – LSR (local set/reset) specifies that no GSR is to be used, that is, that all resets will use local routing resources instead of using the GSR resource.

Note

In the Inferred GSR and User-Specified Inferred GSR usage cases, the software will only connect elements with an asynchronous reset to GSR. Elements requiring a synchronous reset will use only local routing.

Inferred GSR The Inferred GSR usage case is the simplest to use. If everything is left to default software settings and no GSR component is instantiated in the design, then the software will implement a design using GSR for the reset signal with the highest fan-out.

Inferred GSR is the recommended usage case unless any of the following conditions exist:

- If you need to use a specific reset signal for GSR.
- If you need to globally use GSR even when there are multiple resets.
- If you need to completely disable GSR.

To use the Inferred GSR usage case, there are no design changes necessary. You simply implement the design using Diamond with default settings. The necessary software settings are:

- Synplify Synthesis Properties: **Force GSR: False (default)**
- LSE Synthesis Properties: **Force GSR: Auto (default)**
- Precision Synthesis Properties: **Force GSR: False (default)**
- Map Properties: **Infer GSR: True (default)**

- Preferences: **Do not specify GSR_NET in the .lpf file**

Note

When LSE is enabled, Diamond software infers GSR at the synthesis stage of the process flow. When other synthesis tools are selected, Map infers GSR.

LSE also has the ability to look into black box modules (.ngo files) for any GSR settings. If LSE finds a GSR instance or attribute in a module, LSE will not infer GSR and will instead pass the GSR information to Map to handle.

User Specified Inferred GSR The User Specified Inferred GSR usage case is identical to the Inferred GSR usage case except that the reset signal on which GSR is inferred is specified in the preference (.lpf) file instead of being automatically determined by fan-out.

If default software settings are enabled and no GSR component is instantiated in the design, and a preference exists for GSR_NET, then the software will implement a design using GSR for the reset signal specified by GSR_NET. This usage case is best for a design with multiple resets where a specific reset is required to use GSR regardless of the fan-out of the net.

To use the User-Specified Inferred GSR usage case, there are no design changes necessary. You simply implement the design using Diamond with default settings and a GSR_NET preference specified. The necessary software settings are:

- Synplify Synthesis Properties: **Force GSR: False (default)**
- LSE Synthesis Properties: **Force GSR: False**
- Precision Synthesis Properties: **Force GSR: False (default)**
- Map Design option (Strategies dialog): **Infer GSR: True (default)**
- Preferences: **Specify GSR_NET in the .lpf file.** The syntax of the preference is GSR_NET net “reset_signal_name”.

Global GSR The Global GSR usage case is intended for all elements in a design to be reset using the GSR resource. This usage is a good fit for a design with a single reset. It can also be used with multiple resets in the design, but it can produce unexpected functionality in this case. For example, if the GSR resource is used for the reset with the largest fan-out, elements on a second reset signal will still be reset by the first reset signal. Additionally, any registers with a synchronous reset will be attached to their local reset as well as the GSR reset (which asserts asynchronously).

Note also that the GSR resource is active low. In the case of a register using an active high reset, that register will remain connected to the signal but will have GSR enabled. This will cause the register to remain in reset. If a mix of active low and active high resets are used in a design or a mix of synchronous and asynchronous resets are used, then the Inferred GSR usage case should be used. In the Inferred GSR usage case, the software will automatically take into account whether a reset is synchronous, asynchronous, active high, or active low. In the Global GSR usage case, the software assumes the user knows what the design intent is and makes minimal design changes in order

to allow the user intent to be implemented. Global GSR is meant for a true global reset application.

To use the Global GSR usage case, a GSR component must be instantiated in the design and connected to the signal that is targeted as the reset signal, usually a primary input. If a GSR component is not instantiated in the design, the software will not treat the design as a Global GSR usage case. The GSR component must be instantiated into the design itself, not into the testbench for the design. Below are examples of how to instantiate the GSR library element in both Verilog and VHDL.

GSR VHDL Example:

```
GSR_INST:   GSR port map (GSR=><global reset sig>);
```

GSR Verilog HDL Example:

```
GSR     GSR_INST (.GSR (<global reset sig>));
```

Note that in Verilog the GSR instantiation must be in the top-level module of the design and it must be named GSR_INST. The necessary software settings are:

- Synplify Synthesis Properties: **Force GSR: False (default)**
- LSE Synthesis Properties: **Force GSR: Auto (default)**
- Precision Synthesis Properties: **Force GSR: False (default)**
- Map Design option (Strategies dialog): **Infer GSR: True (default)**. If a GSR component is already instantiated, this property will be ignored.
- Preferences: **Do not specify GSR_NET in the .lpf file**. If a GSR_NET preference is specified and a GSR component is already instantiated, the preference will be ignored.

LSR (No GSR) The LSR (local set/reset) usage case always uses local routing for the reset signals and does not use the GSR resource. This is the recommended usage case if there is a requirement to do timing analysis on the reset signals or if synchronous reset is being used throughout the design.

To use the LSR usage case there must be no GSR instantiated in the design, no GSR_NET preference specified, and the software settings used do not infer any GSR resource. The necessary software settings are

- Synplify Synthesis Properties: **Force GSR: False (default)**
- LSE Synthesis Properties: **Force GSR: False**
- Precision Synthesis Properties: **Force GSR: False (default)**
- Map Design option (Strategies dialog): **Infer GSR: False**
- Preferences: **Do not specify GSR_NET in the .lpf file**.

Using the GSR Resource with Lattice IPs Lattice IPs use the GSR resource when running in evaluation mode and may require it on an individual basis for performance reasons. For all current IP, no individual GSR option is

available. These IPs will function correctly in all usage cases for GSR. For any IP that requires the use of GSR on it's reset for performance issues, the User-Specified Inferred GSR usage case or Global GSR usage case should be used. For the User-Specified Inferred GSR usage case, the reset signal the IP is connected to should be entered in the preferences as the GSR_NET preference.

RTL Functional Simulation and the GSR Resource If the GSR resource is used as a routing replacement for one of the reset signals in a design using the Inferred GSR or User-Specified GSR usage cases, then the functional simulation will be correct for both the RTL (pre-synthesis) design and the netlist (post-synthesis and post-map) versions of the design.

If the GSR resource is used as a global reset, however, the RTL functional simulation will not correctly simulate the reset functionality if the design uses multiple resets. Global GSR causes all Lattice components in the design to respond to the reset used for the GSR whether they are connected to that reset or not. In the RTL representation the use of the GSR resource is not modeled in synthesizable RTL code, but in the post-map netlist, the entire design will respond correctly to the reset used for GSR. This is because the design will now consist of Lattice components that have been modeled to take the GSR information into account as part of their functionality. The post-map design will reset all elements sensitive to GSR when the reset signal assigned to GSR is used. Even if an element is connected to a different reset, it will still reset when the GSR signal is used if it is sensitive to GSR.

If the design contains both RTL code and Lattice component instantiations, the design may need some additions to prevent simulation problems. Verilog simulations will produce errors if there are library elements in the design that use the GSR information and instantiations of both GSR and PUR components are not present in the top-level of the design. For Verilog designs, you must instantiate the GSR component in the top level of the design hierarchy with the instance name of GSR_INST if the design contains any instantiation of library elements that are affected by the GSR settings (sequential and memory components in general). Additionally, you must also instantiate the PUR component in the top level of the design hierarchy with the instance name of PUR_INST for these same components. Below are examples of the Verilog instantiations of GSR and PUR.

GSR Verilog HDL Example:

```
GSR     GSR_INST (.GSR (<global reset sig>));
```

PUR Verilog HDL Example:

```
PUR     PUR_INST (.PUR (<powerup reset sig>));
```

If these instantiations are not present, you will see errors in your simulator. Following is an example error produced in Aldec Active-HDL if the GSR instantiation is not present.

```
ELBREAD: Error: Hierarchical reference not found:
GSR_INST.GSRNET (from "tb.__.EFBInst_0")
KERNEL: Error: E8005 : Kernel process initialization failed.
```

```
VSIM: Fatal error: Fatal error occurred during simulation
initialization.
```

If the PUR instantiation is not present a similar error will be shown for PUR_INST.PURNET.

If any usage case other than the Global GSR usage case is desired, the GSR and PUR components must be removed from the top-level hierarchy before synthesizing the design (Translate Database process step) if the top level is part of the design. The one exception to this requirement is if the GSR and PUR components are connected to VCC instead of a design signal. The GSR and PUR components do not require removal if they are connected to VCC. If the top level of the design hierarchy is the test bench, then the GSR and PUR components do not need to be removed for any of the usage cases.

Mixed Language Simulation and the GSR Resource The ability to simulate the GSR resource is handled differently in Verilog and VHDL due to differences in the languages. This difference can make simulating the GSR functionality in a mixed language difficult.

Verilog simulation models access the GSR state by referring to a signal inside the GSR component that must be instantiated at the top level of the design. This can be seen in the following piece of Verilog code inside a simulation library module:

```
parameter GSR = "ENABLED";

tri1 GSR_sig = GSR_INST.GSRNET;
tri1 PUR_sig = PUR_INST.PURNET;

always @ (GSR_sig or PUR_sig ) begin
if (GSR == "ENABLED") begin
SRN = GSR_sig & PUR_sig ;
end
else if (GSR == "DISABLED")
SRN = PUR_sig;
end
```

VHDL simulation models access the GSR state by referring to a signal in a package that is used by the model. Below are sections of the package and its use in a simulation model.

```
-------------Package Declaration----------------------
PACKAGE global IS
SIGNAL gsrnet: std_logic := 'H';
SIGNAL purnet: std_logic := 'H';
SIGNAL tsallnet: std_logic := 'H';
END global;

------------Entity Usage Statement------------------
USE work.global.gsrnet;
USE work.global.purnet;

-------------Entity Declaration-------------------------
GENERIC (
```

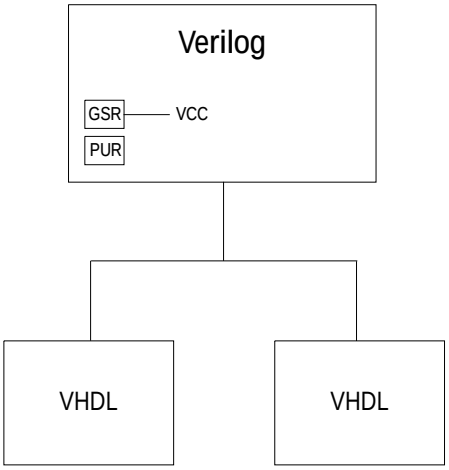
```
gsr             : String  := "ENABLED");

-------------Architecture Body-----------------------
IF (gsr = "DISABLED") THEN
set_reset := purnet;
ELSE
set_reset := purnet AND gsrnet;
END IF;
```

If the desired simulation is post-synthesis, or post-map, the easiest solution is to generate a netlist in the same language as the top-level testbench. Then the simulation can be done in a single language with respect to GSR and the correct functionality can be simulated. This occurs automatically if the simulation is run from Diamond by selecting the testbench and then selecting **Post-Route Functional Simulation** or **Post-Route Timing Simulation**.

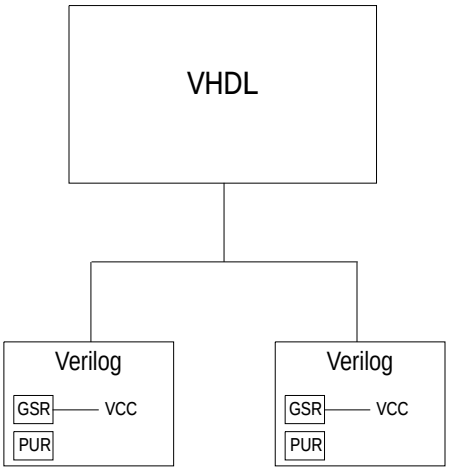
If the simulation is an RTL functional simulation, the same issues described above in the RTL functional simulation section exist along with the complication of the differences in how the languages deal with GSR. There are two different issues (initialization and functionality) and different usage cases to be considered in mixed language simulation. The different relevant combinations are discussed below.

- *Simulation Initialization, Verilog top, VHDL bottom*. When a simulator starts or initializes a design, it elaborates the design and assembles all the required information. In Lattice VHDL simulation libraries, components access GSR information via a VHDL package.



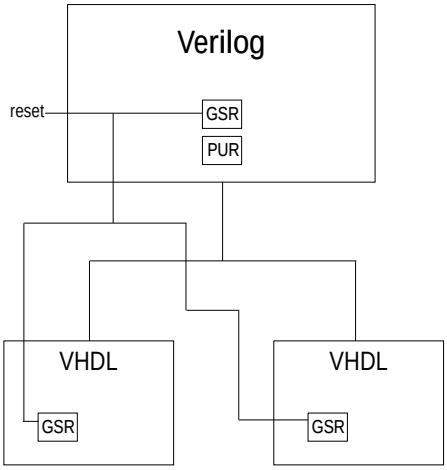
The package is provided with the simulation library so no extra information is required to initialize the simulator. In Lattice Verilog simulation libraries, the GSR information is accessed from an instantiation at the top of the Verilog part of the design. This requires a GSR and PUR component instantiation as shown in the section, RTL Functional Simulation and the GSR Resource. These instantiations are required in the Verilog hierarchy if it contains any Lattice Verilog library components that access GSR information even if GSR is not functionally used in the design. For this design structure, the Verilog GSR and PUR instantiation must be at the top of the hierarchy, either the top-level netlist or the test bench.

- *Simulation Initialization, VHDL top, Verilog bottom*. When a simulator starts or initializes a design, it elaborates the design and assembles all the required information. In Lattice VHDL simulation libraries, components access GSR information via a VHDL package.



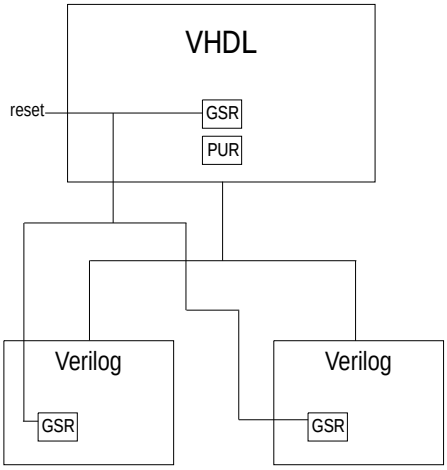
The package is provided with the simulation library so no extra information is required to initialize the simulator. In Lattice Verilog simulation libraries, the GSR information is accessed from an instantiation at the top of the Verilog part of the design. This requires a GSR and PUR component instantiation as shown in the section, RTL Functional Simulation and the GSR Resource. These instantiations are required in the Verilog hierarchy by any Lattice Verilog library component that accesses GSR information even if GSR is not functionally used in the design. For this design structure, the Verilog GSR and PUR instantiations must be at the top of the Verilog hierarchy, not the top of the whole hierarchy since the top is VHDL. If the design has a VHDL top and there are multiple Verilog instantiations or modules within the VHDL design, then each separate Verilog hierarchy must have its own GSR and PUR component instantiation. The GSR and PUR component instantiations in one Verilog hierarchy are not visible to other separate hierarchies.

- *Global GSR functional simulation, Verilog top, VHDL bottom*. Since the GSR information for Lattice simulation libraries is simulated in Verilog and VHDL using different mechanisms, it is required to have a GSR component instantiation in each language section.



A GSR component should be instantiated in the Verilog top hierarchy and connected to the desired reset signal. A GSR component should be instantiated in the VHDL hierarchy and connected to the same reset signal. If there are separate VHDL hierarchies within the Verilog top hierarchy, each VHDL hierarchy must have its own GSR component instantiated and connected to the reset signal. GSR components instantiated in one VHDL hierarchy do not affect other VHDL hierarchies. A PUR component is still required in the Verilog for simulation initialization purposes.

- *Global GSR functional simulation, VHDL top, Verilog bottom*. Since the GSR information for Lattice simulation libraries is simulated in Verilog and VHDL using different mechanisms, it is required to have a GSR component instantiation in each language section.



A GSR component should be instantiated in the VHDL top hierarchy and connected to the desired reset signal. A GSR component should be instantiated in the Verilog hierarchy and connected to the same reset signal. If there are separate Verilog hierarchies within the VHDL top hierarchy, each Verilog hierarchy must have its own GSR component instantiated and connected to the reset signal. GSR components instantiated in one Verilog hierarchy do not affect other Verilog hierarchies.

- *Inferred GSR, User Specified Inferred GSR, and LSR (No GSR) functional simulation*. Unlike the Global GSR usage case, the functionality of the design can be simulated correctly for the other usage cases without requiring special simulation techniques since the functionality will be simulated using the reset signals in the design. However, the issue with initializing the Verilog section of the design is the same as described in the simulation initialization sections above. A GSR and PUR component instantiation must be present in the Verilog hierarchy or in each separate Verilog hierarchy if there are multiple ones under a VHDL top hierarchy. The signal input to the GSR component can be assigned to the desired reset signal or to a logical value of '1' if the GSR functionality is not used.

Using Attributes to Control GSR Resource Usage This section contains details on how to control the behavior of GSR usage on a module or component level. This information is intended for expert usage only. This information is not required for any of the usage flows discussed earlier in this topic to function correctly.

One example of the need to use this information is in the case of using Global GSR. If one section of the design is required to continue functioning during the use of reset (such as a communication port), then it is possible to use attributes to prevent the GSR resource from being implemented in a particular hierarchy or component. Likewise, it is possible to force a hierarchy or component to respond to GSR even if it was on a different reset in the Inferred GSR case. To correctly use these attributes, it is necessary to understand both the hierarchy inheritance order and how each attribute is treated in the different usage cases.

GSR Attribute Values and Syntax You must specify which portions of the design that you wish to alter the way in which they respond to the GSR reset signal. Unless specified otherwise, by default, all design elements will respond to the global reset signal if it is present. The available values are as follows.

- ENABLED – This is the default value on most library elements. This value allows the software to determine the final value and will be overridden by the parent hierarchy if the parent has a value of anything other than ENABLED.
- DISABLED – This prevents the hierarchy or element from responding to the GSR value. It cannot be changed by the parent's value.
- FORCEENABLE – This forces the hierarchy or element to respond to the GSR value. It cannot be changed by the parent's value.
- IPENABLE – This forces the hierarchy or element to respond to the GSR value when IP is being used in evaluation mode. It cannot be changed by the parent's value. This is only meant for internal Lattice IP to use. This value should never be used within a design itself.

These values are then placed as synthesis attributes in the design which synthesis will pass to the Map program. The attributes can be placed on any instance whether it is a level of hierarchy or a leaf component. Map will then interpret the attributes along with the usage case and make the necessary changes to the design. After Map is finished, all elements in the design will have GSR values of either ENABLED or DISABLED only. The syntax of the

attributes is shown below for Verilog and VHDL with “VALUE” shown as the placeholder for legal values.

Synplify or LSE GSR Attributes Verilog GSR attribute syntax:

```
modname modinst (signal list) /* synthesis GSR=VALUE */;
```

VHDL GSR attribute syntax:

```
attribute GSR : string;
attribute GSR of comp_instance: label is "VALUE";
component_instance: component_name port map (signal list);
```

Note

Replace the placeholder VALUE in the above syntax examples with legal values from the value list.

Precision GSR Attributes Verilog GSR attribute syntax:

```
modname modinst (signal list) //exemplar attribute modinst GSR
VALUE;
```

VHDL GSR attribute syntax:

```
attribute GSR : string;
attribute GSR of comp_instance: label is "VALUE";
component_instance: component_name port map (signal list);
```

Note

Replace the placeholder VALUE in the above syntax examples with legal values from the value list.

Determining Actual Pre-Map GSR Attribute Value Following are the precedence rules to use to determine the “actual” GSR value an instance has in the pre-map netlist.

The first column in the table below represents the possible explicit values an instance can have. An explicit value is one which has been put directly on the instance. The first row represents the possible implicit values a library element can have via GSR attribute set at a parent module that includes the

instance. The “parent” term is used loosely here as more precisely, the GSR value could be sitting on one or more levels of hierarchy above the parent.

Table 135: Determining “Actual” GSR Value

Explicit child GSR value in pre-map netlist	Parent module GSR value (explicit)				
	<none>	DISABLED	ENABLED	FORCEENABLE	IPENABLE
<not set> (component default value ENABLED)	ENABLED	DISABLED	ENABLED	FORCEENABLE	IPENABLE
<not set> (component default value DISABLED)	DISABLED	DISABLED	DISABLED	DISABLED	DISABLED
<not set> (hierarchy level not leaf component)	ENABLED	DISABLED	ENABLED	FORCEENABLE	IPENABLE
DISABLED	DISABLED	DISABLED	DISABLED	DISABLED	DISABLED
ENABLED	ENABLED	DISABLED	ENABLED	FORCEENABLE	IPENABLE
FORCEENABLE	FORCEENABLE	FORCEENABLE	FORCEENABLE	FORCEENABLE	FORCEENABLE
IPENABLE	IPENABLE	IPENABLE	IPENABLE	IPENABLE	IPENABLE

Determining Final Post-Map GSR Attribute Value Following are the rules that the map software uses to determine the GSR attribute value of the physical component that a pre-map library element gets mapped into in the post-map netlist.

The first column represents the possible “actual” values that a pre-map library element can have. The top row represents the usage case map is operating under.

The final post-map GSR value a component has will depend on the following conditions.

- The usage case (Global GSR or either Inferred or User Specified Inferred)
- If the component is on the inferred reset domain or not
- If any Lattice IP is being used in evaluation mode

If the “actual” value of a pre-map library element is,

- DISABLED - It will be mapped to a component which has GSR=DISABLED regardless of the usage case.
- ENABLED – This value allows the software to automatically determine the necessary value, so final value depends on the usage case
  - Global GSR - Final value is ENABLED since this should respond to the global reset

- Inferred GSR or User Specified Inferred GSR & element is on the inferred reset - Final value is ENABLED since this will cause the element to respond to the reset being put on to the GSR resource
- Inferred GSR or User Specified Inferred GSR & element is NOT on the inferred - Final value is DISABLED since this component is not on the inferred reset and therefore should not respond to GSR resource

- FORCEENABLE – This will always be ENABLED regardless of the usage case. This is how a component can be reset by GSR resource in the Inferred GSR usage case even if that component is not on the inferred reset.
- IPENABLE – This will always be ENABLED regardless of the usage case except when an IP license is present and the IP is not on the inferred reset. In this case only, GSR will be set to DISABLED.

Note

A consequence of the IPENABLE functionality is that the IP reset will function differently when it is not on the inferred GSR reset between licensed and evaluation mode. This is an unavoidable consequence of how the evaluation mode functions. It is important to note the licensed mode is functionality correct and will not cause any functional issues in the final design. This issue is not present in the Global GSR usage case.

Table 136: Determining Post-Map GSR Value

Actual Pre-Map Value	**Global GSR Usage Case**	**Inferred GSR and User-Specified Inferred GSR Usage Cases**		
		On Inferred Reset	No Inferred Reset	No Inferred Reset plus IP Evaluation Mode
DISABLED	DISABLED	DISABLED	DISABLED	DISABLED
ENABLED	ENABLED	ENABLED	DISABLED	DISABLED
FORCEENABLE	ENABLED	ENABLED	ENABLED	ENABLED
IPENABLE	ENABLED	ENABLED	DISABLED	ENABLED

Issues Using Global GSR and GSR=DISABLED Attribute Due to Synthesis Optimizations In the GSR flow synthesis does not perform any GSR inferencing done in legacy Lattice software releases. Additionally, synthesis does not understand the attributes used for GSR control, but will pass them in the design to the map software which will perform the correct changes.

However, synthesis normally will perform optimizations it is aware of. Synthesis will see a GSR component that has been instantiated in a design for the Global GSR usage case and may automatically optimize out the signal connections for the reset signal to components if an active low reset signal is defined. However, since synthesis is unaware of the meaning of the GSR attributes, any components in a Global GSR usage case that have GSR=DISABLED on them may be left without any ability to be reset (reset

signal disconnected and GSR=DISABLED). Note that this issue will not occur on the Inferred GSR or User Specified Inferred GSR usage cases.

In order to avoid this issue the User Specified Inferred GSR usage case can be used. The desired reset signal should be specified in the preferences as defined for this usage case. Additionally at the top of the design, the attribute GSR=FORCEENABLED should be specified. This will force all components, even in a multiple reset design, to be reset by GSR similar to the Global GSR usage case. Design elements that need to be prevented from resetting can use the GSR=DISABLED attribute to block reset for those components or hierarchies since they will not be affected by the GSR=FORCEENABLED as shown in Table 135.

Issues with Synthesis Hierarchy Flattening or Optimization Synthesis tools can potentially flatten a hierarchy or optimize hierarchies to improve results. When this occurs, attributes assigned to a hierarchy level will be lost. This is true for the GSR attributes since synthesis is not aware of any special meaning for these attributes. If this occurs, you can prevent the flattening from occurring by adding an additional attribute to the hierarchy.

Below are code examples that illustrate how to preserve hierarchical attributes for the Synplify and Precision synthesis tools:

Synplify or LSE Hierarchy Attributes Verilog hierarchy attribute syntax:

```
modname modinst (signal list) /* synthesis syn_hier=hard */;
```

VHDL hierarchy attribute syntax:

```
attribute syn_hier : string;
attribute syn_hier of comp_instance: label is "hard";
component_instance: component_name port map (signal list);
```

Precision Hierarchy Attributes Verilog hierarchy attribute syntax:

```
modname modinst (signal list) //pragma attribute modinst
hierarchy preserve;
```

VHDL hierarchy attribute syntax:

```
attribute syn_hier : string;
attribute syn_hier of comp_instance: label is "preserve";
component_instance: component_name port map (signal list);
```

How to Use the Power Up Set/Reset (PUR) Global Signal

This topic provides guidelines and specific instructions for interfacing to the Power Up Set/Reset (PUR) signals of a Lattice FPGA device simulation model for use with all Lattice FPGAs. Details regarding the architecture of global signals are described in the data sheet for each device family. For more information on the PUR library element, see "PUR" on page 2345. For more information on using Lattice library elements in HDL, see Lattice Synthesis Header Libraries topic.

About the GSR and PUR Signals Both Global Set/Reset (GSR) and PUR are global RESET signals that will initialize the chip to some known reset state. In a given device, GSR has a dedicated input pad; however, PUR is not driven by any external pad. PUR is only activated upon device startup, just after configuration is complete, which is basically power-up of the device. Unlike PUR, the GSR signal can be called at any time during operation to reset the devices initial values.

Major items discussed in this topic are as follows:

- Using the PUR Library Element
- PUR Verilog HDL Example
- PUR VHDL Example

Using the PUR Library Element The Power Up Set/Reset (PUR) signal is activated during device configuration and is driven by internal circuitry. PUR is often used in the context of a system-level simulation where the power up control of the PC board is verified. You can model the behavior of this signal by adding the PUR library element to your test fixture. When the PUR input port is driven all register elements of the design will respond as if a global set/reset was asserted. PUR is in an active LOW state by default.

You commonly instantiate the PUR element in the test fixture with the instance name PUR_INST.

Note: Verilog simulations will produce errors if there are library elements in your design that require the instantiation of GSR, PUR, and TSALL elements and they are not present. For Verilog designs, you must instantiate the PUR and GSR elements in their top-level netlists with instance names PUR_INST and GSR_INST respectively if the design contains any instantiation of library elements which are affected by GSR.

The examples below shows proper syntax for instantiating a PUR element in Verilog HDL or VHDL.

PUR Verilog HDL Examples `PUR PUR_INST (.PUR (<powerup reset sig>));`

The PUR element instantiation below also shows a parameter called RST_PULSE with a value of 10 ns that is used to set the required reset pulse

length. You can pass a required numerical value such as 10 ns or 100 ns. If you do not specify this parameter, by default it will be set at 1 ns.

```
PUR     PUR_INST (.PUR (<powerup reset sig>));
defparam PUR_INST.RST_PULSE = 10;
```

PUR VHDL Examples `PUR_INST: PUR port map (PUR=><powerup reset sig>);`

As shown in the Verilog PUR example, this VHDL PUR element instantiation below also shows a parameter called RST_PULSE with a value of 10 ns that is used to set the required reset pulse length.

```
PUR_INST : PUR
generic map (RST_PULSE => 10)
port map (PUR => <signal>);
```

Note: PUR library elements should be used as part of a Verilog test fixture or VHDL test bench to model power up set/reset only. PUR library elements can not interface to a signal of the FPGA design itself.

References For more information refer to the following documentation.

- PUR library element description in "PUR" on page 2345.

See Also "Hardware How-To" on page 1162

How to Use the Tristate Interface (TSALL) Global Signal

This topic provides guidelines and specific instructions for interfacing to the Global Tristate Interface (TSALL) signal of a Lattice FPGA device for use with the Lattice MachXO and LatticeSC/M FPGA devices. Details regarding the architecture of global signals are described in the data sheet for each device family. For more information on the TSALL library element, see "TSALL" on page 2397. For more information on using Lattice library elements in HDL, see Lattice Synthesis Header Libraries topic.

Major items discussed in this topic are as follows:

- Using the TSALL Library Element
- TSALL Verilog HDL Example
- TSALL VHDL Example

Using the TSALL Library Element By default the tristate enable of PIO blocks will be assigned to local output enable signals of the design. To explicitly connect a design signal to the global tristate network of the device then it is necessary to instantiate the TSALL library element in your design. TSALL is considered active LOW to enable output.

Important

You must instantiate the TSALL with the instance name TSALL_INST. The port name for the MachXO TSALL library element is TSALL. The port name for the LatticeSC/M TSALL library element is TSALLN.

Note

Verilog simulations will produce errors if there are library elements in your design that require the instantiation of GSR, PUR, or TSALL elements and they are not present.

The examples below show proper syntax for instantiating the MachXO and LatticeSC/M TSALL element in Verilog HDL or VHDL, respectively.

TSALL Verilog HDL Example (MachXO)

```
TSALL   TSALL_INST (.TSALL ());
```

TSALL VHDL Example (MachXO)

```
component TSALL
        port( TSALL: in STD_ULOGIC );
    end component;
    -- Attributes for Synplify
    attribute syn_black_box: boolean ;
    attribute syn_black_box of TSALL: component is true;
    attribute syn_noprune: boolean ;
    attribute syn_noprune of TSALL: component is true;
    -- Attributes for Precision RTL
    attribute BLACK_BOX : boolean;
    attribute BLACK_BOX of TSALL: component is true;
    attribute DONT_TOUCH : boolean;
    attribute DONT_TOUCH of TSALL_INST: label is true;
begin

    TSALL_INST: TSALL port map (TSALL=><global tristate sig>);
```

TSALL Verilog HDL Example (LatticeSC/M)

```
TSALL   TSALL_INST (.TSALLN ());
```

TSALL VHDL Example (LatticeSC/M)

```
component TSALL
        port( TSALLN: in STD_ULOGIC );
    end component;
    -- Attributes for Synplify
    attribute syn_black_box: boolean ;
    attribute syn_black_box of TSALL: component is true;
    attribute syn_noprune: boolean ;
    attribute syn_noprune of TSALL: component is true;
    -- Attributes for Precision RTL
    attribute BLACK_BOX : boolean;
    attribute BLACK_BOX of TSALL: component is true;
    attribute DONT_TOUCH : boolean;
    attribute DONT_TOUCH of TSALL_INST: label is true;
```

```
begin
    TSALL_INST: TSALL port map (TSALLN=><global tristate sig>);
```

Note

Lattice Applications recommends using “don't touch” synthesis directives, like syn_noprune and DONT_TOUCH, with library elements that you instantiate in VHDL designs. For more information on Lattice library elements, see “FPGA Libraries Reference Guide” on page 1664.

References For more information refer to the following documentation.

- TSALL library element description in “TSALL” on page 2397

See Also “Hardware How-To” on page 1162

How to Use the Internal Oscillator

This topic provides guidelines and specific instructions for instantiating the internal oscillator (OSCA, OSCC, OSCD, OSCE, OSCF, OSCG, OSCH, OSCI, OSCJ) element in your Verilog and VHDL code for a given device family. It also contains specific code examples. For more information on these library elements, see “FPGA Libraries Reference Guide” on page 1664. For more information on using Lattice library elements in HDL, see Lattice Synthesis Header Libraries topic.

Major items discussed in this topic are as follows:

- Using Internal Oscillator Library Elements
- Internal Oscillator Verilog HDL Example
- Internal Oscillator VHDL Example

Using Internal Oscillator Library Elements To interface a user-defined clock signal to the internal oscillator, instantiate the appropriate library element from “FPGA Libraries Reference Guide” on page 1664. The following library elements are internal oscillators for their respective architectures:

- OSCA (LatticeSC/M)
- OSCC (MachXO)
- OSCD (LatticeECP2/M)
- OSCF (LatticeECP3)
- OSCE (LatticeXP2)
- OSCG (ECP5)
- OSCH (MachXO2)
- OSCI (LIFMD)
- OSCJ (MachXO3D)

For information on internal clock frequencies, clock divider settings, default settings, and other details, see “FPGA Libraries Reference Guide” on page 1664.

Note: Lattice Applications recommends using “don't touch” synthesis directives with library elements that you instantiate in your design.

The examples below shows proper syntax for instantiating an internal oscillator library element in Verilog HDL or VHDL for miscellaneous internal oscillators.

OSCD Verilog Example

```
module OSC_TOP (OSC_CLK);
output   OSC_CLK;
OSCD OSCinst0 (.CFGCLK(OSC_CLK));
defparam OSCinst0.NOM_FREQ = "2.5" ;
endmodule
```

OSCE VHDL Example

```
COMPONENT OSCE
-- synthesis translate_off
GENERIC (NOM_FREQ: string := "2.5");
-- synthesis translate_on

Chapter 17

Constraints Reference Guide

Constraints are instructions that you specify to guide your design toward desired results and performance goals. In the Lattice Diamond design flow, constraints include logical preferences and HDL attributes.

You can assign constraints using one or both of the following methods:

- Assign post-synthesis design preferences using the logical preference file (.lpf).

  See the "Preferences" on page 1195 section for complete descriptions of each preference, including syntax rules and examples.

- Assign HDL or schematic-based attributes using the design source files. These attributes are used to direct Map and Place & Route.

  See the "HDL Attributes" on page 1281 section for complete descriptions of each attribute, including conventions and examples.

If you are using the Lattice Synthesis Engine (LSE), constraints will also include Synopsys Design Constraints (SDC) as well as HDL attributes and directives that influence the optimization or structure of the output netlist. See the "Lattice Synthesis Engine (LSE) Constraints" on page 1338 section for descriptions of these LSE constraints.

See Also "Applying Design Constraints" on page 358

- "Using Preference Scripts" on page 534
- "Integrated Synthesis" on page 581
- "Applying Design Constraints" on page 358

Preferences

Preferences are implementation constraints for assigning design logic to physical resources. Preferences, unlike HDL attributes, are written to the logical preference file (.lpf).

The following table shows the device support for each preference and the preferences that are supported by TRACE.

Preference	Devices	TRACE
ASIC	all	✓
BANK	all	
BLOCK	all	✓
CLKDELAY	LatticeSC/M only	✓
CLKSKEWDIFF	all	✓

ASIC

Specifies either black box or ASIC cell element programming properties.

Device Support All

Syntax ASIC <*asic_instance_name*> TYPE <*lib_element_type*> (<*keyword*>=<*value*>)+;

where:

<*asic_instance_name*> ::= ASIC instance name (string)

<*lib_element_type*> ::= Library element type (string)

<*keyword*> ::= string

<*value*> ::= string

Example:

```
ASIC "my_dll" TYPE "CIMDLLA" CLKOP_PHASE=90 PHASELOCK=DISABLED;
```

The ASIC instance names and their types in a design are listed in the "ASIC Components" section of the Map Report.

ASIC Types for Implementing the LatticeSC SMI Bus For LatticeSC and LatticeSCM devices, an ASIC TYPE must be specified when assigning a serial management interface offset value (SMI_OFFSET) for PLLs, DLLs, or select MACO blocks. The SMI_OFFSET value must be set in the preference file for mapping, placement and routing.

DLL Example:

```
ASIC “dll/dll_0_0” TYPE “CIMDLLA” SMI_OFFSET=”0x420”;
```

PLL Example:

```
ASIC “pll/pll_0_0” TYPE “EHXPLLA” SMI_OFFSET=“0x410“;
```

MACO Example:

```
ASIC "flxmc_sys_ge/flxmc_top_sys/flxmc_top_ebr/flxmc_top_mib"
TYPE "FLXMC" SMI_OFFSET="0x500";
```

LatticeSC DLL and PLL ASIC Types The following list shows the ASIC TYPE keyword for each LatticeSC PLL and DLL that can be implemented with the SMI system bus.

- CIDDLLA – DLL clock injection delay removal. Reduces clock injection delay, which is the delay from the input pin of the device to a destination element such as a flip-flop.
- CIMDLLA – DLL clock injection delay match. Allows two synchronous clock inputs to be used to create a digital control (DCNTL) vector that is the delta of the delay between the two clocks.
- SDCDLLA – single delay cell dll. Corrects for clock injection and enables the 9-bit ALU output
- TRDLLA – time reference delay. Generates four phases of the clock—0, 90, 180, 270 degrees—along with the control setting used to generate these phases.
- EHXPLLA – enhanced extended performance PLL.

See *Technical Note 1098, LatticeSC sysCLOCK PLL/DLL User’s Guide,* for more information.

LatticeSCM MACO ASIC Types The following list shows the MACO blocks that can be implemented with the SMI system bus and the ASIC type keywords for each.

- FLXMC – ethernet flexiMAC, a media access controller. The FLXMC includes the following ASIC type:
  - FLXMC.

  See *User Guide 48, LatticeSCM Ethernet flexiMAC MACO Core*, for more information.
- SPI4.2 – system packet interface level 4 IP core. The ASIC type for the SPI4.2 depends on the size of the device and the site used for the SPI4.2 MACO. Therefore, the SPI4.2 includes the following ASIC types:
  - SPI4_15LLM0

- SPI4_25LLM0
- SPI4_25RLM0
- SPI4_40LLM0
- SPI4_40RLM0
- SPI4_80LLM0
- SPI4_80RLM0
- SPI4_115LLM0
- SPI4_115RLM0

See *User Guide 44, LatticeSCM SPI4.2 MACO Core,* for more information.

BANK

Sets the VCCIO voltage level of the IO bank. In cases where design signals are not assigned to a device site or bank (floating), the BANK preference can be applied to direct the IO placer algorithm of Place and Route (par) to assign only design IO signals with compatible signal standards to the bank.

Device Support All

Note

For LatticeSC devices, you must use the configuration bank, Bank 1, to set the VCCIO voltage level. See BANK 1, following.

For more details on assigning signal standards to a design signal, see the IOBUF preference. See the LOCATE preference for details on assigning I/O signals to a device site.

Usage The BANK preference can be set manually in the logical preference file. For MachXO2, MachXO3D, and MachXO3L devices, it can also be set in the Global preference sheet of Spreadsheet View.

Syntax BANK <*n*> VCCIO <*x*> V;

where:

<*n*>= bank number

<*x*> can be any compatible voltage supply to that bank; for example, 2.5, 3.3

Care must be taken not to create conflicting preferences that locate I/O signals to a bank that are incompatible with the voltage supply designated by the BANK preference. VCCIO voltage is automatically set when an I/O signal is assigned to a package pin using the LOCATE preference.

LatticeSC/M devices are unique, because the user might need to float I/O signals yet specify the voltage that a bank is running at to enable the 3.3V

protection circuit. Any bank could be attached to a 3.3V power supply on the board, and even if no user I/O signals are assigned to it, this will lead to a hot device and/or excess power consumption.

Example – 3.3V VCCIO If 3.3V is defined, then bank *n* will run as if a 3.3V VCCIO voltage will be supplied:

- PAD Specification File (<*project*>.pad) will report bank *n* as having VCCIO of 3.3V
- PAR will not allow the placement of any I/O signals that are incompatible with 3.3V VCCIO. An error will be generated if there is a LOCATE of an incompatible I/O signal assigned to bank *n*.
- The 3.3V protection circuit will be enabled.

Example – 2.5V VCCIO If a value other than 3.3V is defined—for example, 2.5V—then bank *n* will run as if that VCCIO voltage will be supplied:

- PAD Specification File (<*project*>.pad) will report bank *n* as having VCCIO of 2.5V
- PAR will not allow the placement of any I/O signals that are incompatible with 2.5V VCCIO. An error will be generated if there is a LOCATE of an incompatible I/O signal assigned to Bank *n*.
- The 3.3V protection circuit will be disabled.

Example – Undefined VCCIO Values If no BANK preference is defined, then:

- PAD Specification File (<*project*>.pad) will report bank *n* as having the voltage that is required by the I/O signals placed there. If no design I/O signals are placed into bank *n*, then default 2.5V is used.
- If the VCCIO in the PAD Specification File (<*project*>.pad) is 3.3V, then the 3.3V protection circuit will be enabled; otherwise, it will be turned off.
- It is the user's responsibility to supply the VCCIO voltages reported in the PAD Specification File to the device.

BANK 1 A requirement for LatticeSC devices is that all banks be powered during power-up. Because of this requirement, a configuration bank (Bank 1), must be used to set VCCIO voltage for LatticeSC devices. The BANK 1 preference directs the Place and Route (PAR) engine to place only IO signals with compatible standards into the Bank 1. By ensuring that pins in Bank 1 are not set to a different voltage level than the configuration pins, the BANK 1 preference helps prevent overheating.

BANK 1 Syntax BANK 1 VCCIO <*x*> V;

where:

<*x*> can be any compatible voltage supply to Bank 1; for example, 2.5, 3.3

BANK 1 Example – 3.3V VCCIO If 3.3V is defined, then Bank 1 will run as if a 3.3V VCCIO voltage will be supplied:

- PAD Specification File (<*project*>.pad) will report Bank 1 as having VCCIO of 3.3V
- PAR will not allow the placement of any I/O signals that are incompatible with 3.3V VCCIO. A PAR error will be generated if there is a LOCATE of an incompatible IO to Bank 1.
- The 3.3V protection circuit will be enabled.

BANK 1 Example – 2.5V VCCIO If a value other than 3.3V is defined—for example, 2.5V—then Bank 1 will run as if that VCCIO voltage will be supplied:

- PAD Specification File (<*project*>.pad) will report Bank 1 as having VCCIO of 2.5V
- PAR will not allow the placement of any IOs that are incompatible with 2.5V VCCIO. An error will be generated if there is a LOCATE of an incompatible IO to Bank 1.
- The 3.3V protection circuit will be disabled.

BANK 1 Example – No Bank 1 Preference defined If no BANK 1 preference is defined, then:

- PAD Specification File (<*project*>.pad) will report Bank 1 as having the voltage that is required by the I/O signals placed there. If no design I/O signals are placed into Bank 1, then the default 2.5V is used.
- If the VCCIO in the PAD Specification File is 3.3V, then the 3.3V protection circuit will be enabled; otherwise, it will be turned off.
- It is the user's responsibility to supply the VCCIO voltage that is reported in the PAD Specification File.

BLOCK

Blocks timing analysis on nets, paths, buses, or component pins that are irrelevant to the timing of the design. If a net is specified, the net and all paths through the specified net will blocked. If a bus is specified, the bus, all nets in the bus, and all paths through the nets defined by the bus will be blocked. If a component pin is specified, any path going through the specified pin of the named component will be blocked.

The TRACE report will include all paths that are covered with the BLOCK PATH preference, but it will not include details for a BLOCK NET preference. In TRACE, the signal defined in a BLOCK NET preference is removed from the timing-graph analysis completely. Because there is no path or coverage

related to this signal any longer, all paths through the signal are blocked/ removed and considered covered.

Note

If two input clocks are related according to the board designs, then use CLKSKEWDIFF (which can only be used for port) preference to tell the TRACE that the two clocks are related. Then, when you use the BLOCK FROM CLKNET (/TO CLKNET) preference, Cross Domain Crossing (CDC) paths that under these two input clocks will be blocked.

Otherwise, if these two inputs are unrelated, there is no need to (and user cannot) use BLOCK FROM CLKNET (/TO CLKNET) for these CDC paths.

Device Support All

Syntax BLOCK NET <*net_name*> ;

BLOCK BUS <*bus_name*> ;

BLOCK COMP <*comp_name*> PIN <*pin_name*> ;

BLOCK PATH <*path_spec*> ;

BLOCK <*path_class*> ;

where:

<*path_spec*> ::= [FROM <*obj_type*> <*obj_name*>][TO <*obj_type*> <*obj_name*>]

<*obj_type*> ::= CELL | PORT | CLKNET | ASIC PIN | GROUP

<*obj_name*> ::= identifier

For example, CELL <*identifier*>, PORT <*identifier*>, CLKNET <*identifier*> (ASIC <*identifier*> PIN <*identifier*>), GROUP <*indentifier*>

Note

The object type in BLOCK PATH FROM <obj_type>TO <obj_type> must be of the same category, as follows:

Category 1: PORT/CELL/ASIC PIN/GROUP
Category 2: CLKNET

BLOCK preferences using the following syntax examples are valid, since the FROM and TO object types are from Category 1.

BLOCK PATH FROM CELL TO PORT;
BLOCK PATH FROM PORT TO PORT;
BLOCK PATH FROM GROUP TO PORT;
BLOCK PATH FROM ASIC PIN TO CELL;

But BLOCK preferences using the following syntax are invalid, since the Category 2 CLKNET is mixed with Category 1 object types:

BLOCK PATH FROM CLKNET TO CELL/PORT/GROUP/ASIC PIN;
BLOCK PATH FROM CELL/PORT/GROUP/ASIC PIN to CLKNET;

For Category 2, the path must be from CLKNET to CLKNET.

where:

<*path_class*> can be any one of the following general path classes:

RESETPATHS – Specifies all asynchronous set/reset paths, through an asynchronous set/reset pin on a design component. This is in the "ON" condition by default, so when a new project is created in Diamond, the BLOCK RESETPATHS preference will appear in the project's preference file.

ASYNCPATHS – Blocks all paths from pads to FF inputs for the frequency and period preferences. This is in the "ON" condition by default, so when a new project is created in Diamond, the BLOCK ASYNCPATHS preference will appear in the project's preference file.

JTAGPATHS – Identifies any output signal from "JTCK" of cellmode "JTAG" and blocks all registers driven by this signal when doing FMAX analysis.

RD_DURING_WR_PATHS – Globally blocks RAM read paths during the write operation. This is in the "OFF" condition by default.

The following keyword can also be used with the BLOCK preference but is not recommended, as explained in the Note that follows:

INTERCLOCKDOMAIN PATHS – Specifies all paths involving data transfer between registers that are clocked by different clock nets—even when those clock nets are related.

Note:

Even *without* the BLOCK INTERCLOCKDOMAIN PATHS preference, TRACE does not time data transfers between registers that are clocked by unrelated clock nets. Related clock nets are those that come from different outputs of the same PLL, through different inferred DCS elements, through a CLKDIV, and others. These paths are not generally false paths. When the BLOCK INTERCLOCKDOMAIN PATHS preference is used, these paths are blocked, which is very risky.

JITTER – Blocks jitter from timing analysis. This includes any input clock jitter specified by a PERIOD or FREQUENCY preference, as well as system jitter.

Using Wildcards For the logical BLOCK preference, NET names with wildcard expressions are allowed. PORT or CELL names with wildcard expressions are also allowed. See “Using Wildcard Expressions in Preferences” on page 531 for details about wildcard usage and range expansion.

Examples The following preference command blocks timing analysis on a net named n1:

```
BLOCK NET n1;
```

The following preference command blocks timing analysis on pin A1 of component SLICE_4.

```
BLOCK COMP "SLICE_4" PIN "A1" ;
```

The following preference command blocks timing analysis on all paths terminating at an asynchronous set/reset input of a design component:

```
BLOCK RESETPATHS;
```

The following preference command blocks the path between two ports:

```
BLOCK PATH FROM PORT "LOCAL_CMD0" TO PORT "RAM_RD";
```

The following preference blocks specific interclock domains between clock nets. All maximum frequency (fMAX) paths from clknet_1 to clknet_2 will be blocked from timing analysis.

```
BLOCK PATH FROM CLKNET "clknet_1 " TO CLKNET "clknet_2 ";
```

The following preference blocks all jitter from timing analysis, including all system jitter as well as jitter that has been specified through a PERIOD or FREQUENCY preference:

```
BLOCK JITTER;
```

See Also ▶"Setting TRACE Options" on page 693

CLKDELAY

Sets delays for clock boosting on a CELL (flip-flop).

Device Support LatticeSC/M

Syntax CLKDELAY CELL <*cell_name*><*delay*>;

CLKDELAY GROUP <*group_name*><*delay*>;

where:

<*cell_name*> ::= string

<*group_name*> ::= string

<*delay*> ::= DEL0 | DEL1 | DEL2 | DEL3

The <*cell_name*> and <*group_name*> identifiers must be the flattened logical instance names. Applicable components include instances of flip-flops in PFUs and I/O registers.

The value of DEL0 is no delay. For values of DEL1, DEL2, AND DEL3, refer to the LatticeSC data sheet.

Example The following preference constrains an I/O register for clock boosting:

```
CLKDELAY CELL "my_delay" DEL0
```

CLKSKEWDIFF

Enables TRACE (trce) to take into account the input skew between two top-level, input clock ports. When applied, this preference influences the fMAX-path clock skew crossing over these two clock domains. You specify the targeted input skew delay in a relative manner or as a range. See examples below.

Note

CLKSKEWDIFF can only be applied to input clock skew between two input clock ports and does not support references between different clock nets (CLKNETs). In addition, CLKSKEWDIFF is not applicable to a phase-shifted clock produced by a sysCLOCK PLL. The skew on these clocks are calculated automatically by TRACE and processed in the flow, so there is no need to use a CLKSKEWDIFF preference in these cases.

Device Support All

Syntax CLKSKEWDIFF CLKPORT <*port_name*> CLKPORT <*port_name*> <*max_time_unit*> [MIN <*time_unit*>];

where:

CLKPORT <*port_name*> ::= the name of a top level clock port (IO).

<*max_time_unit*> ::= the maximum skew between two top-level ports. (Refer to Units section “Preference Syntax Guidelines and Conventions” on page 525.)

<*time_unit*> ::= the skew between two top-level ports. (Refer to Units section “Preference Syntax Guidelines and Conventions” on page 525.)

MIN <*time_unit*> ::= specifies the minimum clock skew time between two top-level clock ports.

These keywords for minimum and maximum setup and hold time account for how the skew varies, within some range, between the primary input clocks in actual operating conditions. TRACE reports these min/max values for setup and hold times. This syntax guarantees that correct setup is handled by PAR and that any hold violation is reported. PAR follows TRACE in checking setup times, but it cannot fix hold violations.

Examples In the following example, the clock arrives at "clock1" with a 2 ns delay compared to when it arrives at "clock2." TRACE takes this 2 ns value into account while performing clock skew computation.

```
CLKSKEWDIFF CLKPORT "clock1" CLKPORT "clock2" 2 NS;
```

The following example uses a min/max specification, which allows TRACE to derive a correct number for setup/hold time.

```
clkskewdiff clkport "clka" clkport "clkb" 1.4ns Min 0.4ns;
```

The above example defines that "clka" is lagging behind "clkb" within a range of 0.4ns to 1.4ns. Therefore, the data path from “clka” to “clkb” will use 1.4ns (max) for the setup and 0.4ns (min) for the hold.

The above preference example also defines that “clkb” is lagging before “clka” within a range of 0.4ns to 1.4ns, which is equivalent to the following:

```
clkskewdiff clkport "clkb" clkport "clka" -0.4ns Min -1.4ns;
```

Therefore, the data path from “clkb” to “clka” will use -0.4ns for the setup and -1.4 ns for the hold.

CLKSKEWDISABLE

CLKSKEWDISABLE affects the timing analysis resulting from other preferences such as MULTICYCLE. It disables clock skew computation between two nets. These two nets can be related (originate from the same clock source) or unrelated. Data paths that have the same source and destination clock nets cannot be disabled by using this preference. When CLKSKEWDISABLE is applied to two clock nets, TRACE will always consider the two clock domains related, and it will time the signals between them accordingly. Since the preference also causes the timing analysis to ignore clock skew, any timing analysis done will include only datapath delays.

Device Support All

Syntax CLKSKEWDISABLE CLKNET <*clknetname*> [CLKNET <*clknetname*>];

where:

CLKNET <*clknetname*> ::= the name of source clock net of paths to be disabled from skew calculation in TRACE

Examples The following preference prevents skew calculation by TRACE on any path whose source is clocked by "clock_int1" and whose destination is clocked by "clock_int2." Nets "clock_int1" and "clock_int2" are related clock nets, that is, nets derived from the same source component.

```
CLKSKEWDISABLE CLKNET "clock_int1" CLKNET "clock_int2";
```

The following preference prevents skew calculation by TRACE on any path whose source is clocked by "clock_int1" or whose destination is clocked by "clock_int1".

```
CLKSKEWDISABLE CLKNET "clock_int1";
```

The CLKSKEWDISABLE preference is directional. This means that the following example defines the skew ignored for the datapath from “clkA” to “clkB”:

```
CLKSKEWDISABLE CLKNET “clkA” CLKNET “clkB”;
```

whereas the following example defines the skew ignored for the datapath from “clkB” to “clkA”

```
CLKSKEWDISABLE CLKNET “clkB” CLKNET “clkA”;
```

CLOCK_TO_OUT

Specifies the required timing constraint to meet on FPGA output relative to its clock.

Device Support All

Syntax CLOCK_TO_OUT ([PORT] <*port_name*> | GROUP <*group_name*> | ALLPORTS)
([[MAX] <*time_spec*>] | [OUTPUT_DELAY <*time_spec*>]
[MIN <*time_spec*>]
(CLKNET [=] <*clkin_netname*>) | CLK PORT <*clkout_portname*>)
[FROM <startpoint>]
(CLKPORT [=]<*clkin_portname*>) | [CLKOUT PORT <*clkout_portname*>]
[PLL_PHASE_BACK]
[CLK_OFFSET <*n*> X] ;

where:

PORT <*port_name*>: uses the name of a top level output port to specify the data path.

GROUP <*group_name*>*:* is a given group definition you defined with the DEFINE GROUP preference.

ALLPORTS: designates that all input ports in the given clock port/net path are affected by the time value specified.

MAX (or blank): defines a CLOCK_TO_OUT goal such that the internal timing of the FPGA will produce the output signal by this goal or earlier in time.

MIN: specifies the fastest clock-to-out time for which the board level hold time requirement is still met. MAX is an optional keyword that assists readability by differentiating the MAX clock-to-out requirement from the MIN value.

<time_spec> ::= <number> <time_unit>

(Refer to Units section of Preference Syntax Guidelines and Conventions.)

OUTPUT_DELAY: is an alternate form for defining the MAX constraint goal. Its value is the amount of time that the board and downstream device take from the clock period. If P is the clock period, then the FPGA internal timing must produce the output signal within P – OUTPUT_DELAY time. Another way to look at it is the OUTPUT_DELAY value is the time from the point the data arrives at the output until the next clock edge. Using this keyword (instead of MAX) allows you to change the FREQUENCY preference without having to change the CLOCK_TO_OUT MAX time_spec value requirement.

See the output delay example.

CLKNET=<*clkin_netname*>: uses a net name to specify the reference clock.

FROM <startpoint>: specifies a maximum delay from a register starting point.

CLKPORT=<*clkin_portname*> uses a port name to specify the reference clock.

Note

In some earlier releases, both the CLOCK_TO_OUT preference that specifies either a CLKNET or a CLKPORT in the syntax would yield the same information about the clock path in the Physical Path Details section. That is, TRACE (**trce**) would trace the clock path to the port in both cases. Specifying the CLKNET was for purposes of convenience only. Now, TRACE will stop at the CLKNET specified and it will not go back to report the port unless CLKPORT is specifically used in the preference. Since the behavior of keywords CLKPORT and CLKNET is now differentiated, the enhancement provides more control. See the example at the end of this topic.

CLKOUT PORT <*clkout_portname*>: is the name of the output clock port with respect to the output data delay that needs to be to be measured. This option can be used with both CLKPORT and CLKNET. This is used for source synchronous interfaces. MAX and MIN values are defined relative to the data output and the clock output. As an example, if the MAX value is set to 2ns, this means that the data will be output from the FPGA at most 2ns after the clock outputs (via the CLKOUT PORT) from the FPGA.

PLL_PHASE_BACK reverses the offset direction of the phase delay programmed into a PLL. For example, you might program a PLL to delay the clock phase by 7/8ths of its cycle. Then Trace timing analysis will add 7/8ths of a cycle to the clock insertion delay. However, the PLL_PHASE_BACK keyword directs Trace to subtract 1/8th (7/8 -1 = -1/8) of a cycle from the clock insertion delay.

When two PLL's are cascaded, the scenarios will become more complex, especially with PLL Bypass. However, as a general rule, if a PLL_PHASE_BACK is applied to a cascaded PLL chain of two and none of the PLL's are bypassed or with zero phase shift, then the result will be the same as if PLL_PHASE_BACK had been applied to each of them individually.

If one of them is bypassed or with zero phase shift, the effective result will be the same as if PLL_PHASE_BACK had not been applied to that PLL.

PLL_PHASE_BACK gives you the ability to control the desired effect of the phase delay to match your intent. There is a startup one-cycle latency incurred by using this keyword, so design the system accordingly.

CLK_OFFSET <n> X: adjusts the analysis by a multiple of the clock period. The clock_to_out clock path timing will be adjusted by:

<*n*>::= is a floating point number and can be negative.

Since <n> can be a floating point number, this can be used to pick the opposite clock edge for the analysis; the analysis will then adjust automatically to changes to the clock's frequency or period specification. When this option is not specified, the default value of n=0 is assumed, meaning that no adjustment is made and the edge at the pin is the edge used in the analysis.

Note

CLOCK_TO_OUT syntax must specify either a CLKPORT or CLKNET or a syntax error will result. The use of wildcards is supported for port name identifiers.

Using Wildcards For the logical CLOCK_TO_OUT preference, port and register names with wildcard expressions are allowed. See "Using Wildcard Expressions in Preferences" on page 531 for details about wildcard usage and range expansion.

General Syntax Examples The following are examples of general CLOCK_TO_OUT syntax:

```
CLOCK_TO_OUT ALLPORTS 10ns CLKPORT "clkin";

CLOCK_TO_OUT RESP_REQ 80 NS CLKNET = "N28";
```

Examples Using HOLD Value The following examples specify HOLD Values. The use of the keyword MAX before the output delay time unit value is not necessary, since it is implicit. So the following two preferences are equivalent for specifying HOLD values:

```
CLOCK_TO_OUT RESP_REQ MAX 80 ns MIN 60 ns CLKPORT "clkin";

CLOCK_TO_OUT RESP_REQ 80 ns MIN 60 ns CLKPORT "clkin";
```

When TRACE (trce) is run without the -hld option in the following example, where "dataout" is an output data port clocked by a signal from port "clockin", the preference states that the maximum allowable output delay on "dataout" with respect to the output port "clockout" is 4 ns.

```
CLOCK_TO_OUT "dataout" 4NS CLKPORT = "clockin" CLKOUT PORT
"clockout";
```

In the following example, "dataout" is an output data port clocked by a signal from port "clockin." The preference states that the minimum allowable output delay on "dataout" with respect to output port "clockout" is 4 ns. This MIN constraint will be analyzed by Trace when it does Hold time analysis. the MAX constraint will be analyzed by Trace when it does Setup Time analysis.

```
CLOCK_TO_OUT dataout MAX 10NS MIN 4NS CLKPORT = "clockin"
CLKOUT PORT "clockout";
```

You will receive a TRACE (**trce**) syntax error message if you do not also include the MAX delay number in the CLOCK_TO_OUT preference syntax. For example, in the following preference, only the MIN number is specified, resulting in an error:

```
ERROR - trce: line 5: syntax error on, "MIN", in this
preference,
"CLOCK_TO_OUT Q MIN 2 ns CLKPORT CKIN1 CLKOUT PORT CKOUT;"
```

The following preference will set the output delay for all output ports with relation to CLKIN1:

```
CLOCK_TO_OUT ALLPORTS OUTPUT_DELAY 10ns CLKPORT CKIN1;
```

Examples Using CLKPORT and CLKNET Keywords Here are two preferences using both the CLKPORT and CLKNET keywords, showing the corresponding scope of TRACE reporting. In this case, the CLKNET will stop tracing the path before the PLL, so you will not get PLL compensation timing numbers.

```
CLOCK_TO_OUT PORT "RxAddr_0" 6.000000 ns CLKNET "pll_rxclk" ;
```

The preference will yield the following clock path:

```
Physical Path Details:
       Clock path pll_inst/pll_utp_0_0 to PFU_33:
    Name    Fanout   Delay (ns)          Site               Resource
  ROUTE        49     2.892    ULPPLL.MCLK to     R3C14.CLK0 pll_rxclk
                    --------
                      2.892   (0.0% logic, 100.0% route), 0 logic levels.
```

In this case, the trace is complete back to the clock port resource and provides PLL compensation timing numbers.

```
CLOCK_TO_OUT PORT "RxAddr_0" 6.000000 ns CLKPORT "RxClk" ;
```

The preference will yield the following clock path:

```
  Clock path RxClk to PFU_33:
    Name    Fanout   Delay (ns)          Site               Resource
  IN_DEL      ---     1.431         D5.PAD to        D5.INCK RxClk
  ROUTE         1     0.843        D5.INCK to   ULPPLL.CLKIN RxClk_c
  MCLK_DEL    ---     3.605   ULPPLL.CLKIN to    ULPPLL.MCLK pll_inst/pll_utp_0_0
  ROUTE        49     2.892    ULPPLL.MCLK to     R3C14.CLK0 pll_rxclk
                   --------
                     8.771   (57.4% logic, 42.6% route), 2 logic levels.
```

Example Using FROM Register/Path Option The following example defines I/O timing relative to source registers using the FROM <register_name> syntax.

```
CLOCK_TO_OUT PORT “dataio*” 11 ns CLKPORT “clkr” FROM r1data_0io_0;
```

The preference will yield the following clock path:

```
  Clock path clkr to data_in_0_IOLOGIC_S:
 Name      Fanout  Delay (ns)      Site             Resource
IN_DEL      ---     0.744        K30.PAD to      K30.PADDI clkr
ROUTE        33     1.968      K30.PADDI to *LOGICB17A.CLK clkr_c
                  --------
                    2.712   (27.4% logic, 72.6% route), 1 logic levels.
```

Examples Using CLK_OFFSET Option The following example uses a CLK_OFFSET of 0.5X:

```
CLOCK_TO_OUT RESP_REQ 80 NS CLKNET = "N28" CLK_OFFSET 0.5X ;
```

An additional half period of the clock will be used in the analysis. This would be appropriate for a negative edge triggered flop driving RESP_REQ. The constraint is that RESP_REQ must update its value at the device pin no later than 80 ns after the rising edge of the clock N28 at its device pin. The CLK_OFFSET of 0.5 X will analyze the negative clock edge after the rising clock edge arrives at the flop from the device pin, meaning that an additional half period will be added to the clock to out path. This example increases the constraint by using CLK_OFFSET.

```
CLOCK_TO_OUT RESP_REQ 80 NS CLKNET = "N28" CLK_OFFSET -0.5X ;
```

This is similar to the previous example, except that the CLK_OFFSET of -0.5 X will analyze the negative clock edge *before* the rising clock edge arrives at the flop from the device pin, which means that half a clock period will be subtracted from the clock to out path. This example relaxes the constraint by using CLK_OFFSET.

See Also ▶"Setting TRACE Options" on page 693

CUSTOM_IDCODE

Specifies a 32-bit value to be used as the JTAG ID of the device when the MY_ASSP feature is enabled.

Device Support MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2

Syntax CUSTOM_IDCODE {HEX | bin} <value);

Examples The following examples show the two available formats.

```
CUSTOM_IDCODE HEX "0000FFFF";
CUSTOM_IDCODE BIN "00001111000011110000111100001111";
```

CUSTOM_IDCODE is a global preference. If it is included more than once in the preference file, only the last instance will be honored.

See Also ▶"SYSCONFIG" on page 1250

DEFINE BUS

Specifies a grouping of nets to be used in the following preferences: BLOCK, MAXDELAY, MAXSKEW, PRIORITIZE.

Device Support All

Syntax DEFINE BUS <*bus_name*> (NET <*net_name*>)+;

Examples The following command defines a bus named busA composed of eight nets named net pen (0-7):

```
DEFINE BUS "busA" NET "pen0" NET "pen1" NET "pen2" NET "pen3"
NET "pen4" NET "pen5" NET "pen6" NET "pen7";
```

DEFINE GROUP

Defines a single identifier that will refer to a group of objects.

PORT/CELL/ASIC groups can be defined using Spreadsheet View or manually in a text editor. For more information, see “Defining Port, Cell, and ASIC Groups” on page 504.

Device Support All

Syntax DEFINE <*obj_type*> GROUP <*group_name*> (ASIC <*identifier*> PIN <*identifier*>)+ | (<*obj_name*>)+ ;

where:

<*group_name*> ::= string

<*obj_type*> ::= CELL | PORT | ASIC

Note

The DEFINE GROUP preference should be used instead of the legacy PIO-based PGROUP preference. Although you can still create a PIO-based PGROUP in the logical preference file using a text editor, this is not recommended. The Diamond preference views do not support the display or editing of PIO-based PGROUPs.

Using Wildcards For the logical DEFINE GROUP preference, wildcard expressions are allowed on CELLs, PORTs, and ASIC PINs. See “Using Wildcard Expressions in Preferences” on page 531 for details about wildcard usage and range expansion.

Note

The use of wildcards is supported for names in the identifier list. All objects named in the group must be of the same type as specified by <*obj_type*>.

General Syntax Examples In the following examples, groups are defined and then used with MULTICYCLE and MAXDELAY preferences.

```
DEFINE CELL GROUP "slow_group" "data*" "other_reg_{0-1}""flop";

DEFINE PORT GROUP "fast_ins" data* adr*;

DEFINE ASIC GROUP "asic1group" ASIC "serdes_fifo0_3" PIN "Q34"
ASIC "serdes_fifo0_3" PIN "Q33";

DEFINE ASIC GROUP "asic2group" ASIC "serdes_fifo3_0" PIN "D1*"
ASIC "serdes_fifo3_0" PIN "D2*";

MULTICYCLE FROM GROUP slow_group 3 X;

MULTICYCLE FROM GROUP fast_ins 1 X;

MAXDELAY FROM GROUP "asic1group" 10 ns;

MULTICYCLE TO GROUP "asic2group" 10 ns;
```

Example Using IOBUF attributes on PORT GROUPs In the following example, IOBUF properties are applied on PORT GROUPS:

```
DEFINE PORT GROUP "grp1" "a1" "a2" "a3";
IOBUF GROUP "grp1"  IO_TYPE=LVCMOS33 PULLMODE=UP BANK=4;
```

During the map process, all of the IOBUF attributes will be attached to individual ports in the physical design (.ncd) file. The DEFINE PORT GROUP will be converted to a PGROUP by the mapper, and the bank assignment on the group "grp1" will have a LOCATE PGROUP in the schematic section. A DEFINE GROUP preference will be included in the section following the schematic section.

The .prf file will have the following preferXences:

```
SCHEMATIC START;
PGROUP "grp1" COMP "a1" COMP "a2" COMP "a3";
            LOCATE PGROUP "grp1" BANK 4;
SCHEMATIC END;
DEFINE PORT GROUP "grp1" "a1" "a2" "a3";
```

Troubleshooting Group Conflicts Redundant DEFINE GROUP declarations in the .lpf file are not handled consistently across “Lattice Diamond” programs and should be avoided. Such multiple definitions of the same group name might appear in the .lpf file because of a semantic error in the original definition. For example, a group created in the .lpf ASCII file might contain a semantic error and not show up in Diamond.

When the software encounters a DEFINE GROUP conflict in the .lpf file, it processes the groups using the following rules:

- Only one group definition is recognized for each group name. When two group definitions with the same name appear in the .lpf file, the software recognizes only the group listed last, whereas the TRACE and PAR programs recognize the group listed first.
- Groups cannot share the same members. When two groups with different names include some of the same elements, the software assigns only non-conflicting elements to the second group.

See Also ▶“Defining Port, Cell, and ASIC Groups” on page 504

- “Defining I/O Defaults” on page 473

FBEXTDELAY PCM

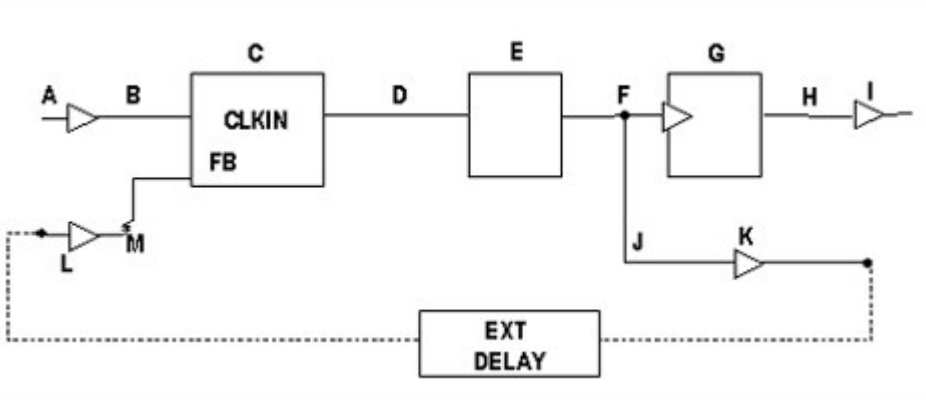
Specifies the external feedback additional delay on a PCM in PLL mode.

Device Support All

Syntax FBEXTDELAY PCM <pcm name> (FROM PORT <*name*> TO PORT <*name*>) <*time*>;

Example `FBEXTDELAY PCM "CLKGEN/PLLDInst_0" FROM PORT "clkout" TO PORT "clkfb" 1 ns;`

Example – Feedback Delay TRACE uses the feedback delay to compensate for the INPUT_SETUP preference.



Feedback delay= C+D+E+J+K+EXT DELAY+L+M

FREQUENCY

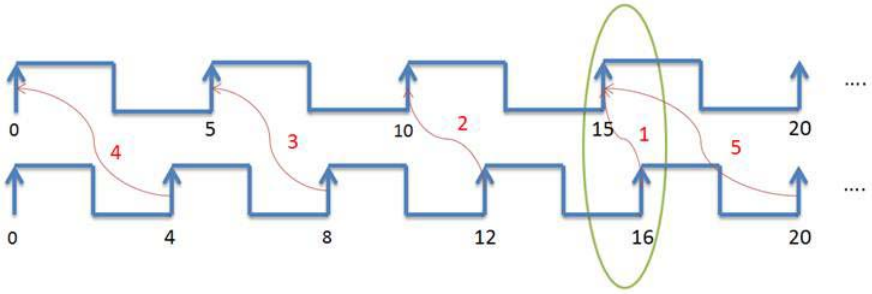
Identifies the minimum operating frequency for all sequential output to sequential input pins clocked by the specified net or port. If no net or port name is given, the preference applies to all clock nets in the design that do not have a specific clock frequency preference.

When two registers are driven by two related clock nets with different frequency requirements, TRACE will automatically use the closest clock-edge gap as the constraint for paths between these two registers. See “Clock Domains Analysis” on page 709 for definition of related clocks.

A delay constraint that is based on different source and destination clocks, with different FREQUENCY preferences defined, is calculated between the closest two active clock edges and is reported as weighted slack in the TRACE report. This can produce a timing error because of the tight timing requirement from the small gap between two clock edges, as shown in the following diagram.

This example shows the clocks aligned at the beginning and an attempt to find the delay constraint in ten cycles of the destination clock. In this case, there are many values: 4ns, 3ns, 2ns, 1ns, 5ns. Trace will pick the worst one, which is 1ns, and use it as delay constraint.

The weighted slack is calculated as destination clock / delay constraint * original slack. If the original slack of this crossing clock domain path (5 ns -> 4



ns) is 0.25 ns, then the weighted slack will be 4/1 * 0.25 = 1 ns. If this is not intentional, you can do one of the following: change the FREQUENCY preferences at the source and destination clocks to adjust the clock-edge gap, use the "MULTICYCLE" on page 1235 preference to define the required time correctly, or use the "BLOCK" on page 1201 preference.

Device Support All

Syntax FREQUENCY <*frequency_value*> [HOLD_MARGIN <*time_spec*>] [CLOCK_JITTER <*time_spec*>];

FREQUENCY NET <*net_name*> <*frequency_value*> MHz | KHz [PAR_ADJ <*par_adj_number*>] [HOLD_MARGIN <*time_spec*>];

FREQUENCY PORT <*clk_port*> <*number*> <*freq_units*> [PAR_ADJ <*par_adj_number*>] [HOLD_MARGIN <*time_spec*>] [CLOCK_JITTER <*time_spec*>];

where:

<*clk_port*> ::= Name of top level clock signal port.

<*freq_units*> ::= MHz | KHz (defaults to MHz)

<*time_spec*> ::= <*number*> <*time_units*>; (defaults to MHz)

<*time_units*> ::= ms, us, ns, ps, fs (defaults to ns)

<*par_adj_number*> ::= Float value for the PAR preference adjustment. This is an absolute value used to adjust the frequency. Defaults to 0.0.

The PAR_ADJ keyword allows you to tighten requirements for placement and routing while preserving the requirements reported by the TRACE static timing analysis tool. The variance in required timing values used in PAR and TRACE allows you to experiment more efficiently with over-constraining your design to determine your best constraint settings for achieving the desired results.

Note

In Diamond, the timing score reported in the PAR report is also based on the actual constraint and not on the PAR_ADJ value.

Constraints will always be tightened when PAR_ADJ is used, and only positive values can be used for this keyword. In addition, you can only use absolute values, not percentages. See the examples below for acceptable usage.

The HOLD_MARGIN keyword allows you to specify a hold margin value per clock domain, in order to avoid possible hold time violations based on design constraints. A hold margin is a time allowance added to the hold time for a path that might be close to failing, as evidenced by timing analysis. Essentially, it allows you to over-constrain the design. When this keyword is present, TRACE will read the user-supplied hold time preferences and apply them to the timing analysis. TRACE will report any path as in violation that fails to meet both the path constraint and the required hold time margin. The hold margin time defaults to 0.0.

For example, TRACE reports a given path with a 1 ps hold margin. It is very likely that a given hold time path that passes at 1 ps will fail on the actual silicon, so a margin is necessary. Prior versions of TRACE would automatically add in a guard band for hold times; however, with the current built-in min/max timing, you should set this margin manually. Generally, adding hold time margins is done with a fixed value such as 200 ps per clock domain. Some clock domains might require less or more of a margin. Hold time margins cannot be achieved by adjusting the fMAX.

The CLOCK_JITTER keyword allows you to specify a peak-to-peak jitter value for the incoming clock and the system jitter affecting the clock port. CLOCK_JITTER is only available for a clock port.

Using Wildcards For the logical FREQUENCY preference, wildcard expressions are allowed for NETs. See “Using Wildcard Expressions in Preferences” on page 531 for details about wildcard usage and range expansion.

Examples The following preference assigns a frequency of 100 MHz to a net named clk1:

```
FREQUENCY NET "clk1" 100 MHz;
```

The following preference assigns a global frequency preference:

```
FREQUENCY 20 MHz;
```

The following preference assigns an adjusted PAR value so that PAR and TRACE timing requirements vary and create the desired results for place-and-route and timing reporting. The keyword PAR_ADJ uses the simple addition formula of 250 + 25 = 275 MHz to direct PAR, while running TRACE on the 250 MHz.

```
FREQUENCY NET "CLK1_c" 250.0 MHz PAR_ADJ 25 ;
```

The following logical preference specifies a hold margin value for each clock domain. It directs that any data path for this preference must meet hold time requirement by at least 1 ns. Those paths that meet the hold time by less than 1 ns will fail in the TRACE report.

```
FREQUENCY NET "RX_CLKA_CMOS_c" 100 MHz HOLD_MARGIN 1 ns;
```

The following logical preference specifies a frequency of 100 MHz to a port named CLK and a clock jitter of 1 ns. The jitter will affect both the rising edge and falling edge timing analysis.

```
FREQUENCY PORT "CLK" 100 MHz CLOCK_JITTER 1 ns ;
```

▶ "Setting TRACE Options" on page 693

GSR_NET

Assigns the specified net as the input to the global set/reset (GSR) buffer inferred by the design mapper (MAP). The GSR_NET preference allows you to specify the net to be applied as the GSR buffer input if more than one net qualifies to serve as the GSR signal.

GSR is a signal that will initialize all registered elements of the design that have the GSR input enabled. If no GSR buffer circuit is included in the input native generic database (NGD), by default, MAP will infer one based on the set/reset signal that has the most loads. To be considered a legal candidate, the net assigned using the GSR_NET preference must drive at least one registered element's set/reset input, and the element must be enabled to be sensitive to GSR.

MAP will ignore GSR_NET preferences if GSR inferencing is disabled (-noinferGSR).

Device Support All

Usage If a GSR buffer has not been included in the design's HDL or schematic source through the GSR library element, it can be inferred automatically by either logic synthesis or Diamond design mapper (MAP). In most scenarios, it is preferable to either instance the GSR buffer or depend on MAP to introduce a correct GSR buffer circuit.

Syntax GSR_NET NET <*net_name*>;

where:

<*net_name*> is a logical net.

Example If your design has multiple set/reset signals, and the automatic detection by logic synthesis or MAP chooses a GSR driver that's not appropriate for your design, you would use the syntax shown in the following example to explicitly assign a net to drive the GSR buffer circuit:

```
GSR_NET NET "rst_pcie";
```

HGROUP

Hierarchical grouping constraint. HGROUP is used to infer a unique placement group for each instance of an object from the logical domain, and it is commonly defined as part of a VHDL architecture or a Verilog module declaration. It indicates a logical partition of a group of components, which gets translated into a physical partition for placement and routing (PAR). HGROUPs are translated by the design mapper into PGROUPs, which direct the placer algorithm of PAR to place the group members in proximity.

The universal grouping constraint, UGROUP, is an alternative to HGROUP and is used to infer a single placement group composed of all instances of an object.

Device Support All

Usage You cannot enter an HGROUP directly in the Diamond preference-editing tools. You must specify an HGROUP definition as a logical preference in the logical preference file (.lpf) or as an HDL attribute in the HDL source files. If you place an HGROUP in an .lpf file, you will need to use the module name and hierarchy that is generated by the synthesis netlist. The reason is that the post-synthesis module name and hierarchy might be different than the name in the HDL. All the subsequent instances will have the HGROUP identifier as part of the normal elaboration performed by logic synthesis.

Note

Synthesis directives to preserve hierarchy are typically needed to retain the instances constrained by the HGROUP attribute.

In the design mapping phase, PGROUPs that are inferred from HGROUPs in the post-synthesis netlist appear in the schematic section of the physical preference file (.prf). Those inferred from the .lpf file appear in the section following the schematic section.

Syntax HGROUP <*hgroup_name*> [TYPE <*type_name*>] [BBOX <height width>];

where:

<*hgroup_name*> is a user-defined name of the HGROUP.

TYPE <*type_name*> Identifies the name of the type of block you are grouping. A given block type can only be assigned membership to one group, either an

HGROUP or an UGROUP. It cannot be in two or more groups at the same time.

BBOX <*height_width*> is used to optionally define the maximum height and width of the group's bounding box. Without a BBOX parameter, the place and route program will default to the minimal square that will accommodate the design logic.

Example Assume that you have defined a top-level block known as "ANEB2" that is instanced four times as "b1" "b2", "b3" and "b4." The .lpf file contains the following preferences:

```
HGROUP "h1" TYPE "ANEB2";
UGROUP "u1" BBOX 2 3 BLKNAME "b1" BLKNAME "b2";
```

This should result in an error condition, because "b1" and "b2" are part of the HGROUP "h1".

Now let us assume that the illegal UGROUP "u1" is removed from the example, and your HGROUP is as follows:

Figure 34:

```
HGROUP "h1" TYPE "ANEB2" BBOX 3 4;
```

After the design is mapped, your resulting .prf file will contain the following PGROUP in the schematic section:

```
PGROUP "h1" BBOX 3 4 DEVSIZE
    COMP "binst/SLICE_0"
    COMP "binst/SLICE_1"
    COMP "binst/SLICE_2"
    COMP "binst/SLICE_3";
```

HGROUPs and Diamond Preference Tools When Diamond encounters an HGROUP, it automatically infers one or more UGROUP instances and presents them as UGROUPs in the Group sheet of Spreadsheet View. If you modify a UGROUP, Diamond will add a new UGROUP declaration to the .lpf file and override the original inferred group.

The HGROUP preference can be applied on a particular block TYPE. All the subsequent block instances of the same type will have the HGROUP identifier. The identifier is then made unique for all the instances.

A given block can be assigned as a member of only one group, either an HGROUP or a UGROUP. See "Troubleshooting UGROUP Conflicts" on page 1264 for information about how the software processes conflicting groups that might appear in the .lpf file.

See Also "UGROUP" on page 1262 (preference)

"UGROUP" on page 1328 (HDL attribute)

I2C ADDRESS

Every slave device, connected to the I2C bus, must have an unique I2C address. The I2C address can be either 7-bits or 10-bits long.

In 7-bit I2C Addressing the first byte (immediately after the START condition) contains the I2C slave address. The I2C address is 7-bits long. It is transmitted in the seven most significant bits (MSB). The last (eighth bit) of the I2C address byte is a data direction bit - a 'zero' indicates a transmission (I2C WRITE), a 'one' indicates a request for data (I2C READ).

With 7-bit addressing only 112 I2C slave addresses are available. To prevent address clashes Philips Semiconductors (now NXP Semiconductors) has introduced a 10 bit address scheme. Devices with 7-bit and 10-bit addresses can be connected to the same I2C-bus.

The 10-bit address is transmitted within the first two bytes following a START condition or a repeated START condition.

Five most significant bits of the first address byte are predefined (1111 0). I2C slave devices with 7-bit addressing ignore transactions with the first byte in the form of '1111 0XXX'.

The I2C address occupies bits 5 and 6 of the first byte and the eight bits of the second byte.

The transfer direction (read or write) is specified in the eighth bit of the first byte. As in the case of 7-bit I2C address, a 'zero' indicates a transmission (I2C WRITE), a 'one' indicates a request for data (I2C READ).

Slave devices with 10-bit I2C addressing will react to a general call in the same way as slave devices with 7-bit I2C addressing. I2C master devices can transmit the 10-bit I2C address after a general call.

The primary I2C port of the CrossLink device can be used as a user I2C port function or as a device programming port. When used for device programming, the primary I2C port is a slave I2C with a default slave address of 7'b1000000 or 10'b1111000000. The primary I2C port must be enabled in order to support the device programming using the I2C protocol.

Device Support All

Syntax I2CADDRESS 7/10BIT <*binary_string*>;

where:

<*binary_string*> ::= binary value of up to 10 bits

Example `I2CADDRESS 10BIT "11111000";`

INPUT_SETUP

Specifies a setup time requirement for input ports relative to a clock net.

Device Support All

Syntax INPUT_SETUP (PORT <*port_name*> | GROUP <*group_name*> | ALLPORTS)
(<*time_spec*> | INPUT_DELAY <*time_spec*>)
[HOLD <*time_spec*>]
((CLKPORT [=] <*clk_portname*>) | (CLKNET [=] <*clk_netname*>))
[PLL_PHASE_BACK]
[CLK_OFFSET <n> X]
[SS];

where:

PORT <*port_name*>: uses the name of a top-level port to specify the data path.

GROUP <*group_name*> is a given group definition you defined with the DEFINE GROUP preference.

ALLPORTS designates that all input ports in the given clock port/net path are affected by the time value specified.

<*time_spec*> ::= <*number*> <*time_unit*>

<*time_unit*> ::= MS | US | NS | PS | FS

(Refer to Units section of Preference Syntax Guidelines and Conventions.)

INPUT_DELAY is an alternate form to define this input timing constraint, where the time value is independent of the frequency/period. As an example, the two constraints below are equivalent if the clock period is 10ns, since 4 = 10-6. For hold time, the software will take the negative of the value you have set for HOLD <*time_spec*> as the HOLD offset.

```
INPUT_SETUP in_data1 INPUT_DELAY 6 CLKPORT clk;
INPUT_SETUP in_data1 4 CLKPORT clk;
```

If the clock period constraint value changes, the input constraint that uses the INPUT_DELAY keyword does not need to be changed, whereas the input constraint that does not use INPUT_DELAY should be changed.

See the example for INPUT_DELAY.

HOLD <time_spec>: specifies the hold time.

CLKPORT=<*clkin_portname*> uses a port name to specify the reference clock.

CLKNET=<*clkin_netname*> uses a net name to specify the reference clock.

PLL_PHASE_BACK reverses the offset direction of phase delay programmed into a PLL. For example, you might program a PPLL/HPPLL to delay the clock phase by 7/8ths of its cycle. Then the Trace Timing Wizard™ will add 7/8ths of a cycle to the clock insertion delay. However, The PLL_PHASE_BACK

keyword directs the Trace Timing Wizard to subtract 1/8th (7/8 -1 = -1/8) of a cycle from the clock insertion delay.

When two PLL's are cascaded, the scenarios will become more complex, especially with PLL Bypass. However, as a general rule, if a PLL_PHASE_BACK is applied to a cascaded PLL chain of two and none of the PLL's are bypassed or with zero phase shift, then the result will be the same as if PLL_PHASE_BACK had been applied to each of them individually. If one of them is bypassed or with zero phase shift, the effective result will be the same as if PLL_PHASE_BACK had not been applied to that PLL.

CLK_OFFSET <n> X: adjusts the analysis by a multiple of the clock period. The input_setup path timing will be adjusted by:

<*n*> ::= floating point number and can be negative.

Since <*n*> can be a floating point number, this can be used to pick the opposite clock edge for the analysis. The analysis will adjust automatically to changes to the clock's frequency or period specification. If this option is not specified, the default value of n=0 is assumed, meaning that no adjustment is made, and the edge at the pin is the edge used in the analysis. One use of this is in the analysis of a set of input registers on a clock domain where some registers are positive edge active and others are negative edge active.

SS: indicates that the data input and clock input are source-synchronous. This allows input jitter specified on the clock to be ignored for setup and hold timing analysis.

Using Wildcards For the logical INPUT_SETUP preference, PORT names with wildcard expressions are allowed. See "Using Wildcard Expressions in Preferences" on page 531 for details about wildcard usage and range expansion.

Examples The following examples show usage that specifies absolute time values:

```
INPUT_SETUP ALLPORTS 10 NS CLKNET="n28";
INPUT_SETUP LOCAL_CMD* 10 ns CLKNET="n28";
INPUT_SETUP "a_1" 4 ns CLKNET "clk3";
```

Given a PERIOD and INPUT_SETUP preference that uses the INPUT_DELAY keyword to place a specific relative time value that is frequency/period dependent, the preference might appear as follows:

```
PERIOD PORT "clk" 104 ns ;
INPUT_SETUP PORT "in1" INPUT_DELAY 6 ns CLKPORT "clk" ;
INPUT_SETUP PORT "in2" 4 ns CLKPORT "clk";
```

Both in1 and in2 have the same input constraint.

The following example uses the CLK_OFFSET option.

```
INPUT_SETUP PORT “RESP_REQ” 4 NS CLKPORT = "clock" CLK_OFFSET
0.5X ;
```

An additional half period of the clock will be used in the analysis. This would be appropriate for a negative edge triggered flop that is capturing the input from port RESP_REQ. The constraint is that RESP_REQ will arrive at the device pin at least 4ns prior to rising edge of “clock”, and the analysis will test whether the data arrives at the capturing flop in enough time prior to the negative edge of the clock signal at the flop. 0.5 X will analyze the negative clock edge after the rising clock edge arrives at the flop from the device pin, meaning an additional half period will be added to the clock to out path.

This next example also uses the CLK_OFFSET option.

```
INPUT_SETUP PORT RESP_REQ 4 NS CLKPORT = "clock" CLK_OFFSET
0.5X ;
```

In this example, -0.5 X will analyze the negative clock edge before the rising clock edge arrives at the flop from the device pin, which means that half a clock period will be subtracted from the clock to out path.

The following example uses the SS option.

```
INPUT_SETUP PORT “datain_0” 0.480000 ns HOLD 0.480000 ns
CLKPORT “CLK” SS;
```

In this example, any input jitter specified on clock port “CLK” will be ignored for both INPUT_SETUP and HOLD analysis.

IOBUF

Defines I/O components.

Device Support All

Note

The only preferences that are not written to the physical preference file (.prf) are IOBUF preferences. This information resides in the physical design (.ncd) file only.

Syntax IOBUF [ALLPORTS] (<*keyword*>=<*value*>)+;

IOBUF [PORT <*port_name*> | GROUP <*group_name*>]
[VREF=<*vref_name*>](<*keyword*>=<*value*>)+;

IOBUF GROUP <*group_name*> (*group_keyword*=*value*)+;

[LOCATE VREF <*vref_name*> SITE <*site_name*>;]

where:

<*port_name*> = string. These are not the actual top-level port names but the signal name attached to the port. PIOs in the physical design (.ncd) file are named using this convention. Any multiple listings or wildcards should be done using GROUPs.

<*group_name*> = string

<keyword> (LatticeECP/EC/XP) ::= IO_TYPE, DRIVE, PULLMODE, SLEWRATE.

group_keyword = string.

<*site_name*> = string

<*vref_name*> = string <*keyword*> (LatticeECP3) ::= IO_TYPE, OPENDRAIN, DRIVE, PULLMODE, PCICLAMP, SLEWRATE, TERMINATEVTT, DIFFRESISTOR, DIFFDRIVE, MULTDRIVE, EQ_CAL

For the IOBUF ALLPORTS preference, any possible sub-attributes of IOBUF, such as IO_TYPE, SLEWRATE, and DIFFCURRENT, will only take effect on buffers that have no other specific IOBUF preferences placed upon them. This is because of the preference precedence rule: more specific preferences override more generally applied ones. For example, in an .lpf file there is a set of the following preferences:

```
IOBUF ALLPORTS SLEWRATE="FAST";
IOBUF PORT ichk IO_TYPE=HSTL15_II SLEWRATE="NA";
IOBUF PORT bchk IO_TYPE=HSTL15_II ;
IOBUF PORT ochk IO_TYPE=LVDS SLEWRATE="NA";
```

The global SLEWRATE "FAST" override in this example will not be applied to the I/O buffer port named "bchk," because there is an explicit IOBUF preference ascribed to it. Consequently, the software will interpret any possible missing sub-attributes by their default conditions. So, a SLEWRATE=SLOW is applied in the resulting .ncd file for the "bchk" buffer. To get the desired results of a fast slew rate, you would have to edit that one particular preference to include the explicit slew rate value on that line. For example,

```
IOBUF PORT bchk IO_TYPE=HSTL15_II SLEWRATE="FAST";
```

The precedence rule applies to the preferences as a whole and not on a per-attribute basis. You cannot use a global (ALLPORTS) preference to override part of a specific IOBUF PORT preference. See “Preference Conflict Resolution” on page 393.

Using Wildcards Wildcards can be used with port names to create a DEFINE PORT GROUP preference, after which IOBUF attributes can be assigned to the entire group. The use of the “*” wildcard, which serves a purpose similar to the ALLPORTS preference, can be used with DEFINE PORT GROUP to assign I/O defaults for all ports in the design. See “Defining I/O Defaults” on page 473.

```
DEFINE PORT GROUP "bank1" "in*" "out_[0-31]";
IOBUF GROUP "bank1" IO_TYPE=SSTL18_II IMPEDANCE=33
TERMINATEVCCIO=120 TERMINATEGND=120;

DEFINE PORT GROUP "all_ports" "*" ;
IOBUF GROUP "all_ports" IO_TYPE=LVCMOS18 PULLMODE=DOWN ;
```

See “Using Wildcard Expressions in Preferences” on page 531 for details about wildcard usage and range expansion.

See Also ▶“IOBUF Attributes” on page 476

▶ “DEFINE GROUP” on page 1213

LOCATE

When applied to a specified component, places the component at a specified site or bank and locks the component to the site or bank. This means that the component will not be unplaced, moved, swapped, or deleted.

When applied to a specified group of instances, places the group at a specified site or within a region. Refer to the “UGROUP” on page 1262 preference topic.

Device Support All

Syntax LOCATE COMP <*comp_name*> [SITE<*site_name*> | BANK<bank_num;] LOCATE [UGROUP <*ugroup_name*>] [SITE <*site_name*> | REGION <*region_name*>;]

where:

<*comp_name*> ::= string
<*site_name*> ::= string
<*bank_num*> ::= number
<*ugroup_name*> ::= string
<*region_name*> ::= string

You can LOCATE a given UGROUP within a specified region. The placer can place it anywhere within the boundary of the region. If the region is not defined in the .lpf file before the LOCATE UGROUP definition, you will encounter error messages.

You can also LOCATE a given UGROUP at a particular site. The specified site can be a slice site or an EBR site. If you use a slice site, the slice name must end with the letter D; for example, R2C2D. Slice sites come in groups of four, and the four site names end with the letters A, B, C, and D respectively.

This specified site will become the upper left corner anchor location where the logic in the UGROUP will be placed.

Examples

```
LOCATE COMP "A" SITE "11" ;  // IO site

LOCATE COMP "A" BANK 2 ;

LOCATE COMP "inst1/PLLInst_0" SITE "PLL_R43C5" ;

LOCATE UGROUP "ugroup_0" SITE "R2C2D" ;//note that ‘D’ site is
the anchor

REGION “my_region” “R3C3D” 17 9;

LOCATE UGROUP "xyz_ugroup" SITE "my_region" ;
```

If the <*comp_name*> or <*site_name*> begins with anything other than an alpha character (for example, “11C7”), you must enclose the name in quotes.

See Also ▶“LOCATE VREF” on page 1228

LOCATE VREF

Assigns a PIO site that will serve as the input pin for an on-chip voltage reference. Referenced input voltage pins are required when implementing an externally referenced signaling standard such as HSTL or SSTL. After the Vref location has been established, it can be associated with a port group.

Device Support All

Syntax LOCATE VREF <*vref_name*> SITE <*site_name*> [RAIL <*rail_number*>] IOTYPE <iotype value>;

where:

<*vref_name*> ::= string

<*rail_num*> ::= integer or [Vref1|Vref2] (LatticeSC/M only)

<*iotype_value*> ::= [HSTL18_I | HTSL18_II | HSTL15_I | SSTL33_I | SSTL3D_II | SSTL25_I, SSTAL25_II, SSTL18_I | SSTL18_II]

For more details regarding I/O type, see the sysIO Usage Guide for your target device family.

For LatticeSC/M devices, each bank can support up to two separate VREF input voltages, VREF1 and VREF2, that set the threshold for the referenced input buffers. Any I/O in the bank can potentially be used to input a VREF voltage. Once the I/O pin within the bank becomes the external VREF input pin, it is no longer available for use as an I/O. If differential outputs that require external bias are implemented in a bank, then the VREF1 of that bank will be used to provide this bias. This VREF1 pin can no longer be available as a VREF pin. For more information, see the LatticeSC PURESPEED I/O Usage Guide, TN1088)

Note

The LOCATE VREF <*vref_name*> preference is not available for MachXO devices.

The LOCATE VREF <*vref_name*> RAIL <*rail_num*> preference is available only for LatticeSC/M devices.

Example – Associate VREF by Signaling Standard This LOCATE preference, in the .lpf file, establishes the N21 pin as a voltage reference named VREF1_BANK_3:

```
LOCATE VREF "VREF1_BANK_3" SITE "N21" IOTYPE "SSTL18_I";
```

The following DEFINE PORT GROUP “d1_group” and IOBUF GROUP create a user-defined alias for d1_0-d1_7 and assign the port group signal standard SSTL18_I.

```
DEFINE PORT GROUP "d1_group" "d1_0"
"d1_1"
"d1_2"
"d1_3"
"d1_4"
"d1_5"
"d1_6"
"d1_7" ;
IOBUF GROUP "d1_group" IO_TYPE=SSTL18_I ;
```

After map the .prf file will contain the following preferences.

Example – Associate VREF with a PORT GROUP This LOCATE preference, in the .lpf file, establishes the D11 pin as a voltage reference named vref_a:

This example, in the .lpf file, defines a port group as “group_a” and assigns it the “vref_a” voltage reference:

```
SCHEMATIC START;
PGROUP "group_a" VREF "VREF1_BANK_3"
COMP "d0_4"
COMP "d0_3"
COMP "d0_2"
COMP "d0_1"
COMP "d0_0";
SCHEMATIC END;
LOCATE VREF "VREF1_BANK_3" SITE "N21";
```

```
LOCATE VREF "vref_a" SITE "D11" ;
```

```
DEFINE PORT GROUP "group_a" "d0_0"
"d0_1"
"d0_2"
"d0_3"
"d0_4" ;
IOBUF GROUP "group_a" IO_TYPE=SSTL18_I VREF=vref_a ;
```

Diamond displays this information in Spreadsheet View. The Spreadsheet View's Port Assignments sheet enables you to set up a Vref location and afterwards assign it to an input port or port group by simply right-clicking in the Vref column.

After map, the .prf file will contain the following preferences:

```
SCHEMATIC START;
PGROUP "group_a" VREF "vref_a"
  COMP "d0_4"
  COMP "d0_3"
  COMP "d0_2"
  COMP "d0_1"
  COMP "d0_0";
SCHEMATIC END ;
COMMERCIAL ;
LOCATE VREF "vref_a" SITE "D11" ;
LOCATE VREF "vref_b" SITE "Y7" ;
DEFINE PORT GROUP "group_a" "d0_0"
"d0_1"
"d0_2"
"d0_3"
"d0_4" ;
```

MAXDELAY

Identifies a maximum total delay for a net, bus, or path in the design. When a net is specified, the maximum delay constraint applies to all driver-to-load connections on the net. When a path is specified, the delay value is the constraint for the path including net and component delays as defined by the pathspec rules.

Note

When the path is from register to register, the constraint time is the cycle time of frequency. The software will automatically take care of the half-cycle if the polarity at the source register is different from the destination register.

When a bus is specified, the delay value is for driver-to-load connections on the nets that belong to the specified bus.

Device Support All

Syntax MAXDELAY <*path_spec*> <*time_spec*> [DATAPATH_ONLY] MIN <*value*>ns;

MAXDELAY [NET <*net_name*> | BUS <*bus_name*> | ALLPATHS | ALLNETS] <*time_spec*>;

where:

<*path_spec*> ::= FROM <*path_elem*> [TO <*path_elem*>] | TO <*path_elem*>

Note

It is recommended that you always specify both the start point and end point of the path. If you do not select a component for both FROM and TO, the default for the unspecified path element will include all I/O ports and registers, which is similar to the preference FREQUENCY. If the BLOCK ASYNCPATH preference is set to ON, all input-pad-to-register paths will be removed for the unspecified start point or end point, in the same way as the preference FREQUENCY

<*path_elem*> ::= <*obj_type*> <*obj_name*>
| ASIC <*block_name*> PIN <*pin_name*>

<*obj_type*> ::= CELL | PORT | GROUP

<*obj_name*> ::= identifier

<*block_name*> ::= identifier

<*pin_name*> ::= identifier

<*time_spec*> ::= <*number*> <*time_unit*> (Refer to the units section of Preference Syntax Guidelines and Conventions.)

DATAPATH_ONLY ::= This is an optional parameter to report only data path delay information. When the DATAPATH_ONLY keyword is used, the preference will only include the data path delay and clock skew and/or a setup/hold requirement will be ignored.

MIN <*value*>ns ::= Sets minimum delay value for hold analysis to allow for bus skew.

Note

The MIN keyword is not supported for NET, BUS, ALLNETS, and ALLPATHS.

The ALLNETS | ALLPATHS command establishes a maximum total delay for all nets or all paths in the design. If ALLNETS is specified, the maximum delay constraint applies to all driver-to-load connections on all nets. If ALLPATHS is specified, the delay value is the constraint for all paths.

The MIN keyword uses a time specification parameter, such as 1 ns, as a directive to TRACE timing analysis. It instructs TRACE to use this value for hold analysis when it is doing a hold check for the MAXDELAY preference.

MAXDELAY can be applied only to registers, block pins and other I/Os. It should not be applied to QN outputs of a flip-flop. Since no QN output exists in hardware, the flip-flop is decomposed into using the non-inverted output driving an inverter. If a MAXDELAY is attached to the flip-flop, then both decomposed elements will inherit the MAXDELAY preference.

Note

There might be times when you need to apply a timing preference, such as MULTICYCLE or MAXDELAY, that requires specification of CELL or ASIC; but you are not sure whether the specific instance is an ASIC or a CELL. In these situations, run the Map Report, which lists all ASICS in the “ASIC Components” section. All other registers in the report are CELLs.

Using Wildcards For the logical MAXDELAY preference, CELL and PORT names with wildcard expressions are allowed. See “Using Wildcard Expressions in Preferences” on page 531 for details about wildcard usage and range expansion.

Examples

```
MAXDELAY FROM CELL "BLKWR_SM_1/state_reg4"
 TO CELL "R5_MUX_1/RAM_OE_N_reg" 15 NS;

MAXDELAY FROM PORT "LOCAL_CMD0" TO CELL
 "R5_MUX_1/RAM_OE_N_reg" 16 NS;

MAXDELAY FROM CELL "BLKWR_SM_1/state_reg4"
 TO PORT "RAM_RD" 17 NS;

MAXDELAY FROM PORT "LOCAL_CMD0" TO PORT "RAM_RD" 18 NS;

MAXDELAY FROM ASIC block_8x850 PIN D0
 TO CELL THIS_IN 12 ns;

MAXDELAY FROM GROUP "asic1group" 10 ns;
```

This preference sets a minimum delay value of 2 nanoseconds for hold analysis.

```
MAXDELAY FROM PORT "a1" to PORT "d1" 5 ns MIN 2 ns ;
```

See Also ▶"Setting TRACE Options" on page 693

MAXSKEW

Specifies a maximum signal skew between a driver and the driver's loads on a specified clock signal. Skew is the difference between minimum and maximum load delays on a clock net. If no signal is specified, MAXSKEW applies to all signals that have clock pins as loads and do not have a specified skew preference.

Device Support All

Syntax MAXSKEW [NET <*net_name*> | PORT <*port_name*> | BUS <*bus_name*>] <*time_spec*> [CLOCKLOAD_ONLY];

If no net is specified, the MAXSKEW constraint applies to all nets.

where:

<*net_name*> | <*bus_name*> | <*port_name*> ::= identifier

<*time_spec*> ::= <*number*> <*time_unit*> (Refer to "Preference Syntax Guidelines and Conventions" on page 525.)

BUS ::= The BUS keyword can be used with MAXSKEW for phase aligning two clocks from the same source, such as a PLL, and meeting a maximum skew between them at the destination registers.

CLOCKLOAD_ONLY ::= This keyword filters out the TRACE report to show only clock destination skews, meaning that it provides an analysis of the clock tree for clock loads only. A clock load means an end point that is used as a clock of a component such as register and does not include a clock generator or mux input.

Examples The following command assigns a maximum skew of 5 nanoseconds to a net named NetB:

```
MAXSKEW NET "NetB" 5 NS;
```

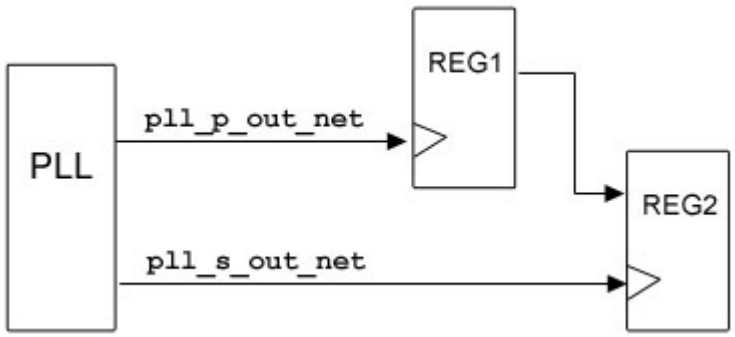
In the following PLL example, "busA" has been defined through the DEFINE BUS preference as

```
DEFINE BUS "busA" NET "pll_p_out_net" NET "pll_s_out_net"
```

This BUS attribute is then used with MAXSKEW to constrain the worst case skew between CLKNET "pll_p_out_net" and "pll_s_out_net." This controls the routing delay for all clock loads. The following command will constrain the skew between Clock nets pll_p_out_net and pll_s_out_net to 1.1 ns:

```
MAXSKEW BUS "busA" 1.1 NS CLOCKLOAD_ONLY;
```

Figure 35:



```
MAXSKEW PORT "NetP" 10 NS;
```

```
MAXSKEW PORT "net1" 4 NS CLOCKLOAD_ONLY;
```

MULTICYCLE

Allows for relaxation of previously defined PERIOD or FREQUENCY constraints on a path.

The MULTICYCLE preference applies only to paths that are covered by the FREQUENCY and PERIOD constraints. It is considered in conjunction with the FREQUENCY and PERIOD constraints specified and will relax ONLY those paths that are constrained by FREQUENCY and PERIOD. Specifying a MULTICYCLE preference without a FREQUENCY or PERIOD preference will not result in paths being timed.

Paths that are not within the domain of the FREQUENCY and PERIOD preference should be constrained by MAXDELAY and not MULTICYCLE.

Device Support All

Recommendation for maximum efficiency: Try to specify all path-based timing constraints in terms of FREQUENCY, MULTICYCLE, CLOCK_TO_OUT, and INPUT_SETUP. If you cannot specify the desired constraints in terms of these preferences, then only use the MAXDELAY and BLOCK PATH preferences where absolutely necessary.

Specifying Multiples Less Than or Equal to Zero for Hold Analysis The MULTICYCLE preference allows you to specify a multiple that is less than or equal to zero. This is useful for hold time analysis.

A typical timing analysis setup time is calculated from a source clock to the next clock cycle of the destination clock. A hold time is calculated from a source clock to the same clock cycle of the destination clock. The MULTICYCLE preference can select how many clock cycles are required for a given path. For example, 2x will allow 2 clock cycles for setup. Therefore, a 0x

will use 0 clock cycles for setup, which simply calculates clock skew. A negative value such as -1x will subtract a clock cycle from the clock skew.

Traditionally, MULTICYCLE is not used for hold analysis. With this feature, the same logic applies to hold analysis, but since hold analysis already only looks at clock skew, a 0x will subtract a clock cycle from the analysis. A -1x will subtract 2 clock cycles from the analysis. This ability to specify less than or equal to zero multicycles should only be used to block paths from timing analysis that are known to have desirable timing. It should only be used for filtering the reports and not for driving place and route.

Syntax MULTICYCLE
[FROM <*path_elem*>] [CLKNET <*Snet*>] [<*path_types*>]
[TO <*path_elem*>][CLKNET <*Dnet*>] <*multiplier*> | <*number NS*>;

where:

<path_elem> :==<obj_type> <obj_name> | ASIC <block_name> PIN <pin_name>

<*obj_type*> ::= CELL | PORT | GROUP

<*obj_name*> ::= identifier

<*block_name*> ::= identifier

<*pin_name*> ::= identifier

<*path_type*> ::= SAMECLKEN | CLKEN_NET <*net_name*> net

SAMECLKEN: the multicycle paths are defined at the source/destination register controlled by the same clock-enable signal.

CLKEN_NET: the multicycle paths are defined at the source/destination register controlled by a given <net_name>.

<*multiplier*> ::= <*factor*> <X | X_SOURCE | X_DEST>

<*multiplier*> is a multiple of the clock period for the clock driving the comp(s). Destination clock period will be applied to the factor when X or X_DEST is used. Source clock period will be applied when X_SOURCE is used.

<*number NS*> is a delay value for the path in nanoseconds.

Note

There might be times when you need to apply a timing preference, such as MULTICYCLE or MAXDELAY, that requires specification of CELL or ASIC; but you are not sure whether the specific instance is an ASIC or a CELL. In these situations, run the Map Report, which lists all ASICS in the “ASIC Components” section. All other registers in the report are CELLs.

Using Wildcards For the MULTICYCLE preference, PORT or CELL names with wildcard expressions are allowed. Like the physical MULTICYCLE preference, this accepts optional CLKNET Snet as Dnet. See “Using Wildcard Expressions in Preferences” on page 531 for details about wildcard usage and range expansion.

Examples When specifying source and destination clock domains, use the keyword CLKNET followed by the clock net name. The multicycle preference will be applied only if the source and destination clock matches the specification. Clock domains can be looked upon as added qualifiers to multicycle.

When nX is used, the constraint is shifted by (n-1) times the source or destination clock period, depending on which keyword is used. When 1X is used, the constraint is shifted by (1 - 1) * period = 0, which makes it the same as in a FREQUENCY preference. When 3X is used, the constraint is shifted by (3 - 1) * period.

In the following command, the X keyword equals X_DEST and uses a factor of 2. If the source clock period is 20 ns and the destination clock period is 40 ns, then the timing constraint for this preference is 20 + (2-1) * 40 = 60 ns.

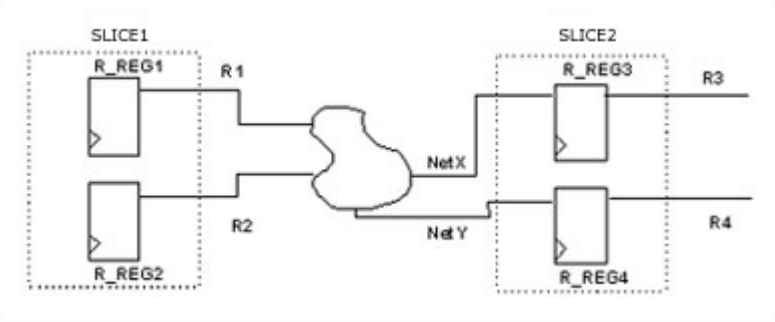
```
MULTICYCLE FROM CLKNET "clk1" TO CLKNET "clk2" 2 X ;
```

The following command will multicycle from R_REG1 to R_REG3 but not from R_REG2.

```
MULTICYCLE FROM CELL "R_REG1" TO CELL "R_REG3" 2 X ;
```

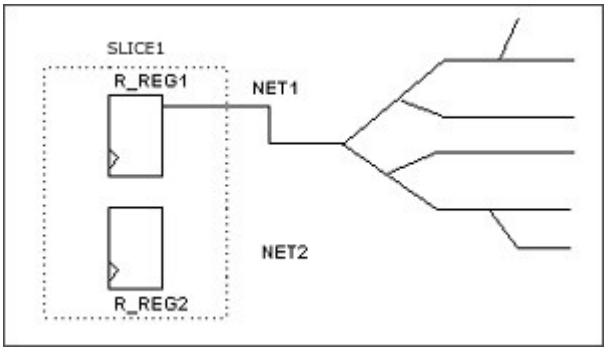
The following command will multicycle from R_REG1 to R_REG3 but not to R_REG4.

```
MULTICYCLE FROM CELL "R_REG1" TO CELL "R_REG3" 2 X ;
```



The following command will multicycle from R_REG1 to all.

```
MULTICYCLE FROM CELL "R_REG1" 2 X ;
```



```
MULTICYCLE FROM GROUP slow_group 3 X;
MULTICYCLE FROM GROUP fast_ins 1 X;
MULTICYCLE TO GROUP "asic2group" 10 ns;
```

```
MULTICYCLE FROM ASIC block_8x850 PIN D0 CLKNET clk100 8 ns;

MULTICYCLE FROM ASIC block_8x850 PIN INT* CLKNET clk100 9 ns;
```

```
MULTICYCLE TO CELL "data_out*" 2 X;
MULTICYCLE FROM CELL "compare*" 5 X ;
```

OUTPUT LOAD

Used to modify loading on output buffers from the default 0 pFs for timing analysis.

Note

This preferences is valid for all FPGAs. However, it applies only to certain I/O buffer types, generally xxCMOS and xxTTL, and to those that are only supported through hardware data within each device family. Refer to technical support.

OUTPUT LOAD is not interpreted by the Diamond Power Calculator for power estimation. Power Calculator allows you to model the average capacitance loading on outputs using the Cload parameter (default 5 pF). See the "I/O" on page 762 section of the Power Calculator online Help for more information.

Device Support All

Syntax OUTPUT [ALLPORTS | PORT <*port_name*> | GROUP <*group_name*>]
LOAD <*capacitance*> ;

where:

<*capacitance*> ::= <*number*> [mF | uF | nF | pF | fF] (Refer to the Units section of "Preference Syntax Guidelines and Conventions" on page 525.)

Note

The use of wildcards is supported for port name identifiers.

PERIOD

Identifies a clock period for all sequential output to sequential input pins clocked by the specified net or port. If no net or port name is given, the specified clock period will apply to all sequential input pins that do not have a specific clock period preference. The period preference allows you to verify sequential data paths internal to the design. It works the same way as the frequency preference, except that time is specified in seconds instead of Hz.

Device Support All

Syntax PERIOD <*time_spec*> [[LOW | HIGH] <*time_spec*> [(LOW | HIGH) <*time_spec*>]] [HOLD_MARGIN <*time_spec*>] [CLOCK_JITTER <*time_spec*>];

PERIOD NET <*net_name*> <*time_spec*> [[LOW | HIGH] <*time_spec*> [(LOW | HIGH) <*time_spec*>]] [PAR_ADJ <*par_adj_number*>] [HOLD_MARGIN <*time_spec*>];

PERIOD PORT <*port_name*> <*time_spec*> [<*polarity*> <*time_spec*> [<*polarity*> <*time_spec*>]] [PAR_ADJ

<*par_adj_number*>] [HOLD_MARGIN <*time_spec*>] [CLOCK_JITTER <*time_spec*>];

where:

<*time_spec*> ::= <*number*> <*time_units*>; (defaults to MHz)

<*polarity*> ::= LOW | HIGH

LOW | HIGH <*time_spec*> specifies pulse width and polarity, effectively allowing you to specify high/low duty cycle and phase.

<*par_adj_number*> ::= Float value for the PAR preference adjustment. This is an absolute value used to adjust the frequency. Defaults to 0.0.

The PAR_ADJ keyword allows you to tighten requirements for placement and routing while preserving the requirements reported by the TRACE static timing analysis tool. The variance in required timing values used in PAR and TRACE allows you to experiment more efficiently with over-constraining your design to determine your best constraint settings for achieving the desired results.

Note

In Diamond, the timing score reported in the PAR report is also based on the actual constraint and not on the PAR_ADJ value.

Constraints will always be tightened when PAR_ADJ is used, and only positive values can by used for this keyword. You can only use absolute values, not percentages. See the examples below for acceptable usage.

The HOLD_MARGIN keyword allows you to specify a hold margin value per clock domain to avoid possible hold time violations based on design constraints. A hold margin is an allowance of additional hold time for a given path that might be close to failing, as evidenced by timing analysis. It allows you to over-constrain the design. When this keyword is present, TRACE will read the user-supplied hold time preferences and apply them to the timing analysis. TRACE will report any path as in violation that fails to meet both the path constraint and the required hold time margin. The hold margin time defaults to 0.0.

For example, TRACE reports a given path with a 1 ps hold margin. It is very likely that a given hold time path that passes at 1 ps will fail on the actual silicon, so a margin is necessary. Prior versions of TRACE would automatically add in a guard band for hold times; however, with the current built-in min/max timing, you should set this margin manually. Generally, adding hold time margins is done with a fixed value such as 200 ps per clock domain. Some clock domains might require less or more of a margin. Hold time margins cannot be achieved by adjusting the fMAX.

The CLOCK_JITTER keyword allows you to specify a peak-to-peak jitter value for the incoming clock and the system jitter affecting the clock port. CLOCK_JITTER is only available for clock ports.

Using Wildcards For the logical PERIOD preference, wildcard expressions are allowed for NETs and PORTs. See “Using Wildcard Expressions in Preferences” on page 531 for details about wildcard usage and range expansion.

Examples The following example assigns a clock period of 100 nanoseconds to the net named NetA, with the first pulse being high with a duration of 75 ns:

```
PERIOD NET "NetA" 100 NS HIGH 75 NS;
```

The following example assigns a clock period of 30 nanoseconds to the port named Clk1:

```
PERIOD PORT "Clk1" 30 NS;
```

The following example assigns an adjusted PAR value so that PAR and TRACE timing requirements vary and create desired results for place-and-route and timing reporting. The preference keyword PAR_ADJ in the following preference uses the simple subtraction formula of 5 - 0.5 = 4.5 ns to direct PAR, while TRACE is running on the 5 ns value:

```
PERIOD NET "CLK2_c" 5 ns PAR_ADJ 0.5 ;
```

The following preferences show how the adjusted PAR value interacts with the polarity (HIGH/LOW) parameters. The two example lines both indicate a waveform of 60 percent duty cycle: 100 PERIOD with 60 HIGH, and 90 PERIOD with 54 HIGH. The PAR_ADJ in the first preference causes PAR to reduce the PERIOD by 10 ns, or 10 percent. Similarly, PAR will then reduce the HIGH time by 10 percent. Therefore the two preferences are equivalent in PAR. TRACE (**trce**) will still treat the first preference as 100 ns / 60 ns.

```
PERIOD NET  "CLK3" 100 ns  HIGH 60 ns  PAR_ADJ 10;
PERIOD NET  "CLK3" 90 ns  HIGH 54 ns
```

The following example specifies a hold margin value for each clock domain:

```
PERIOD NET "RX_CLKA_CMOS_c" 10.000 ns HOLD_MARGIN 1 ns;
```

This preference directs that any data path must meet the hold time requirement by at least 1 ns. Those paths that meet the hold time by less than 1 ns will fail in the TRACE report.

The following example assigns a clock period of 30 ns to a port named clk1 and a clock jitter of 1 ns. The jitter will affect both the rising edge and falling edge timing analysis.

```
PERIOD PORT "clk1" 30 ns CLOCK_JITTER 1 ns ;
```

See Also ▶"SYSTEM_JITTER" on page 1260

PRIORITIZE

Assigns a weighted importance to a net or bus. Values range from 0 (lowest priority) to 100 (highest). The default is 3. Any net with a priority of 3 is not considered critical and will not cause a preference to be generated. The PRIORITIZE preference is used by PAR, which assigns long lines by net priority and routes higher-priority nets before routing lower-priority nets. The PRIORITIZE preference is also used by BITGEN to determine which nets not to use for tiedown. A net with a priority greater than 3 will only be used for tiedown as a last resort.

Device Support All

Syntax PRIORITIZE NET <*net_name*> ;

PRIORITIZE BUS <*bus_name*> 0-100;

Example The following command assigns a priority of 10 to a net named NetB:

```
PRIORITIZE NET "NetB" 10;
```

This change will merely give the specified net "first priority" over clock nets with lower priorities. It will not guarantee that the net will be awarded a clock spine. The preference will resolve ordering of clock nets, but will NOT force a net to get a clock spine if doing so would dislodge a tristate bus.

PROHIBIT

Prohibits the use of a site within PAR.

Device Support All

Syntax PROHIBIT SITE <*site_name*>**;**

PROHIBIT REGION <*region_name*>;

Examples The following command prohibits a site named AB from being used:

```
PROHIBIT SITE "AB";
```

Note

The term FF is a keyword. Any reference to a design element named "FF" must be placed within quotation marks. For example, PROHIBIT SITE "FF";

The following command prohibits a region named reg1 from being defined in the design:

```
REGION "reg1" R2C3 4 5;
PROHIBIT REGION "reg1";
```

PROHIBIT EDGE

Prohibits the use of edge spine resources for routing the net. The edge spine can drive clocks, CEs, resets, or any combination. This preference can only be used for devices with edge clock routing in the architecture.

Device Support LatticeECP/2M

Syntax PROHIBIT EDGE NET <*net_name*>;

where:

<*net_name*> = string

Example This command prohibits the use of an edge clock to route a clock net named edge_clk.

```
PROHIBIT EDGE NET “edge_net”;
```

PROHIBIT PRIMARY

Prohibits the use of primary clock resources for routing the net. The specified net should be a clock net. This preference can be used with all devices that have primary clocking structures.

Device Support All

Syntax PROHIBIT PRIMARY NET <*net_name*>;

where:

<*net_name*> ::= string

Example This command prohibits the use of a primary clock in routing a clock net named bf_clk.

```
PROHIBIT PRIMARY NET "bf_clk";
```

PROHIBIT SECONDARY

Prohibits the use of secondary spine resources for routing the net. The secondary spine can drive clocks, CEs, resets, or any combination. This preference can be used with all devices that have secondary clocking structures.

Device Support All

Syntax PROHIBIT SECONDARY NET <*net_name*>;

where:

<*net_name*> ::= string

Example The following command prohibits the use of a secondary clock to route a clock net named bf_clk:

```
PROHIBIT SECONDARY NET "bf_clk";
```

REGION

Most commonly used to define a rectangular area that will be used by one or more universal groups (UGROUPs). See “UGROUP” on page 1262. UGROUPs explicitly define what components are members of the group. When used with the PROHIBIT REGION preference syntax, the REGION preference excludes an area from placement. These types of REGIONs are always bounded and anchored to a PFU, EBR, or DSP site, and they can overlap.

For LatticeECP3 devices, the REGION preference can also be used to define a secondary clock resource area. After the clock REGION is defined, you can use the USE SECONDARY preference to assign secondary routing. Only a clock REGION can be used for this purpose. See “Clock REGION Syntax” on page 1245 below. Refer to the device’s data sheet for more information about clock regions.

Device Support All

Device Support for Clock REGION LatticeECP3

Notes

For certain MachXO2 devices, the first EBR site on the left is positioned at column 1 and cannot be included in an anchored group or region that contains SLICEs. The column 1 EBR site is not aligned with SLICEs, which begin at column 2. Affected devices include LCMXO2-1200/4000/7000/10000.

REGION Syntax REGION <*region_name*> <*general_space*> <*site_name*> <*height*> <*width*> [DEVSIZE **|** PFUSIZE];
[PROHIBIT REGION <*region_name*>]

where:

<*region_name*> is a user-defined name of the REGION

<*general_space*> ::= <*site_name*> <*height*> <*width*>

<*site_name*> is a row/column Slice D location of the target device in the format R<*n*>C<*m*>D, an EBR site in the format EBR_R<*n*>C<*m*>, or a DSP site in the format DSP_R<*n*>C<*m*>.

<*height*> <*width*> is the height and width of the region in rows and columns, the two coordinates of a site address.

[DEVSIZE | PFUSIZE] is optionally used to indicate that the REGION height accounts for non-PFU rows. PFUSIZE indicates that all rows are PFU rows. The number of PFUs available to a REGION will depend on where it is anchored with the <*site_name*> parameter. DEVSIZE mode is the default behavior if the keyword is not specified.

Note

In Diamond and in ispLEVER 7.0 or later, the PFUSIZE dimension mode has been demoted and will be flagged as a syntax error during design mapping.

[PROHIBIT REGION <*region_name*>] indicates that the area should be excluded during the placement phase of automatic place and route.

Clock REGION Syntax A clock REGION must be defined with <region_name> <region_clock_space>. This can be done manually in the .lpf file, but it is usually done in Diamond's preference tools for the purpose of assigning secondary routing. When used, the REGION <region_name> <region_clock_space> preference must precede the USE SECONDARY preference that references it in the logical preference file.

REGION <*region_name*><*region_clock_space*>

where:

<*region_name*> is a user-defined name of the clock REGION

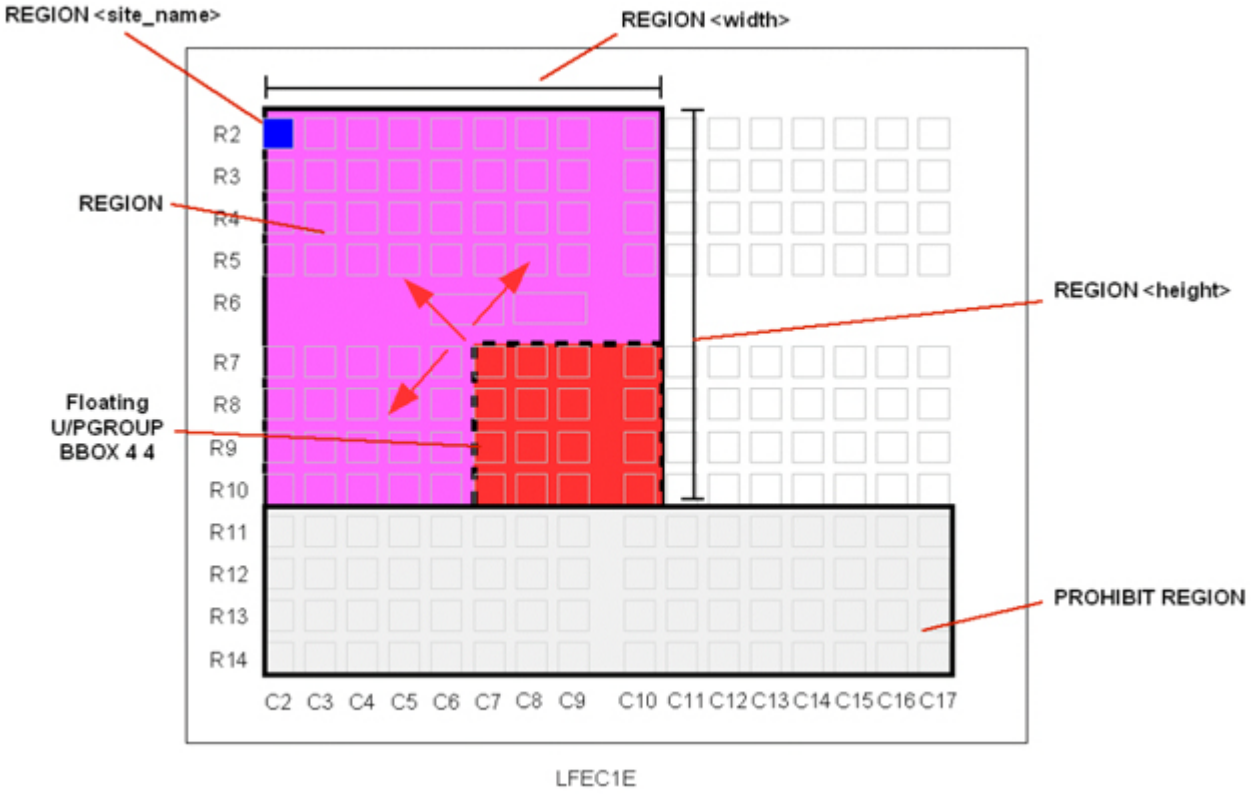
<*region_clock_space*> ::= CLKREG <*clock_region_name*> [<*cr_height*> <*cr_width*>];

<*clk_region_name*> is the site name that identifies the clock_region; for example, CLKREG_R2C2

<*cr_height*><*cr_width*> are integers that describe how many clock_regions are in the region_clock_space. If these are omitted, the default value will be 1, thus creating a region_clock_space of a single clock_region.

Usage REGION is usually defined from within Diamond's Floorplan View, where an abstract view of the target device sites is presented. You can also specify a REGION directly within the .lpf file by specifying a logical preference. REGION can be added directly to HDL code to associate a UGROUP attribute with a REGION. A REGION can also be declared as part of a VHDL component or a Verilog module instance that is also tagged with a UGROUP attribute.

The figure below illustrates two REGION definitions super-imposed on an LFEC1E device floorplan.



Example 1 – Floating UGROUP within a REGION The REGION, UGROUP, and LOCATE UGROUP preference enables you to define a placement group that will float within a certain region. The UGROUP can be bounded or not:

```
REGION "Region_0" "R16C2D" 11 30 DEVSIZE;
UGROUP "mux_group" BBOX 4 4
  BLKNAME mux_1;
LOCATE UGROUP "mux_group" REGION "Region_0" ;
```

Example 2 – Reserved REGION The REGION and PROHIBIT preference enables you to define a region where no logic will be placed by Place & Route:

```
REGION "Region_0" "R16C2D" 11 30 DEVSIZE;
PROHIBIT REGION "Region_0" ;
```

Example 3 – LPF-based Clock Region This REGION preference indicates a 2 x 3 clock region anchored in the upper left corner by clock region CLKREG_R2C2. The REGION will be two clock_regions high and three clock_regions wide. The USE SECONDARY NET preference indicates that all loads related to clk1 are to be placed in the area defined by region_mux.

```
REGION “region_mux” CLKREG “CLKREG_R2C2” 2 3;
USE SECONDARY NET “clk1” REGION “region_mux”;
```

RVL_ALIAS

Provides an alias name for a clock name generated by Reveal Inserter so that it can be mapped to the original clock name used in the design. This ensures that any preferences that use the Reveal clock names will be treated as if they were using the original clock names.

Device Support All

Note

The RVL_ALIAS preference is automatically generated and should not be added manually or edited.

Syntax RVL_ALIAS <reveal_clock_name> <original_clock_name>;

Example `RVL_ALIAS "reveal_ist_9" "clock1/clk_sample";`

SSO

Defines constraints for Simultaneous switching output (SSO) I/O analysis.

Device Support All

Usage The most common usage of SSO constraints is to define them from within Spreadsheet View. You can also specify SSO parameters directly within the .lpf file by specifying the SSO logical preference. SSO I/O analysis reports can be generated from Spreadsheet View.

Syntax SSO [ALLPORTS] (<*keyword*>=<*value*>)+;
SSO [PORT <*port_name*> | GROUP <*group_name*>] (<*keyword*>=<*value*>)+

where:

<*port_name*> = string. These are not the actual top-level port names but the signal name attached to the port. Any multiple listings or wildcards should be done using GROUPS.

<*group_name*> = string

<*keyword*> (Output/Bidir) ::= SwitchingID, SSO_Noise, SSO_Noise_Drop, SSO_Allowance

SwitchingID is an integer identifier to group related pins that will switch at the same time.

SSO_Noise is the estimated noise on the PCB board's ground plane, expressed as a floating point value for millivolt units (mV). The default is 0.00 mV.

SSO_Noise_Drop is the estimated noise on the PBC board's power plane for drop calculations, expressed as a negative floating point value for millivolt units (mV). The default value is -0.00 mV.

SSO_Allowance is the allowable level of I/O SSO per bank expressed as a percentage (%). The default is 100%.

For the SSO ALLPORTS preference, any possible subordinate attributes of SSO, such as SwitchingID will take effect only on ports that have no other specific SSO preferences placed upon them. This is because of the preference precedence rule: more specific preferences override more generally applied ones.

Using Wildcards The use of wildcards for SSO is supported for port names.

```
SSO ALLPORTS SwitchingID=0 SSO_Noise=0.00 SSO_Noise_Drop=-10.00
SSO_Allowance=70;

SSO PORT "port1" SwitchingID=1 SSO_Noise=20.00
SSO_Noise_Drop=-10.00 SSO_Allowance=80;

SSO PORT "port2" SwitchingID=1 SSO_Noise=20.00
SSO_Noise_Drop=-10.00 SSO_Allowance=80;

SSO PORT "port3" SwitchingID=1 SSO_Noise=20.00
SSO_Noise_Drop=-10.00 SSO_Allowance=80;

SSO PORT "port4" SwitchingID=1 SSO_Noise=20.00
SSO_Noise_Drop=-10.00 SSO_Allowance=80;
```

SYSCONFIG

Defines system configuration option settings for the sysCONFIG feature. If you do not specify these settings in the .lpf file, using the Global Preference sheet in Spreadsheet View or manually, some default sysCONFIG preferences will automatically be generated based on device selection.

The SYSCONG preference is available for all Lattice FPGA devices that support the sysCONFIG configuration port. The sysCONFIG port can be a single data line or byte-wide (multiple byte) data port that can support serial and parallel `configuration` streams. The devices also support daisy chaining.

Device Support All

Syntax SYSCONFIG <*keyword*>=<*value*>+

where:

<*keyword*> refers to any of the following keywords. Click on a keyword for further description.

<*value*> refers to any possible values associated with that keyword. The allowed values for the above keywords are device specific.

Recommended Usage You should set the preference configuration options in the pre-map stage using Spreadsheet View or by editing the .lpf file directly. Also see “Setting Global Preferences” on page 459 for details. If you do not set sysCONFIG options, default SYSCONFIG preferences are automatically set in the .prf file based on device selection.

Examples The SYSCONFIG preference allows you to set a series of keyword values in succession after the preference identifier.

```
SYSCONFIG CONFIG_MODE=SLAVE_SERIAL PERSISTENT=OFF DONE_OD=ON;

SYSCONFIG PERSISTENT=OFF CONFIG_MODE=SLAVE_SERIAL WAKE_UP=21
MCCLK_FRQ=0.78 COMPRESS_CONFIG=ON;
```

These examples would set the configuration mode to serial slave. The ability to retain system configuration pin reservation, even during normal operation, is turned OFF with the PERSISTENT keyword. The DONE pin will be configured as an open drain pin when the DONE_OD keyword set to ON.

SYSCONFIG Keyword Settings The following table shows the default settings in bold type and the selectable settings for all of the keyword values for the SYSCONFIG preference. For more details on keyword values pertaining to device requirements, refer to the usage guides under See Also at the end of this topic.

Table 137:

Keyword	Default and Selectable Values	Supported Devices
BACKGROUND_RECONFIG	**OFF** [off, on, sram_only, sram_ebr]	ECP5U/UM, MachXO2, MachXO3D, MachXO3L, MachXO3D
BACKGROUND_RECONFIG_SECURITY	**OFF** [off, on]	MachXO3D
BULK_ERASE	**YES** [yes, no]	MachXO3D
COMPRESS_CONFIG	**ON** [on, off]	LatticeECP/EC, LatticeECP2/M, Lattice ECP3, ECP5, LatticeSC/M, MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2
CONFIG_IOVOLTAGE	**2.5** [2.5, 1.2, 1.5, 1.8, 3.3]	LatticeECP3, ECP5
CONFIG_MODE	Available values vary, depending on the device. Refer to the usage guides under See Also at the end of this topic.	All except MachXO, MachXO2, MachXO3D
CONFIG_SECURE	**OFF** [off, on]	All
CONFIGURATION	CFG [CFG, CFG_EBRUFM, CFGUFM, EXTERNAL]	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2
CUR_DESIGN_BOOT_LOCATION	**IMAGE_0** [IMAGE_0, IMAGE_1]	MachXO3D
CUSTOM_IDCODE	32-bit arbitrary	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2
CUSTOM_IDCODE_FORMAT	**Binary** [Binary, Hex]	MachXO3D
DONE_EX	**OFF** [off, on]	All except MachXO2, MachXO3D
DONE_OD	**ON** [off, on]	LatticeECP/EC, LatticeXP/2, LatticeECP2/M, LatticeECP3, ECP5
DONE_PULL	**ON** [off, on]	LatticeSC/M, ECP5
DUALBOOTGOLDEN	**INTERNAL** [internal, external]	MachXO3D, MachXO3LF
ENABLE_NDR	**OFF** [off, on]	LatticeECP2/M, LatticeECP3
ENABLE_TRANSFR	**DISABLE** [disable, enable]	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2

Table 137:

Keyword	Default and Selectable Values	Supported Devices
I2C_PORT	**DISABLE** [disable, enable]	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2
INBUF	**OFF** [off, on] for ECP5, LatticeECP/EC, LatticeECP2/M **ON** [off, on] for LatticeXP/2and MachXO, Platform Manager	ECP5, LatticeECP/EC, LatticeECP2/M, LatticeXP/2, MachXO, Platform Manager
JTAG_PORT	**ENABLE** [enable, disable]	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2
MASTER_PREAMBLE_DETECTION_RETRY	**0** [0 to 3]	MachXO3D
MASTER_PREAMBLE_DETECTION_TIMER	**0** [0 to 15]	MachXO3D
MASTER_SPI_PORT	**DISABLE** [disable, enable]	ECP5, MachXO2, MachXO3D, MachXO3L, Platform Manager 2, LatticeXP2, not available in MachXO3D
MCCLK_FREQ	Lowest Frequency. Refer to the usage guides under See Also at the end of this topic.	All except LatticeXP2
MUX_CONFIGURATION_PORTS	**DISABLE** [disable, enable]	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2
MY_ASSP	**OFF** [off, on]	LatticeXP2, MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2
ONE_TIME_PROGRAM	**OFF** [off, on]	LatticeXP2, MachXO2, MachXO3D, MachXO3L, Platform Manager 2, not available in MachXO3D
PERSISTENT	**OFF** [off, on] exclusive of LatticeECP3. **OFF** [off, SLAVE_PARALLEL, SSPI] for LatticeECP3 devices.	LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeXP, LatticeSC/M
PRIMARY_BOOT	**IMAGE_0** [image_0, image_1, external, latest, former]	MachXO3D
SDM_PORT	**DISABLE** [disable, programn, programn_done, programn_done_initn, initn, done]	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2
SECONDARY_BOOT	**NONE** [none, image_0, image_1, external, latest, former]	MachXO3D
SFDP_CHECK	**DISABLE** [disable, enable_sfdp, enable_sfdp_preamble]	MachXO3D

Table 137:

Keyword	Default and Selectable Values	Supported Devices
SHAREDEBRINIT	**DISABLE** [disable, enable]	MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2
SLAVE_IDLE_TIMER	**0** [0 to 15]	MachXO3D
SLAVE_PARALLEL_PORT	**DISABLE** [disable, enable]	ECP5
SLAVE_SPI_PORT	**DISABLE** [disable, enable]	ECP5, LatticeXP2, MachXO2, MachXO3D, MachXO3L, MachXO3D
SPIM_ADDRESS_32BIT	**DISABLE** [disable, enable]	MachXO3D
STRTUP	**EXTERNAL** [external, TCLK, CCLK, MCLK]	LatticeECP3
TRANSFR	**OFF** [off, on]	ECP5
WAKE_ON_LOCK	**OFF** [off, on]	LatticeXP2, LatticeECP3
WAKE_UP	**21** (DONE_EX = Off) [1:25] For LatticeECP3, selectable values are 1, 4, 6, 7, 10, 14, 17, 21, 22, 23, 24, 25. **4** (DONE_EX = On) [1:7]	All except MachXO2, MachXO3D

BACKGROUND_RECONFIG= OFF (default) | ON [once] | sram_only | sram_ebr

Allows user to reconfigure device in user mode. The use of this preference is risky and is recommended for advanced users only.

BACKGROUND_RECONFIG_SECURITY=OFF (default) | ON

Allows user to control the CFG access to the ESB. When set to OFF, CFG has read only access. When set to ON, CFG can read/write to ESB.

BULK_ERASE=YES (default) | NO

Allows user to set the bulk erase. When set NO, auto bulk erase is disabled. When set to YES, auto SRAM bulk erase is allowed for power cycling, refresh, or PROGRAMN pin toggling.

COMPRESS_CONFIG=OFF (default) | ON [once]

Bitstream Compression. When set to ON, for those devices that support bitstream compression, the software generates a compressed version of the bitstream file.

CONFIG_IOVOLTAGE=2.5 (default) | 1.2 | 1.5 | 1.8 | 3.3

Sets the voltage for the sysCONFIG bank. When you set this attribute, it tells the software the voltage that is required in this bank to satisfy the sysCONFIG requirements. DRC errors will then be based on CONFIG_IOVOLTAGE and usage of the dual-purpose sysCONFIG pins.

CONFIG_MODE= mode_name

The CONFIG_MODE option tells the software to preserve the appropriate sysCONFIG ports/pins to help the user design flow. After you determine what persistent sysCONFIG pins are available for mapping, the resulting CONFIG_MODE preference will tell the software what you intend to do with the sysCONFIG modes.

The available CONFIG_MODE options sysCONFIG modes are device-specific because each device supports a different set of ports. Refer to the usage guides under See Also at the end of this topic for more information.

The PERSISTENT keyword, when set to ON (for devices other than LatticeECP3), will communicate to the software that the selected CONFIG_MODE attribute is to be PERSISTENT. See the description of PERSISTENT below for more information.

CONFIG_SECURE= OFF (default) | ON [once]

Configuration Security. When set to ON, no readback operation is supported through the sysCONFIG port or ispJTAG port of the general contents. The USERCODE area is readable and not considered securable. The OFF setting indicates that readback is enabled through any port. LatticeSC supports an additional selection ONCE, which blocks the readback operation once.

CONFIGURATION=CFG (default) | CFG_EBRUFM | CFGUFM | EXTERNAL

Configuration settings for storing the configuration bitstream for MachXO2, MachXO3D, MachXO3L, and Platform Manager 2 devices. When set to CFG, the configuration bitstream (including EBR init if any) is stored in the configuration Flash array and is not allowed to overflow into the UFM.

When set to CFG_EBRUFM, the configuration bitstream (NOT including EBR init) is stored in the configuration Flash array. EBR init data, if any, is stored in the lowest page addresses (starting from Page 0) of the user Flash memory (UFM). Any unoccupied UFM pages after the mapping of EBR init data, will be available as general purpose Flash memory.

When set to CFGUFM, the configuration bitstream (including EBR init if any) is allowed to overflow into the UFM.

When set to EXTERNAL, the configuration bitstream (including EBR init if any) is stored in an external memory device. Use this setting when the bitstream does not fit in the internal flash resources of the device. The MASTER_SPI_PORT preference must be set to ENABLE to enable the external Master SPI port for configuring the SRAM fuses using the bitstream.

CUR_DESIGN_BOOT_LOCATION=IMAGE_0 (default) | IMAGE_1

The value (IMAGE_0 and IMAGE_1) determines the .jed filename. For IMAGE_0, <project_name>_a.jed is generated. For IMAGE_1, <project_name>_b.jed is generated. Either project can be downloaded into either FLASH-A or FLASH-B.

CUSTOM_IDCODE=32-bit arbitrary value

This attribute is a 32-bit arbitrary value. When you enable the MY_ASSP feature, this field becomes the JTAG ID of the device.

CUSTOM_IDCODE_FORMAT=Binary (default) | Hex

The user specifies the format for the CUSTOM_ID. The available formats are Hex and Binary.

DONE_EX= OFF (default) | ON

External DONE Control. Determines whether the device wake-up sequence is synchronized with its own internal DONE signal or with an external DONE signal driven by another device. If ON, the device will wait for an external DONE signal to be driven high to wake up. In its OFF default state, the device wakes up on its own after the DONE bit is set.

Specify ON if you want to delay wake up until the DONE pin is driven high by an external signal and synchronous to the clock. Specify OFF if you wish to synchronously wake up when the DONE bit is set and ignore any external driving of the DONE pin. If DONE_EX is set to ON, DONE_OD should be set to its default value of ON. If an external signal is driving the DONE pin, it should be an open drain pin. See DONE_OD for information on DONE pin sysCONFIG and active versus open drain concepts.

DONE_OD= ON (default) | OFF

Done Pin Open Drain. Enables you to configure the DONE pin as an open drain pin. By default, the pullup on the DONE pin is active.

When the DONE pin is released high, this indicates that programming is complete and the device is ready for wake up. Other devices can be used to control the wake-up process of the device by holding the DONE pin low until they are ready to wake up. To allow other devices to hold the DONE pin low, an open drain configuration is needed to avoid contention on the DONE pin from the device trying to drive high when other DONE signals are trying to hold it low.

DONE_PULL= ON (default) | OFF

Internal DONE Pin Pullup. The DONE_PULL keyword enables you to configure the DONE pin with a pullup on or off. The DONE_PULL keyword is only used for the DONE pin. When the DONE pin is driven low, this indicates that programming is complete and the device is ready for wakeup. Other devices can be used to control the wake-up process of the device by holding the DONE pin low. This allows the pin to pull itself high when other devices have released the open drain DONE pin. When you do not want to use an internal active pullup, set the DONE_PULL keyword to OFF.

DUALBOOTGOLDEN= INTERNAL (default) | EXTERNAL

MachXO3D and MachXO3L/LF devices can optionally boot from two patterns, a primary bitstream and a golden bitstream. If the primary bitstream is found to be corrupt while being downloaded into the SRAM, the device shall then automatically re-boot from the golden bitstream. The DUALBOOTGOLDEN preference defines if the Golden file is Internal (on-chip Flash/NVCM) or External (SPI Flash).

ENABLE_NDR=OFF (default) | ON

Non Disruptive Reconfiguration (NDR). When turned on, allows volatile devices to be reconfigured while I/Os are in Leave Alone I/O mode. This is done by latching all user I/Os (except sysCONFIG pins) to a known state when the control register's NDR control bit (bit 25 of control Register 0 for LatticeECP2) is set while the PROGRAMN pin is toggled or when a JTAG refresh command is issued. When turned off, the I/Os are tri-stated during reconfiguration.

ENABLE_TRANSFR= DISABLE (default) | ENABLE

When enabled, turns on the Freeze_IO and Freeze_MIB fuses to enable the TransFR function. The Freeze_IO holds the current logic value (data and tristate) on the pins constant. The Freeze_MIB holds the personalities of the pins constant. When this is enabled, the IOs will not be changed in terms of logic value and all buffer modes of the IOs.

I2C_PORT=DISABLE | ENABLE (default)

For MachXO2, MachXO3D, MachXO3L, and Platform Manager 2 devices, enabling the I2C_PORT makes it active for configuration access and prevents the dual-purpose pins from being used as user I/O pins. When disabled, the pins become available for user I/Os.

INBUF=ON | OFF

Defaults to OFF for ECP5, LatticeECP/EC, and LatticeECP2/M devices. Defaults to ON for LatticeXP/2, MachXO, and Platform Manager devices.

Turns on the input buffers. This attribute must be turned on to perform boundary scan testing. When turned off, all unused input buffers are disabled to save power.

JTAG_PORT=ENABLE (default) | DISABLE

When enabled, it prevents the JTAG pins in a MachXO2, MachXO3D, MachXO3L, and Platform Manager device from being used as I/O pins.

When disabled, signals can be assigned to the shared JTAG pins. A high signal on the JTAGENB would then be required to re-enable the JTAG port, after which the 4 pins would become dedicated JTAG pins.

MASTER_PREAMBLE_DETECTION_RETRY=0 (default) to 3

This attribute sets the Master mode Bitstream preamble detection retry time. The attribute value is 0 to 3. The number of times the preamble detection should be retried in Master mode (booting from external Flash.)

When set to 0, preable detection does not try, then have option to try one time, two times, or three times.

MASTER_PREAMBLE_DETECTION_TIMER=0 (default) to 15

This attribute sets the Master mode Bitstream preamble detection timer count value. When set to 0, the timer's value is set to ~126Kus; there are 16 steps from 126Kus to 3.85us.

MASTER_SPI_PORT=DISABLE (default) | ENABLE | EFB_USER (MachXO2 only)

When enabled, it allows the use of the external Master SPI port for configuring the SRAM fuses using the bitstream.

When EFB_USER is selected for a MachXO2, MachXO3D, MachXO3L device, it reserves the SPI pins for user Master SPI mode in the embedded function block (EFB).

MCCLK_FREQ= <*frequency_value*> (MHz)

Controls the Master Clock frequency. Valid options are 2.5 MHz, 4.3 MHz, 5.4 MHz, 6.9 MHz, 8.1 MHz, 9.2 MHz, 10 MHz, 13 MHz, 15 MHz, 20 MHz, 26 MHz, 30 MHz, 34 MHz, 41 MHz, 45 MHz, 51 MHz, 55 MHz, 60 MHz, 130 MHz. The default is the lowest frequency, 2.5 MHz. Note that 51 MHz is not a valid option for LatticeECP2/M. Refer to the Global Preferences topic for further description.

MUX_CONFIGURATION_PORTS= DISABLE (default) | ENABLE (MachXO2 only)

Allows all Configuration ports to be disabled in order to provide additional user IOs.

MY_ASSP=OFF (default) | ON

LatticeXP2 devices – when set to ON, causes the USERCODE to be used as a custom device ID. When JTAG scanning is done, the device will produce the specified device ID pre-programmed onto the USERCODE fuses.

MachXO2, MachXO3D, and MachXO3L devices – when set to ON, changes the JTAG IDCode of the device to the contents of the CUSTOM_IDCODE field.

ONE_TIME_PROGRAM=OFF (default) | ON

When set to ON, uses the One Time Programmable (OTP) fuse to prevent the on-chip Flash configuration memory from being erased or programmed. This does not prevent the Flash Tag Memory or Flash User memory from being programmed; these features are still available.

PERSISTENT= OFF (default) | ON (exclusive of LatticeECP3) | SLAVE_PARALLEL (LatticeECP3 only) | SSPI (LatticeECP3 only).

Some of the sysCONFIG pins support dual functions, meaning that they serve as sysCONFIG pins during configuration operations and I/O pins during normal operation. The PERSISTENT preference determines whether these pins remain sysCONFIG pins during normal operation. The PERSISTENT keyword can be applied to only certain configuration modes.

When set to ON, for devices other than LatticeECP3, it reserves the dual-purpose pins for configuration and informs the software that these pins are not available as general purpose I/O pins. Note that setting a value of 'ON' can be done in the Diamond Spreadsheet View, Global Preferences tab, by using the ENABLE setting for the appropriate port.

When set to SLAVE_PARALLEL (for LatticeECP3), it signals to the software that all the dual purpose sysCONFIG pins will NOT be available for placement and routing, regardless of the selected CONFIG_MODE.

When set to SSPI (for LatticeECP3), it specifies that only the slave SPI port is to be preserved after configuration.

PRIMARY_BOOT=IMAGE_0 (default) | IMAGE_1 | EXTERNAL | LATEST | FORMER

This attribute specifies the bitstream boot location. IMAGE_0 is loaded from CFG0/UFM0 section of Flash memory, IMAGE_1 is loaded from CFG1/UFM1 section. EXTERNAL option is used for external boot, LATEST is for DUAL_INTERNAL boot - latest first, and FORMER is for DUAL_INTERNAL boot - latest second.

SDM_PORT=DISABLE (default) | PROGRAMN | PROGRAMN_DONE | PROGRAMN_DONE_INITN | INITN | DONE

This preference is used to retain the PROGRAMN, DONE, and INITN pins as dedicated configuration pins for the self-download mode port.

SECONDARY_BOOT= NONE (default) | IMAGE_0 | IMAGE_1 | EXTERNAL | LATEST | FORMER

This attribute can be set as follows: NONE for single boot, IMAGE_0 for CFG0/UFM0, IMAGE_1 for CFG1/UFM1, EXTERNAL for external boot, LATEST for DUAL_INTERNAL boot - latest first, and FORMER for DUAL_INTERNAL boot - latest second.

SFDP_CHECK=DISABLE (default) | ENABLE_SFDP | ENABLE_SFDP_PREAMBLE

When set to DISABLE, this attribute doesn't allow for SFDP checking. When set to ENABLE_SFDP, the SFDP checks and stops as soon as SFDP check fails. When set to ENABLE_SFDP_PREAMBLE, SFDP checks and continues PREAMBLE even though SFDP check fails.

SHAREDEBRINIT=DISABLE (default) | ENABLE

When set to ENABLE, this attribute allows sharing of the same init file that was used by multiple EBRs when they were generated in IPexpress. This reduces the bitstream size by storing only one copy of the init values.

SLAVE_IDLE_TIMER=0 (default) to 15

The attribute will set the Slave Idle Timer count value. There are 15 steps from 128Kms to 10ms; when set to 0, the Slave Idle Timer is disabled, or, in other words, set to Infinite.

SLAVE_SPI_PORT=DISABLE (default) | ENABLE

When enabled, it allows on-chip Flash to be programmed and read back using the external Slave SPI port.

SLAVE_PARALLEL_PORT=DISABLE (default) | ENABLE

When enabled, it makes the 8-bit slave parallel port available after configuration and allows the SRAM to be reconfigured.

SPIM_ADDRESS_32BIT=DISABLE (default) | ENABLE

Allows user to extend the SPIM address to 32-bit address. In default setting, SPIM is a 24-bit address. When set to ENABLE, SPIM is a 32-bit address.

STRTUP=EXTERNAL (default) | TCLK | CCLK | MCLK

Specifies the clock source to be used for synchronization with the start-up sequence and allows a user-defined clock source to be used instead of CCLK or TCK. The clock signal must be specified and the STRTUP library element instantiated in the design.

TRANSFR=OFF (default) | ON

When ON is selected, turns on the Freeze_IO and Freeze_MIB fuses to enable the TransFR function.

WAKE_ON_LOCK=OFF (default) | ON

Determines whether the device will wait for the PLL to lock before beginning the wake-up process.

By default (OFF), the device will wake up regardless of the state of the PLL lock signal. When set to ON, the device will not wake up until the PLL lock signal for the given PLL is active.

WAKE_UP= 21 (DONE_EX = OFF) | 4 (DONE_EX = ON)

Wake Up. Wake Up is a controlled event after a part has been configured. External control of the DONE pin can be selected to either delay wake up or be ignored. See DONE_EX.

The Wake Up sequence controls three internal signals, and the DONE Pin will be driven after configuration and prior to user mode. If DONE_EX = ON, the WAKE_UP keyword will take your selected option (1-7), and then the software will set wake-up signal bits accordingly. If you do not select a wake-up sequence, the default wake-up sequence will be 4. If DONE_EX = OFF (default), the WAKE_UP keyword will take your selected option (1-25), and then the software will set wake-up signal bits accordingly. If you do not select a wake-up sequence, the default wake-up sequence will be 21.

SYSTEM_JITTER

Specifies the peak-to-peak system jitter for timing analysis. This global preference is used to overwrite the default system jitter. It will affect both the rising edge and falling edge timing analysis. Trace will use half of the specified peak-to-peak jitter for all analysis.

Device Support All

Syntax SYSTEM_JITTER <*time_spec*><*time_unit*>

where:

<*time_spec*> ::= <*number*>

<*time_unit*> ::= ps | ns

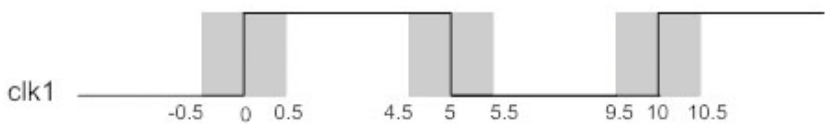
The system jitter value should not be smaller than the default system jitter for the device.

Example

```
SYSTEM_JITTER 1.0 ns;
```

In the following waveform for this example, the rising edge for clk1 is in the range of -0.5 to 0.5 nanoseconds. The falling edge is the range of 4.5 to 5.5 nanoseconds.

Figure 36:



TEMPERATURE

Assigns an operating junction temperature for the part that changes the derating factor for timing. You can use this preference to override the default temperature, which is 85C (commercial) and 100C (industrial) for all speed grades. If no temperature or voltage preference is specified, the derating factor is 1.0.

Device Support All

Syntax TEMPERATURE <*temp*>;

where:

<*temp*> ::= <*number*> (C | F | K)

Note

The temperature can be specified in C (Celsius), F (Fahrenheit) or K (Kelvin). Internally it is converted to Celsius. The use of a space between the number and the voltage symbol is optional. See examples.

Examples The following preference sets the operating junction temperature to 45 degrees Celsius.

```
TEMPERATURE 45C;
```

The following preferences set both the junction temperature and voltage derating parameters for LatticeSC/M devices.

```
TEMPERATURE 25C;
VCC_DERATE NOMINAL;
VCCAUX_DERATE NOMINAL;
VCCIO_DERATE BANK 0 NOMINAL;
VCCIO_DERATE BANK 1 NOMINAL;
VCCIO_DERATE BANK 2 NOMINAL;
VCCIO_DERATE BANK 3 NOMINAL;
VCCIO_DERATE BANK 4 NOMINAL;
VCCIO_DERATE BANK 5 NOMINAL;
VCCIO_DERATE BANK 6 NOMINAL;
VCCIO_DERATE BANK 7 NOMINAL;
```

TRACEID

Specifies a code for storing device data, much like USERCODE but in binary format.

Device Support MachXO2, MachXO3D, MachXO3L, MachXO3D, Platform Manager 2

Syntax TRACEID<*binary_string*>;

where:

<*binary_string*> ::= binary value of up to 8 bits

Example `TRACEID "00001111";`

TWR_REPORT_LIMIT

Specifies the number of items (paths) to be reported by the TRACE timing analysis tool (**trce**) for each preference in the .twr file.

To use this preference, the command-line options -v and -e must not be used. Otherwise, the path limit defined at the command line will override this preference.

Device Support All

Syntax TWR_REPORT_LIMIT <*number*>;

where:

<*number*> ::= integer;

Example This command specifies that TRACE reports 20 paths in the output .twr file:

```
TWR_REPORT_LIMIT  20;
```

UGROUP

Universal logical grouping constraint. UGROUP is used to infer a single placement group (PGROUP) for multiple instances of an object from the logical domain. UGROUPs are translated by the design mapper (map) into PGROUPs, which direct the placer algorithm of PAR to place the group members in proximity. UGROUP members refer to logical component names in the EDIF/NGD netlist. Universal groups can include PFU/PFF, EBR, or DSP-based logic.

The hierarchical grouping constraint, HGROUP, is an alternative to UGROUP and is used to infer a unique placement group for each instance of a block.

UGROUP is also available as an HDL attribute that can be added directly to HDL source as a means to infer PGROUPs from a VHDL architecture or component instance or from a Verilog module declaration or module instance.

Device Support All

Usage A UGROUP preference can be defined from within Spreadsheet View or Floorplan View, where the post-synthesis netlist (EDIF/NGD) is presented, or it can be defined directly within the logical preference file (.lpf). UGROUPs can be anchored or floating, bounded or unbounded. UGROUPs that include DSP blocks must be anchored. If a floating UGROUP that includes a DSP block is encountered, the system will issue a warning and ignore the block.

A UGROUP can also be defined as an HDL attribute as part of a VHDL component or Verilog module instance. When Diamond encounters a UGROUP declaration from the post-synthesis netlist, it presents it in Spreadsheet View. If you modify a UGROUP that originated in the post-synthesis netlist, Diamond will add the UGROUP declaration to the .lpf file and override the original inferred group based on the precedence rules of the Diamond preference flow.

One or more UGROUPs can be members of a REGION. Any PFU, EBR, or DSP site can serve as an anchor. UGROUPs can overlap as long as enough device sites are available to accommodate the design logic. A given block can only be assigned membership to one group, either a UGROUP or an HGROUP. See “Troubleshooting UGROUP Conflicts” on page 1264.

Members of a UGROUP are automatically translated by the design mapper into PGROUPs that comprise post-map physical domain elements. After mapping, PGROUPs inferred from UGROUPs of the post-synthesis netlist appear in the schematic section of the physical preference file (.prf), and those inferred from the .lpf file appear in the user defined section of the .prf file. This organization enables you to easily override an HDL-based declaration in the post-synthesis stage. If you wish to later restore an HDL-based UGROUP, use the Group sheet in Spreadsheet View to delete the UGROUP from the .lpf file.

Note

The legacy PGROUP preference is no longer supported in the logical preference file for grouping PFF, PFU, and DSP-based logic. Use the UGROUP preference instead.

Syntax UGROUP <*ugroup_name*> [BBOX <*height width*>] (BLKNAME <*blkname*>)+;
[LOCATE UGROUP <*ugroup_name*> SITE <*site_name*>;]
[LOCATE UGROUP <*ugroup_name*> REGION <*region_name*>;]

where:

<*ugroup_name*> is the user-defined name of the UGROUP.

BBOX <*height_width*> is used to optionally define the maximum number of rows (R) and columns (C), of the group's bounding box. The bounding box can include PFF, PFU, EBR, and DSP sites.

Note

For certain MachXO2 devices, the first EBR site on the left is positioned at column 1 and cannot be included in an anchored group or region that contains SLICEs. The column 1 EBR site is not aligned with SLICEs, which begin at column 2. Affected devices include LCMXO2-1200/4000/7000/10000.

BLKNAME <*blkname*> Identifies the name of the logical block you are grouping. A given block can only be assigned membership in one group, either a UGROUP or an HGROUP (hierarchical group). It cannot be in two or more groups at the same time.

[LOCATE UGROUP <*ugroup_name*> SITE <*site_name*>] is used to optionally specify the UGROUP position. The <*site_name*> can be a Slice D row/column location of the target device in the format R<*n*>C<*m*>D; it can be an EBR site in the format EBR_R<*n*>C<*m*>; or it can be a DSP site in the format DSP_R<*n*>C<*m*>.

[LOCATE UGROUP <*ugroup_name*> REGION <*region_name*>] is used to optionally specify the REGION within which the UGROUP will float.

Example Given a UGROUP and LOCATE preference:

```
UGROUP "rot_grp" BBOX 8 3
  BLKNAME rotate_1;
LOCATE UGROUP "rot_grp" SITE "R2C23D"
```

After design mapping, the resulting .prf file will contain the following in the schematic section:

```
PGROUP "rot_grp" BBOX 8 3  DEVSIZE
  COMP "rotate_1/SLICE_0"
  COMP "rotate_1/SLICE_1"
  COMP "rotate_1/SLICE_2"
  COMP "rotate_1/SLICE_3";
LOCATE PGROUP "rot_grp" SITE "R2C23D" ;
```

Troubleshooting UGROUP Conflicts Multiple definitions of the same group name can sometimes appear in the .lpf file because of changes in the design or semantic errors. For example, a UGROUP in the .lpf ASCII file might contain a semantic error and not show up in the Diamond preference tools. When the UGROUP is recreated in the preference tools, it produces redundant groups in the .lpf file.

When the software encounters a UGROUP conflict in the .lpf file, it produces warnings messages and processes the groups using the following rules:

- Only one group definition is recognized for each UGROUP name. When two group definitions with the same name appear in the .lpf file, only the UGROUP listed first is recognized.
- UGROUPs cannot share the same members. When two UGROUPs with different names include some of the same elements, only non-conflicting elements are assigned to each group. When each group contains identical members, the first group is ignored.

See Also "HGROUP" on page 1220 (preference)

- "UGROUP" on page 1328 (HDL attribute)

UNIQUE_ID

Defines the upper sixteen bits of an automatic 32-bit USERCODE that will be used to identify the design. UNIQUE_ID becomes available only when AUTO has been specified as USERCODE format. If AUTO is not used, this preference has no effect.

Device Support ECP5

Syntax UNIQUE_ID <16-bit hex value>;

or

UNIQUE_ID HEX <16-bit hex value>;

Examples
```
UNIQUE_ID "FFFF";
UNIQUE_ID_HEX "FFFF";
```

USE DIN CELL

Specifies the given register to be used as an input Flip Flop. The default value is TRUE. TRUE means that registers will be moved into I/Os, and FALSE means that registers will be moved out of I/Os. The software distributes the USE DIN CELL setting to the .nmc file after mapping.

Device Support All except MachXO, MachXO2, MachXO3D, MachXO3L, MachXO3D

Syntax USE DIN [TRUE|FALSE] CELL <*cell_name*>;

where:

<*cell_name*> ::= string

Examples
```
USE DIN CELL "din0";
USE DIN FALSE CELL "din0"
```

USE DOUT CELL

Specifies the given register to be used as an output Flip Flop. TRUE means that registers will be moved into I/Os, and FALSE means that registers will be moved out of I/Os. The software distributes the USE DOUT CELL setting to the .nmc file after mapping.

Device Support All except MachXO, MachXO2, MachXO3D, MachXO3L, MachXO3D

Syntax USE DOUT [TRUE|FALSE] CELL <*cell_name*>;

where:

<*cell_name*> ::= string

```
USE DOUT CELL "dout1";
USE DOUT FALSE CELL "dout0"
```

USE EDGE

Runs a clock signal through edge clock resources and minimizes the delay from the clock sources to I/O registers. Use an edge clock resource to route the specified net. The specified net should be a clock net.

When USE EDGE is specified, the Place & Route process will try to use edge clock routing resources, provided that the following conditions are true: the source of the clock is capable of driving an edge clock; all destinations of the clock are capable of receiving an edge clock; and edge clock resources are available in the bank structure.

Device Support LatticeECP2/M

Syntax USE EDGE NET <*net_name*>;

Example The following preference specifies that an edge clock resource should be used when routing a clock net named clk_fast:

```
USE EDGE NET "clk_fast";
```

USE EDGE2EDGE

Enables a clock to route to multiple-edge clocks on the device using a 3-way (left/right/top) bridge. There are two bridges on the left side of device: one for ECLK1 and a second one for ECLK2. Each bridge connects the respective left, right, or top edge clocks.

Device Support LatticeECP3 EA devices, which provide 3-way bridge usage. This preference is not supported for LatticeECP3 E devices.

ECLK1 Bridge For the ECLK1 bridge, the clock can be sourced from a dedicated left PLL PIO, a dedicated path from the left GDLL CLKOP, a dedicated path from the left GPLL CLKOP, a dedicated path from a GDLL slave delay block, or a primary clock input (dedicated PIO, PLL, DLL, CLKDIV, or PCS).

ECLK2 Bridge For the ECLK2 bridge, the clock can be sourced from a dedicated left PLL PIO, a dedicated path from the left GDLL CLKOS, a dedicated path from the left GPLL CLKOS, a dedicated path from a GDLL slave delay block, or a primary clock input (dedicated PIO, PLL, DLL, CLKDIV, or PCS).

EDGE2EDGE vs. PRIMARY2EDGE The EDGE2EDGE preference is intended for well-controlled timing skew when the number of ECLK I/O loads is more than the number of IOs per side using the 3-way (left/right/top) bridge.

The PRIMARY2EDGE preference is useful for implementing a low-skew clock path to the left and right sides of the device. The primary clock must be sourced from a dedicated primary clock source such as a primary clock input, PLL, DLL, CLKDIV, or PCS.

Syntax USE EDGE2EDGE NET <*net_name*>

where:

<*net_name*> is the name (<*string*>) of a specific edge clock net.

Architecture Support The USE EDGE2EDGE preference is supported for MachXO2 devices. It is also supported for LatticeECP3 EA devices, which provide 3-way bridge usage. This preference is not supported for LatticeECP3 E devices.

Recommendations The following guidelines should be followed in using EDGE2EDGE and PRIMARY2EDGE.

- Do not assign the same clock net to both EDGE2EDGE and PRIMARY2EDGE.
- Spread the clock loads of PRIMARY2EDGE and/or EDGE2EDGE signals to appropriate banks by using the LOCATE preference. For example: Locate I/O loads of EDGE2EDGE clock signals to the top, left and right side I/O banks (bank 0, 1, 2, right porting of bank 3, left portion of bank 6, 7) for LatticeECP3 EA devices.

Example The following example defines the tx_clk signal as an EDGE2EDGE signal. In this example, the source for tx_clk is a non primary clock input (dedicated PIO, dedicated path from GDLL, dedicated path from GPLL, dedicated path from GDLL slave delay block).

```
USE EDGE2EDGE NET "tx_clk" ;
```

The following example defines the tx_clk signal as an EDGE2EDGE signal. In this example, the source for tx_clk is a primary clock input (dedicated PIO, PLL, DLL, CLKDIV, or PCS).

```
USE EDGE2EDGE NET "tx_clk" ;
USE PRIMARY NET “tx_clk”;
```

See Also ▶“USE PRIMARY2EDGE” on page 1269

USE PRIMARY

Uses a primary clock resource to route the specified net. The specified net should be a clock net. A USE SECONDARY preference overrides a USE PRIMARY for the same net if it appears later in the preference file.

The USE PRIMARY and USE SECONDARY physical preferences are needed when user intervention is required to route nets using primary and secondary clock resources. PAR uses various criteria for selecting the nets, including the number and type of loads, the availability of clock drivers, and the availability of clock trees.

Device Support All

Syntax USE PRIMARY [PURE | DCS] [NET <*net_name*> [<*quadrant_type*>+]];

where:

<*net_name*> ::= specific clock net name <*string*>

[(quadrant_type)+] ::= [QUADRANT_TL | QUADRANT_TR | QUADRANT_BL | QUADRANT_BR]

QUADRANT_TL ::= Top left

QUADRANT_TR ::= Top right

QUADRANT_BL ::= Bottom left

QUADRANT_BR ::= Bottom right

Note

Currently, a clock cannot be distributed to a set of quadrants where two of the quadrants are diagonal from each other unless the clock is distributed to all quadrants. This means that any set of three quadrants is illegal, as is a set of two quadrants that are diagonal from each other.

PURE ::= Clock spine will be routed without using DCS routing resource

DCS ::= Clock spine will be routed using DCS routing resource

Note

The DCS keyword uses DCS clock spines for routing only. To implement the actual DCS functionality, you must instantiate the DCS in the netlist.

When PURE or DCS is not specified, the clock spine routing can use DCS or PURE resources.

The PURE and DCS keywords are not supported for LatticeSC/M devices.

Examples The following command specifies that a primary clock resource will be used to route a clock net named **clk_fast**:

```
USE PRIMARY NET “clk_fast”;
```

The following command specifies that a primary clock resource will be used to route the clock net **bf_clk**. The clock spine will be routed using the DCS routing resource.

```
USE PRIMARY DCS NET “bf_clk”;
```

The following command specifies that a primary clock resource will be used to route the clock net. The clock spine will be routed without using the DCS routing resource, and it will use the Top Left Quadrant.

```
USE PRIMARY PURE NET “bf_clk” QUADRANT_TL;
```

USE PRIMARY2EDGE

Note

If there are multiple assignments for the same net, the last preference in the file will take precedence. This is a general condition for all preferences. See “Preference Conflict Resolution” on page 393.

Enables a primary clock to route to a single-edge clock or multiple-edge clocks on the device.

Device Support LatticeECP2/M, LatticeECP3, LatticeSC/M

Syntax USE PRIMARY2EDGE NET <*net_name*>

For LatticeECP2 and LatticeECP3 devices, use this syntax:

USE PRIMARY2EDGE NET <*net_name*>

USE PRIMARY NET <*net_name*>

where:

<*net_name*> is the name (<*string*>) of a specific edge clock net.

The PRIMARY2EDGE preference enables you to select a primary clock and route this clock to a single-edge clock or to multiple-edge clocks. It is useful for implementing a low-skew clock path to all sides of the device. The primary clock must be sourced from a dedicated primary clock source, such as a primary clock input, PLL, DLL, CLKDIV, or PCS.

Architecture Support For LatticeSC devices:

- Banks 1, 4, and 5 support two inputs for primary clocks to route to edge clocks.
- Banks 6 and 7 support two inputs for primary clocks to route to edge clocks for the entire side of the device.
- Banks 2 and 3 support two inputs for primary clocks to route to edge clocks for the entire side of the device.

For LatticeECP2 and LatticeECP3 devices:

- Single-edge and multiple-edge clocks are restricted to the left edge and the right edge.
- A maximum of two multiple-edge clocks are allowed.
- Only two clock signals can be assigned as PRIMARY2EDGE.

Note

Since a primary clock input is used instead of an edge clock input, the clock-injection delay is larger than that of a standard-edge clock.

Recommendations The following recommendations apply to LatticeSC devices:

- Locate any inputs or outputs using the clock to a specific bank. The Place and Route process will find a solution inside the bank, and the bank location will guide the placer.
- Do not include loads of this clock in a PGROUP, since this might cause a resource conflict.
- The same clock should not be assigned to both PRIMARY2EDGE and EDGE2EDGE, else the software will error out. See USE EDGE2EDGE for additional details.
- Locate I/O loads of PRIMARY2EDGE clock signals to the left and right side I/O banks for LatticeECP2/M and LatticeECP3 devices (bank 2, 3, 6, 7).

Examples The following example defines the tx_clk signal as a PRIMARY2EDGE signal for a LatticeSC device.

```
USE PRIMARY2EDGE NET "tx_clk" ;
```

The next example defines the tx_clk signal as a PRIMARY2EDGE signal for a LatticeECP2 or LatticeECP3 device.

```
USE PRIMARY2EDGE NET "tx_clk" ;
USE PRIMARY NET “tx_clk” ;
```

USE SECONDARY

Uses a secondary clock resource to route the specified net. The specified net should be a net driving CLK/CE/LSR inputs. A USE PRIMARY preference overrides a USE SECONDARY for the same net if it appears later in the preference file.

The USE PRIMARY and USE SECONDARY physical preferences are needed when user intervention is required to route nets using primary and secondary clock resources. PAR uses various criteria for selecting the nets, including the number and type of loads, the availability of clock drivers, and the availability of clock trees.

Device Support All except ECP5

Syntax USE SECONDARY [NET <*net_name*> [<*quadrant_type*>+]];

Note

QUADRANT assignments for the USE SECONDARY preference are supported only for LatticeXP and LatticeECP devices.

For LatticeECP3 devices, a net load driven by a secondary clock can be assigned to a particular clock region. Refer to the device’s data sheet for more information about clock regions. See Also “REGION” on page 1244.

USE SECONDARY [NET <*net_name*> [(clock_region_site_name) | REGION <*clock_region_name*>]];

where:

<*net_name*> ::= the specific name of a net to be routed using a secondary spine <*string*> (the secondary spine can drive clocks, CEs, resets, or some nodes in switch boxes)

<*quadrant_type*> ::= [QUADRANT_TL | QUADRANT_TR | QUADRANT_BL | QUADRANT_BR]

QUADRANT_TL ::= Top left

QUADRANT_TR ::= Top right

QUADRANT_BL ::= Bottom left

QUADRANT_BR ::= Bottom right

Note

Currently, a clock cannot be distributed to a set of quadrants where two of the quadrants are diagonal from each other unless the clock is distributed to all quadrants. This means that any set of three quadrants is illegal, as is a set of two quadrants that are diagonal from each other.

<clock_region_site_name> ::= the site of a clock region, identified by its location; for example, CLKREG_R2C2

<clock_region_name> ::= The user-defined alias of a clock REGION and its size. The alias is created using the REGION constraint.

Note

REGION <clock_region_name> is optional and can only be used when a separate clock region has been defined using the REGION <clock_region_name> <region_clock_space> preference. When REGION <clock_region_name> <region_clock_space> is used for secondary routing, it must precede the USE SECONDARY preference that references it in the logical preference file.

Using Wildcards For the USE SECONDARY preference, NET names with wildcard expressions are allowed. See “Using Wildcard Expressions in Preferences” on page 531 for details about wildcard usage and range expansion.

Example – secondary clock net loads assigned to a quadrant The following command specifies that a secondary clock resource will be used to route a clock net named clk_lessfast:

Note

If there are multiple assignments for the same net, the last preference in the file will take precedence. This is a general condition for all preferences. See “Preference Conflict Resolution” on page 393.

```
USE SECONDARY NET "clk_lessfast" QUADRANT_TL;
```

Example – secondary clock net loads assigned to a clock region This command specifies that a secondary clock resource will be used to route a clock net named clk1 and that all loads should be constrained to the clock region CLKREG_R5C2.

Note

It is possible to specify both placement of a component group (LOCATE UGROUP) and a net group (USE SECONDARY NET) to the same geographic area of the device. Since a net will drive certain logic, it is possible to make the component and net placements incompatible to each other. If a conflict occurs, the net placement has precedence and component placement will be ignored. Conflicts can be avoided by not using both types of placement constraints. However, there may be situations where net placement alone is not enough control where the logic should be placed

```
USE SECONDARY NET “clk1” “CLKREG_R5C2”;
```

See Also ▶“Defining a Clock REGION” on page 519

USERCODE

Specifies a code for storing device data such as firmware version number, manufacturer’s ID, programming date, programmer make, pattern code, or JEDEC file checksum. USERCODE assists with record maintenance and product flow control. The USERCODE format can be binary, hexadecimal, or ASCII. For LatticeXP/XP2 and MachXO devices, CHECKSUM can be used as USERCODE. For ECP5 devices, the Auto option is available, which enables you to specify a UNIQUE_ID for the design.

Device Support All

Syntax USERCODE <*usercode_format*> <*usercode*>;

USERCODE CHECKSUM;

USERCODE AUTO;

where:

<*usercode_format*> ::= BIN | HEX | ASCII | AUTO

Specifies one of the available formats for codes: binary (BIN), hexadecimal (HEX), text (ASCII), AUTO

<*usercode*> ::= string

Observe the following guidelines when specifying strings for user codes:

- For binary or BIN format, specify a 32-bit user code string using only 1 or 0 digits.

- For hexadecimal or HEX format, specify an eight-character user code string using only 0 through F values. If you enter a lowercase letter value, it will be converted to uppercase.
- For text or ASCII format, specify a four character user code string using only alpha and numeric values. Characters are case sensitive.
- For LatticeXP/XP2 and MachXO devices, CHECKSUM can be specified as user code in the logical preference file or in the Global Preferences sheet of Spreadsheet View.

Note

If you specify fewer characters than expected, the software will pad the code with zeroes to the correct number of characters. The software will not accept codes that exceed the expected number of characters for a given format.

In addition to the physical preference file (.prf), USERCODE is recorded in the data file: the JEDEC file (.jed) for non-volatile devices or the bitstream file (.bit) for volatile devices. The USERCODE can be read back by means of the JTAG port using the Diamond Programmer, a third-party programmer, or an embedded system.

Examples The following are examples of USERCODE preference usages for the various formats.

```
USERCODE BIN "01010011011001010110110101101001";
USERCODE HEX "53656D69";
USERCODE ASCII "Semi";
USERCODE CHECKSUM;
USERCODE AUTO;
```

Each of these USERCODE preference examples is reflected in the data file. For binary format (BIN), the JEDEC file will show U00000000000000000000010000011111* [bit order[31:0]. Notice that the USERCODE is padded by zeros on the left. For HEX format, the JEDEC file will contain the code UHEF456ADFF*. For ASCII format, the JEDEC file will contain the code UAanytext*. CHECKSUM will appear as HEX format in the JEDEC file.

For bitstream files, the USERCODE will only be stored in binary, since a bitstream is a binary file.

Refer to the Programmer online Help for more information about the use of USERCODE, CHECKSUM, and data files.

See Also ▶"USERCODE" on page 1336 attribute

VCC_DERATE

Defines the core voltage for derating.

Device Support All

Syntax VCC_DERATE <*volt_spec_vcc*>;

where:

<*volt_spec_vcc*> ::= NOMINAL | PERCENT (+<*number*> | -<*number*>)

Note

For parts that include a regulator, the correct value to enter is the core voltage after the regulator and not the VCC pin voltage for upper voltage parts.

NOMINAL: Nominal VCC core voltage value as specified in Supported Temperature and Voltage Range for Derating topic.

PERCENT (+<*number*> | -<*number*>): Nominal VCC value plus <*number*>% of VCC value or nominal VCC value minus <*number*>% of VCC value. The legal range is +5 to –5 in increments of 1.

Note

Allow up to +10 percent for MachXO2 HC devices.

Example The following preferences include VCC_DERATE that set both temperature and voltage derating for LatticeSC devices.

```
TEMPERATURE 25C;
VCC_DERATE NOMINAL;
VCCAUX_DERATE NOMINAL;
VCCIO_DERATE BANK 0 NOMINAL;
VCCIO_DERATE BANK 1 NOMINAL;
VCCIO_DERATE BANK 2 NOMINAL;
VCCIO_DERATE BANK 3 NOMINAL;
VCCIO_DERATE BANK 4 NOMINAL;
VCCIO_DERATE BANK 5 NOMINAL;
VCCIO_DERATE BANK 6 NOMINAL;
VCCIO_DERATE BANK 7 NOMINAL;
```

See Also ▶"Specifying Voltage and Temperature" on page 482

VCC_NOMINAL

Designates a nominal power supply voltage to a common collector terminal for a given circuit design. It is used to differentiate between chips running at different nominal voltages. The VCC_NOMINAL preference can be used with the VCC_DERATE value to derive a new voltage value. The priority of a given voltage preference would be as follows:

1. VCC_NOMINAL with VCC_DERATE preferences to specify a particular voltage

2. VOLTAGE preference only to specify a particular voltage
3. VCC_NOMINAL preference only to define a standard voltage without derating

Device Support All

Syntax VCC_NOMINAL <*volt_spec_vcc*>;

where:

<*volt_spec_vcc*> ::= (+<*number*>) V

Example The following examples show what occurs in different cases.

In the following case, the VCC_NOMINAL preference is ignored and the software honors the VOLTAGE preference.

```
VCC_NOMINAL 1.2V;
VOLTAGE 1.0V;
```

In the following case, the VOLTAGE preference is ignored because VCC_NOMINAL and VCC_DERATE coexist.

```
VCC_NOMINAL 1.2V;
VOLTAGE 1.0V;
VCC_DERATE PERCENT 5;
```

See Also ►"Specifying Voltage and Temperature" on page 482

VCC1P2_DERATE

Defines VCC12 core voltage for LatticeSC devices for derating.

Device Support LatticeSC/M

Syntax VCC1P2_DERATE <*volt_spec_vcc1p2*>;

where:

<*volt_spec_vcc1p2*> ::= NOMINAL | PERCENT (+<*number*> | -<*number*>)

NOMINAL: Nominal VCC12 core voltage value as specified in Supported Temperature and Voltage Range for Derating topic.

PERCENT (+<*number*> | -<*number*>): Nominal VCC12 value plus <*number*>% of VCC12 value or nominal VCC12 value minus <*number*>% of VCC12 value. The legal range is +5 to –5 in increments of 1.

Examples The following preferences include VCC12P_DERATE that set both temperature and voltage derating for LatticeSC devices.

```
TEMPERATURE 25C;
VCC_DERATE NOMINAL;
VCC1P2_DERATE NOMINAL;
VCCAUX_DERATE NOMINAL;
VCCIO_DERATE BANK 0 NOMINAL;
VCCIO_DERATE BANK 1 NOMINAL;
VCCIO_DERATE BANK 2 NOMINAL;
VCCIO_DERATE BANK 3 NOMINAL;
VCCIO_DERATE BANK 4 NOMINAL;
VCCIO_DERATE BANK 5 NOMINAL;
VCCIO_DERATE BANK 6 NOMINAL;
VCCIO_DERATE BANK 7 NOMINAL;
```

See Also ▶"Specifying Voltage and Temperature" on page 482

VCCA_DPHY0_DERATE / VCCA_DPHY1_DERATE

VCCA_DPHY0_DERATE / VCCA_DPHY1_DERATE is used to derate the MIPIDPHY power supply. Valid values are from -5% to 5%, starting from a base 1.2V.

Device Support LIFMD

Note

Only the UCFBGA64 package type of the LIFMD family of devices supports these two constraints.

Syntax VCCA_DPHY0/1_DERATE <volt_spec_vcc>;

where:

<*volt_spec_vcc*> ::= NOMINAL | PERCENT (+<*number*> | -<*number*>)

NOMINAL: 1.2V

PERCENT (+<*number*> | -<*number*>): Nominal VCC value plus <*number*>% of VCC value or nominal VCC value minus <*number*>% of VCC value. The legal range is +5 to -5 in increments of 1.

Example The following preferences include VCCA_DPHY0_DERATE / VCCA_DPHY1_DERATE that sets MIPIDPHY voltage derating for LIFMD devices.

```
VCCA_DPHY0_DERATE PERCENT -4;
VCCA_DPHY1_DERATE PERCENT -4;
```

VCCAUX_DERATE

Defines VCCAUX IO voltage for derating.

Device Support All

Syntax VCCAUX_DERATE <*volt_spec_vccaux*>;

where:

<*volt_spec_vccaux*> ::= NOMINAL | PERCENT (+<*number*> | -<*number*>)

NOMINAL: Nominal VCCAUX voltage value as specified in Supported Temperature and Voltage Range for Derating topic.

PERCENT (+<*number*> | -<*number*>): Nominal VCCAUX value plus <*number*>% of VCCAUX value or nominal VCCAUX value minus <*number*>% of VCCAUX value. The legal range is +5 to –5 in increments of 1.

Example The following preferences include VCCAUX_DERATE that set both temperature and voltage derating for LatticeSC devices.

```
TEMPERATURE 25C;
VCC_DERATE NOMINAL;
VCCAUX_DERATE NOMINAL;
VCCIO_DERATE BANK 0 NOMINAL;
VCCIO_DERATE BANK 1 NOMINAL;
VCCIO_DERATE BANK 2 NOMINAL;
VCCIO_DERATE BANK 3 NOMINAL;
VCCIO_DERATE BANK 4 NOMINAL;
VCCIO_DERATE BANK 5 NOMINAL;
VCCIO_DERATE BANK 6 NOMINAL;
VCCIO_DERATE BANK 7 NOMINAL;
```

See Also ▶"Specifying Voltage and Temperature" on page 482

VCCIO_DERATE

Defines VCCIO bank voltage for derating.

Device Support All

Syntax VCCIO_DERATE [BANK <*bank_number*>] <*volt_spec_vccio*>;

where:

The keyword BANK is optional. The <*bank_number*> field specifies the bank number of an I/O bank. The following are the supported I/O bank numbers:

- 0 for Bank0
- 1 for Bank1

- 2 for Bank2
- 3 for Bank3
- 4 for Bank4
- 5 for Bank5
- 6 for Bank6
- 7 for Bank7

<*volt_spec_vccio*> ::= NOMINAL | PERCENT (+<*number*> | -<*number*>)

NOMINAL: Nominal VCCIO value of the buffer type placed in a particular I/O bank. See available data sheets for information on nominal values.

PERCENT (+<*number*> | -<*number*>): Nominal VCCIO value plus or minus the <*number*>% VCCIO value of the buffer type placed in a particular I/O bank. The legal range is +5 to –5 in increments of 1.

Note

Allow up to +10 percent for MachXO2 HC devices.

Examples The following preferences include VCCIO_DERATE that set both temperature and voltage derating of "nominal" for your buffer type.

```
TEMPERATURE 25C;
VCC_DERATE NOMINAL;
VCCAUX_DERATE NOMINAL;
VCCIO_DERATE BANK 0 NOMINAL;
VCCIO_DERATE BANK 1 NOMINAL;
VCCIO_DERATE BANK 2 NOMINAL;
VCCIO_DERATE BANK 3 NOMINAL;
VCCIO_DERATE BANK 4 NOMINAL;
VCCIO_DERATE BANK 5 NOMINAL;
VCCIO_DERATE BANK 6 NOMINAL;
VCCIO_DERATE BANK 7 NOMINAL;
```

Like all other preferences, more specific VCCIO_DERATE preferences will override more generalized preferences. For example:

```
VCCIO_DERATE PERCENT -2;
VCCIO_DERATE BANK 3 PERCENT -5;
```

In this case, the banks 0-2 and 4-7 are covered by -2, while bank 3 is -5. When the preference engine reads those preferences, it will interpret PERCENT -2 for banks 0-2 and 4-7, while it uses PERCENT -5 for bank 3. When the changes are saved to the preference file the preferences will be written as follows:

See Also ▶"Specifying Voltage and Temperature" on page 482

```
VCCIO_DERATE BANK 0 PERCENT -2;
VCCIO_DERATE BANK 1 PERCENT -2;
VCCIO_DERATE BANK 2 PERCENT -2;
VCCIO_DERATE BANK 3 PERCENT -5;
VCCIO_DERATE BANK 4 PERCENT -2;
VCCIO_DERATE BANK 5 PERCENT -2;
VCCIO_DERATE BANK 6 PERCENT -2;
VCCIO_DERATE BANK 7 PERCENT -2;
```

VOLTAGE

Assigns a value for nominal FPGA core voltage. That is the central array and excluding I/Os. If no temperature or voltage preference is specified, the derating factor is 1.0.

Device Support All

Syntax VOLTAGE <*number*>V;

A space between the number and the voltage symbol is optional. See example.

Example The following preference assigns a value for nominal voltage of 1.5 V.

```
VOLTAGE 1.5V;
```

See Also ►"Specifying Voltage and Temperature" on page 482

HDL Attributes

HDL attributes are constraints that are attached as text to design objects and interpreted by the Diamond software. A design object can be a specific port, component pin, net, instance, instantiation, or even the entire design. An attribute provides information about the object. For example, an attribute might specify where a component in the logical design must be placed in the physical device, or it might specify a frequency constraint for a net that timing-driven place and route will attempt to meet.

The HDL attributes described in this section are those most commonly used as constraints in HDL source files or schematics. They generally apply to all designs and are not specific to any architecture. Unlike preferences that appear in the logical preference file (.lpf), these attributes must appear in the netlist. It is quite common, however, to use both preferences and HDL attributes. When both are included, the Diamond software uses the union of logical preferences and HDL attributes during an FPGA implementation.

HDL attributes are typically declared using comment notation in Verilog HDL or the VHDL Attribute keyword. They can also be assigned in the Schematic Editor using the property feature. HDL attributes are passed to the EDIF netlist through synthesis tools or by editing the netlist directly. Refer to the individual synthesis tool documentation for instructions. When EDIF2NGD reads the EDIF file, the attributes become part of the FPGA native generic database (.ngd).

Note

A comprehensive guide to library element HDL attributes is available in the "FPGA Libraries Reference Guide" on page 1664. For specific applications, refer to the technical notes that are available on the Lattice web site. Editing these library element attributes is not recommended, because they are usually generated from an array of choices that are made for module generation using IPexpress.

See Also ▶"Adding FPGA Attributes to HDL" on page 567

ALU_LOCK_CNT

Convention ALU_LOCK_CNT= 3, 4, 5,...15

Description Lock Count Cycles. Attached to a DLL element. Takes the integer set of 3 to 15.

Device Support LatticeECP3, LatticeSC/M

Examples For generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

ALU_UNLOCK_CNT

Convention ALU_UNLOCK_CNT= 3, 4, 5,...15

Description Unlock Count Cycles. Attached to a DLL element. Takes the integer set of 3 to 15.

Device Support LatticeECP3, LatticeSC/M

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

BBOX

Convention BBOX= x,x

Description Indicates the bounding box or the area given in number of rows and columns for a given UGROUP. The attribute must appear on the same block as the UGROUP attribute. This has replaced the old PBBOX attribute which is also still valid for backwards compatibility.

Device Support All

Syntax BBOX= H,W

where H is height, W is width.

For example, the following parameter indicates a BBOX that is three rows high and seven columns wide.

Figure 37:

```
BBOX= 3,7
```

The examples below show the BBOX attribute with an HGROUP definition. You will also see BBOX with the UGROUP definition.

VHDL Syntax attribute HGROUP: string;
attribute BBOX: string;

VHDL Example Code

```
attribute HGROUP of struct: architecture is
"reg_group";
attribute BBOX  of struct: architecture is "5,5";
```

Verilog Syntax – Precision //pragma attribute x HGROUP <hgroup_name>
//pragma attribute x BBOX <h,w>

Verilog Example Code – Precision

```
//pragma attribute x HGROUP
reg_group
```

```
//pragma attribute x BBOX 5,5
```

Verilog Syntax – Synplify /* synthesis HGROUP= "<hgroup_name>" BBOX= "<h,w>" */;

Verilog Example Code – Synplify `/* synthesis HGROUP= "reg_group" BBOX= "5,5" */;`

More Examples This is used in conjunction with a UGROUP definition, for example in the EDIF you would see BBOX appear as shown the following:

Figure 38:

```
(property UGROUP (string "SAND") )
(property BBOX (string "3, 20") )
```

After mapping, this would result as the following preference in the PRF file:

Figure 39:

```
PGROUP  "SAND"  BBOX  3  20
```

See Also ▶"Adding FPGA Attributes to HDL" on page 567

BLOCKNET

Convention BLOCKNET= name

Description Applied to a net, blocks timing analysis on the net when PAR or TRACE performs a timing analysis on the design. Any paths through the specified net are also blocked from the timing analysis.

When the design is mapped and the MAP program creates a preference file, the BLOCKNET attribute causes MAP to write a BLOCK NET preference into the preference file.

A net on which you attach a BLOCKNET attribute may not exist after the design is mapped, since it may be absorbed into a device logic cell. To avoid losing the net, attach a NOMERGE attribute to the net in addition to the BLOCKNET attribute. If the net is an output of sequential logic, you do not have to attach the NOMERGE attribute; these nets are never absorbed into logic cells.

Device Support All

Examples For generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

BUS

Convention BUS= name

Description This attribute is placed on a net or group of nets and defines a bus structure to be used in the following preferences: BLOCK, MAXDELAY, MAXSKEW, LOCK, PRIORITIZE, USE LONGLINE, and USE HALFLINE. All nets with the same BUS= attributes are identified as belonging to that bus. Translated by the mapper into the DEFINE BUS preference.

Name refers to the name applied to the bus. If attached to multiple nets, the resultant preference would be:

Figure 40:

```
DEFINE BUS <bus_name> NET <net1> NET <net2> NET <netN>;
```

Specifying these attributes in a netlist relieves designers of the task of searching for and identifying components and nets to construct preferences.

Device Support All

See Also ▶"Adding FPGA Attributes to HDL" on page 567

CLAMP

Convention CLAMP= OFF | ON | PCI

Default value of CLAMP for OUTPUT = OFF.

Default value of CLAMP for INPUT = ON if vccio is same as I/O standard.

Default value of CLAMP for INPUT = OFF if vccio is some other value than I/O standard.

Description The CLAMP option can be enabled for each IO independently. The available settings on the bottom edge of the 1200, 2k, 4k, 7k, and 10k devices is PCI or OFF. All other I/O can use the ON or OFF settings only. The CLAMP attribute is not supported for LVCMOS I/O types used in an under-drive or over-drive mode.

Device Support ECP5, MachXO2, MachXO3D, MachXO3L

VHDL Syntax – Synplify ATTRIBUTE CLAMP: string;
ATTRIBUTE CLAMP OF [pin_name]: SIGNAL IS "[mode]";

VHDL Example Code ATTRIBUTE CLAMP OF md: SIGNAL IS "PCI";

Verilog Syntax – Synplify PinType [pin_name] /* synthesis CLAMP="[mode]"*/;
[mode] = OFF, ON, PCI

Verilog Example Code output [4:0] portA /* synthesis CLAMP="ON"*/;

CLKDELAY

Convention CLKDELAY= DEL0|1|2|3

Description A CLKDELAY attribute can be placed on I/O platform registers for specifying cycle stealing. Map will determine the proper delay, ECLKDEL, CLKIDEL, or CLKODEL, based on clock usage. Attributes are attached to the registers themselves.

Related Attributes:

- CLKIDEL
- CLKODEL
- ECLKDEL

Device Support LatticeSC/M, LatticeXP/2, LatticeECP/EC

VHDL Syntax ATTRIBUTE CLKDELAY : string;
ATTRIBUTE CLKDELAY OF [pin_type]: SIGNAL IS "[signal_name]";

VHDL Example Code
```
attribute clkdelay : string;
attribute clkdelay of input_vector : signal is "DEL0";
```

Verilog Syntax – Precision //pragma attribute [pin_type] CLKDELAY [signal_name]

Verilog Example Code – Precision
```
//pragma attribute load clkdelay del1
```

Verilog Syntax – Synplify PinType [pin_type] /* synthesis CLKDELAY="[signal_name]"*/;

Verilog Example Code – Synplify
```
//input load /* synthesis CLKDELAY="DEL1" */;
```

CLKDELAY Written Out to Preference (.prf) File Here is an example of how CLKDELAY attributes might appear after they are written out to the preference file as the CLKDELAY logical preference in the post-map phase:

```
CLKDELAY CELL "clkdelay0" DEL0 ;
```

See Also CLKDELAY (Logical preference)

- “Adding FPGA Attributes to HDL” on page 567

CLKFB_FDEL

Convention CLKFB_FDEL= 0, 100, 200,...700

Description CLKFB Fine Delay Setting. Attached to a PLL element (e.g., EHXPLLA). Attribute can take the integer value set of 0, 100, 200,...700.

Device Support LatticeSC/M

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

CLKIDEL

Convention CLKIDEL= DEL0|1|2|3

Description A CLKIDEL attribute may be placed on input DDR registers for specifying cycle stealing and is used in conjunction with ECLKDEL attribute which is used for the EC Clock. The attributes belong on DDR instances.

Related Attributes:

- CLKODEL
- ECLKDEL
- CLKDELAY

Device Support LatticeSC/M, LatticeXP/2, LatticeECP/EC

VHDL Syntax ATTRIBUTE CLKIDEL : string;
ATTRIBUTE CLKIDEL OF [pin_type]: SIGNAL IS "[signal_name]";

VHDL Example Code
```
attribute clkidel : string;
attribute clkidel of input_vector : signal is "DEL0";
```

Verilog Syntax – Precision //pragma attribute [pin_type] CLKIDEL [signal_name]

Verilog Example Code – Precision)
```
//pragma attribute load clkidel del1
```

Verilog Syntax – Synplify PinType [pin_type] /* synthesis CLKIDEL="[signal_name]"*/;

Verilog Example Code – Synplify)
```
//input load /* synthesis CLKIDEL="DEL2" */;
```

CLKIDEL Written Out to Preference (.prf) File Here is an example of how CLKIDEL attributes might appear after they are written out to the preference file as the CLKDELAY logical preference in the post-map phase:

```
CLKDELAY CELL "clkidel0" DEL0 ;
```

See Also ▶CLKDELAY (Logical preference)

- ▶ “Adding FPGA Attributes to HDL” on page 567

CLKI_DIV

Convention CLKI_DIV= value

Description Input clock divider setting attached to a PLL element such as EHXPLLB. For LatticeSC/M and LatticeECP2/3 devices, can also be attached to a DLL element such as CIDLLA.

Device Support LatticeSC/M, LatticeECP2/3

Examples For generic examples of how to use FPGA attributes in your HDL, see Adding FPGA Attributes to HDL.

CLKI_FDEL

Convention CLKI_FDEL= 0, 100, 200,...700

Description CLKI Fine Delay Setting. Attached to a PLL element (e.g., EHXPLLA). Attribute can take the integer value set of 0, 100, 200,...700.

Device Support LatticeSC/M

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

CLKMODE

Convention CLKMODE= mode

Description Valid mode values are SCLK and ECLK. The default is SCLK.

Attached to either a register declaration for an I/O flip-flop, or an I/O flip-flop instance. CLKMODE directs mapper to use a clock by the edge clock routing. When applied with the value ECLK, the register will be clocked by ECLK.

It is recommended that this preference is put on the net closest to the flip-flop.

Device Support LatticeSC/M, LatticeECP2

VHDL Syntax ATTRIBUTE CLKMODE: string;
ATTRIBUTE CLKMODE OF [signal_name]: SIGNAL IS "[value]";

VHDL Example Code `attribute CLKMODE : string;`
`attribute CLKMODE of input1 : signal is "ECLK";`

Verilog Syntax – Precision //pragma attribute [signal_name] CLKMODE [value]

Verilog Example Code – Precision `//pragma attribute input1 CLKMODE ECLK`

Verilog Syntax – Synplify PinType [signal_name] /* synthesis CLKMODE ="[value]"*/;

Verilog Example Code – Synplify `input input1 /* synthesis CLKMODE ="ECLK" */;`

CLKODEL

Convention CLKODEL= DEL0|1|2|3

Description A CLKODEL attribute may be placed on output DDR registers for specifying cycle stealing and is used in conjunction with ECLKDEL attribute which is used for the EC Clock. The attributes belong on DDR instances.

Related Attributes:

- CLKIDEL
- ECLKDEL
- CLKDELAY

Device Support LatticeSC/M, LatticeXP/2, LatticeECP/EC

VHDL Syntax ATTRIBUTE CLKODEL : string;
ATTRIBUTE CLKODEL OF [pin_type]: SIGNAL IS "[signal_name]";

VHDL Example Code `attribute clkodel : string;`
`attribute clkodel of input_vector : signal is "DEL0";`

Verilog Syntax – Precision //pragma attribute [pin_type] CLKODEL [signal_name]

Verilog Example Code – Precision `//pragma attribute load clkodel del1`

Verilog Syntax – Synplify PinType [pin_type] /* synthesis CLKODEL="[signal_name]"*/;

Verilog Example Code – Synplify `//input load /* synthesis CLKODEL="DEL2" */;`

CLKODEL Written Out to Preference (.prf) File Here is an example of how CLKODEL attributes might appear after they are written out to the preference file as the CLKDELAY logical preference in the post-map phase:

```
CLKDELAY CELL "clkodel0" DEL0 ;
```

Figure 41: HDL Example

```
timescale 100ps/10ps
module
clkdiv_test(clk,reset,d_0,d_1,d_2,d_3,d_4,d_5,d_6,d_7,q_0,q_1,q
_2,q_3,q_4,q_5,q_6,q_7);
input clk;
input reset;
input d_0,d_1,d_2,d_3,d_4,d_5,d_6,d_7;

output q_0,q_1,q_2,q_3,q_4,q_5,q_6,q_7;

IFS1P3DX iff0 (.D(d_0), .SP(1'b1), .SCLK(clk),
.CD(reset),.Q(q_0)) /* synthesis CLKMODE = "ECLK" */;
IFS1P3DX iff1 (.D(d_1), .SP(1'b1), .SCLK(clk),
.CD(reset),.Q(q_1)) /* synthesis CLKMODE = "ECLK" */;
IFS1P3DX iff2 (.D(d_2), .SP(1'b1), .SCLK(clk),
.CD(reset),.Q(q_2)) /* synthesis CLKMODE = "ECLK" */;
IFS1P3DX iff3 (.D(d_3), .SP(1'b1), .SCLK(clk),
.CD(reset),.Q(q_3)) /* synthesis CLKMODE = "ECLK" */;
IFS1P3DX iff4 (.D(d_4), .SP(1'b1), .SCLK(clk),
.CD(reset),.Q(q_4)) /* synthesis CLKMODE = "ECLK" */;
IFS1P3DX iff5 (.D(d_5), .SP(1'b1), .SCLK(clk),
.CD(reset),.Q(q_5)) /* synthesis CLKMODE = "ECLK" */;
IFS1P3DX iff6 (.D(d_6), .SP(1'b1), .SCLK(clk),
.CD(reset),.Q(q_6)) /* synthesis CLKMODE = "ECLK" */;
IFS1P3DX iff7 (.D(d_7), .SP(1'b1), .SCLK(clk),
.CD(reset),.Q(q_7)) /* synthesis CLKMODE = "ECLK" */;
endmodule
```

See Also ▶CLKDELAY (Logical preference)

- “Adding FPGA Attributes to HDL” on page 567

CLKOP_DUTY

Convention CLKOP_DUTY= DISABLED | ENABLED

Description CLKOP Duty Cycle Disable/Enable. Attached to a PLL element (e.g., EHXPLLA). Attribute can take DISABLED or ENABLED values.

Device Support LatticeSC/M

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

CLKOS_DIV

Convention CLKOS_DIV= 1, 2, 3,...63, 64

Description CLKOS Divider Value Select. Attached to a PLL element (e.g., EHXPLLA). Attribute can take the integer values of 1-64.

Device Support LatticeSC/M, LatticeECP2/M, LatticeECP3, ECP5

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

CLKOS_FDEL

Convention CLKOS_FDEL= 0, 100, 200,...700

Description CLKOS Fine Delay Setting. Attached to a PLL element (e.g., EHXPLLA). Attribute can take the integer value set of 0 to 700.

Device Support LatticeSC/M

Examples For generic examples of how to use FPGA attributes in your HDL, “Adding FPGA Attributes to HDL” on page 567.

CLKOS_FPHASE

Convention CLKOS_FPHASE= 0, 11.25, 22.5, 45

Description CLKOS Fine Phase Select. Attached to a DLL element (e.g., TRDLLA). The parameters are decimal values 0, 11.25, 22.5, and 45.

Device Support LatticeSC/M, LatticeECP2/M, LatticeECP3, ECP5

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

CLKOS_PHASE

Convention CLKOS_PHASE= 0, 90, 180, 270, 360

Description CLKOS Phase Select. Attached to a PLL element (e.g., EHXPLLA). Attribute can take the integer value set of 0, 90, 180, 270, 360 degrees. CLKOS_PHASE and CLKOS_VCODEL. These two types of delays

are additive to create the final delay. CLKOS_PHASE works in terms of degrees of the VCO period. CLKOS_VCODEL works in terms of full VCO periods.

Device Support LatticeSC/M, LatticeECP2/M, LatticeECP3

Examples For generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

COARSE

Convention COARSE= CDEL0, CDEL1, CDEL2, CDEL3

Description Course delay. Attached to the DELAY element, this attribute takes CDEL delay parameters. The opposite is FINE.

Device Support LatticeSC/M

See Also ▶"Adding FPGA Attributes to HDL" on page 567

COMP (PLC)

Convention COMP (PLC)= <comp_name>

Description Attached to a block, specifies a name for the device component that is created when the block is mapped. If attached to multiple blocks, indicates that these blocks are to be mapped together in a component with the specified name.

When the device is mapped, the MAP program tries to map all blocks with the same COMP name in a single component, then give the resulting component the name specified by comp_name. If all of the blocks with the attribute cannot be placed in the same component, MAP groups together as many as possible.

If an I/O buffer is assigned a comp_name, the name must match the comp_name on the corresponding pad.

Device Support All

See Also ▶"Adding FPGA Attributes to HDL" on page 567

DCSMODE

Convention DCSMODE= NEG | POS | HIGH_LOW | HIGH_HIGH | LOW_LOW | LOW_HIGH | CLK0 | CLK1

Description Attached to a DCS element to set the particular mode. See the FPGA Libraries Help System for more on usage. The chart below shows possible values.

Figure 42:

Attribute Name	Description	Output		Value	DCS Fuse Settings				
		SEL = 0	SEL = 1		0	1	2	3	4
DCS MODE	Rising edge triggered, latched state is high	CLK0	CLK1	POS	1	0	0	0	0
	Falling edge triggered, latched state is low	CLK0	CLK1	NEG	0	0	0	0	0
	Sel is active high, Disabled output is low	0	CLK1	HIGH_LOW	0	1	0	0	0
	Sel is active high, Disabled output is high	1	CLK1	HIGH_HIGH	1	1	0	0	0
	Sel is active low, Disabled output is low	CLK0	0	LOW_LOW	0	0	1	0	0
	Sel is active low, Disabled output is high	CLK0	1	LOW_HIGH	1	0	1	0	0
	Buffer for CLK0	CLK0	CLK0	CLK0	0	0	1	0	1
	Buffer for CLK1	CLK1	CLK1	CLK1	0	1	0	1	0

Device Support LatticeSC/M, LatticeXP/2, LatticeECP/EC/ECP2

See Also ▶TN1103 - LatticeECP2/M sysCLOCK PLL/DLL Design and Usage Guide

- ▶ TN1049 - LatticeECP/EC and LatticeXP sysCLOCK PLL Design and Usage Guide

- ▶ “Adding FPGA Attributes to HDL” on page 567

DELAYTYPE

Convention DELAYTYPE= CFGBIT | DLL | PCLK | ECLK | ECLKINJ

Description This attributes specifies that delay type on the DELAY element.

Device Support LatticeSC/M

See Also ▶“Adding FPGA Attributes to HDL” on page 567

DIFFCURRENT

Convention DIFFCURRENT= NA, 2, 3P5, 4, 6

Description The differential current-source type driver has programmable output current in each mode of operation. The differential current-source type driver is available on the left and right sides only, primary pairs.

See the LatticeSC PURESPEED I/O Usage Guide for more information on this and related attributes. This is an attribute that is used with in conjunction IOBUF preference. To see how global preferences are honored for DIFFCURRENT in an IOBUF preference please see that topic.

Device Support LatticeSC/M, LatticeECP/EC

See Also ▶IO_TYPE

- "Adding FPGA Attributes to HDL" on page 567

DIFFDRIVE

Convention DIFFDRIVE= 1.6, 1.65, 1.7, 1.75, 1.81, 1.87, 1.93, 2.0

Description This attribute sets the differential current drive strength for the MINILVDS output standard. An IO bank can only have differential outputs with the same DIFFDRIVE setting. The default value is set to 1.6mA.

Device Support LatticeECP3, ECP5, MachXO2, MachXO3D, MachXO3L

VHDL Syntax ATTRIBUTE DIFFDRIVE : string;

ATTRIBUTE DIFFDRIVE OF [pin_name]: SIGNAL IS "[diffdrive_strength]";

VHDL Example Code
```
ATTRIBUTE DIFFDRIVE OF portD: SIGNAL IS "1.6";
```

Verilog Syntax – Precision //pragma attribute [pin_name] DIFFDRIVE [diffdrive _strength]

Verilog Example Code – Precision
```
//pragma attribute q_minilvds DIFFDRIVE 1.6
```

Verilog Syntax – Synplify PinType [pin_name] /* synthesis IO_TYPE="[type_name]" DIFFDRIVE="[diffdrive_strength]"*/;

Verilog Example Code – Synplify
```
output mypin /* synthesis IO_TYPE="MINILVDS" DIFFDRIVE="1.6"*/;
```

See Also ▶"MULTDRIVE" on page 1313

- "IOBUF Attributes" on page 476

DIFFRESISTOR

Convention DIFFRESISTOR= OFF (default), 120, 150, 220, 420 (Only for differential buffers)

Description Attribute attached to input and output buffers (e.g., IB, OB) and is used to provide differential termination. It is only available for differential I/O types (see IO_TYPE). In case of a differential output termination, this is only available on the primary pads of the PIO. You have the option to turn on the common mode differential termination. See the VCMT attribute for details.

Device Support LatticeSC/M, LatticeECP3

See the LatticeSC PURESPEED I/O Usage Guide for more information on this and related attributes. This is an attribute that is used with in conjunction IOBUF preference. To see how global preferences are honored for DIFFRESISTOR in an IOBUF preference please see that topic.

See Also ▶"Adding FPGA Attributes to HDL" on page 567

DIN

Convention DIN= <signal_name> [FALSE | TRUE] [CELL <cell_name>]

Description This attribute instructs map to pack a DIN/DOUT register into PIO/IOLOGIC sites. A DIN attribute must occur on the register rather than on a buffer as for legacy architectures. See also USE DIN CELL logical preference.

Device Support LatticeSC/M, LatticeXP/2, LatticeECP/EC, LatticeECP2/M

Rules for using DIN/DOUT

- ▶A DIN attribute must occur on the register rather than on a buffer.
- Mapper attempts to map DIN/DOUT register into PIO/IOLOGIC sites. If unsuccessful, an error message is printed and mapper terminates.
- The registers must conform to PIO/IOLOGIC rules in order for them to be mapped properly. If not, error messages are printed.
- DIN will not work when the input flip-flop is driven by combinational logic.
- DOUT will not work when the output flip-flop drives combinational logic other than OS(E)MUX21.

VHDL Syntax ATTRIBUTE DIN : string;
ATTRIBUTE DIN OF [pin_type]: SIGNAL IS "[signal_name]";

VHDL Example Code
```
attribute din : string;
attribute din of input_pin_abc : signal is "TRUE";
```

Verilog Syntax – Precision //pragma attribute [pin_type] DIN [signal_name]

Verilog Example Code – Precision
```
//pragma attribute input_pin_abc din TRUE
```

Verilog Syntax – Synplify PinType [pin_type] /* synthesis DIN="[signal_name]"*/;

Verilog Example Code – Synplify `//input input_pin_abc /* synthesis din="TRUE" */;`

DIN/DOUT Logical Preference (.lpf) File

```
USE DIN CELL "r" ;
USE DIN FALSE CELL "r" ;
USE DIN TRUE CELL "r" ;
USE DOUT CELL "q" ;
```

DIN/DOUT Written Out to Physical Preference (.prf) File Here is an example of how DIN/DOUT attributes might appear after they are written out to the physical preference file in the post-map phase:

Figure 43:

```
LOCATE COMP "DD1" SITE "29" ;
USE DIN COMP "DD1" ;
LOCATE COMP "QQ2" SITE "75" ;
USE DOUT COMP "QQ2" ;
LOCATE COMP "BIDIPIN" SITE "127" ;
USE DIN COMP "BIDIPIN" ;
USE DOUT COMP "BIDIPIN" ;
LOCATE COMP "QQ5" SITE "180" ;
USE DOUT COMP "QQ5" ;
```

See Also ▶"Adding FPGA Attributes to HDL" on page 567

DOUT

Convention DOUT= <signal_name> [FALSE | TRUE] [CELL <cell_name>]

Description This attribute instructs map to pack a DIN/DOUT register into PIO/IOLOGIC sites. A DIN attribute must occur on the register rather than on a buffer as for legacy architectures. See also USE DOUT CELL logical preference.

Device Support LatticeSC/M, LatticeXP/2, LatticeECP/EC, LatticeECP2/M

Rules for using DIN/DOUT ▶A DIN attribute must occur on the register rather than on a buffer.

- Mapper attempts to map DIN/DOUT register into PIO/IOLOGIC sites. If unsuccessful, an error message is printed and mapper terminates.
- The registers must conform to PIO/IOLOGIC rules in order for them to be mapped properly. If not, error messages are printed.
- DIN will not work when the input flip-flop is driven by combinational logic.

- DOUT will not work when the output flip-flop drives combinational logic other than OS(E)MUX21.

VHDL Syntax ATTRIBUTE DOUT : string;
ATTRIBUTE DOUT OF [pin_type]: SIGNAL IS "[signal_name]";

VHDL Example Code
```
attribute dout : string;
attribute dout of output_pin_abc : signal is "TRUE";
```

Verilog Syntax – Precision //pragma attribute [pin_type] DOUT [signal_name]

Verilog Example Code – Precision
```
//pragma attribute
output_pin_abc dout TRUE
```

Verilog Syntax – Synplify PinType [pin_type] /* synthesis DOUT="[signal_name]"*/;

Verilog Example Code – Synplify
```
//output output_pin_abc /*
synthesis dout="TRUE" */;
```

DIN/DOUT Logical Preference (.lpf) File
```
USE DIN CELL "r" ;
USE DIN FALSE CELL "r" ;
USE DIN TRUE CELL "r" ;
USE DOUT CELL "q" ;
```

DIN/DOUT Written Out to Physical Preference (.prf) File Here is an example of how DIN/DOUT attributes might appear after they are written out to the physical preference file in the post-map phase:

Figure 44:

```

USE DIN COMP "DD1" ;
LOCATE COMP "QQ2" SITE "75" ;
USE DOUT COMP "QQ2" ;
LOCATE COMP "BIDIPIN" SITE "127" ;
USE DIN COMP "BIDIPIN" ;
USE DOUT COMP "BIDIPIN" ;
LOCATE COMP "QQ5" SITE "180" ;
USE DOUT COMP "QQ5" ;
```

See Also ▶"Adding FPGA Attributes to HDL" on page 567

DRIVE

Convention DRIVE= NA, 2, 4, 8 (default), 12, 16, 24

Description Attached to bidirectional and output buffers (e.g., BB, BBPD, OB, OBW), the drive strength attribute is available for output standards that support programmable drive strength. Refer to the SysIO Usage Guides to see the IOTYPES that support valid drive strength standards.

See the LatticeSC PURESPEED I/O Usage Guide for more information on this and related attributes. This is an attribute that is used with in conjunction IOBUF preference. Refer to IOBUF to see how global preferences are honored for DRIVE in an IOBUF preference.

The programmable drive available on a pad will depend on the VCCIO. Also, not all drive strengths are available on an alternate PIO pad. Both the single-ended driver and differential current source driver have programmable drive strength. Only three drive settings are available when operating at 3.3 volts.

Table 138: Valid Drive Strength Table

Drive Strength (mA)	VCCIO 1.2V	VCCIO 1.5V	VCCIO 1.8V	VCCIO 2.5V	VCCIO 3.3V
2	X				
4	X	X	X	X	
8	X	X	X	X	X
12	X	X	X	X	
16		X	X	X	X
24					X

Device Support All

VHDL Syntax ATTRIBUTE DRIVE : string;
ATTRIBUTE DRIVE OF [pin_name]: SIGNAL IS "[drive_strength]";

VHDL Example Code `ATTRIBUTE DRIVE OF portD: SIGNAL IS "8";`

Verilog Syntax – Precision //pragma attribute [pin_name] DRIVE [drive_strength]
[drive_strength] = 2, 4, 8, 12, 16, 20

Verilog Example Code – Precision `//pragma attribute q_lvttl33_20 DRIVE 20`

Verilog Syntax – Synplify PinType [pin_name] /* synthesis IO_TYPE="[type_name]" DRIVE="[drive_strength]" PULLMODE="[mode]" SLEWRATE="[value]"*/;
[drive_strength] = 2, 4, 8, 12, 16, 20

Note: Example given for Pin I/O Type configuration.

Verilog Example Code – Synplify `//output mypin /* synthesis IO_TYPE="LVTTL33D" DRIVE="16" PULLMODE="UP" SLEWRATE="FAST"*/;`

More Examples The following are examples I/O Type settings using the LatticeEC device family for purposes of demonstration. These all include DRIVE attribute examples:

- VHDL source attribute example

  Path: *<install_dir>/examples/fpga/LatticeEC/preferences_attributes/iotype_drive_pullmode_slewrate/VHDL/iovhdl.vhd*

- Verilog source attributes example (Precision)

  Path: *<install_dir>/examples/fpga/LatticeEC/preferences_attributes/iotype_drive_pullmode_slewrate/verilog_mentor/vlogio.v*

- Verilog source attribute example (Synplify)

  Path: *<install_dir>/examples/fpga/LatticeEC/preferences_attributes/iotype_drive_pullmode_slewrate/verilog_synplify/vlogio.v*

Note

There are also example files for other FPGA architectures available in corresponding directories in the <install_dir>/ispcpld/examples path. For generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

See Also ▶IO_TYPE

ECLKDEL

Convention ECLKDEL= DEL0|1|2|3

Description Used for the EC Clock, an ECLKDEL attribute may be placed on input DDR registers for specifying cycle stealing. The attribute belongs on DDR instances.

Related Attributes:

- CLKIDEL
- CLKODEL
- CLKDELAY

Device Support LatticeSC/M, LatticeXP/2, LatticeECP/EC

VHDL Syntax ATTRIBUTE ECLKDEL : string; ATTRIBUTE ECLKDEL OF [pin_type]: SIGNAL IS "[signal_name]";

VHDL Example Code
```
attribute eclkdel : string;
attribute eclkdel of input_vector : signal is "DEL0";
```

Verilog Syntax – Precision //pragma attribute [pin_type] ECLKDEL [signal_name]

Verilog Example Code – Precision
```
//pragma attribute load eclkdel del1
```

Verilog Syntax – Synplify PinType [pin_type] /* synthesis ECLKDEL="[signal_name]"*/;

Verilog Example Code – Synplify `//input load /* synthesis ECLKDEL="DEL2" */;`

ECLKDEL Written Out to Preference (.prf) File Here is an example of how ECLKDEL attributes might appear after they are written out to the preference file as the CLKDELAY logical preference in the post-map phase:

Figure 45:

```
CLKDELAY CELL "eclkdel0" DEL0 ;
```

See Also ▶CLKDELAY (Logical preference)

- Adding FPGA Attributes to HDL

EQ_CAL

Convention EQ_CAL=value

Description Equalization filtering, available for single-ended inputs on both true and complementary I/Os and for differential inputs on true I/Os. Equalization is required to compensate for the difficulty of sampling alternating logic transitions with relatively slow slew rate.

Value: 0

Device Support LatticeECP3

VHDL Syntax ATTRIBUTE EQ_CAL : string;
ATTRIBUTE EQ_CAL OF [*pin_name*] : signal is “[*value*]”;

VHDL Example Code

```
attribute eq_cal: string;
attribute eq_cal of input1: signal IS "0";
```

Verilog Syntax – Precision //pragma attribute *pin_name* EQ_CAL [*value*]

Verilog Example Code – Precision `//pragma attribute input1 EQ_CAL 0`

Verilog Syntax – Synplify PinType [*pin_name*] /* synthesis EQ_CAL ="[value]"*/;

Verilog Example Code – Synplify `input input1 /* synthesis EQ_CAL ="0"*/;`

EQ_CAL Logical Preference (.lpf) File EQ_CAL = value

Preference File Example EQ_CAL=0 ;

FDEL

Convention FDEL=value

Description Fine delay adjust. Attached to a PLL element (e.g., EHXPLLB). Attribute can take the integer value set of {-8...8).

Device Support LatticeSC/M, LatticeXP/2, LatticeECP/EC

Examples For generic examples of how to use FPGA attributes in your HDL, see Adding FPGA Attributes to HDL.

FINE

Convention FINE= FDEL0, FDEL1, FDEL2,... FDEL47

Description Fine delay. Attached to the DELAY element, this attribute takes FDEL delay parameters. The opposite is COARSE.

Device Support LatticeSC/M

See Also ▶Adding FPGA Attributes to HDL

FIXEDDELAY

Convention FIXEDDELAY= FALSE | TRUE

Description FIXEDDELAY can be used to achieve zero hold time for the input registers when a direct drive primary clock (no PLL) is employed. In order for zero hold time to be achieved, the fixed delay must delay the data by at least as much as the primary clock injection delay.

(MachXO) The MachXO 1K and 2K devices have a programmable input delay element at all the input pins. This programmable delay can be turned on or off. The attribute can be used when the input is tied to an I/O register. The programmable input delay is used to achieve zero hold time. For MachXO 256 and 640 device fixed delay, the software determines whether to turn the delay fuse on or off depending on the tCO constraints. For MachXO 1200 and 2280 programmable delay, the software sets the delay fuse depending on both placement and tCO constraints.

This attribute takes the following string values as shown below and as illustrated in the syntax above:

Values: TRUE, FALSE

Default: FALSE

Device Support LatticeXP/2, MachXO, LatticeECP/EC, LatticeECP3

Note

The FIXEDDELAY attribute can only be applied to input signals of input registers in VHDL or Verilog files. By default, Synplify no longer infers input registers, so when you use Synplify with a VHDL or Verilog file that contains the FIXEDDELAY attribute, the mapper issues an error message.

For the FIXEDDELAY attribute to work with Synplify, you must also add the SYN_USEIOFF attribute to the VHDL or Verilog file to infer I/O registers.

Error Checking in Map Report FIXEDDELAY can be assigned to input signals of registers that are present in the Programmable I/O (PIO) cells. If FIXEDDELAY is assigned to any registers elsewhere, it will cause Map errors. You can see what is happening by viewing the Map report (.mrp) file. In the Design Summary section, you will see a line similar to the following:

Figure 46:

```
Number of PIO FIXEDDELAY:  7
```

This identifies the number of input registers with a FIXEDDELAY=TRUE attribute value. Secondly, the IO (PIO) Attributes section will show any input register that has this FIXEDDELAY attribute set to TRUE.

See Also ▶Adding FPGA Attributes to HDL

FREQUENCY

Convention FREQUENCY= xxx

Description Clock net attribute used to identify the minimum operating frequency for all sequential output to sequential input pins clocked by the specified net. This is translated by the mapper into the FREQUENCY preference. If the net is optimized away, no preference is generated.

The xxx value is expressed in MHz. The resultant preference would be:

Figure 47:

```
FREQUENCY NET <netname> xxx MHz;
```

Device Support All

See Also ▶Adding FPGA Attributes to HDL

GSR

Convention GSR= DISABLED | ENABLED

Description Use to enable/disable the global set/reset (GSR) for all registered elements from these families. For example, this attribute is applicable to registers, PLLs, and memories such as SP8KA, DP8KA and the like.

Device Support All

Examples For specific usage examples for the GSR attribute, see the "Programmable GSR Verilog HDL Example for a Synchronous RTL Module" section in the "How to Use the Global Set/Reset (GSR) Signal" on page 1174 topic. For generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

HGROUP

Convention HGROUP= <identifier>

Description Hierarchical grouping construct. HGROUP is used for grouping components that are to be instantiated multiple times. It indicates a logical partition of a group of components that gets translated into a physical partition for PAR.

Note

In Diamond, use the HGROUP attribute instead of PGROUP. This topic remains viable for earlier versions of the software and for purposes of forward compatibility.

Device Support All

VHDL Syntax attribute HGROUP: string;
attribute BBOX: string;

VHDL Example Code:
```
attribute HGROUP of struct: architecture
is "reg_group";
attribute BBOX  of struct: architecture is "5,5";
```

Verilog Syntax – Precision //pragma attribute x HGROUP <hgroup_name>
//pragma attribute x BBOX <h,w>

Verilog Example Code – Precision
```
//pragma attribute x HGROUP
reg_group
//pragma attribute x BBOX 5,5
```

Verilog Syntax – Synplify /* synthesis HGROUP= "<hgroup_name>" BBOX= "<h,w>" */;

Verilog Example Code – Synplify
```
/* synthesis HGROUP= "reg_group" BBOX= "5,5" */;
```

See Also ▶HGROUP (preference)

- UGROUP (attribute)
- UGROUP (preference)
- REGION (attribute)
- REGION (preference)
- “Adding FPGA Attributes to HDL” on page 567

HULOC

Convention HULOC = <row#col#>

Description HULOC indicates the physical location of the northwest corner of an HGROUP or UGROUP assignment. This should be attached to same block where HGROUP/UGROUP is specified. This attribute must appear on same block as HGROUP/UGROUP. This has replaced the old PLOC attribute which is also still valid for backwards compatibility.

Device Support All

In the following examples, HULOC is used to anchor a UGROUP definition.

VHDL Syntax attribute UGROUP: string;
attribute UGROUP of <object>: label is "<ugroup_name>";
[attribute HULOC: string;
attribute HULOC of <object>: label is "<site_name>";]
[attribute BBOX: string;
attribute BBOX of <object>: label is "<height>,<width>";

VHDL Example Code
```
attribute UGROUP: reg_group;
attribute UGROUP of x: label is "reg_group";
[attribute HULOC: R10C22D;
attribute HULOC of x: label is "R10C22D";]
[attribute BBOX: 9,7;
attribute BBOX of <object>: label is "9,7";]
```

Verilog Syntax – Precision // pragma attribute <object> UGROUP <ugroup_name>
[// pragma attribute <object> HULOC <site_name>]
[// pragma attribute <object> BBOX <height>,<width>]

Verilog Example Code – Precision
```
//pragma attribute x UGROUP reg_group
//pragma attribute x HULOC R5C19D
//pragma attribute x BBOX 6,4
```

Verilog Syntax – Synplify /* synthesisUGROUP= "<hgroup_name>"
HULOC= "<site_name>"
BBOX= "<h,w>"
*/;

Verilog Example Code – Synplify
```
/* synthesis UGROUP= "reg_group"
HULOC= "R5C19D"
BBOX= "6,4"
*/;
```

More Examples For more generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

See Also ▶HGROUP (attribute)

- ▶ HGROUP (preference)
- ▶ UGROUP (attribute)
- ▶ UGROUP (preference)

HURLOC

Convention HURLOC = <row#col#>

Description HURLOC indicates the northwest corner of a region for a given HGROUP or UGROUP definition. This attribute must appear on the same block as REGION attribute (old attribute is PREGION). Required if REGION exists. This has replaced the old PRLOC attribute which is also still valid for backwards compatibility.

Device Support All

Examples For generic examples of how to use FPGA attributes in your HDL, see the "Adding FPGA Attributes to HDL" on page 567 topic.

See Also ▶REGION (attribute)

- ▶ REGION (preference)

HYSTERESIS

Convention HYSTERESIS=SMALL | LARGE | NA

Description The ratioed input buffers have 2 input hysteresis settings. The HYSTERESIS option can be used to change the amount of hysteresis for the PCI, LVTTL and LVCMOS input and bidirectional I/O standards, except for the LVCMOS12 inputs.

The LVCMOS25R33, LVCMOS18R25, LVCMOS18R33, LVCMOS15R25, and LVCMOS15R33 input types do not support HYSTERESIS so this setting is

always disabled for these types. HYSTERESIS is not supported for LVCMOS I/O types when used in an under-drive or over-drive mode.

The HYSTERESIS option for each of the input pins can be set independently when hysteresis is supported for the IO_TYPE assigned to the input pin.

Device Support ECP5, MachXO2, MachXO3D, MachXO3L

VHDL Syntax – Synplify ATTRIBUTE HYSTERESIS: string; ATTRIBUTE HYSTERESIS OF [signal_name]: SIGNAL IS "[SMALL | LARGE | NA]";

VHDL Example Code ATTRIBUTE HYSTERESIS OF q_lvttl33_17: SIGNAL IS " LARGE ";

Verilog Syntax – Synplify /* synthesis attribute HYSTERESIS [of] signal_name [is] [SMALL | LARGE | NA] */;

Verilog Example Code /* synthesis attribute HYSTERESIS of q_lvttl33_17 is LARGE */;

IMPEDANCE

Convention IMPEDANCE= OFF (default), 25, 33, 50, 100

Description This attribute sets the on-chip programmable output impedance. This programmable option can be set for each of the I/O individually. This attribute sets a series termination. Programmable output impedance is not supported for 3.3 volt drivers. In programmable output impedance mode, the driver legs and passgates are calibrated against an external resistor connected on pin XRES. The default is OFF. See the LatticeSC PURESPEED I/O Usage Guide for more information on this and related attributes.

Device Support LatticeSC/M

Examples For generic examples of how to use FPGA attributes in your HDL, see the "Adding FPGA Attributes to HDL" on page 567 topic.

See Also ▶"IO_TYPE" on page 1309

IMPEDANCEGND

Convention IMPEDANCEGND= OFF (default), 16.7, 20, 25, 33, 50, 100 (Impedance down)

Description Attached to output and bidirectional buffers, this attribute is OFF by default. This attribute sets the on chip series terminations. This programmable option can be set for each of the I/O individually. This attribute sets a pull down series impedance.

The 25, 20 and 16.7 ohm terminations are only available on the primary pads of the PIO, the rest are available for both primary and alternate pads. The impedance for GND can be set to the values of 16.7, 20, 25, 33, 50 and 100.

Device Support LatticeSC/M

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

See Also ▶“IO_TYPE” on page 1309

IMPEDANCEVCCIO

Convention IMPEDANCEVCCIO= OFF (default), 16.7, 20, 25, 33, 50, 100 (Impedance up)

Description Attached to output and bidirectional buffers, this attribute is OFF by default. This attribute sets the on chip series terminations. This programmable option can be set for each of the I/O individually. This attribute sets a pullup series impedance.

The 25, 20 and 16.7ohm terminations are only available on the primary pads of the PIO, the rest are available for both primary and alternate pads. The impedance for VCCIO can be set to the values of 16.7, 20, 25, 33, 50 and 100.

Device Support LatticeSC/M

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

See Also ▶“IO_TYPE” on page 1309

INBUF

Convention INBUF= OFF | ON

Description INBUF is a global setting. All unused input buffers are disabled when INBUF is OFF to save power. When you need to perform boundary scan testing, you must turn ON the INBUF attribute. Turning ON this INBUF attribute will turn on the input buffers.

Defaults are OFF for ECP5, LatticeECP/EC and LatticeECP2/M and ON for LatticeXP/2, MachXO, MachXO2. MachXO3D, and MachXO3L/LF. See the chart below for defaults for all device families.

For LatticeECP2/M devices, powersave is always on by default. There is no powersave mode. Built-in intelligence will turn ON powersave when it sees no inputs are used in the design.

Below is a table listing the defaults of INBUF based on device family.

Table 139: INBUF Defaults for Device Families

Device Family	Default for INBUF
ECP5	OFF
LatticeEC	OFF
LatticeXP/LatticeXP2	ON
LatticeECP/LatticeECP2/M	OFF
MachXO	ON
MachXO2	ON
MachXO3D	ON
MachXO3L/LF	ON

This attribute can also be set in the Global Preferences sheet of Spreadsheet View.

Device Support ECP5, LatticeECP/EC, LatticeXP/2, LatticeECP2/M, MachXO, MachXO3D, MachXO2, and MachXO3L/LF.

VHDL Syntax ATTRIBUTE INBUF : string;
ATTRIBUTE INBUF OF [module_name]: entity IS "[value]";

VHDL Example Code
```
ATTRIBUTE INBUF : string;
ATTRIBUTE INBUF OF behave: entity IS "OFF";
```

Verilog Syntax – Precision //pragma attribute module_name INBUF [value]

Verilog Example Code – Precision
```
//pragma attribute pci_top
INBUF OFF
```

Verilog Syntax – Synplify module [module_name] (ports) /* synthesis INBUF= "[value]"*/;

Verilog Example Code – Synplify
```
module pci_top (portA, portB) /*
synthesis INBUF= "OFF" */;
```

More Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

INIT

Convention INIT= value
INIT=ENABLED | DISABLED (LatticeSC Memory)

Description Initializes the look-up table values for all device families. Provides initialization control for some LatticeSC memories.

INIT is required to specify the look-up table values for LUT elements ORCALUT4, 5, 6, 7, or 8.

When attached to LatticeSC RAM elements PDP16KA, SP16KA, and DP16KA, the INIT attribute is set to ENABLED to allow memory initialization. (Back-end tools will set this value if an initialization file is provided.)

See INITVAL and the FPGA Libraries Guide for DP16KA and other memories for details on memory initialization.

See the ORCALUT4 topic in the FPGA Libraries Help for code examples and more information on INIT attribute usage.

Device Support All

Example – ORCALUT4 LUT Value This VHDL example demonstrates the use of INIT with the ORCALUT4 library element.

Figure 48:

```
 component ORCALUT4  port (
      A,B,C,D : In    std_logic;
            Z : Out   std_logic );
   end component;
   attribute INIT: string;
--                                  FEDCBA9876543210
-- attribute INIT of I2: label is "1000000000000000"; --
Z=A*B*C*D
   attribute INIT of I2: label is "1111111111111110"; --
Z=A+B+C+D
```

For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

INITVAL

Convention INITVAL= value

Description Specifies the initialization value for memory elements such as SPR16X2 and DPR16X2. These elements carry prescribed initialization values. For example, DPR16X2 has an initialization value of 0x0000000000000000.

Refer to the “FPGA Libraries Reference Guide” on page 1664.

for more details on memory elements and the INITVAL attribute.

Device Support All

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

IO_TYPE

Convention IO_TYPE= buffer type

Description This is used to set the I/O standard for an I/O (input, output, and bidirectional buffers, e.g., IB, OB, and BB). It can takes multiple values that differ slightly depending on which element you are using. The VCCIO required to set these IO standards are embedded in the attribute names. There is no separate attribute to set the VCCIO requirements.

This attribute is used in conjunction with the IOBUF preference. Refer to IOBUF to see how global preferences are honored for IO_TYPE. For valid buffer types, refer to the specific element in the FPGA Libraries Help. See the sysIO usage guides for legal IO_TYPE for inputs and outputs.

Examples of attribute usage for VHDL and Verilog are included in this topic.

Device Support All

Values LVDS, BLVDS25, MLVDS25, RSDS, LVPECL25, LVPECL33, HSTL15_I, HSTL15_II, HSTL15_III, HSTL15_IV, HSTL15D_I, HSTL15D_II, HSTL18_I, HSTL18_II, HSTL18_III, HSTL18_IV, HSTL18D_I, HSTL18D_II, SSTL18_I, SSTL18_II, SSTL18D_I, SSTL18D_II, SSTL25_I, SSTL25_II, SSTL25D_I, SSTL25D_II, SSTL33_I, SSTL_II, SSTL33D_I, SSTL33D_II, GTLPLUS15, GTL12, LVTTL33, LVTTL33D, LVCMOS33, LVCMOS25, LVCMOS18, LVCMOS15, LVCMOS12, PCI33, PCIX33, PCIX15, AGP1X33, AGP2X33, LVCMOS25D, LVCMOS33D, LVCMOS18D, LVCMOS15D, LVCMOS12D

Default LVCMOS25

VHDL Syntax ATTRIBUTE IO_TYPE : string;
ATTRIBUTE IO_TYPE OF [pin_name]: SIGNAL IS "[type_name]";

Example Code:
```
ATTRIBUTE IO_TYPE OF portA: SIGNAL IS "PCI33";
ATTRIBUTE IO_TYPE OF portB: SIGNAL IS "LVCMOS33";
ATTRIBUTE IO_TYPE OF portC: SIGNAL IS "SSTL33_II";
ATTRIBUTE IO_TYPE OF portD: SIGNAL IS "LVCMOS25";
```

Verilog Syntax – Precision //pragma attribute [pin_name] IO_TYPE [type_name]
[type_name] = (valid I/O type, e.g., LVCMSO18)

Verilog Example Code – Precision
```
//pragma attribute d_lvds25e IO_TYPE LVDS25E
```

Verilog Syntax – Synplify PinType [pin_name] /* synthesis IO_TYPE="[type_name]" DRIVE="[drive_strength]" PULLMODE="[mode]" SLEWRATE="[value]"*/;
[value] = (valid I/O type, e.g., LVCMSO18)

Note: Example given for Pin I/O Type configuration.

Verilog Example Code – Synplify
```
output [4:0] portA /* synthesis IO_TYPE="LVTTL33" DRIVE="16" PULLMODE="UP" SLEWRATE="FAST"*/;
```

More Examples The following examples demonstrate I/O Type settings using the LatticeEC device family:

- VHDL source attribute example

  Path: *<install_dir>/examples/fpga/LatticeEC/preferences_attributes/iotype_drive_pullmode_slewrate/VHDL/iovhdl.vhd*

- Verilog source attributes example (Precision)

  Path: *<install_dir>/examples/fpga/LatticeEC/preferences_attributes/iotype_drive_pullmode_slewrate/verilog_mentor/vlogio.v*

- Verilog source attribute example (Synplify)

  Path: *<install_dir>/examples/fpga/LatticeEC/preferences_attributes/iotype_drive_pullmode_slewrate/verilog_synplify/vlogio.v*

▶ “Adding FPGA Attributes to HDL” on page 567

LOAD

Convention LOAD= xx.xxx

Description Attached to an output buffer, modifies loading on outputs from the default 50 PFs for timing analysis. Translated by the mapper into the OUTPUT LOAD preference.

The xx.xxx represents the loading on the output in picofarads. The resultant preference would be:

Figure 49:

```
OUTPUT COMP <name> LOAD xx.xxx PF;
```

Device Support All

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

LOC

Convention LOC= site_name (PIN | POS)

Description Specifies a site location for the component that is created when this block is mapped. If attached to multiple blocks, indicates that these blocks are to be mapped together in the specified site.

When the device is mapped, the Map Design process (**map**) first maps blocks to PLCs without looking at LOC attributes. Then it tries to merge all PLCs with the same LOC attribute into a single PLC, and then it assigns this PLC to the site with the specified site name. If all of the blocks with the LOC attribute cannot be mapped into a single component, MAP groups together as many as possible.

When it encounters a LOC preference, MAP also writes a LOCATE preference for the component into the preference file. The LOCATE preference locks the component to the site. When you run PAR, the component cannot be unplaced, moved, swapped, or deleted.

The LOC attribute can be attached to anything that will end up on an I/O cell, and to clocks and internal flip-flops, but it should not be attached to combinational logic that will end up on a logic cell; doing so could fail to generate a locate preference. The LOC attribute overrides register ordering.

Device Support All

VHDL Syntax ATTRIBUTE LOC : string;
ATTRIBUTE LOC OF [pin_name]: SIGNAL IS "[site_name]";

VHDL Example Code
```
ATTRIBUTE LOC : string;
ATTRIBUTE LOC OF output_vector : SIGNAL IS "H5";
```

Verilog Syntax – Precision //pragma attribute [pin_name] LOC [site_name]

Verilog Example Code – Precision
```
// pragma attribute rst LOC H5
```

Verilog Syntax – Synplify PinType [pin_name] /* synthesis LOC="[site_name]"*/;

Verilog Example Code – Synplify
```
//input rst  /* synthesis LOC="H5" */ ;
```

The following examples show slice locations for packing registers:

VHDL Example Code for Register Packing
```
ATTRIBUTE LOC : string;
ATTRIBUTE LOC OF inreg : SIGNAL IS "R2C9D R2C9D R2C8D R2C8D
R2C7D R2C7D R2C6D R2C6D R2C5D R2C5D R2C4D R2C4D R2C3D R2C3D
R2C2D R2C2D";
```

Verilog Example Code for Register Packing (Precision)
```
// pragma attribute inreg LOC R2C9D R2C9D R2C8D R2C8D R2C7D R2C7D R2C6D
R2C6D R2C5D R2C5D R2C4D R2C4D R2C3D R2C3D R2C2D R2C2D
```

See Also ▶"Conflicting IOBUF Constraints" on page 396

▶ "Adding FPGA Attributes to HDL" on page 567

LOCK_DELAY

Convention LOCK_DELAY= <integer>

Description This is a PLL lock time attribute used for simulation. Valid integer values are 0 to 100. The default value is 100 ns. This attribute is optional. If you wish to enter other than the default value of 100 ns, it can be done by adding this attribute in the DEFPARAM section of the code generated by IPexpress. You can also set this attribute in Spreadsheet View.

Device Support LatticeEC, LatticeECP/2/3, LatticeSC/M, LatticeXP/2

Examples For generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

MAXDELAY

Convention MAXDELAY= xxx

Description Net attribute that identifies a maximum total delay for a net, bus, or path in the design. Translated by the mapper into the MAXDELAY preference.

The xxx value is expressed in nanoseconds. The resultant preference would be:

Figure 50:

```
MAXDELAY NET  <netname>  xxx NS;
```

Device Support All

MULTDRIVE

Convention MULTDRIVE= 1X, 2X, 3X, 4X

Description This attributes sets the drive strength for individual output buffers for the MINILVDS output standard. Differential outputs with different MULTDRIVE settings can be placed in the same IO bank. The default value is set to 1X.

Device Support LatticeECP3

VHDL Syntax ATTRIBUTE MULTDRIVE : string;

ATTRIBUTE MULTDRIVE OF [*pin_name*]: SIGNAL IS "[*multdrive_value*]";

VHDL Example Code `ATTRIBUTE MULTDRIVE OF portD: SIGNAL IS "1X";`

Verilog Syntax – Precision //pragma attribute [pin_name] MULTDRIVE [multdrive_value]
[diffdrive _strength] = 1X, 2X, 3X, 4X

Verilog Example Code – Precision `//pragma attribute q_minilvds MULTDRIVE 1X`

Verilog Syntax – Synplify The following syntax is used for Pin I/O Type configuration:

PinType [pin_name] /* synthesis IO_TYPE="[type_name]"

DIFFDRIVE="[diffdrive_strength]" MULTDRIVE="[multdrive_value]"*/;

Verilog Example Code – Synplify `output mypin /* synthesis IO_TYPE="MINILVDS" DIFFDRIVE="1.6" MULTDRIVE = “1X”*/;`

See Also ▶“DIFFDRIVE” on page 1293

NOCLIP

Convention NOCLIP

Description Assigned to a net or an instance, indicates that the net or instance cannot be removed as unused logic.

When the design is mapped, the default MAP setting removes any unused logic from the design. In most cases, you will want to do this, since unused logic takes up device components and routing resources unnecessarily. However, when you want to keep unused logic in the design, place a NOCLIP attribute on selected nets, and the nets on which you place the attribute are protected from removal, along with any valid logic connected to these nets.

For a path to be considered valid, it must have a valid input and a valid output.

Valid path inputs include:

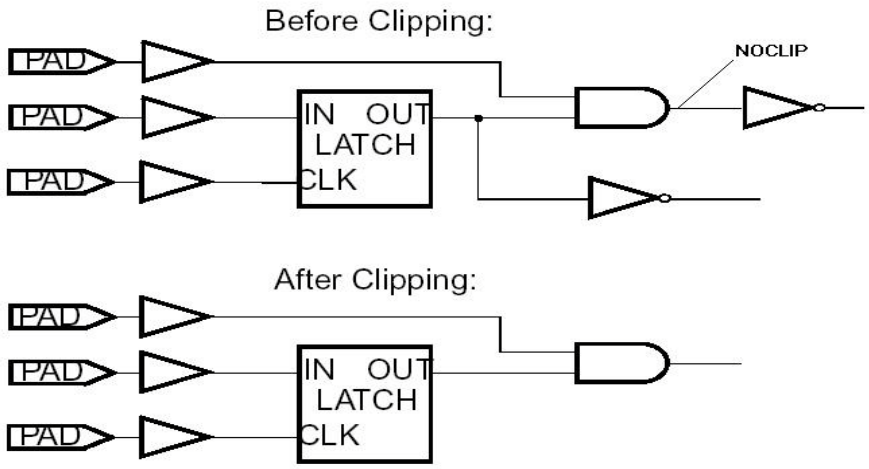
- An input pad or the input portion of a bidirectional pad
- A pullup or pulldown resistor
- An oscillator primitive
- A logic 1 or logic 0 primitive
- A net with a NOCLIP attribute on it

Valid path outputs include:

- An output pad or the output portion of a bidirectional pad
- A net with a NOCLIP attribute on it

If a path is not valid, the MAP program removes its logic as unused. To protect all or part of an invalid path from being removed, add a NOCLIP attribute to the appropriate net. The attribute can act as either a valid input or a valid output, depending on what is necessary to complete the path.

The figure below shows an example of how a NOCLIP attribute affects clipping:



Some notes about using the NOCLIP attribute:

- If you design an on-chip oscillator (by building one from components in the device instead of using an oscillator primitive), the MAP program assumes the logic is unused and removes it because the oscillator logic does not contain a valid driver. To retain your oscillator logic, protect it by placing NOCLIP on the appropriate nets.
- If you design a circuit with a feedback loop, and the looped signal is not driving any other loads but the loop itself, the loop is eliminated as unused logic. If you want to keep the loop in the design, make sure you protect the loop with a NOCLIP attribute.

Device Support All

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

NOM_FREQ

Convention NOM_FREQ= value

Description Nominal Frequency selection (MHz) for oscillator elements OSC and OSCD. Values are 2.5 (default), 4.3, 5.4, 6.9, 8.1, 9.2, 10.0, 13.0, 15.0, 20.0, 26.0, 30.0, 34.0, 41.0, 45.0, 55.0, 60.0, and 130.0.

Device Support LatticeECP2/M, LatticeECP3

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

NOMERGE (SAVE)

Convention NOMERGE (SAVE)= <net_name>

Description Assigned to a net, specifies that the net cannot be absorbed into a logic block when the design is mapped. This may happen, for example, if the components connected to each side of a net are mapped into the same logic block. The net may then be absorbed into the block containing the components. When a net is absorbed into a block, it can no longer be seen in the physical design (.ncd) file.

If you want to ensure that a net remains outside of a logic block, attach a NOMERGE attribute to the net. The MAP program then maps the net in a way that ensures you do not “lose” the net inside a logic block.

Device Support All

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

NORETIME

Convention NORETIME= string
NORETIME IO

Description An instance with NORETIME attribute will prevent re-timing on its hierarchy. Global NORETIME IO disallows re-timing on I/O registers. I/O register instances named "IFS*" and "OFS*" may be touched by default depending on tSU (INPUT_SETUP) and tCO (CLOCK_TO_OUT) constraints if the attribute "NORETIME IO" is not found.

Device Support All

VHDL Syntax ATTRIBUTE NORETIME : string;
ATTRIBUTE NORETIME OF [instance_name]: LABEL IS "[label_name]";

VHDL Example Code
```
attribute NORETIME  : string;
attribute NORETIME of and2  : label is "IO";
```

Verilog Syntax – Synplify Instance [instance_name] /* synthesis NORETIME="[string]"*/;

Verilog Example Code – Synplify
```
//module and2 (A,B,Z) /*
synthesis NORETIME = 1 */ ;
```

For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

OPENDRAIN

Convention OPENDRAIN= OFF | ON | PLUS

Description You can assign OPENDRAIN to all the LVCMOS and LVTTL standards. OFF is the default.

If OPENDRAIN is used on a bidirectional pin or an output pin, to be valid (does not generate design errors) it either must, 1) be a non-differential output buffer with OPENDRAIN attached, or 2) a non-differential outputZ/bidi buffer in which the "I" (input to output buffer) pin is set to GND and "T" (tristate enable) is live whether the OPENDRAIN attribute is passed or not. The "I" signal can be a GND signal or optimized into output buffer. In cases where a non-differential outputZ/bidi buffer that has the "I" and "T" signals connected together, it does not matter. If the "I" and "T" of outputZ are unique signals and the "I" signal is not set to GND, then OPENDRAIN is not valid.

The OPENDRAIN=PLUS value is available for LatticeECP2, LatticeECP2M, and LatticeXP2 devices. The PLUS value must be used when the user intends to use external pullup greater than VCCIO. When OPENDRAIN = PLUS is used, The software will not use the OPENDRAIN fuse but will instead have to emulate the open drain by tieing the DO to TO of the output buffer. This value of PLUS is only available for OUTPUT and not for BIDI.

Device Support All

VHDL Syntax ATTRIBUTE OPENDRAIN: string;
ATTRIBUTE OPENDRAIN OF [signal_name]: SIGNAL IS "ON";

VHDL Example Code `ATTRIBUTE DRIVE OF q_lvttl33_17: SIGNAL IS "ON";`

Verilog Syntax – Precision //pragma attribute [signal_name] OPENDRAIN [OFF | ON]

Verilog Example Code – Precision `//pragma attribute q_lvttl33_17 OPENDRAIN ON`

Verilog Syntax – Synplify output signal_name /* synthesis OPENDRAIN="ON | OFF" */;

Verilog Example Code – Synplify `output q_lvttl33_17 /* synthesis OPENDRAIN="ON" */;`

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

See Also ▶“IO_TYPE” on page 1309

PCICLAMP

Convention PCICLAMP= OFF | ON

Description Turns on the programmable PCI clamp diode. The PCICLAMP options can be enabled for each I/O independently. For MachXO, The PCICLAMP is only available on the TOP bank on 1K and 2K devices. PCICLAMP are NOT available for the 256 and 640 devices. OFF is the default.

(LatticeXP2) When IO_TYPE is PCI33, then the default for this attribute is ON. You can select PULLMODE to PCICLAMP. If the standard is PCI33 with PCICLAMP=ON, then place in Banks 4, 5. If PCICLAMP=OFF then place in Banks 0, 1, 2, 3, 6, 7, 8. You should use external clamps for PCI outputs placed in Banks 0, 1, 2, 3, 6, 7, 8. This limits the signals to LVCMOS33 and LVTTL33 standards.

See the LatticeSC PURESPEED I/O Usage Guide for more information on this and related attributes. This is an attribute that is used in conjunction with the IOBUF preference. To see how global preferences are honored for PCICLAMP in an IOBUF preference, see that topic.

Device Support LatticeECP/EC, LatticeSC/M, LatticeXP/2, MachXO

VHDL Syntax ATTRIBUTE PCICLAMP: string;
ATTRIBUTE PCICLAMP OF [pin_name]: SIGNAL IS "[mode]";

VHDL Example Code
```
ATTRIBUTE PCICLAMP OF md: SIGNAL IS "ON";
```

Verilog Syntax – Precision //pragma attribute [pin_name] PCICLAMP [mode]

[mode] = OFF, ON

Verilog Example Code – Precision
```
//pragma attribute d_lvcmos33_keeper PCICLAMP ON
```

Verilog Syntax – Synplify PinType [pin_name] /* synthesis PCICLAMP="[type_name]"*/;

[mode] = OFF, ON

Verilog Example Code – Synplify
```
output [4:0] portA /* synthesis PCICLAMP="ON"*/;
```

For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

See Also ▶“IO_TYPE” on page 1309

PERIOD

Convention PERIOD = xxx

Description Clock net attribute used to identify a clock period for all pins clocked by the specified net. If the net is optimized away, no preference is generated. Translated by the mapper into the PERIOD preference. The xxx value is expressed in ps (the resultant preference is expressed in ns).

Device Support All

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

PHASEADJ

Convention PHASEADJ= value

Description (LatticeSC/M) VCO Output Phase. Attached to a PLL element (e.g., EHXPLLA), the PHASEADJ attribute adjusts phase relative to CLKOP. PHASEADJ takes the value parameter set of 0, 45, 90, 135, 190, 225, 270, or 315.

(LatticeXP/2, LatticeECP2/M, LatticeECP/EC) Coarse Phase Shift Selection. Attached to a PLL element (e.g., EHXPLLB). Attribute takes the value parameter set of 0, 45, 90, 135, 190, 225, 270, or 315.

Default value is 0.

Device Support LatticeSC/M, LatticeXP/2, LatticeECP2/M, LatticeECP/EC

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

PRIORITY

Convention PR | PRIORITY= 0-100

Description Expressed as an integer, PR and PRIORITY are converted to the PRI attribute with the same value.

Device Support All

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

PULLMODE

Convention PULLMODE= UP (default), DOWN, NONE, KEEPER, PCICLAMP

Description Attached to output buffer elements (e.g., OB, OBW) and bidirectional buffers, the PULLMODE attribute mode parameters are UP, DOWN, NONE, KEEPER, PCICLAMP. The PULLMODE options can be enabled for each I/O independently. The KEEPER option is not available for the PULLMODE attribute when VCCIO = 3.3V for LatticeSC/M. The default is UP.

See the LatticeSC PURESPEED I/O Usage Guide for more information on this and related attributes. This is an attribute that is used in conjunction with the IOBUF preference. To see how global preferences are honored for PULLMODE in an IOBUF preference please see that topic.

Device Support All

VHDL Syntax ATTRIBUTE PULLMODE: string;
ATTRIBUTE PULLMODE OF [pin_name]: SIGNAL IS "[mode]";

Example Code: `ATTRIBUTE PULLMODE OF md: SIGNAL IS "PCICLAMP";`

Verilog Syntax – Precision //pragma attribute [pin_name] PULLMODE [mode]

[mode] = UP (default), DOWN, NONE, KEEPER, PCICLAMP

Verilog Example Code – Precision `//pragma attribute d_lvcmos33_keeper PULLMODE KEEPER`

Verilog Syntax – Synplify PinType [pin_name] /* synthesis IO_TYPE="[type_name]" DRIVE="[drive_strength]" PULLMODE="[mode]" SLEWRATE="[value]"*/;

[mode] = UP (default), DOWN, NONE, KEEPER, PCICLAMP

Note: Example given for Pin I/O Type configuration.

Verilog Example Code Synplify `output [4:0] portA /* synthesis IO_TYPE="LVTTL33_OD" DRIVE="16" PULLMODE="UP" SLEWRATE="FAST"*/ ;`

More Examples The following are examples I/O Type settings using the LatticeEC device family for purposes of demonstration. These all include PULLMODE attribute examples:

- VHDL source attribute example

  Path: *<install_dir>/examples/LatticeEC/preferences_attributes/iotype_drive_pullmode_slewrate/VHDL/iovhdl.vhd*

- Verilog source attributes example (Precision)

Path: *<install_dir>/examples/LatticeEC/preferences_attributes/iotype_drive_pullmode_slewrate/verilog_mentor/vlogio.v*

- Verilog source attribute example (Synplify)

  Path: *<install_dir>/examples/LatticeEC/preferences_attributes/iotype_drive_pullmode_slewrate/verilog_synplify/vlogio.v*

There are also example files for other FPGA architectures available in corresponding directories in the <install_dir>/ispcpld/examples path.

See Also ▶"IO_TYPE" on page 1309

- "Adding FPGA Attributes to HDL" on page 567

PWRSAVE

Convention PWRSAVE= OFF (default) | ON

Description Powersave feature. This is used on input combinations to reduce the common mode range. When using comparator type inputs pins (pins that use VREF) like HSTL, SSTL etc., when under certain frequencies the user can turn ON the PWRSAVE option to reduce power dissipation on the input pins.

The default for the PWRSAVE feature is OFF so that it will not interfere with JTAG testing of the device. The default is OFF for LVDS and other differential input standards, and default ON for input standards where the full common mode range is not required.

See the LatticeSC PURESPEED I/O Usage Guide for more information on this and related attributes.

Device Support LatticeSC/M

Examples For generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

See Also ▶"IO_TYPE" on page 1309

RBBOX

Convention RBBOX = H,W (where H is height, W is width)

Description RBBOX indicates the area size a region. This attribute must appear on the same block as REGION attribute (old attribute is PREGION). Required if REGION exists. This has replaced the old PRBBOX attribute which is also still valid for backwards compatibility.

Device Support All

Examples For generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

See Also "HGROUP" on page 1302 (attribute)

- "HGROUP" on page 1220 (preference)
- "UGROUP" on page 1328 (attribute)
- "UGROUP" on page 1262 (preference)
- "REGION" on page 1322 (attribute)
- "REGION" on page 1244 (preference)

REFCIRCUIT

Convention REFCIRCUIT= OFF (default), INTERNAL, EXTERNAL (for differential buffer)

Description (Attached to output buffers (e.g., OB, OBW) and bidirectional buffers, this attribute allows you to choose this internal reference circuit or an external one. The REFCIRCUIT attribute parameters are OFF, INTERNAL, and EXTERNAL. OFF is the default. There is an internal circuit to turn on the bias for LVDS IOTYPE (see IO_TYPE). If you choose the external option then you must provide an external bias.

See the LatticeSC PURESPEED I/O Usage Guide for more information on this and related attributes. This is an attribute that is used in conjunction with the IOBUF preference. To see how global preferences are honored for REFCIRCUIT in an IOBUF preference please see that topic.

Device Support LatticeSC/M

Examples For generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

See Also "IO_TYPE" on page 1309

REGION

Convention REGION = <identifier>

Description REGION indicates the region to which a given HGROUP or UGROUP belongs. This attribute must appear on a block that has a HGROUP or UGROUP attribute. This has replaced the old PREGION attribute which is also still valid for backwards compatibility.

Device Support All

Examples For generic examples of how to use FPGA attributes in your HDL, see Adding FPGA Attributes to HDL.

See Also ▶"HGROUP" on page 1302 (attribute)

- "HGROUP" on page 1220 (preference)
- "UGROUP" on page 1328 (attribute)
- "UGROUP" on page 1262 (preference)
- "REGION" on page 1244 (preference)

RST_PULSE

Convention RST_PULSE= <integer>

Description This is an attribute used with the Power Up Reset (PUR) element used for setting a required reset pulse length for this signal. You can pass a required numerical value such as 10 ns or 100 ns. The default value for this attribute is 1 ns.

Device Support All

Verilog HDL Example
```
PUR     PUR_INST (.PUR (<powerup reset sig>));
defparam PUR_INST.RST_PULSE = 10;
```

VHDL HDL Example
```
PUR_INST : PUR
generic map (RST_PULSE => 10)
port map (PUR => <signal>);
```

The RST_PULSE parameter in the PUR element instantiations for Verilog and VHDL above shows a a value of 10 ns assigned to set the required reset pulse length.

Examples For generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

SLEW

Convention SLEW= 1-100

Description Attached to an output buffer or pad, specifies the relative speed (slew rate) of the output driver, with 1 indicating the slowest and 100 the fastest.

The SLEW attribute applies if the I/O cell output slew rate can be programmed in the device to which the design is mapped. If so, MAP programs the output

driver for the specified slew rate in the cell into which the component is mapped. The SLEW attribute is interpreted in this way:

Table 140: Slew Rate Settings

SLEW Attribute Setting	Programmed Slew Rate
0-33	SLEWLIM (Slow)
34-66	SINKLIM (Medium)
67-100	FAST

Device Support All

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

SLEWRATE

Convention SLEWRATE= FAST | SLOW | NA (LatticeSC/M only)

Description Attached to all output buffers (e.g., OB, OBW) and bidirectional buffers, the SLEWRATE attribute mode parameters are FAST or SLOW for all families except LatticeSC/M which also has an NA value. The NA value refers to a "non applicable" condition for some I/O standards in the LatticeSC device family only.

Each I/O pin has an individual slew rate control. This allows designer to specify slew rate control on pin by pin basis. This slew rate control affects both the rising edge and the falling edges. The default condition for SLEWRATE is SLOW for all I/O standards except for LatticeECP3 devices, where the default SLEWRATE is FAST.

See the LatticeSC PURESPEED I/O Usage Guide for more information on this and related attributes. This is an attribute that is used in conjunction with the IOBUF preference. To see how global preferences are honored for SLEWRATE in an IOBUF preference please see that topic.

Device Support All

VHDL Syntax ATTRIBUTE SLEWRATE: string;
ATTRIBUTE SLEWRATE OF [pin_name]: SIGNAL IS "[value]";

VHDL Example Code
```
ATTRIBUTE SLEWRATE OF portA: SIGNAL IS "SLOW";
```

Verilog Syntax – Precision //pragma attribute [pin_name] SLEWRATE [value]

```
[value] = FAST, SLOW
```

Verilog Example Code – Precision `//pragma attribute portA SLEWRATE SLOW`

Verilog Syntax – Synplify PinType [pin_name] /* synthesis IO_TYPE="[type_name]" DRIVE="[drive_strength]" PULLMODE="[mode]" SLEWRATE="[value]"*/;

[value] = FAST, SLOW

Note: Example given for Pin I/O Type configuration.

Verilog Example Code – Synplify `output [4:0] portA /* synthesis IO_TYPE="LVTTL33_OD" DRIVE="16" PULLMODE="UP" SLEWRATE="FAST"*/ ;`

More Examples The following are examples I/O Type settings using the LatticeEC device family for purposes of demonstration. These examples all contain SLEWRATE attributes:

- VHDL source attribute example

  Path: *<install_dir>/examples/LatticeEC/preferences_attributes/iotype_drive_pullmode_slewrate/VHDL/iovhdl.vhd*

- Verilog source attributes example (Precision)

  Path: *<install_dir>/examples/LatticeEC/preferences_attributes/iotype_drive_pullmode_slewrate/verilog_mentor/vlogio.v*

- Verilog source attribute example (Synplify)

  Path: *<install_dir>/examples/LatticeEC/preferences_attributes/*

See Also ▶"Adding FPGA Attributes to HDL" on page 567

SMI_OFFSET

Convention SMI_OFFSET= hexadecimal number

Description System Management Interrupt Offset. Attached to DLL element, the attribute is set with a default offset start value of 12h'410'.

Device Support LatticeECP2/M, LatticeSC/M

Examples For generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

SPREAD_DRIFT

Convention SPREAD_DRIFT= 1, 2, 3

Description Spread Spectrum BW. Attached to the PLLA element, the SPREAD_DRIFT attribute takes integer parameters of 1, 2, or 3.

Device Support LatticeSC/M

Examples For generic examples of how to use FPGA attributes in your HDL, see “Adding FPGA Attributes to HDL” on page 567.

TERMINATEGND

Convention TERMINATEGND= OFF (default), 50, 100, 120 (Termination Down)

Description This attribute determines the on-chip parallel input and output termination. It is available for certain I/O types. Refer to the sysIO Usage Guides to see the I/O types that support this parallel termination to GND. TERMINATEGND is available for each individual pin in the bank, independent of all other pins in the bank.

Attached to output buffer elements—for example, OB, OBW— the TERMINATEGND attribute is OFF by default. You can attach the resistance parameters for 50, 100, and 120 for termination down. See the LatticeSC PURESPEED I/O Usage Guide for more information on this and related attributes.

Device Support LatticeSC/M

Split Termination If you wish to split termination—for example, a parallel termination of type 50 ohm to VCCIO/2—you must turn on both the TERMINATEVCCIO and TERMINATEGND to a value of 100ohm to get the termination you require.

Parallel Termination The following table shows all the parallel terminations supported for LatticeSC/M and the required values for the TERMINATEGND and TERMINATEVCCIO attributes.

Table 141: Parallel Termination

Input & Output Parallel Termination	TERMINATEVCCIO	TERMINATEGND
DEFAULT	OFF	OFF
120 to VCCIO	120	OFF
120 to GND	OFF	120
60 to VCCIO/2	120	120
100 ohm to GND	OFF	100
100 ohm to VCCIO	100	OFF
50 ohm to GND	OFF	50

Table 141: Parallel Termination

Input & Output Parallel Termination	TERMINATEVCCIO	TERMINATEGND
50 ohm to VCCIO	50	OFF
50 ohm to VCCIO/2	100	100
33 ohm to VCCIO	50	OFF
33 ohm to GND	OFF	50
25 ohm to VCCIO/2	50	50

Examples For generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

See Also ▶"TERMINATEVCCIO" on page 1327

▶ "IO_TYPE" on page 1309

TERMINATEVCCIO

Convention TERMINATEVCCIO= OFF (default), 50, 100, 120 (Termination Up)

Description This attribute determines the on-chip parallel input and output termination. It is a programmable option that is available for certain I/O types. Refer to the sysIO Usage Guides to find the I/O types that support this parallel termination to VCCIO. This attribute is available for each individual pin in the bank. The VCCIO to which the termination is available depends on the VCCIO of the bank.

Attached to output buffer elements (e.g., OB, OBW), the TERMINATEVCCIO attribute is by default OFF. You can attach the resistance parameters for 50, 100, and 120 for termination up. See the Split Termination and Parallel Termination section in the TERMINATEGND topic. See the LatticeSC PURESPEED I/O Usage Guide for more information on this and related attributes.

Device Support LatticeSC/M

Examples For generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

See Also ▶"TERMINATEGND" on page 1326

▶ "IO_TYPE" on page 1309

TERMINATEVTT

Convention TERMINATEVTT= OFF (default), 40, 50, 60, 75, 120, 150, 210

Description This attribute sets the on-chip input parallel termination to VTT. This programmable option can be set for each of the I/O individually. When VCCIO is 3.3V, parallel input termination to VTT is still supported in the bank, as long as the PAD itself is not at 3.3 volts. See the LatticeSC PURESPEED I/O Usage Guide for more information on this and related attributes.

Device Support LatticeSC/M, LatticeECP3

Examples For generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

See Also ▶"IO_TYPE" on page 1309

TERMINATION

Sets the on-chip input parallel termination to VCCIO/2. This parallel termination is achieved using a programmable Thevenin termination scheme of 50/75/150 ohms to VCCIO/2.

Device Support ECP5

Syntax TERMINATION=OFF | ON;

UGROUP

Convention UGROUP = <identifier>

Description Universal grouping construct. Use the UGROUP attribute to group blocks within different hierarchies or with no hierarchy. UGROUP differs from HGROUP attributes in that its identifier is not changed by pre-appending the hierarchy and the block instance. See "UGROUPs in the HDL" on page 392.

You can add UGROUP anchor and bounding box information to the HDL with the HULOC and BBOX attributes, or you can add this information later using the Group sheet in Spreadsheet View. Alternatively, you can allow a UGROUP to float within a REGION.

Device Support All

Syntax UGROUP="<ugroup_name>"
[HULOC="<site_name>"]
[BBOX="<height>,<width>"]

where:

<ugroup_name> is a user-defined name.

<site_name> is a row/column Slice D location of the target device in the format R<n>C<m>D, an EBR site in the format EBR_R<n>C<m>, or a DSP site in the format DSP_R<n>C<m>.

<height> is the number of device rows of a rectangular bounding box.

<width> is the number of device columns of a rectangular bounding box.

Note

For certain MachXO2 devices, the first EBR site on the left is positioned at column 1 and cannot be included in an anchored group or region that contains SLICEs. The column 1 EBR site is not aligned with SLICEs, which begin at column 2. Affected devices include LCMXO2-1200/4000/7000/10000.

The VHDL and Verilog examples show anchored UGROUPs. Completely floating HGROUPs would preclude the use of the HULOC attribute that specifies the anchor point at a specific site location.

VHDL Syntax attribute UGROUP: string;
attribute UGROUP of <object>: label is "<ugroup_name>";
[attribute HULOC: string;
attribute HULOC of <object>: label is "<site_name>";]
[attribute BBOX: string;
attribute BBOX of <object>: label is "<height>,<width>";]

VHDL Example Code
```
attribute UGROUP: reg_group;
attribute UGROUP of x: label is "reg_group";
[attribute HULOC: R10C22D;
attribute HULOC of x: label is "R10C22D";]
[attribute BBOX: 9,7;
attribute BBOX of <object>: label is "9,7";]
```

Verilog Syntax – Precision // pragma attribute <object> UGROUP <ugroup_name>
[// pragma attribute <object> HULOC <site_name>]
[// pragma attribute <object> BBOX <height>,<width>]

Verilog Example Code – Precision
```
//pragma attribute x UGROUP reg_group
//pragma attribute x HULOC R5C19D
//pragma attribute x BBOX 6,4
```

Verilog Syntax – Synplify /* synthesis UGROUP= "<hgroup_name>"
HULOC= "<site_name>"
BBOX= "<h,w>"
*/;

Verilog Example Code – Synplify
```
/* synthesis UGROUP= "reg_group"
HULOC= "R5C19D"
BBOX= "6,4"
```

```
*/;
```

Note

Synthesis directives to preserve hierarchy are typically needed to retain the instances constrained by the UGROUP attribute.

Example of Floating UGROUP Attribute Given a Verilog module instance:

Figure 51:

```
rotate rotate_1 (q, reg_out, clk, r_l, rst)
 /* synthesis UGROUP= ”rot_group”
 */ ;
 // pragma attribute rotate_1 UGROUP rot_group;
 // pragma attribute rotate_1 hierarchy preserve
```

the resulting .prf file will contain the following in the schematic section after mapping:

Figure 52:

```
PGROUP "rot_group"
  COMP "rotate_1/SLICE_0"
  COMP "rotate_1/SLICE_1"
  COMP "rotate_1/SLICE_2"
  COMP "rotate_1/SLICE_3";
```

Example of Anchored and Bounded UGROUP Attribute Given a Verilog module instance:

Figure 53:

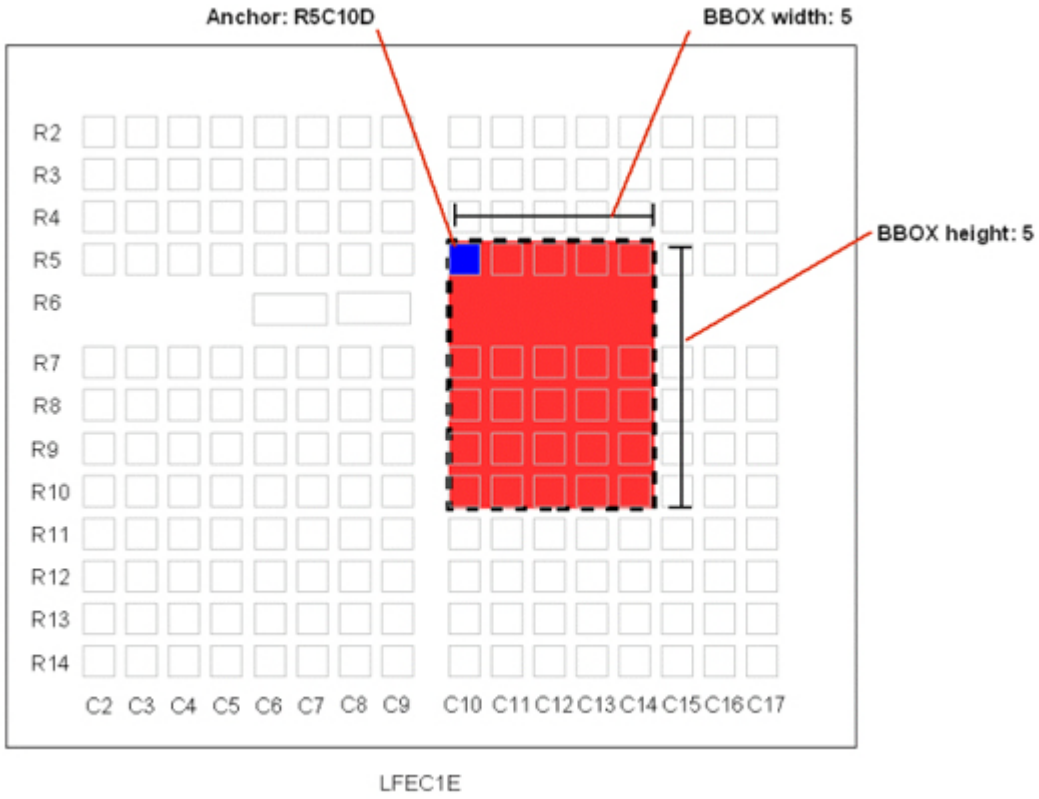
```
rotate rotate_1 (q, reg_out, clk, r_l, rst)
  /* synthesis UGROUP= “rot_group”
     HULOC= “R5C10D”
     BBOX= “5,5”
  */ ;
  // pragma attribute rotate_1 UGROUP     rot_group
  // pragma attribute rotate_1 HULOC      R5C10
  // pragma attribute rotate_1 BBOX       5,5
  // pragma attribute rotate_1 hierarchy  preserve
```

the resulting PRF file will contain the following in the schematic section after mapping:

Figure 54:

```
PGROUP "rot_group" BBOX 5 5
  COMP "rotate_1/SLICE_0"
  COMP "rotate_1/SLICE_1"
  COMP "rotate_1/SLICE_2"
  COMP "rotate_1/SLICE_3";
LOCATE PGROUP "rot_group" SITE "R5C10D" ;
```

The figure below illustrates the rot_group PGROUP in the context of an LFEC1E FPGA device.



Example of Anchored and Bounded UGROUP Attribute on Multiple Instances When the HDL includes multiple instances of the same UGROUP, it is good practice to declare HULOC and BBOX only once to ensure that no conflicting constraints will occur. Given Verilog module instances:

Figure 55:

```
reg pipest_1 (q, d0, clk, r_l, rst)
 /* synthesis UGROUP=   “reg_group”
    HULOC=“R5C15D”
    BBOX=“5,5”
 */ ;
 // pragma attribute pipest_1 UGROUP reg_group
 // pragma attribute pipest_1 HULOC R5C15D
 // pragma attribute pipest_1 BBOX 5,5
 // pragma attribute pipest_1 hierarchy preserve

 reg pipest_2 (q, reg_out1, clk, r_l, rst)
 /* synthesis                UGROUP=   “reg_group”
 */ ;
 // pragma attribute pipest_2  UGROUP  reg_group
 // pragma attribute pipest_2  hierarchy preserve

 reg pipest_3 (q, reg_out2, clk, r_l, rst)
 /* synthesis                 UGROUP= “reg_group”
 */ ;
 // pragma attribute pipest_3  UGROUP  reg_group
 // pragma attribute pipest_3  hierarchy preserve
```

the resulting PRF file will contain the following in the schematic section after mapping:

Figure 56:

```
PGROUP "reg_group" BBOX 5 5
  COMP "pipest_1/SLICE_4"
  COMP "pipest_1/SLICE_5"
  COMP "pipest_1/SLICE_6"
  COMP "pipest_1/SLICE_7"
  COMP "pipest_2/SLICE_8"
  COMP "pipest_2/SLICE_9"
  COMP "pipest_2/SLICE_10"
  COMP "pipest_2/SLICE_11"
  COMP "pipest_3/SLICE_12"
  COMP "pipest_3/SLICE_13"
  COMP "pipest_3/SLICE_14"
  COMP "pipest_3/SLICE_15";
LOCATE PGROUP "reg_group" SITE "R5C15D" ;
```

Example of UGROUP Attribute with a Register Declaration Given a Verilog module instance:

Figure 57:

```
 reg [7:0] q /* synthesis UGROUP=rot_reg_group */;
```

the resulting PRF file will contain the following in the schematic section after mapping:

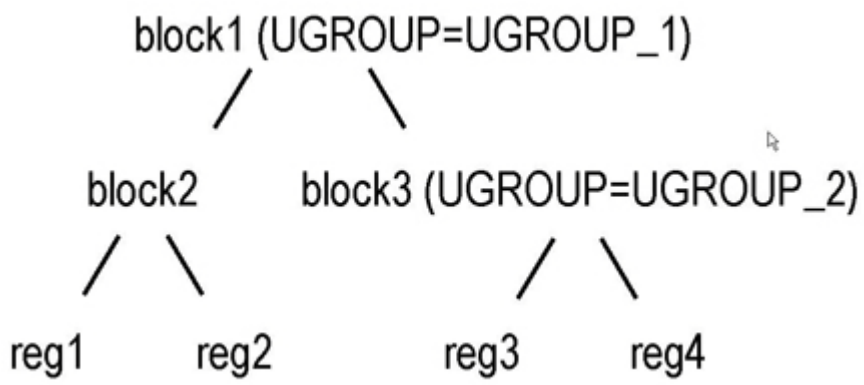
Figure 58:

```
PGROUP "rot_group" BBOX 5 5
  COMP "rotate_1/SLICE_0"
  COMP "rotate_1/SLICE_1"
  COMP "rotate_1/SLICE_2"
  COMP "rotate_1/SLICE_3";
LOCATE PGROUP "rot_group" SITE "R5C15D" ;
```

UGROUP Attribute Usage Rules and Restrictions Observe the following conditions for proper UGROUP attribute usage:

- All elements within the UGROUP'd block belong to that particular UGROUP.
- Nested UGROUP blocks are considered as unique individual UGROUPs.
- All blocks belong to the UGROUP attached to their nearest ancestor in the hierarchy.
- Unlike PGROUP, the mapper will not append the hierarchical path plus the block instance name.
- UGROUP differs from HGROUP in that pre-appending the hierarchy and the block instance does not change its identifier.

For example:



REG1 and REG2 belong to UGROUP_1.
REG3 and REG4 belong to UGROUP_2.

Also, assuming that REG1, REG2 are mapped to PFU_0 and that REG3, REG4 are mapped to PFU_1, the resulting preferences generated in the preference file are as follows:

Figure 59:

```
PGROUP "UGROUP_1"
COMP PFU_0;
PGROUP "UGROUP_2"
COMP PFU_1;
```

If block1 has a UGROUP that is also located, HULOC = R1C1, then the additional preference

Figure 60:

```
LOCATE PGROUP "UGROUP_1" SITE "R1C1"
```

will appear in the preference file.

If block1 has REGION=ONE, HURLOC=R1C1, RBBOX=2,2, then the preferences generated will be as follows:

Figure 61:

```
REGION "ONE" "R1C1" 2 2;
PGROUP "UGROUP_1"
COMP PFU_0;
PGROUP "UGROUP_2"
COMP PFU_1;
LOCATE PGROUP "UGROUP_1" REGION "ONE"
LOCATE PGROUP "UGROUP_2" REGION "ONE"
```

Note: Like HGROUPs, UGROUPs are also resolved into the PGROUP physical preference.

For backward compatibility of existing HDL designs, the property filter file will translate the old attributes to the new set. For HDL attributes, NGDBUILD will resolve HGROUP identifiers on hierarchical blocks, but it will not push the identifier down onto all individual blocks in the hierarchy.

- "REGION" on page 1322 (attribute)
- "REGION" on page 1244 (preference)

USERCODE

Convention USERCODE=<string>

Description Attached to the top of the design, specifies a binary, hexadecimal, or ASCII usercode for storing device data such as firmware version number, manufacturer's ID, programming date, programmer make, pattern code, or JEDEC file checksum. Usercode definitions at lower hierarchy levels will be ignored. A USERCODE preference in the logical preference file (.lpf) will override the USERCODE attribute.

Device Support All

Guidelines Observe the following guidelines for the usercode format:

- For binary format, specify a string beginning with the characters "0b" followed by 32 binary digits.
- For hexadecimal format, specify a string beginning with the characters "0h" followed by eight hexadecimal values. If you enter a lowercase letter value, it will be converted to uppercase.

- For text or ASCII format, specify a four-character string using only alpha and numeric values. Characters are case sensitive.
- For LatticeXP/XP2 and MachXO devices, you can specify CHECKSUM as USERCODE.

VHDL Syntax attribute usercode : string;

VHDL Example Code
```
architecture behave of prep1 is
attribute usercode : string;
attribute usercode of behave : architecture is
"0b00001111000011111111000011110000";
```

Verilog Syntax – Precision // pragma attribute USERCODE <string>

Verilog Example Code – Precision
```
module count(c,clk,rst);
// pragma attribute count USERCODE "0h0123ABCD"
```

Verilog Syntax – Synplify /* USERCODE=<string> */;

Verilog Example Code – Synplify
```
module count(c,clk,rst)/*
Synthesis USERCODE="0h0123ABCD"*/;
```

See Also ▶"USERCODE" on page 1273 Preference

VCMT

Convention VCMT= OFF (default) | VCMT | VTT | DDR_II

Description Attached to input buffer elements (e.g., IB), assigning value types allows you to enable a common mode voltage, that is, choose between common mode termination or VTT termination. For the DDR memory interface, the attribute allows you to choose DDT_II as an option. DDT_II allows Parallel input termination to VTT when receiving and series output termination during transmittal.

This is available for all the differential and complementary inputs. Refer to the sysIO Usage Guides for more details.

Device Support LatticeSC/M

Examples For generic examples of how to use FPGA attributes in your HDL, see "Adding FPGA Attributes to HDL" on page 567.

See Also ▶"IO_TYPE" on page 1309

Lattice Synthesis Engine (LSE) Constraints

The Lattice Synthesis Engine (LSE) enables you to use constraints that are directly interpreted by the synthesis engine. This new category of constraints includes “Synopsys Design Constraints (SDC)” on page 1338, such as create_clock, and “Lattice Synthesis Engine-Supported HDL Attributes” on page 1348 such as syn_black_box. These constraints influence the optimization or structure of the output netlist.

See Also ▶“Integrated Synthesis” on page 581

- “Applying Lattice Synthesis Engine Constraints” on page 364

Synopsys Design Constraints (SDC)

This section describes the Synopsys® Design Constraint (SDC) language elements for timing-driven synthesis that are supported by the Lattice Synthesis Engine (LSE). When you use LSE, these SDC constraints are saved to a Lattice Design Constraints file (.ldc). A new .ldc file can be created and edited using the LDC Editor or the Source Editor. You can select the .ldc file to be the active synthesis constraint file for an implementation.

When the “Use LPF Created from SDC in Project” option is set to True (-lpf 1) in the active strategy file, the constraints contained in the .ldc file will be output into a synthesis logical preference file:

<*project_name*>_<*implementation_name*>.lpf.

The SDC constraints will drive optimization of the design if LSE’s Optimization Goal is set for timing in the active strategy file.

Considerations about LSE Timing The module delay in LSE is based on the primitive level, before logic is packed into a slice. Therefore, the delay might be different from the slice-based MAP or PAR in the TRACE analysis report (.twr). Also, some elements are modeled as black boxes in LSE; for example, EFB in MachXO2.

The routing delay algorithm in LSE is different from the estimated routing delay in Map or Place.

The current LSE timing does not take the PLL/DLL frequency or phase shift properties into account. It also does not model the different IO_TYPE in the PIO. Therefore, it is necessary to adjust the timing constraint. For example, you can explicitly include a timing constraint on the PLL outputs with the phase-shift property.

Design Objects

Design objects can be referred to in the SDC as a single object, or as a collection of objects. Single objects must be referred to as a collection of a single object. The current implementation of the SDC commands allows only single objects in the collection. The exception to this are the all_* commands.

In the examples below, <*target name*> is a regular expression that matches just one object only.

Clock Object

SDC Collection	Description
[get_clocks <*target name*>]	<*target name*> is the name of the clock. Clock is either given a name or gets its name from the port/net on which it is defined.
[all clocks]	Collection of all clocks in the design.

Examples: [get_clocks clock_fast]

[all_clocks]

Port Object

SDC Collection	Description
[get_ports <*target name*>]:	Collection of a design port that matches <*target name*>
[all_inputs]	Collection of all design input ports
[all_outputs]	Collection of all design output ports

Examples: [get_ports indata*]

[all_inputs]

Cell Object

SDC Collection	Description
[get_cells <*target name*>]:	Collection of a design instance that matches <*target name*>

Net Object

SDC Collection	Description
[get_nets <*target name*>]:	Collection of a design net that matches <*target name*> Hierarchy is specified using regular expression.

Pin Object

SDC Collection	Description
[get_pins <*instance name*> | <*pin name*>]:	Collection of a design pin that matches <*target name*> Hierarchy is specified using regular expression.

The get_nets command, for instance, can used to define the target for a create_generated_clock command.

Wildcard support

Only one wildcard (*) is supported. Also the wildcard should be at the end or beginning of the object name string. For example:

ab* matches abc, ab, abdefg, etc.

*bc matches abc, bbc, debc, etc.

Following is not supported:

a*b or a*b*c

See Also ▶"Synopsys Design Constraints (SDC)" on page 1338

create_clock

Creates a clock and defines its characteristics.

Note

In LSE timing, interclock domain paths are always blocked for create_clock. However, the interclock domain path is still valid for constraints such as set_false_path and set_multicycle_path.

Syntax create_clock [-name *name*] -period *period_value* [-waveform {value1 value2}] *source_object*

Arguments -name *name*

The name string specifies the name of the clock. If this parameter is not given, the name of the source object is used as the name of the clock. Virtual clocks are currently not supported.

-period *period_value*

This value is required and it specifies the clock period in nanoseconds. The value you specify is the minimum time over which the clock waveform repeats. The value specified for the period must be positive as the period of a clock must be greater than zero. The duty cycle of the clock is 50 percent.

-waveform {value1 value2}

The values are a list of edge values. Only two edges are supported. Floating values are accepted. Value1 must be less than value2, and the difference must be less than the clock period.

source_object

The source object is the object on which the clock constraint is defined. The source object can be a port object or a net object in the design. The object is obtained by using one of the get_ports or get_nets commands. If you specify a clock constraint on a source object that already has a clock, the new clock replaces the existing one. Only one source object is accepted. Wildcards are accepted as long as the resolution shows one port or net object.

Example The following example creates two clocks on ports CK1 and CK2 with a period of 6:

```
create_clock -name my_user_clock -period 6 [get_ports CK1]
create_clock -name my_other_user_clock -period 6 [get_ports CK2]
```

Example The following example creates a clock on port CK3 with a period of 7.1, and has two edges at 0 and 4.1:

```
create_clock -period 7.1 -waveform {0 4.1} [get_ports CK3]
```

See Also ▶"Synopsys Design Constraints (SDC)" on page 1338

create_generated_clock

Creates an internally generated clock and defines its characteristics. This command is used when the clock being created is related to another clock. The generated clock will now be considered a clock when defining constraints such as input_delay.

Syntax create_generated_clock -source *reference_object* [-*master_clock clock_object*] [-divide_by *factor*] [-multiply_by *factor*] [-duty_cycle *value*] net_object

Arguments -source *reference_object*

The reference object is an object on which the source clock of the generated clock is defined. The source object can be a net object or a port object. The period of the generated clock is derived from the clock on the reference object using the multiply and divide factors.

-master_clock *clock_object*

If the master is defined, the master clock object becomes the source clock for the generated clock. This is an optional object used to identify a specific clock, if there is more than one clock on the source object.

-divide_by *factor*

This factor is the frequency division factor. The frequency of the generated clock is equal to the frequency of the source clock divided by this factor, if the multiply by factor is not specified. For instance, if this factor is equal to 2, the generated clock period is twice the reference clock period. Default value is 1.

-multiply_by *factor*

This factor specifies the frequency multiplication number to be used when finding the generated clock frequency. For instance, if the factor is equal to 2, the generated clock period is half the reference clock period. If both multiply_by and divide_by factors are used, the frequency is obtained by using both factors. Default value is 1.

-duty_cycle *value*

This value specifies the duty cycle in percentage of the clock period. The value can be floating point and ranges from 0 to 100. The default value is 50.

net_object

The net_object specifies the source of the clock constraint. This is usually an internal -net of the design. If you specify a clock constraint on a net that already has a clock, the new clock replaces the existing clock. Only one source is accepted. Wildcards are accepted as long as the resolution shows one net.

This command creates a generated clock in the current design at a declared net_object by defining its frequency with respect to the frequency at the reference object. The static timing analysis tool uses this information to compute and propagate the generated clock's waveform across the clock network to the clock pins of all sequential elements driven by this target

Examples The following example creates a generated clock on pin pll1/CLKOP with a period twice as long as the period at the reference port CLK:

```
create_generated_clock -divide_by 2 -source [get_ports CLK]
[get_pins pll1/CLKOP]
```

The following example creates a generated clock at the primary output of myPLL with a period 3/4 of the period at the reference pin clk:

```
create_generated_clock -divide_by 3 -multiply_by 4  -source
[get_ports clk]  [get_pins myPLL/CLK1]
```

The following example shows a clock with a duty cycle of 60 percent:

```
create_generated_clock -duty_cycle 60 -source [get_ports clk]
[get_pins myPLL/CLK1]
```

See Also ▶"Synopsys Design Constraints (SDC)" on page 1338

set_clock_groups

Specifies clock groups that are mutually exclusive or asynchronous with each other in a design so that the paths between these clocks are not considered during timing analysis.

Syntax set_clock_groups *-asynchronous* | *-exclusive* -group *clock_objects* [-group *clock_objects*]

Arguments -asynchronous

Specifies that the clock groups are asynchronous to each other (meanwhile, Lattice assume all clocks are asynchronous). Two clocks are asynchronous with respect to each other if they have no phase relationship at all.

-exclusive

Specifies that clocks are mutually exclusive. Only one clock group will be active at any given time.

-group *clock_object*

Specifies the clock objects in a group. If you specify only one group, it means that the clocks in that group are exclusive or asynchronous with all other clocks in the design. A default other group is created for this single group. Whenever a new clock is created, it is automatically included in this group.

Examples The following example specifies two clock ports (clka and clkb) are asynchronous to each other.

```
create_clock -period 10.000 -name clka_port [get_ports clka]
create_clock -period 10.000 -name clkb_port [get_ports clkb]
# Set clka_port and clkb_port to be mutually exclusive clocks.
set_clock_groups -asynchronous -group [get_clocks clka_port] -
group [get_clocks clkb_port]
# The previous line is equivalent to the following two
commands.
set_false_path -from [get_clocks clka_port] -to [get_clocks
clkb_port]
set_false_path -from [get_clocks clkb_port] -to [get_clocks
clka_port]
```

The following example specifies four clock constraints that won't be active at the same time:

```
create_clock -period 10.000 -name clka_port [get_ports clka]
create_clock -period 10.000 -name clkb_port [get_ports clkb]
create_clock -period 10.000 -name clkc_port [get_ports clkc]
set_clock_groups -exclusive -group [get_clocks {clka_port
clkb_port}] -group [get_clocks clkc_port]
```

See Also ▶"Synopsys Design Constraints (SDC)" on page 1338

set_false_path

Identifies paths that are considered false and excluded from timing analysis.

Syntax set_false_path [-from *from port_object or cell_object*] [-to *to port_object or cell_object*]

or

set_false_path [-through *through_net_object*]

Arguments -from *from port_object or cell_object*

Specifies the timing path start point. A valid timing starting point is a clock, a primary input, a combinational logic cell, or a sequential cell (clock-pin).

-to *to port_object or cell_object*

Specifies the timing path end point. A valid timing end point is a primary output, a combinational logic cell, or a sequential cell (data-pin).

-through *through_net_object*

Specifies a net through which the paths should be blocked.

Examples The following example specifies all paths from clock pins of the registers in clock domain clk1 to data pins of a specific register in clock domain clk2 as false paths:

The following example specifies all paths through the net UO/sigA as false:

```
set_false_path –from [get_ports clk1] –to [get_cells reg_2]
```

```
set_false_path –through [get_nets UO/sigA]
```

See Also ▶"Synopsys Design Constraints (SDC)" on page 1338

set_input_delay

Defines the arrival time of an input relative to a clock.

Syntax set_input_delay *delay_value* [-max |-min] -clock *clock_object* *input_port_object*

Arguments *delay_value*

Specifies the arrival time in nanoseconds that represents the amount of time for which the signal is available at the specified input after a clock edge.

-max

Specifies that the delay value is the maximum delay.

-min

Specifies that the delay value is the minimum delay.

-clock *clock_object*

Specifies the clock reference to which the specified input delay is related. This is a mandatory argument.

input_port_object

Provides one or more input ports in the current design to which delay_value is assigned. You can also use the keyword "all_inputs" to include all input ports.

Example The following example sets an input delay of 1.2 ns for port data1 relative to the rising edge of CLK1:

```
set_input_delay 1.2 -clock [get_clocks CLK1] [get_ports data1]
```

Example The following example sets an input delay of 1.2 ns minimum and 1.5 ns maximum for port data1 relative to the rising edge of CLK1:

```
set_input_delay 1.2 -min -clock [get_clocks CLK1] [get_ports
data1]
set_input_delay 1.5 -max -clock [get_clocks CLK1] [get_ports
data1]
```

See Also ▶"Synopsys Design Constraints (SDC)" on page 1338

set_max_delay

Specifies the maximum delay for the timing paths.

Syntax set_max_delay *delay_value* [-from *from port_object or cell_object*] [-to *to port_object or cell_object*]

Arguments *delay_value*

Specifies a floating point number in nanoseconds that represents the required maximum delay value for specified paths.

If the path ending point is on a sequential device, the tool includes library setup time in the computed delay.

-from *from port_object or cell_object*

Specifies the timing path start point. A valid timing start point is a clock, a primary input, a combinational logic cell, or a sequential cell (clock pin).

-to *to port_object or cell_object*

Specifies the timing path end point. A valid timing end point is a primary output, a combinational logic cell, or a sequential cell (data pin)

Examples The following example sets a maximum delay by constraining all paths from ff1a:CLK to ff2e:D with a delay less than or equal to 5 ns:

```
set_max_delay 5 -from [get_cells ff1a] -to [get_cells ff2e]
```

See Also ▶"Synopsys Design Constraints (SDC)" on page 1338

set_min_delay

Specifies the minimum delay for the timing paths.

Syntax set_min_delay *delay_value* [-from *from port_object or cell_object*] [-to *to port_object or cell_object*]

Arguments *delay_value*

Specifies a floating point number in nanoseconds that represents the required minimum delay value for specified paths.

If the path ending point is on a sequential device, the tool includes library hold time in the computed delay.

-from *from port_object or cell_object*

Specifies the timing path start point. A valid timing start point is a clock, a primary input, a combinational logic cell, or a sequential cell (clock pin).

-to *to port_object or cell_object*

Specifies the timing path end point. A valid timing end point is a primary output, a combinational logic cell, or a sequential cell (data pin)

Examples The following example sets a minimum delay by constraining all paths from ff1a:CLK to ff2e:D with a delay greater than or equal to 5 ns:

```
set_min_delay 5 -from [get_cells ff1a] -to [get_cells ff2e]
```

See Also ▶"Synopsys Design Constraints (SDC)" on page 1338

set_multicycle_path

Defines a path that takes multiple clock cycles.

Syntax set_multicycle_path *ncycles* [-from *from net_object or cell_object*] [-to *to net_object or cell_object*]

Arguments *ncycles*

Specifies a value that represents the number of cycles the data path must have for setup check. The value is relative to the ending point clock and is defined as the delay required for arrival at the ending point.

-from *from net_object or cell_object*

Specifies the timing path start point. A valid timing start point is a sequential cell (clock pin) or a clock net (signal). You can also use the keyword "all_registers" to include all registers' clock inputs.

-to *to net_object or cell_object*

Specifies the timing path end point. A valid timing end point is a sequential cell (data-pin) or a clock-net (signal). You can also use the keyword "all_registers" to include all registers' data inputs.

Example The following example sets all paths between reg1 and reg2 to 3 cycles for setup check. Hold check is measured at the previous edge of the clock at reg2.

```
set_multicycle_path 3 –from [get_cells reg1] –to [get_cells
reg2]
```

See Also ▶"Synopsys Design Constraints (SDC)" on page 1338

set_output_delay

Defines the output delay of an output relative to a clock.

Syntax set_output_delay *delay_value* [-max |-min] -clock *clock_object output_port_object*

Arguments *delay_value*

Specifies the amount of time from a reference clock to a primary output port.

-max

Specifies that the delay value is the maximum delay.

-min

Specifies that the delay value is the minimum delay.

-clock *clock_object*

Specifies the clock reference to which the specified output delay is related. This is a mandatory argument.

output_port_object

Provides one or more (by wildcard) output ports in the current design to which delay_value is assigned. You can also use the keyword "all_outputs" to include all output ports.

Example The following example sets an output delay of 1.2 ns for all outputs relative to clki_c:

```
set_output_delay 1.2 -clock [get_clocks CLK1] [get_ports OUT1]
set_output_delay 1.2 -clock [get_clocks CLK1] [all_outputs]
```

Example The following example sets an output delay of 1.2 ns minimum and 1.5 ns maximum for port data1 relative to the rising edge of CLK1:

```
set_output_delay 1.2 -min -clock [get_clocks CLK1] [get_ports
data1]
set_output delay 1.5 -max -clock [get_clocks CLK1] [get_ports
data1]
```

Lattice Synthesis Engine-Supported HDL Attributes

This section describes the Synplify Lattice Attributes that are supported by the Lattice Synthesis Engine (LSE). These attributes are directly interpreted by the engine and influence the optimization or structure of the output netlist. Traditional HDL attributes, such as UGROUP, are also compatible with LSE and are passed into the netlist to direct Map and Place & Route.

All HDL attributes have priority over Strategy settings.

See Also ►"black_box_pad_pin" on page 1350

black_box_pad_pin

This attribute specifies pins on a user-defined black box module. The pins are defined as I/O pads that are visible outside of the black box. If there is more than one port that is an I/O pad, list the ports inside double-quotes ("), separated by commas (,), and without enclosed spaces. This attribute must be used in conjunction with the syn_black_box attribute.

Verilog Syntax object /* synthesis syn_black_box black_box_pad_pin = "portList" */ ;

where object is a module declaration, and portList is a spaceless, comma-separated list of the black box port names that are I/O pads.

Verilog Example

```
module black_box_pad_pin2(
                    input[4:0] in1,
                    input[4:0] in2,
                    input clk,
                    output[4:0] q
                    )/*          synthesis          syn_black_box
                    black_box_pad_pin="in1(4:0),q" */;

  reg [4:0] q;
  always @(posedge clk)
    begin
       q <= in1 + in2;
    end
endmodule

module black_box_pad_pin_instan(
  input[4:0] in1,
  input[4:0] in2,
  input[4:0] in3,
  input clk,
  output[5:0] q_out
  );

  wire [4:0] q;
  reg [5:0] q_out;
  black_box_pad_pin2 test_123(
                           .in1(in1),
                           .in2(in2),
                           .clk(clk),
                           .q(q)
                           );

  always @(posedge clk)
    begin
       q_out <= q + in3;
    end
endmodule
```

VHDL Syntax attribute black_box_pad_pin of object : architecture is "portList" ;

where object is the architecture name of a black box. Data type is string. The portList is a spaceless, comma-separated list of the black box port names that are I/O pads.

VHDL Example

```
entity BBDLHS is
  port (D: in std_logic;
    E: in std_logic;
    GIN : in std_logic_vector(2 downto 0);
    Q : out std_logic );
end;

architecture BBDLHS_behav of BBDLHS is
end bl_box_behav;
attribute syn_black_box : boolean;
attribute syn_black_box of BBDLHS_behav : architecture is true;
attribute black_box_pad_pin : string;
attribute black_box_pad_pin of BBDLHS_behav : architecture is
"GIN(2:0),Q";
```

full_case

Directive. For Verilog designs only. When used with a case, casex, or casez statement, this directive indicates that all possible values have been given, and that no additional hardware is needed to preserve signal values.

Verilog Syntax object /* synthesis full_case */

Verilog Example

```
module full_case1 (q, in1, in2, in3, in4, sel);
  output q;
  input in1, in2, in3, in4;
  input [3:0] sel;
  reg q;
  always @(sel or in1 or in2 or in3 or in4)
    begin
      casez (sel) /* synthesis full_case */
        4'b11??: q = in4;
        4'b?1??: q = in3;
        4'b???1: q = in1;
        4'b??1?: q = in2;
        default: q = 'bx;
      endcase
    end
endmodule
```

GSR

This attribute specifies the use of the global set/reset routing resources. Allows the user to specify which portions of the design are to be altered in the way they respond to the GSR reset signal. Unless specified otherwise, all design elements will respond to the global reset signal if it is present.

Available values:

- ENABLED – This is the default value on most library elements. This value allows the software to determine the final value and will be overridden by the parent hierarchy if the parent has a value of anything other than ENABLED.
- DISABLED – This prevents the hierarchy or element from responding to the GSR value. It cannot be changed by the parent's value.
- FORCEENABLE – This forces the hierarchy or element to respond to the GSR value. It cannot be changed by the parent's value.
- IPENABLE – This forces the hierarchy or element to respond to the GSR value when IP is being used in evaluation mode. It cannot be changed by the parent's value. This value is only for internal Lattice IP to use. It should never be used within a design itself.

Verilog Syntax object /* synthesis GSR = {ENABLED | DISABLED | FORCEENABLE | IPENABLE} */ ;

Verilog Example

```
`timescale 1 ns / 1 ns
module top (reg_q, rotate_q, a, b, r_l, clk, rst)/* synthesis
GSR = "ENABLED" */;
output [7:0] reg_q, rotate_q;
input [7:0] a, b;
input clk, rst, r_l;

sub1 reg8_1 (.clk(clk), .data(a), .q(reg_q), .rst(rst));
sub2 rotate_1 (rotate_q, b, clk, r_l, rst);
endmodule
```

VHDL Syntax attribute gsr of object : objectType is ENABLED | DISABLED | FORCEENABLE | IPENABLE;

VHDL Example

```
architecture archtest of test is
attribute gsr : string;
attribute gsr of archtest : architecture is “ENABLED”;
```

loc

The loc attribute specifies pin locations for Lattice I/Os, instances, and registers, and forward-annotates them to the place-and-route tool. Refer to the Lattice databook for valid pin location values. If the attribute is on a bus, the software writes out bit-blasted constraints for forward-annotation.

Verilog Syntax object /* synthesis loc = "pinLocations" */ ;

In the syntax, pin_locations is a spaceless, comma-separated list of pin locations, starting with the lowest-indexed port and read left-to-right.

Verilog Example

```
I/O pin location
input [3:0]DATA0 /* synthesis loc="p10,p12,p11,p15" *;
Register pin location
reg data_in_ch1_buf_reg3 /* synthesis loc="R40C47" */;
Vectored internal bus
reg [3:0] data_in_ch1_reg /*synthesis loc =
"R40C47,R40C46,R40C45,R40C44" */;
```

VHDL Syntax attribute loc of object : objectType is "pinLocations" ;

In the syntax, pinLocations is a spaceless, comma-separated list of pin locations, starting with the lowest-indexed port and read left-to-right.

VHDL Example

```
entity mycomp is port(DATA0 : in std_logic_vector (3 downto 0);
                .
                .
                .
                );
attribute loc : string;
attribute loc of DATA0 : signal is "p10,p12,p11,p15";
```

parallel_case

Directive. For Verilog designs only. Forces a parallel-multiplexed structure rather than a priority-encoded structure. This is useful because case statements are defined to work in priority order, executing (only) the first statement with a tag that matches the select value.

If the select bus is driven from outside the current module, the current module has no information about the legal values of select, and the software must create a chain of disabling logic so that a match on a statement tag disables all following statements. However, if you know the legal values of select, you can eliminate extra priority-encoding logic with the parallel_case directive. In the following example, the only legal values of select are 4'b1000, 4'b0100, 4'b0010, and 4'b0001, and only one of the tags can be matched at a time. Specify the parallel_case directive so that tag-matching logic can be parallel and independent, instead of chained.

Note

Designers should be aware that it is possible for the priority of overlapping cases in post-synthesis simulation to mismatch with the priority behavior in RTL simulation when using this pragma.

Verilog Syntax You specify the directive as a comment immediately following the select value of the case statement.

object /* synthesis parallel_case */

where object is a case, casex or casez statement declaration.

Verilog Example

```
module parallel_case1 (q, in1, in2, in3, in4, sel);
  output q;
  input in1, in2, in3, in4;
  input [3:0] sel;
  reg q;
  always @(sel or in1 or in2 or in3 or in4)
    begin
      casez (sel) /* synthesis parallel_case */
        4'b11??: q = in4;
        4'b?1??: q = in3;
        4'b???1: q = in1;
        4'b??1?: q = in2;
        default: q = 'bx;
      endcase
    end
endmodule
```

If the select bus is decoded within the same module as the case statement, the parallelism of the tag matching is determined automatically, and the parallel_case directive is unnecessary.

syn_black_box

This attribute specifies that a Verilog module or VHDL architecture declaration is for a black box. Only the module's interface is defined for synthesis. The contents of a black box cannot be optimized during synthesis. A module can be a black box whether it is empty or not. However, the syn_black_box attribute cannot be used with the top-level module or architecture of a design. Additionally, the syn_black_box attribute is not supported for instances in Verilog or components in VHDL.

This attribute has an implicit Boolean value of 1 or true.

If any of the ports are I/O pads, add the black_box_pad_pin attribute. See "black_box_pad_pin" on page 1350.

Verilog Syntax object /* synthesis syn_black_box */ ;

where *object* is a module declaration.

Verilog Example

```
module bl_box(out,data,clk) /* synthesis syn_black_box */;
```

VHDL Syntax attribute syn_black_box of object : architecture is true ;

where *object* is an architecture name. Data type is Boolean.

VHDL Example

```
entity bl_box is
  port (data : in std_logic_vector (7 downto 0);
    clk : in std_logic;
    out : out std_logic);
end;

architecture bl_box_behav of bl_box is
end bl_box_behav;
attribute syn_black_box : boolean;
attribute syn_black_box of bl_box_behav : architecture is true;
```

See Also ▶"Creating Your Own Black Box Modules" on page 205

syn_encoding

This attribute specifies the encoding style for a finite state machine (FSM), overriding the default LSE encoding. The default encoding is based on the number of states in the FSM. This attribute takes effect only when LSE infers an FSM. This attribute has no effect when syn_state_machine is 0, which blocks inference of an FSM.

Values for syn_encoding are as follows:

- sequential – More than one bit of the state register can change at a time, but because more than one bit can be hot, the value must be decoded to determine the state. For example: 000, 001, 010, 011, 100
- onehot – Only two bits of the state register change (one goes to 0; one goes to 1) and only one of the state registers is hot (driven by a 1) at a time. For example: 0001, 0010, 0100, 1000
- gray – Only one bit of the state register changes at a time, but because more than one bit can be hot, the value must be decoded to determine the state. For example: 000, 001, 011, 010, 110

  There can be no more than four states for gray encoding. If the FSM has more than four states, LSE switches to sequential encoding.
- safe – If the state machine enters an invalid state, additional logic will drive the state machine into its reset state. The design must have a defined reset state.

  Safe encoding can be combined with either sequential or onehot encoding (not with gray encoding) as in:

  ```
  syn_encoding = "safe,onehot"
  ```

  If the safe value is given by itself, it combines with the encoding method of a preceding syn_encoding statement or the default method.

Verilog Syntax Object /* synthesis syn_encoding = "value" */;

Where object is an enumerated type and value is from the list above.

Verilog Example

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.std_logic_unsigned.all;

entity syn_state_machine2 is
  port(
    clk : in std_logic;
    reset: in std_logic;
    en   : in std_logic;
    q  : out std_logic_vector(1 downto 0)
    );

end entity;

architecture behave of syn_state_machine2 is
  type state_type is(state0,state1,state2,state3);
  signal state,next_state:state_type;
  attribute syn_state_machine : boolean;
  attribute syn_state_machine of behave : architecture is true;
  attribute syn_encoding : string;
  attribute syn_encoding of state,next_state: signal is
"binary";
begin
  process(clk,reset)
  begin
    if reset = '1' then
      state <= state0;
    elsif clk'event and clk = '1' then
      state <= next_state;
    end if;
  end process;
  process(state)
  begin
    case state is
      when state0 =>
        if (en = '1') then
           q <= "00";
        end if;
        next_state <= state1;
      when state1=>
        if (en = '1') then
           q <= "01";
        end if;
        next_state <= state2;
      when state2 =>
        if (en = '1') then
           q <= "10";
        end if;
        next_state <= state3;
      when state3 =>
        if (en = '1') then
           q <= "11";
        end if;
        next_state <= state0;
    end case;
  end process;
end behave
```

VHDL Syntax attribute syn_encoding of object: objectType is "value";

Where object is an enumerated type and value is from the list above.

VHDL Example

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.std_logic_unsigned.all;

entity syn_encoding1 is
  port(
    clk : in std_logic;
    reset: in std_logic;
    en   : in std_logic;
    q  : out std_logic_vector(1 downto 0)
    );
end entity;

architecture behave of syn_encoding1 is
  signal state : std_logic_vector(3 downto 0);
  constant state0 : std_logic_vector(3 downto 0) := "1000";
  constant state1 : std_logic_vector(3 downto 0) := "0100";
  constant state2 : std_logic_vector(3 downto 0) := "0010";
  constant state3 : std_logic_vector(3 downto 0) := "0001";
  attribute syn_encoding : string;
  attribute syn_encoding of state : signal is "safe,onehot";
begin
  process(clk,reset,en)
  begin
    if reset = '1' then
      state <= state0;
      q <= "00";
    elsif clk'event and clk = '1' then
      case state is
        when state0 =>
          if (en = '1') then
             q <= "00";
          end if;
          state <= state1;
        when state1=>
          if (en = '1') then
             q <= "01";
          end if;
          state <= state2;
        when state2 =>
          if (en = '1') then
             q <= "10";
          end if;
          state <= state3;
        when state3 =>
          if (en = '1') then
             q <= "11";
          end if;
          state <= state0;
        when others => null;
      end case;
    end if;
  end process;
end behave
```

syn_force_pads

This attribute prevents unused ports from being optimized away to allow I/O pad insertion on the unused port. This attribute is not supported at the global level. Instead, set the use_io_insertion option to control I/O insertion globally.

This attribute is supported in the rtl, and it will override the global use_io_insertion option setting on the given input, output, or bidir port.

For example, in the following Verilog file, the syn_force_pads attribute can be set to 1 on an unused input port (dataz), and it will not be optimized away, regardless of the use_io_insertion global setting.

Verilog syntax object /* synthesis syn_force_pads = {1 | 0} */;

where object is port declaration.

Verilog Example

```
`define DSIZE 9
`define OSIZE 18

module multp9x9(dataout, dataax, dataay, dataz, clk, rst, ce);
   output [`OSIZE-1:0] dataout;
   input [`DSIZE:0] dataz /* synthesis syn_force_pads = 1*/;
   input [`DSIZE-1:0] dataax, dataay;
   input clk, rst, ce;
   reg  [`DSIZE-1:0] dataax_reg, dataay_reg;

   reg [`OSIZE-1:0] dataout;
   wire [`OSIZE-1:0] dataout_tmp ;
   assign dataout_tmp = dataax_reg * dataay_reg;

   always @(posedge clk or posedge rst)
   begin
     if (rst)
     begin
         dataax_reg <= 0;
         dataay_reg <= 0;
         dataout <= 0;
     end
     else if (ce == 1'b1)
     begin
         dataax_reg <= dataax;
         dataay_reg <= dataay;
         dataout <= dataout_tmp;
     end
   end
endmodule
```

To force I/O pads to be inserted for input ports that do not drive logic, follow the guidelines below.

- To force I/O pad insertion on an individual port, set the syn_force_pads attribute on the port with a value to 1. To disable I/O insertion for a port, set the attribute on the port with a value of 0.

Enable this attribute to preserve user-instantiated pads, insert pads on unconnected ports, insert bi-directional pads on bi-directional ports instead of converting them to input ports, or insert output pads on unconnected outputs.

If you do not set the syn_force_pads attribute, the synthesis design optimizes any unconnected I/O buffers away.

VHDL syntax Attribute syn_force_pads of object: objectType is "true | false" ;

VHDL Example

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.std_logic_arith.all;
use ieee.std_logic_unsigned.all;

entity multp9x9 is
  port ( dataout : out std_logic_vector(17 downto 0);
      dataax, dataay: in std_logic_vector( 8 downto 0);
           dataz : in std_logic_vector(8 downto 0);
           clk,rst,ce: in std_logic
    );
  attribute syn_force_pads : string;
  attribute syn_force_pads of dataz : signal is "true";

end multp9x9;

architecture rtl of multp9x9 is

signal dataax_reg,dataay_reg: std_logic_vector(8 downto 0);
signal dataout_tmp: std_logic_vector(17 downto 0);

begin

  dataout_tmp <= dataax_reg * dataay_reg;
  process (clk, rst)
  begin
      if rst = '1' then
           dataax_reg <= (others => '0');
           dataay_reg <= (others => '0');
           dataout <= (others => '0');
      elsif clk'event and clk = '1' then
        if ce = '1' then
           dataax_reg <= dataax;
           dataay_reg <= dataay;
           dataout <= dataout_tmp;
      end if;
      end if;
  end process;

end rtl;
```

syn_hier

This attribute allows you to control the amount of hierarchical transformation that occurs across boundaries on module or component instances during optimization. This attribute cannot be applied globally. The user must set this attribute on the selective modules to stop cross-boundary optimizations.

syn_hier Values The following value can be used for syn_hier:

hard – Preserves the interface of the design unit with no exceptions. This attribute affects only the specified design units.

Verilog Syntax object /* synthesis syn_hier = "value" */ ;

where *object* can be a module declaration and value can be any of the values described in syn_hier Values. Check the attribute values to determine where to attach the attribute.

Verilog Example

```
module top1 (Q, CLK, RST, LD, CE, D)
   /* synthesis syn_hier = "hard" */;
```

VHDL Syntax attribute syn_hier of object : architecture is "value" ;

where *object* is an architecture name and value can be any of the values described in syn_hier Values. Check the attribute values to determine the level at which to attach the attribute.

VHDL Example

```
architecture struct of cpu is
attribute syn_hier : string;
attribute syn_hier of struct: architecture is "hard";
```

syn_insert_pad

This attribute removes an existing I/O buffer from a port or net when I/O buffer insertion is enabled.

The syn_insert_pad attribute is used when the use_io_insertion global option is enabled (when I/O buffers are automatically inserted) to allow users to selectively remove an individual buffer from a port or net.

It can also be used to force an I/O buffer to be inserted on a specific port or net, if the use_io_insertion global option is disabled.

- Setting the attribute to 0 on a port or net removes the I/O buffer (or prevents an I/O buffer from being automatically inserted, if the use_io_insertion global option is enabled).
- Setting the attribute to 1 on a port or net forces an I/O buffer to be inserted if the use_io_insertion global option is disabled.

Verilog Syntax object /* synthesis syn_insert_pad = {1 | 0} */;

where *object* is a port or net declaration.

Verilog Example

```
`define OSIZE 16
`define DSIZE 8

module mac8x8 (dataout, x, y, clk, rst);
 output [`OSIZE:0] dataout;
 input [`DSIZE-1:0] x, y;
 input clk;
 input rst /* synthesis syn_insert_pad = 0 */;
 reg  [`OSIZE:0] dataout;
 reg [`DSIZE-1:0] x_reg, y_reg;
 wire [`OSIZE-1:0] multout ;
 wire [`OSIZE:0] sum_out;

 assign multout = x_reg * y_reg;
 assign sum_out = multout + dataout;

 always @(posedge clk or posedge rst)
 begin
   if (rst)
   begin
      x_reg = 0;
      y_reg = 0;
      dataout = 0;
   end
   else
   begin
      x_reg = x;
      y_reg = y;
      dataout = sum_out;
   end
 end
endmodule
```

In the previous example, the input port labeled “rst” will not have an input buffer connected to it in the technology-mapped netlist after LSE completes.

VHDL Syntax attribute syn_insert_pad of object : objectType is "true | false" ;

VHDL Example

```
library ieee;
use ieee.std_logic_1164.all;

entity register_en_reset is
          generic (
                    width : integer := 8
                     );
  port (
    datain  : in std_logic_vector(width-1 downto 0);
    clk     : in std_logic;
    enable  : in std_logic;
    reset   : in std_logic;
    dataout : out std_logic_vector(width-1 downto 0)
    );
  attribute syn_insert_pad : string;
  attribute syn_insert_pad of reset : signal is "false";

end register_en_reset;

architecture lattice_behav of register_en_reset is

begin
    process (clk,reset)
    begin
      if (reset = '1') then
                     dataout <= (others => '0');
      elsif (rising_edge(clk) and enable = '1') then
        dataout <= datain;
      end if;
    end process;
end lattice_behav;
```

syn_keep

This attribute keeps the specified net intact during optimization and synthesis.

Verilog Syntax object /* synthesis syn_keep = 1 */ ;

where *object* is a wire or reg declaration. Make sure that there is a space between the object name and the beginning of the comment slash (/).

Verilog Example

```
module syn_keep1(
        input a,
        input b,
        input clk,
        output q1,
        output q2);
  reg temp1;
  reg temp2;
  reg q1;
  reg q2;
  wire or_result;
  wire keep1/* synthesis syn_keep=1 */;
  wire keep2/* synthesis syn_keep=1 */;

  always @(posedge clk)
    begin
      temp1 = a;
      temp2 = b;
    end
  assign or_result = (temp1 | temp2);
  assign keep1 = or_result;
  assign keep2 = or_result;
  always@(posedge clk)
    begin
      q1 = keep1;
      q2 = keep2;

    end
endmodule
```

VHDL Syntax attribute syn_keep of object : objectType is true ;

where *object* is a single or multiple-bit signal.

VHDL Example

```
library ieee;
use ieee.std_logic_1164.all;

entity syn_keep1 is
  port(
    a : in std_logic;
    b : in std_logic;
    clk: in std_logic;
    q1: out std_logic;
    q2: out std_logic
    );
end entity;

architecture behave of syn_keep1 is
  signal temp1 : std_logic;
  signal temp2 : std_logic;
  signal keep1 : std_logic;
  signal keep2 : std_logic;
  signal or_result : std_logic;
  attribute syn_keep: boolean;
  attribute syn_keep of keep1,keep2: signal is true;
begin
  process(clk)
  begin
    if clk'event and clk = '1' then
      temp1 <= a;
      temp2 <= b;
    end if;
  end process;

  or_result <= (temp1 or temp2);
  keep1 <= or_result;
  keep2 <= or_result;

  process(clk)
  begin
    if clk'event and clk = '1' then
      q1 <= keep1;
      q2 <= keep2;
    end if;
  end process;

end behave;
```

syn_maxfan

This attribute overrides the default (global) fan-out guide for an individual input port, net, or register output.

Verilog Syntax object /* synthesis syn_maxfan = "value" */ ;

Note

LSE will take integer values for non-integral values to syn_maxfan attribute.

For example, syn_maxfan value of 5.1 will be truncated to 5.

Verilog Example

```
module test (registered_data_out, clock, data_in);
output [31:0] registered_data_out;
input clock;
input [31:0] data_in /* synthesis syn_maxfan=1000 */;
reg [31:0] registered_data_out /* synthesis syn_maxfan=1000 */;
```

VHDL Syntax attribute syn_maxfan of object : objectType is "value" ;

VHDL Example

```
entity test is
   port (clock : in bit;
         data_in : in bit_vector(31 downto 0);
         registered_data_out: out bit_vector(31 downto 0) );
attribute syn_maxfan : integer;
attribute syn_maxfan of data_in : signal is 1000;
```

See Also “Optimizing LSE for Area and Speed” on page 579

syn_multstyle

This attribute specifies whether the multipliers are implemented as dedicated hardware blocks or as logic.

syn_multstyle Values block_mult | logic

Value Description Default block_mult Implements the multipliers as dedicated hardware blocks (Lattice: DSP blocks)

This attribute only applies to families that use DSP blocks on the device. To override this behavior, specify a value of logic.

Verilog Syntax input net /* synthesis syn_multstyle = "block_mult | logic" */;

Verilog Example

```
module syn_multstyle1(
            input [7:0] in1,
            input [7:0] in2,
            input rst,
            input clk,
            output [15:0] result);

  reg [7:0] temp1,temp2;
  reg [15:0] result;
  wire [15:0] product /*synthesis syn_multstyle = "logic"*/;

  always@(posedge clk ,negedge rst)
    begin
      if(!rst)
        begin
          temp1 = 'b0;
          temp2 = 'b0;
        end
      else
        begin
          temp1  = in1;
          temp2  = in2;
        end
    end

  assign product = temp1*temp2;

  always@(posedge clk, negedge rst)
    begin
      if(!rst)
        begin
          result  = 'b0;
        end
      else
        begin
          result = product;
        end
      end
endmodule
```

VHDL Syntax attribute syn_multstyle of instance : signal is "block_mult | logic";

VHDL Example

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.std_logic_arith.all;
use ieee.std_logic_unsigned.all;

entity mac_ecp4_m5678_09x09_ir_or_bit_up is generic (widtha :
natural := 9;
         widthb : natural := 9);
port (
      ina     : in  std_logic_vector (0 to widtha - 1);
      inb_0   : in  std_logic;
      inb_1   : in  std_logic;
      inb_2   : in  std_logic;
      inb_3   : in  std_logic;
      inb_4   : in  std_logic;
      inb_5   : in  std_logic;
      inb_6   : in  std_logic;
      inb_7   : in  std_logic;
      inb_8   : in  std_logic;
      clk     : in  std_logic;
      mout    : out  std_logic_vector (0 to widtha+widthb -
1));
    attribute syn_multstyle : string;
  attribute syn_multstyle of mout: signal is "block_mult"; end
mac_ecp4_m5678_09x09_ir_or_bit_up;

architecture rtl of mac_ecp4_m5678_09x09_ir_or_bit_up is
signal mout_s     : std_logic_vector (0 to widtha+widthb - 1);
signal reg1_ina : std_logic_vector(0 to widtha - 1); signal
reg1_inb : std_logic_vector(0 to widthb - 1); signal reg_mout :
std_logic_vector(0 to widtha+widthb - 1);
signal inb     : std_logic_vector (0 to widthb - 1);
begin

inb <= inb_8 & inb_7 & inb_6 & inb_5 & inb_4 & inb_3 & inb_2 &
inb_1 & inb_0 ;

 reg_mout <= reg1_ina * reg1_inb+mout_s;
  mout <= mout_s;

process (clk) begin
  if
   rising_edge (clk) then
      reg1_ina <= ina;
      reg1_inb <= inb;
      mout_s <= reg_mout;
  end if;
end process;

end rtl;
```

syn_noprune

This attribute prevents instance optimization for black-box modules (including technology-specific primitives) with unused output ports. This attribute is not a global attribute. It works on the component basis. The user must set the attribute on the instance.

Verilog Syntax object /* synthesis syn_noprune = 1 */ ;

where object is a module an instance. The data type is Boolean.

Verilog Example

```
module top(a1,b1,c1,d1,y1,clk);
output y1;
input a1,b1,c1,d1;
input clk;
wire x2,y2;
reg y1;
syn_noprune u1(a1,b1,c1,d1,x2,y2) /* synthesis syn_noprune=1 */
;

always @(posedge clk)
   y1<= a1;

endmodule
```

VHDL Syntax attribute syn_noprune of object : objectType is true ;

where the data type is boolean, and object is a component.

VHDL Example

```
library ieee;
use ieee.std_logic_1164.all;
entity top is
   port (a1, b1 : in std_logic;
         c1,d1,clk : in std_logic;
         y1 :out std_logic );
end ;
architecture behave of top is
component noprune
port (a, b, c, d : in std_logic;
      x,y : out std_logic );
end component;
signal x2,y2 : std_logic;
attribute syn_noprune : boolean;
attribute syn_noprune of noprune : component is true;
begin
   u1: noprune port map(a1, b1, c1, d1, x2, y2);
   process begin
      wait until (clk = '1') and clk'event;
      y1 <= a1;
   end process;
end;
```

syn_pipeline

This attribute permits registers to be moved to improve timing. Specifies that registers that are outputs of Multipliers/Adders can be moved to improve timing. Depending on the criticality of the path, the tool moves the output register to the input side.

Verilog Syntax object /* synthesis syn_pipeline = {1 | 0} */ ;

where *object* is a register declaration.

The value of 0 (or false) indicates pipelining for the specified register is disabled, which means the register position in the design is fixed.

The value of 1 (or true) indicates pipelining for the specified register is allowed, which means the register may be moved if it helps improve timing.

LSE will identify registers that are candidates for possible pipelining based on running RTL timing analysis. It may identify some candidate registers, or it may determine there are none that are suitable.

If LSE decides no candidate registers for pipelining exist, if the user sets the syn_pipeline attribute to “1” on a specific register in the RTL to force pipelining for that register, that attribute will not be honored.

If global pipelining is enabled for a design, and given one or more registers that LSE has identified as possible candidates for pipelining, the user may prevent these registers from being pipelined by setting synthesis attribute syn_pipeline=0 for each of those registers in the RTL.

Verilog Example

```
module pipeline (a,b,c,d,clk,out);

input [3:0] a,b,c,d;
input clk;
output[7:0]out;

reg[7:0]out,out1 /* synthesis syn_pipeline = 0 */;
reg[3:0] a_temp,b_temp,c_temp,d_temp;

always @(posedge clk)
begin
   a_temp <= a;
   b_temp <= b;
   c_temp <= c;
   d_temp <= d;
   out1 <= (a_temp * b_temp) +(c_temp * d_temp);
   out <= out1;
end
endmodule
```

In the previous example, the registers labeled “out1” will not be moved to the input side of the adder to improve timing.

VHDL Syntax attribute syn_pipeline of object : objectType is {true|false} ;

VHDL Example

```
library ieee;
use ieee.std_logic_1164.all;
USE ieee.numeric_std.all;
use ieee.std_logic_unsigned.all;

entity syn_pipeline_exp is
port (CLK_0 : in std_logic;
    A_IN : in std_logic_vector(3 downto 0);
    B_IN : in std_logic_vector(3 downto 0);
    RST : out std_logic_vector(7 downto 0)
    );
end syn_pipeline_exp;

architecture rtl of syn_pipeline_exp is
signal A_REGSTR : std_logic_vector(3 downto 0);
signal B_REGSTR : std_logic_vector(3 downto 0);
signal TMP : std_logic_vector(7 downto 0);
signal TMP1 : std_logic_vector(7 downto 0);
signal TMP2 : std_logic_vector(7 downto 0);
attribute syn_pipeline : string;
attribute syn_pipeline of TMP1 : signal is "true";

begin
  process(CLK_0)
  begin
    if (CLK_0'event and CLK_0 = '1') then
      TMP <= A_REGSTR * B_REGSTR;
      A_REGSTR <= A_IN;
      B_REGSTR <= B_IN;
      TMP1 <= TMP;
      TMP2 <= TMP1;
      RST <= TMP2;
    end if;
  end process;

end rtl;
```

syn_preserve

This attribute prevents sequential optimizations such as constant propagation and inverter push-through from removing the specified register. The syn_encoding attribute is not honored if there is a syn_preserve attribute on any of the state machine registers.

Verilog Syntax object /* synthesis syn_preserve = 1 */ ;

where object is a register definition signal or a module.

Verilog Example

```
module syn_preserve1(
          input[3:0]in1,
          input[3:0]in2,
          input[3:0]in3,
          input clk,
          output [7:0] result,
          output [3:0] sum
          )/* synthesis syn_preserve= 1*/;

reg [7:0] result/*synthesis syn_multstyle = "EBR"*/;
reg [3:0] temp1,temp2,temp3;
reg [3:0] sum;

always@(posedge clk)
  begin
    temp1 = in1 & in2;
    temp2 = !temp1;
    temp3 = temp1 & temp2;
    result = temp3*in3;
    sum = temp3 + in3;
  end
endmodule
```

VHDL Syntax attribute syn_preserve of object : objectType is true ;

where object is an output port or an internal signal that holds the value of a state register or architecture.

VHDL Example

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.std_logic_unsigned.all;

entity syn_preserve2 is
  port(
     in1: in std_logic_vector(3 downto 0);
     in2: in std_logic_vector(3 downto 0);
     in3: in std_logic_vector(3 downto 0);
     clk: in std_logic;
     result: out std_logic_vector(7 downto 0);
     sum   : out std_logic_vector(3 downto 0)
    );
end entity;

architecture behave of syn_preserve2 is
  signal temp1,temp2,temp3 : std_logic_vector(3 downto 0);
  attribute syn_preserve : boolean;
  attribute syn_preserve of behave: architecture is true;
  attribute syn_multstyle : string;
  attribute syn_multstyle of result: signal is "EBR";
begin
  process(clk)
  begin
    if clk'event and clk = '1' then
      temp1 <= in1 and in2;
      temp2 <= not temp1;
      temp3 <= temp1 and temp2;
      result <= temp3*in3;
      sum <= temp3 + in3;
    end if;
  end process;
end behave;
```

syn_ramstyle

The syn_ramstyle attribute specifies the implementation to use for an inferred RAM. You apply syn_ramstyle globally, to a module, or to a RAM instance. To turn off RAM inference, set its value to registers.

The following values can be specified globally or on a module or RAM instance:

- registers – Causes an inferred RAM to be mapped to registers (flip-flops and logic) rather than the technology-specific RAM resources.
- distributed – Causes the RAM to be implemented using the distributed RAM or PFU resources.
- block_ram – Causes the RAM to be implemented using the dedicated RAM resources. If your RAM resources are limited, you can use this attribute to map additional RAMs to registers instead of the dedicated or distributed RAM resources.
- no_rw_check (some modes, but all technologies). – You cannot specify this value alone. Without no_rw_check, the synthesis tool inserts bypass logic around the RAM to prevent the mismatch. If you know your design does not read and write to the same address simultaneously, use no_rw_check to eliminate bypass logic. Use this value only when you cannot simultaneously read and write to the same RAM location and you want to minimize overhead logic.

Verilog Syntax object /* synthesis syn_ramstyle = "string" */ ;

where object is a register definition (reg) signal. The data type is string.

Verilog Example

```
module ram4 (datain,dataout,clk);
output [31:0] dataout;
input clk;
input [31:0] datain;
reg [7:0] dataout[31:0] /* synthesis syn_ramstyle="block_ram" */;
```

VHDL Syntax attribute syn_ramstyle of object : objectType is "string" ;

where object is a signal that defines a RAM or a label of a component instance. Data type is string.

VHDL Example

```
library ieee;
use ieee.std_logic_1164.all;
entity ram4 is
   port (d : in std_logic_vector(7 downto 0);
         addr : in std_logic_vector(2 downto 0);
         we : in std_logic;
         clk : in std_logic;
         ram_out : out std_logic_vector(7 downto 0) );
end ram4;
library synplify;
architecture rtl of ram4 is
type mem_type is array (127 downto 0) of std_logic_vector (7
downto 0);
signal mem : mem_type; -- mem is the signal that defines the
RAM
attribute syn_ramstyle : string;
attribute syn_ramstyle of mem : signal is "block_ram";
```

syn_replicate

This attribute controls replication. The synthesis tool can automatically replicate registers during optimization. This attribute disables replication either globally or on a per register basis.

Verilog Syntax object /* synthesis syn_replicate = 1 | 0 */;

Verilog Example For example:

```
module syn_replicate1 (en1,en2,clk,in1,in2,q);
  input en1,en2;
  input clk;
  input [6:0]in1,in2;
  output [6:0]q;
  reg [6:0]q;
  reg enc /* synthesis syn_maxfan = 1 syn_replicate = 1*/;

  always @(posedge clk)
    begin
      enc = en1 & en2;
    end

  always @(posedge clk)
    begin
      if (enc)
        q = in1;

      else
        q = in2;
    end
endmodule
```

VHDL Syntax attribute syn_replicate of object : objectType is true | false ;

VHDL Example For example:

```
library ieee;
use ieee.std_logic_1164.all;

entity syn_replicate2 is
  port(
     en1: in std_logic;
     en2: in std_logic;
     clk: in std_logic;
     in1: in std_logic_vector(6 downto 0);
     in2: in std_logic_vector(6 downto 0);
     q:  out std_logic_vector(6 downto 0)
    );
end entity;

architecture behave of syn_replicate2 is
  signal enc : std_logic;
  attribute syn_maxfan: integer;
  attribute syn_maxfan of behave : architecture is 1;
  attribute syn_replicate: boolean;
  attribute syn_replicate of enc : signal is false;
begin
  process(clk)
  begin
    if clk'event and clk = '1' then
      enc <= (en1 and en2);
    end if;
  end process;

  process(clk)
  begin
    if enc = '1' then
      q <= in1;
    else
      q <= in2;
    end if;
  end process;
end behave;
```

See Also “Optimizing LSE for Area and Speed” on page 579

syn_romstyle

This attribute allows you to implement ROM architectures using dedicated or distributed ROM. Infer ROM architectures using a CASE statement in your code.

For the synthesis tool to implement a ROM, at least half of the available addresses in the CASE statement must be assigned a value. For example, consider a ROM with six address bits (64 unique addresses). The case statement for this ROM must specify values for at least 32 of the available addresses. You can apply the syn_romstyle attribute globally to the design by adding the attribute to the module or entity.

The following values can be specified globally on a module or ROM instance:

- auto – Allows the synthesis tool to chose the best implementation to meet the design requirements for speed, size, etc.
- logic – Causes the ROM to be implemented using the distributed ROM or PFU resources.
- EBR – Causes the ROM to be implemented using the dedicated ROM resources. If your ROM resources are limited, you can use this attribute to map additional ROM to registers instead of the dedicated or distributed RAM resources.

Verilog Syntax object /* syn_romstyle = "auto(default) | EBR | logic" */ ;

Verilog Example

```
reg [8:0] z /* synthesis syn_romstyle = "EBR" */;
```

VHDL Syntax attribute syn_romstyle of object : object_type is "auto(default) | EBR | logic" ;

VHDL Example

```
signal z : std_logic_vector(8 downto 0);
attribute syn_romstyle : string;
attribute syn_romstyle of z : signal is "logic";
```

syn_srlstyle

This attribute determines how to implement the sequential shift components.

Verilog Syntax object /* synthesis syn_srlstyle = "string",

where string can take one of the following values:

registers: seqShift register components are implemented as registers.

distributed: seqShift register components are implemented as distributed RAM.

block_ram: seqShift register components are implemented as block RAM

If the attribute value set by the user cannot be honored (for example, the user sets the attribute value to "block_ram", however, the selected device does not contain enough available EBR blocks to implement the shift register), LSE will display a message to indicate this.

" | registers | distributed | |block_ram" */ ;

In the above syntax, *object* is a register declaration.

Verilog Example The following example implements seqShift components as distributed memory with any required fabric logic.

```
module test_srl(clk, enable, dataIn, result, addr);
input clk, enable;
input [3:0] dataIn;
input [3:0] addr;
output [3:0] result;
reg [3:0] regBank[15:0]
  /* synthesis syn_srlstyle="distributed" */;
integer i;
always @(posedge clk) begin
  if (enable == 1) begin
    for (i=15; i>0; i=i-1) begin
      regBank[i] <= regBank[i-1];
    end
  regBank[0] <= dataIn;
  end
end
assign result = regBank[addr];
endmodule
```

The following example implements a seqShift for 16x256 bits wide and serial in and serial out register using syn_srlstyle set to block_ram.

VHDL Syntax attribute syn_srlstyle of object : signal is

" registers | distributed |block_ram " ;

In the above syntax, object is a register.

```
// shift left register with 16X256 bits width and serial in and
serial out
module test(clock, arst, sr_en, shiftin, shiftout);
parameter sh_len=16;
parameter sh_width=256;
parameter ARESET_VALUE = {(sh_width){1'b0}};
input clock,arst,sr_en;
input [sh_width-1:0] shiftin;
output [sh_width-1:0] shiftout;
integer i;
reg [sh_width-1:0] sreg [sh_len-1:0] /* synthesis
syn_srlstyle="block_ram" */;
  always @(posedge clock or posedge arst)
  begin
    if(arst)
      begin
        for(i = 0;i <= sh_len-1;i = i+1)
        sreg[i] <= ARESET_VALUE ;
      end
    else
  begin
    if(sr_en)
    begin
      sreg[0] <= shiftin;
      for(i=sh_len-1;i>0;i=i-1)
        sreg[i] <= sreg[i-1];
      end
    end
  end
assign shiftout = sreg[sh_len-1];
endmodule
```

Verilog Example The example below implements seqShift components as distributed memory primitives:

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.std_logic_unsigned.all;
entity d_p is
  port (clk : in std_logic;
    data_out : out std_logic_vector(127 downto 0));
  end d_p;

architecture rtl of d_p is
type dataAryType is array(3 downto 0) of
  std_logic_vector(127 downto 0);
signal h_data_pip_i : dataAryType;
attribute syn_srlstyle : string;
attribute syn_srlstyle of h_data_pip_i : signal
is "distributed";
begin
  process (Clk)
  begin
    if (Clk'Event And Clk = '1') then
      h_data_pip_i <= (h_data_pip_i(2 DOWNTO 0)) &
      h_data_pip_i(3);
    end if;
  end process;
data_out <= h_data_pip_i(0);
end rtl;
```

syn_sharing

Directive. Enables or disables the sharing of operator resources during the compilation stage of synthesis.

The syn_sharing directive controls resource sharing during the compilation stage of synthesis. This is a compiler-specific optimization that does not affect the mapper; this means that the mapper might still perform resource sharing optimizations to improve timing, even if syn_sharing is disabled.

If you disable resource sharing globally, you can use the syn_sharing directive to turn on resource sharing for specific modules or architectures.

Verilog Syntax object /* synthesis syn_sharing=”on | off” */ ;

Verilog Example

```
module syn_sharing1 (
          input [7:0] inA1,
          input [7:0] inA2,
          input [7:0] inB1,
          input [7:0] inB2,
          input clk,
          input sel1,
          input sel2,
          input rst,
          output [15:0] product1,
          output [15:0] product2
          )/*synthesis syn_sharing = 1*/;

  reg [15:0] product1,product2;
  wire [15:0] temp1,temp2;
  assign temp1 = inA1*inB1;
  assign temp2 = inA2*inB2;
  always@(posedge clk)
    begin
      if(sel1)
        begin
          if (sel2)
            product1 = temp1;
          else
            product1 = temp2;
        end
      else
        begin
          if (sel2)
            product2 = temp1;
          else
            product2 = temp2;
        end
    end
endmodule
```

VHDL Syntax attribute syn_sharing of object : objectType is “true | false” ;

VHDL Example

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.std_logic_unsigned.all;

entity syn_sharing2 is
  port(
    inA1 : in std_logic_vector(7 downto 0);
    inA2 : in std_logic_vector(7 downto 0);
    inB1 : in std_logic_vector(7 downto 0);
    inB2 : in std_logic_vector(7 downto 0);
    clk  : in std_logic;
    sel1 : in std_logic;
    sel2 : in std_logic;
    rst  : in std_logic;
    product1 : out std_logic_vector(15 downto 0);
    product2 : out std_logic_vector(15 downto 0)
    );
end entity;

architecture behave of syn_sharing2 is
 signal temp1,temp2: std_logic_vector(15 downto 0);
 attribute syn_sharing : boolean;
 attribute syn_sharing of behave : architecture is false;
begin
  temp1 <= inA1*inB1;
  temp2 <= inA2*inB2;
  process(clk)
  begin
    if clk'event and clk ='1' then
      if sel1 = '1' then
        if sel2 = '1' then
          product1 <= temp1;
        else
          product1 <= temp2;
        end if;
      else
        if sel2 = '1' then
          product2 <= temp1;
        else
          product2 <= temp2;
        end if;

      end if;
    end if;
  end process;
end behave;
```

syn_state_machine

This attribute enables/disables state-machine optimization on individual state registers in the design. To extract some state machines, use this attribute with a value of 1 on just those individual state-registers to be extracted. If there are state machines in your design that you do not want extracted, use syn_state_machine with a value of 0 to override extraction on just those individual state registers.

All state machines are usually detected during synthesis. However, on occasion there are cases in which certain state machines are not detected. You can use this attribute to declare those undetected registers as state machines.

The syn_sharing attribute only can be used in architecture. The syn_sharing attribute cannot be used in entity.

Verilog Syntax object /* synthesis syn_state_machine = 0 | 1 */ ;

where *object* is a state register. Data type is Boolean: 0 does not extract an FSM, 1 extracts an FSM.

Verilog Example

```
module syn_state_machine1 (clk, reset, en, q);
  input clk, reset, en;
  output[1:0]q;
  reg q;
  reg [3:0] state,next_state /* synthesis syn_state_machine = 0
*/;
  parameter state0 = 4'b1000;
  parameter state1 = 4'b0100;
  parameter state2 = 4'b0010;
  parameter state3 = 4'b0001;
  always @(posedge clk or posedge reset)
    begin
      if (reset)
          state <= state0;
      else
        state <= next_state;
    end

  always @(state)
    begin
      case (state)
        state0:
          begin
            if (en == 1)
              q <= 2'b00;
            next_state <= state1;
          end

        state1:
          begin
            if (en == 1)
              q <= 2'b01;
            next_state <= state2;
          end
        state2:
          begin
            if (en == 1)
              q <= 2'b10;
            next_state <= state3;
          end
        state3:
          begin
            if (en == 1)
              q <= 2'b11;
            next_state <= state0;
          end
      endcase
    end
endmodule
```

VHDL Syntax attribute syn_state_machine of object : objectType is true | false ;

where *object* is a signal that holds the value of the state machine.

VHDL Example

```
attribute syn_state_machine of current_state: signal is true;
```

Following is the source code used for the example in the previous figure.

```
library ieee;
use ieee.std_logic_1164.all;
entity syn_statemachine_exp is
port (CLK_0, RESET, IN1 : in std_logic;
                  OUT1 : out std_logic_vector (2 downto 0)
      );
end syn_statemachine_exp;

architecture behave of syn_statemachine_exp is
type ST_VALS is (STATE0, STATE1, STATE2, STATE3);
signal STATE, NXT_ST: ST_VALS;
attribute syn_state_machine : boolean;
attribute syn_state_machine of STATE : signal is true;

begin
  process (CLK_0, RESET)
  begin
    if RESET = '1' then
      STATE <= STATE0;
    elsif rising_edge(CLK_0) then
      STATE <= NXT_ST;
    end if;
  end process;

  process (STATE, IN1)
  begin
    case STATE is
      when STATE0 =>
        OUT1 <= "000";
        if IN1 = '1' then NXT_ST <= STATE1;
        else NXT_ST <= STATE0;
        end if;
      when STATE1 =>
        OUT1 <= "001";
        if IN1 = '1' then NXT_ST <= STATE2;
        else NXT_ST <= STATE1;
        end if;
      when STATE2 =>
        OUT1 <= "010";
        if IN1 = '1' then NXT_ST <= STATE3;
        else NXT_ST <= STATE2;
        end if;
      when others =>
        OUT1 <= "XXX"; NXT_ST <= STATE0;
    end case;
  end process;

end behave;
```

syn_use_carry_chain

This attribute is used to turn on or off the carry chain implementation for adders.

Verilog Syntax object synthesis syn_use_carry_chain = {1| 0} */ ;

Verilog Example To use this attribute globally, apply it to the module.

```
module test (a, b, clk, rst, d) /* synthesis
syn_use_carry_chain = 1 */;
```

VHDL Syntax attribute syn_use_carry_chain of object : objectType is true | false ;

VHDL Example

```
architecture archtest of test is
signal temp : std_logic;
signal temp1 : std_logic;
signal temp2 : std_logic;
signal temp3 : std_logic;
attribute syn_use_carry_chain : boolean;
attribute syn_use_carry_chain of archtest : architecture is
true;
```

syn_useenables

This attribute controls the use of clock enables on registers in the design. Usually exploiting clock enables on registers is beneficial. However, there are timing closure situations where clock enable routing causes timing violations. This is one reason why the user may want to stop the use of clock enable on the register.

Verilog Syntax: object /* synthesis syn_useenables = "0 | 1" */;

Verilog Example

```
module syn_useenable1 (Din1,Din2,en,clk,Dout);
  input [7:0] Din1, Din2;
  input clk,en;
  output [7:0] Dout;
  reg [7:0] temp1;
  reg [7:0] Dout /* synthesis syn_useenables = 0*/;
  always@(posedge clk)
    begin
      temp1 <= Din1 & Din2;
    end
  always @(posedge clk)
    begin
      if(en)
        Dout <= temp1;
    end
endmodule
```

VHDL Syntax: attribute syn_useenables of object : objectType is "true | false";

VHDL Example

```
library ieee;
use ieee.std_logic_1164.all;

entity syn_useenable2 is
  port(
     Din1 : in std_logic_vector(7 downto 0);
     Din2 : in std_logic_vector(7 downto 0);
     clk  : in std_logic;
     en   : in std_logic;
     Dout : out std_logic_vector(7 downto 0)
    );
end entity;

architecture behave of syn_useenable2 is
  signal temp1 : std_logic_vector(7 downto 0);
  attribute syn_useenables: boolean;
  attribute syn_useenables of Dout: signal is false;
begin
  process(clk)
  begin
    if clk'event and clk = '1' then
      temp1 <= Din1 and Din2;
    end if;
  end process;

  process(clk)
  begin
    if clk'event and clk = '1' then
      if en = '1' then
        Dout <= temp1;
      end if;
    end if;
  end process;
end behave;
```

syn_useioff

This attribute overrides the default behavior to pack registers into I/O pad cells based on timing requirements for the target Lattice families. Attribute syn_useioff is Boolean-valued: 1 enables (default) and 0 disables register packing. You can place this attribute on an individual register or port or apply it globally. When applied globally, the synthesis tool packs all input, output, and I/O registers into I/O pad cells. When applied to a register, the synthesis tool packs the register into the pad cell; and when applied to a port, it packs all registers attached to the port into the pad cell.

The syn_useioff attribute can be set on the following ports:

- top-level port
- register driving the top-level port
- lower-level port, if the register is specified as part of the port declaration

Verilog Syntax object /*synthesis syn_useioff = {1 | 0} */ ;

Verilog Example To use this attribute globally, apply it to the module.

```
module test (a, b, clk, rst, d) /* synthesis syn_useioff = 1 */;
```

To use this attribute on individual ports, apply it to individual port declarations.

```
module test (a, b, clk, rst, d);
input a;
input b /* synthesis syn_useioff = 1 */;
```

VHDL Syntax attribute syn_useioff of object : objectType is true | false ;

VHDL Example

```
architecture archtest of test is
signal temp : std_logic;
signal temp1 : std_logic;
signal temp2 : std_logic;
signal temp3 : std_logic;
attribute syn_useioff : boolean;
attribute syn_useioff of archtest : architecture is true;
```

translate_off/translate_on

This attribute allows you to synthesize designs originally written for use with other synthesis tools without needing to modify source code. All source code that is between these two attributes is ignored during synthesis.

Verilog Syntax /* pragma translate_off */
/* pragma translate_on */

Verilog Example

```
module real_time (ina, inb, out);
input ina, inb;
output out;
/* synthesis translate_off */
realtime cur_time;
/* synthesis translate_on */
assign out = ina & inb;
endmodule
```

VHDL Syntax pragma translate_off
pragma translate_on

VHDL Example

```
library ieee;
use ieee.std_logic_1164.all;
entity adder is
   port (a, b, cin:in std_logic;
         sum, cout:out std_logic );
end adder;
architecture behave of adder is
signal a1:std_logic;
--synthesis translate_off
constant a1:std_logic:='0';
--synthesis translate_on
begin
   sum <= (a xor b xor cin);
   cout <= (a and b) or (a and cin) or (b and cin); end behave;
```

Chapter 18

Lattice Module Reference Guide

IPexpress provides a variety of modules to assist your design work. These modules cover a variety of common functions and can be customized. They are optimized for Lattice device architectures. Use these modules to speed your design work and to get the most effective results.

PMI (Parameterized Module Instantiation) is an alternate way to use some of the modules that come with IPexpress. With PMI, instead of using IPexpress, you directly instantiate a module into your HDL and customize it by setting parameters in the HDL. You may find this easier than using IPexpress with the simpler modules.

This guide describes the modules that come with IPexpress and the related PMI modules. The descriptions mainly cover the options and controls of the configuration dialog boxes for the modules. When there is a related PMI module, the descriptions also include specifications for the PMI module's customizable parameters and ports.

See Also

- "Use PMI or IPexpress?" on page 190
- "Creating IPexpress Modules and IP" on page 190
- "Using PMI" on page 199

Finding Modules in This Guide

The module descriptions are arranged alphabetically. To find modules by their functional type, see the following lists. To look up a specific PMI module, see Table 142 on page 1401.

Architecture

I/O

Other

Arithmetic

DSP

Memory

Distributed RAM

EBR components

Other

Table 142: PMI Module Lookup

PMI Module Name	IPexpress Module Name
pmi_add	Adder
pmi_addsub	Adder_Subtractor
pmi_complex_mult	Multiplier
pmi_constant_mult	Multiplier
pmi_counter	Counter
pmi_distributed_dpram	Distributed_DPRAM
pmi_distributed_rom	Distributed_DPRAM
pmi_distributed_shift_reg	RAM_Based_Shift_Register
pmi_distributed_spram	Distributed_SPRAM
pmi_dsp_casmultaddsub	MULTADDSUB
pmi_dsp_mac	MAC
pmi_dsp_mult	MULT
pmi_dsp_multaddsub	MULTADDSUB
pmi_dsp_multaddsubsum	MULTADDSUBSUM
pmi_dsp_preadd_slice	SLICE
pmi_fifo	FIFO
pmi_fifo_dc	FIFO_DC
pmi_mac	Multiply_Accumulate
pmi_mult	Multiplier
pmi_multaddsub	Mult_Add_Sub
pmi_multaddsubsum	Mult_Add_Sub_Sum
Spmi_pll	PLL
pmi_pll_fp	PLL
pmi_ram_dp	RAM_DP
pmi_ram_dp_be	RAM_DP
pmi_ram_dp_true	RAM_DP_TRUE
pmi_ram_dp_true_be	RAM_DP_TRUE
pmi_ram_dq	RAM_DQ
pmi_ram_dq_be	RAM_DQ
pmi_rom	ROM
pmi_sub	Subtractor

1D_FILTER

1D FIR filter that can be either symmetrical or asymmetrical.

Table 143: 1D_FILTER Dialog Box

Feature	Description
Mode	Choose either symmetrical, asymmetrical serial, or asymmetrical parallel mode.
Number of Taps	Enter the number of taps wanted.
Symmetry	If in Symmetry mode, specify either positive or negative symmetry.
Reset Mode	Specify either a synchronous or asynchronous reset.
Dual Channel Mode	Select to double the DataA input and the Result output signals. DataA and DataB are automatically signed.
DATAA Width	Choose the width of the DataA input signal. The actual width depends on this value, the number of taps, and the mode: ▶ Asymmetry Serial: Width ▶ Asymmetry Parallel: Width x taps ▶ Symmetry: Width
DATAB Width	Choose the width of the DataB input signal. The actual width depends on this value, the number of taps, and the mode: ▶ Asymmetry: Width x taps ▶ Symmetry: Width x taps/2 (taps/2 is rounded up to an integer.)
DATAA, DATAB Sign	Specify whether the data input signals are signed or unsigned. Only available without high speed operation.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

See Also ▶"Generating a Module or IP with IPexpress" on page 194

Adder

A two-input adder that performs signed or unsigned addition of the data from input ports DataA and DataB. If the optional port Cin is used, the addition result DataA[size-1..0] + DataB[size-1..0] + Cin is returned to the output port Result. For a description of some of the possible ports, see Table 145.

Table 144: Adder Dialog Box

Feature	Description
Specify the Data Width of the Adder	Specifies the input bus width of the module.
Specify the Representation of the Adder	Selections can be either signed or unsigned. Choosing the signed representation will keep the signed bit on the output. Unsigned will remove the signed bit from the output.
Complex Inputs	Allows implementation of complex adder.
Use Carry-in port	If selected will add a carry-in port to the module.
Specify the Carry-out Port	Use the carry-out port, overflow port, or none. Carry-out is available with unsigned addition. Overflow is available with signed addition.
Enable Output Register	Allows the implementation of registers on the outputs.
Specify number of pipeline stages	Specifies the number of register stages inserted into the adder. More stages improves achievable frequency of operation, but the latency for the output increases. To enable this option, the data width must be at least 9 bits
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 145: Adder Ports

If the Complex Inputs option is selected, each of these ports will come in pairs: *_Re (real part) and *_Im (imaginary part).

Name	Description
Cin	Carry-in to the low-order bit. (Optional)
DataA[size-1..0]	Augend.
DataB[size-1..0]	Addend
Result[size-1..0]	DataA[size-1..0] + DataB[size-1..0] + Cin

Table 145: Adder Ports (Continued)

If the Complex Inputs option is selected, each of these ports will come in pairs: *_Re (real part) and *_Im (imaginary part).

Name	Description
Cout	Carry-out of the most significant bit to detect overflow in unsigned representation. When Cout is prepended to Result, the result is a vector that always has sufficient precision to represent the result of the operation, {Cout, Result} = DataA + DataB + Cin. (Optional)
Overflow	Result exceeds available precision when used with signed representation. XOR of the carry into the most significant bit and Cout. (Optional)

pmi_add

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_add.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	DataA	Bus	(pmi_data_width - 1):0
I	DataB	Bus	(pmi_data_width - 1):0
I	Cin	Bit	N/A
O	Result	Bus	(pmi_result_width - 1):0
O	Cout	Bit	N/A
O	Overflow	Bit	N/A

Verilog pmi_add Definition

```
module pmi_add
  #(parameter pmi_data_width = 8,
    parameter pmi_result_width = 8,
    parameter pmi_sign = "off",
    parameter pmi_family = "EC",
    parameter module_type = "pmi_add"
    )

    (
     input [pmi_data_width-1:0] DataA,
     input [pmi_data_width-1:0] DataB,
     input Cin,
```

```
     output [pmi_data_width-1:0] Result,
     output Cout,
     output Overflow)/*synthesis syn_black_box */;
endmodule // pmi_add
```

VHDL pmi_add Definition

```
component pmi_add is
     generic (
       pmi_data_width : integer := 8;
       pmi_result_width : integer := 8;
       pmi_sign : string := "off";
       pmi_family : string := "EC";
       module_type : string := "pmi_add"

    );
    port (
     DataA : in std_logic_vector(pmi_data_width-1 downto 0);
     DataB : in std_logic_vector(pmi_data_width-1 downto 0);
     Cin: in std_logic;
     Result : out std_logic_vector(pmi_data_width-1 downto 0);
     Cout: out std_logic;
     Overflow: out std_logic
   );
  end component pmi_add;
```

Parameter Names and Values

The following table contains the pmi_add module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_data_width	1 to 64	8	The LatticeSC/M devices' data and result widths range from 1 to 256.
pmi_result_width	1 to 64	8	The LatticeSC/M devices' data and result widths range from 1 to 256.
pmi_sign	"on" | "off"	"off"	
pmi_family	"EC" | "ECP" | "ECP2" | "ECP2M" | "ECP3" | "ECP5U" | "ECP5UM" | "SC" | "SCM" | "XP" | "XP2" | "XO" | "XO2" | "XO3L" | "LPTM"	"EC"	

See Also

- "Using PMI" on page 199

Adder_Subtractor

A two-input adder/subtractor that performs signed or unsigned addition/ subtraction of the data from input ports DataA and DataB based on the specification from the input port Add_Sub. If the optional port Cin is used, the addition/subtraction result DataA + DataB + Cin / DataA - DataB + Cin - 1 are returned to the output port Result. An optional Overflow port is provided to detect overflow conditions when doing operations on signed data. or a description of some of the possible ports, see Table 147 on page 1406.

Table 146: Adder_Subtractor Dialog Box

Feature	Description
Specify the Data Width of the Adder_Subtractor	Specifies the input bus width of the module.
Specify the Representation of the Adder_Subtractor	Selections can be either signed or unsigned. Choosing the signed representation will keep the signed bit on the output. Unsigned will remove the signed bit from the output.
Complex Inputs	Allows implementation of complex adder_subtractor.
Use Carry-in port	If selected will add a carry-in port to the module. This port will be Active High in Adder mode. This port will be Active Low in Subtractor mode.
Specify the Carry-out Port	Use the carry-out port, overflow port, or none at all. Overflow port is allowed only when the representation is signed. This port will be Active High in Adder mode. This port will be Active Low in Subtractor mode.
Enable Output Register	Allows the implementation of registers on the outputs.
Specify number of pipeline stages	Specifies the number of register stages inserted into the adder/subtractor. More stages improves achievable frequency of operation, but the latency for the output increases. To enable this option, the data width must be at least 9 bits.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 147: Adder_Subtractor Ports

Name	Description
Add_Sub	Add_Sub=1, then Result=DataA+DataB+Cin. Add_Sub=0, then Result=DataA-DataB+Cin-1.
Cin (optional)	Carry-in to the low-order bit.

Table 147: Adder_Subtractor Ports

Name	Description
DataA[size-1..0]	Augend (Add_Sub=1) / Minuend (Add_Sub=0)
DataB[size-1..0]	Addend (Add_Sub=1) / Subtrahend (Add_Sub=0)
Result[size-1..0]	Result (Add_Sub=1) = DataA + DataB + Cin Result (Add_Sub=0) = DataA - DataB + Cin - 1
Cout (optional)	Carry-out of the MSB to detect overflow in unsigned representation. When Cout is prepended to the Result, the result is a vector that always has sufficient precision to represent the result of the operation. {Cout, Result} = DataA + DataB + Cin (Add_Sub=1) {Cout, Result} = DataA - DataB + Cin - 1 (Add_Sub=0)
Overflow (optional)	Result exceeds available precision when used with signed representation. XOR of the carry into the MSB and Cout.

pmi_addsub

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_addsub.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	DataA	Bus	(pmi_data_width - 1):0
I	DataB	Bus	(pmi_data_width - 1):0
I	Cin	Bit	N/A
I	Add_Sub	Bit	N/A
O	Result	Bus	(pmi_result_width - 1):0
O	Cout	Bit	N/A
O	Overflow	Bit	N/A

Verilog pmi_addsub Definition

```
module pmi_addsub #(parameter pmi_data_width = 8,
        parameter pmi_result_width = 8,
        parameter pmi_sign = "off",
        parameter pmi_family = "EC",
        parameter module_type = "pmi_addsub"
        )
```

```
  (
   input [pmi_data_width-1:0] DataA,
   input [pmi_data_width-1:0] DataB,
   input Cin,
   input Add_Sub,
   output [pmi_data_width-1:0] Result,
   output Cout,
   output Overflow)/*synthesis syn_black_box */;
endmodule // pmi_addsub
```

VHDL pmi_addsub Definition

```
component pmi_addsub is
     generic (
       pmi_data_width : integer := 8;
       pmi_result_width : integer := 8;
       pmi_sign : string := "off";
       pmi_family : string := "EC";
       module_type : string := "pmi_addsub"

    );
    port (
     DataA : in std_logic_vector(pmi_data_width-1 downto 0);
     DataB : in std_logic_vector(pmi_data_width-1 downto 0);
     Cin: in std_logic;
     Add_Sub: in std_logic;
     Result : out std_logic_vector(pmi_data_width-1 downto 0);
     Cout: out std_logic;
     Overflow: out std_logic
   );
  end component pmi_addsub;
```

Parameter Names and Values

The following table contains the pmi_addsub module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value
pmi_data_width	1 to 64	8
pmi_result_width	1 to 64	8
pmi_sign	“on” | “off”	“off”
pmi_family	“EC” | “ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” | “ECP5UM” | “XP” | “XP2” | “XO” | “XO2” | “XO3L” | “LPTM”	“EC”

ADDER_TREE

Adder that can accept several input values simultaneously. The result is the same width as the inputs, so you must control overflow.

Table 148: ADDER_TREE Dialog Box

Feature	Description
Width	Specifies the width of the input data buses and of the Result bus.
Number of Inputs	Specifies the number of input data buses.
Reset Mode	Specify either a synchronous or asynchronous reset.
Enable Fully Pipelined Mode	Enables the output registers of all stages.
Enable Input Register	Allows the implementation of registers on the inputs.
Enable Output Register	Allows the implementation of a register on the output.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

BARREL_SHIFTER

Shifts a data word multiple positions in a single clock cycle.

Table 149: BARREL_SHIFTER Dialog Box

Feature	Description
Shift Direction	Specify the direction to shift the data.
Type	Select the type of shift: Zero Insert, Sign Extension, or Rotate. Sign Extension is available only when the shift direction is to the right.
Data Width	Specify the width of the input and output data buses.
Maximum Number of Shifts	Specify the maximum number of bits that can be shifted in a single clock cycle. This value can be up to one less than the data width.
Reset Mode	Choose between synchronous and asynchronous reset.
Enable Input Register	Adds registers to the input bus.

Table 149: BARREL_SHIFTER Dialog Box (Continued)

Feature	Description
Enable Pipeline Register	Adds pipeline registers.
Enable Output Register	Adds registers to the output bus.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Comparator

A two-input comparator that performs signed or unsigned comparison of the value represented by DataA versus the value represented by DataB, the electrical equivalent of bit-pattern comparison operation. The module outputs the results of comparisons in terms of larger than, smaller than, equal to, or combinations of these operations.

Table 150: Comparator Dialog Box

Feature	Description
Specify the data width of the comparator	Specifies the width of the comparator.
Specify the representation of comparator	Specify the input representation to be signed or unsigned. For signed inputs, the output depends on the sign bit.
Specify the output port compare function	Specify the output port compare function. This function can be A != B, A < B, A <= B, A = B, A > B, A >= B.
Use LUT based implementation	Uses a LUT-based implementation to use fewer resources. Available only with the A = B and A != B functions.
Enable Output Register	Allows the implementation of registers on the outputs.
Specify number of pipeline stages	Specifies the number of register stages inserted into the comparator. More stages improves achievable frequency of operation, but the latency for the output increases. To enable this option, the data width must be at least 9 bits.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.

Table 150: Comparator Dialog Box (Continued)

Feature	Description
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Complex_Multiplier

Takes two inputs and multiplies them. For example, y1 = a1 + jb1 and y2 = a2 + jb2 - the product is a1a2 - b1b2 + j(a1b2 + a2b1).

Look-up table (LUT) implementation is available. For DSP devices, DSP implementation is also available.

Table 151: Complex_Multiplier Dialog Box

Feature	Description
Block Implementation	Allows you to choose between LUT-based implementation and DSP. DSP is only available with ECP5, LatticeECP, LatticeECP2/M, LatticeECP3, and LatticeXP2.
Input A Width	Bit size of Multiplier input. Bit width range is 2 to 36. The default value is 8.
Input B Width	Bit size of Multiplicand input. Bit width range is 2 to 36. The default value is 8.
Product Width	Bit size of product, equal to Input A Width + Input B Width + 1. This field is read-only.
Representation	Selections can be either signed or unsigned. Choosing the signed representation will keep the signed bit on the output. Unsigned will remove the signed bit from the output.
Specify the Number of Pipeline Stages	Specifies the number of register stages inserted into the complex multiplier. The default value is 1.
Enable Input Register	Allows you to register the data inputs. Default is enabled.
Enable Output Registers	Allows you to register the data outputs. Default is enabled.
Implementation	**3 Multiplier** - Implements the complex multiplier using three multipliers but requires more implementation logic. **4 Multiplier** - Implements the complex multiplier using four multipliers.
Bus Ordering Style	Specifies whether the numbers should begin at the high end ("Big Endian"- BusA[7 to 0]) or at the low end ("Little Endian"-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.

Convert

Converts from one format to another, performing rounding or saturation as required.

Table 152: Convert Dialog Box

Feature	Description
Input	**Width** - Number of bits in the input word. A positive integer that specifies the total number of bits that will be used to represent the data in twos complement format. Valid values are from 1 to 256. **Binary Point** - A positive integer that specifies the position of the binary point in the input data word. Valid values for unsigned word are from 0 to the output width. Valid values for signed word are from 0 to the output width minus 1. The MSB is treated as the sign bit. **Sign** - The format of the data value. The available values are signed and unsigned.
Output	**Width** - Number of bits in the output word. A positive integer that specifies the total number of bits that will be used to represent the data in twos complement format. Valid values are from 1 to 256. **Binary Point** - A positive integer that specifies the position of the binary point in the output data word. Valid values for unsigned word are from 0 to the output width. Valid values for signed word are from 0 to the output width minus 1. The MSB is treated as the sign bit. **Sign** - The format of the data value. The available values are signed and unsigned. **Rounding** - Three settings exist and determine the manner in which the input format value is shortened to the output format: Truncate, Nearest, and Convergent. - **Truncate** shortens the format by simply discarding the excess bits of the larger input format over the output format. - **Nearest** adds or subtracts an LSB if the excess bits sum to an absolute value that exceeds an LSB of the output format. - **Convergent** is the same as Nearest except when the excess bits add to exactly one-half an LSB, in which case a refinement to Nearest algorithm is employed. If the number of output fractional bits is less than the input, then quantization will be done according to this selection. Note that choosing any selection other than Truncate will result in an increase in the hardware requirements and potentially a lower overall performance. **Saturate** - If the number of integer output bits is less than that of the input, then any overflow or underflow will be treated according to this selection. - **Wrap** discards excess bits. - **Min_Max** sets to minimum or maximum value.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified and saves the files in the project folder.
Close	Cancels the dialog box without generating the module.
Help	Opens the Help Contents.

Counter

An up, up-down, or down counter. For a description of some of the possible ports, see Table 154 on page 1414.

Table 153: Counter Dialog Box

Feature	Description
Specify the data width of the counter	Specifies the input bus width of the module.
Specify the direction of the counter	Selects the counter direction to be Up, Down, or Up-Down. Up-Down is not available with LatticeSC/M.
Optimized for speed	Allows you to improve speed by using more logic resources. Only available with data widths of 33 bits or more. Not available with the Up-Down direction.
Lower count value	This specifies the lower count value of the counter. This is a double-precision number that will be converted to the specified format. If the value exceeds the range achievable by the selected format an error will be issued. Only available with data widths of 32 bits or fewer.
Upper count value	This specifies the upper count value of the counter. This is a double-precision number that will be converted to the specified format. If the value exceeds the range achievable by the selected format an error will be issued. For limited counting, this value must be an even multiple of the count range. Otherwise, an error will be issued. Only available with data widths of 32 bits or fewer.
Enable load input	Check this box to provide load and data input pins to the block. When the load pin goes high, the data on the data in pin will be loaded into the counter. If an enable pin is provided, it must also be high in order to load the data. With most devices, this option is only available with data widths of 32 bits or fewer. With MachXO and Platform Manager, this option is available with all data widths.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 154: Counter Ports

Name	Description
Clock	Positive, edge-triggered clock input
Clk_En	Clock Enable

Table 154: Counter Ports

Name	Description
Aclr	Asynchronous clear input
UpDown (Optional)	Controls the direction of the counter when **UpDown** direction option is selected: 1 for up and 0 for down.
Load (Optional)	Enables the loading of the counter from LData. Added when **Enable load input** check box is selected.
Ldata (Optional)	Parallel load value for counter. Added when **Enable load input** check box is selected.
Q[size-1..0]	Counter output

pmi_counter

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_counter.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	Clock	Bit	N/A
I	Clk_En	Bit	N/A
I	Aclr	Bit	N/A
I	UpDown	Bit	N/A
O	Q	Bus	(pmi_data_width - 1):0

Verilog pmi_counter Definition

```
module pmi_counter
  #(parameter pmi_data_width = 8,
    parameter pmi_updown = "up",
    parameter pmi_family = "EC",
    parameter module_type = "pmi_counter"
    )

  (
   input Clock,
   input Clk_En,
   input Aclr,
   input UpDown,
   output [pmi_data_width-1:0] Q)/*synthesis syn_black_box */;
endmodule // pmi_counter
```

VHDL pmi_counter Definition

```
component pmi_counter is
     generic (
       pmi_data_width : integer := 8;
       pmi_updown : string := "up";
       pmi_family : string := "EC";
       module_type : string := "pmi_counter"

    );
    port (
     Clock: in std_logic;
     Clk_En: in std_logic;
     Aclr: in std_logic;
     UpDown: in std_logic;
     Q : out std_logic_vector(pmi_data_width-1 downto 0)
   );
  end component pmi_counter;
```

Parameter Names and Values

The following table contains the pmi_counter module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_data_width	1 to 64	8	The LatticeECP/EC, LatticeECP2, LatticeXP, Platform Manager, and MachXO device families support a data width range from 1 to 64. The data width range for LatticeSC/M device families is from 1 to 256.
pmi_updown	“up” | “down” | “up-down”	“up”	Up-down mode is not supported for the LatticeSC/M devices.
pmi_family	“EC” | “ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” | “ECP5UM” | “SC” | “SCM” | “XP” | “XP2” | “XO” | “XO2” | “XO3H” | “LPTM”	“EC”

DDR

A DDR of specified width and mode. Although a DDR generated for a specific width can be used for other widths, it usually requires extra care in specifying the connection while instantiating.

The module dialog box has two tabs:

- Configuration, below

- Advanced, see Table 156 on page 1418

Table 155: DDR Dialog Box—Configuration Tab

Feature	Description
Mode	Specify the Mode of the DDR. The DDR can be used as an input, output, tristate, or bidirectional. A tristate mode consists of two output DDRs. A bidirectional mode has one input and two output DDRs. Values: Input, Output, Bidirectional, Tristate
Bus Width	Specify the width of the desired DDR. Values: 1 to 64
Gearing Ratio	Specify the gearing ratio. A 1x is the regular DDR where the output width is twice the input bus width. For gear ratio of 2x and 4x, the output width is 4 or 8 times the input width. The clock rate will be slower by the same amount.
Input Clock Mode	Specifies the type of input clock to use when no gearing is used. Values: Edge, Primary/Secondary
Output Clock Mode	Specifies the type of output clock to use when no gearing is used. Values: Edge, Primary/Secondary
Data Delay	Specify the Data Delay type. By default, there is no delay in the data path. The delay may be set at configuration to values specified by CDEL and FDEL, set to match the primary or edge clock, or set to match the DLL Delay Controls (DCNTL bus). Values: None, DLL, Edge Clock, Primary Clock, ECLK Injection, User Defined
CDEL	Specify the coarse delay setting. Values: 0, 1, 2, 3
FDEL	Specify the fine delay setting. Values: 0 to 47
Use CLKDIV	Specify the use of CLKDIV element to get the slower clock. Using the clock and reset from the CLKDIV will reduce the skew between the two. This is useful for high-speed interfaces that have gearing. This option is only available for Input DDR with a gearing ratio of 2x or 4x.
Use Single Clock for 1x	Specify that only one clock is required for the DDR module. This option is only available for Input and Bidirectional DDR with a gearing ratio of 1x.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 156: DDR Dialog Box—Advanced Tab

Feature	Description
Use AIL	Specify that the Adaptive Input Logic (AIL) is used. This is available for the Input and Input DDRs of bidirectional DDRs. The AIL is the ability of the I/O logic to automatically control coarse and fine delay settings to guarantee setup and hold times for a single I/O by sliding the data to a particular clock edge. The AIL features are not bus-based, but rather, per input port. Since the AIL will slide the data to a particular clock edge, the bits of a bus may not be latched on the same clock edge. For this reason, a training pattern will be required to realign the individual bits of the input data bus to the same clock edge. For single bit instances, this training pattern is not required. An AIL deskew reference design is available from Lattice Semiconductor that provides an example of the circuitry and training pattern required to align the bits of a bus. Please contact Lattice Semiconductor for more information on this reference design.
AIL Acquisition Window (ps)	Specify the window size in ps where data transitions are not allowed. The AIL continuously delays data to keep the AIL Acquisition Window within the data pulse width away from the transition edges. Values: 400, 720, 1040, 1360
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

DDR_GENERIC Options (ECP5)

The module dialog box has two tabs:

- Pre-Configuration, below
- Configuration, see Table 158 on page 1420

First, fill out the Pre-Configuration tab. The Configuration tab is automatically filled out based on the specifications in the Pre-Configuration tab. This is sufficient for most uses. Use the Configuration tab only if you want to further customize the module.

Table 157: DDR_GENERIC Dialog Box for ECP5—Pre-Configuration Tab

Feature	Description
Interface Type	Specify whether the interface is for transmit or receive.
Enable Tri-state Control	Available only with the Transmit interface type.
I/O Standard for this Interface	Choose an I/O standard.
Bus Width for this Interface	Specify the width of the bus in bits. The maximum possible bus width depends on the I/O standard.
Clock Frequency for this Interface	Specify the frequency of the clock in megahertz.
Interface Bandwidth	Shows the resulting bandwidth in megabits/second. Bandwidth is the bus width multiplied by the clock frequency times 2. This field is read-only.
Clock to Data Relationship at the Pins	Choose the clock-to-data relationship.

Table 157: DDR_GENERIC Dialog Box for ECP5—Pre-Configuration Tab (Continued)

Feature	Description
Next	Displays the Configuration tab.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 158: DDR_GENERIC Dialog Box for ECP5—Configuration Tab

Feature	Description
Interface selection based on pre-configuration	After filling out the Pre-Configuration tab, clear this option to further customize the module. Select this option to change the settings to match the Pre-Configuration tab.
Interface Type	Specify whether the interface is for transmit or receive.
Enable Tri-state Control	Available only with the Transmit interface type.
I/O Standard	Choose an I/O standard.
Clock Frequency	Specify the frequency of the clock in megahertz.
Gearing Ratio	Choose the gearing ratio. 4:1 is required for frequencies greater than 200 MHz. For a gearing ratio of 4:1, the output width is four times the input width.
Alignment	Choose the clock-to-data relationship.
Bus Width	Specify the width of the bus in bits. The maximum possible bus width depends on the I/O standard.
Organize Parallel Data	Specify how to organize parallel data.
Enable ECLK Bridge	If the bus is going to cross sides of the device, select this option to include an ECLK bridge.
Interface	Shows the interface in terms of primitives. This field is read-only.
Data Path Delay	Shows the delay type: ▶ Bypass means no delay. (Transmit only.) ▶ Static sets a fixed delay. ▶ Dynamic adds a data_direction, data_loadn, data_move, and data_cflag ports each of which is as wide as the Bus Width. (Transmit only.) ▶ User Defined allows you to set a delay value in the Delay Value for User Defined field. Not available with the Receive MIPI interface type.
Delay Value for User Defined	If Data Path Delay is “User Defined,” specify the number of fine delay increments. Refer to the device datasheet to see the delay value for each increment.
Enable Dynamic Margin Control on Clock Delay	Select to enable dynamic margin control on clock delay.

Table 158: DDR_GENERIC Dialog Box for ECP5—Configuration Tab (Continued)

Feature	Description
Generate PLL with this Module	Select to include a PLL (Phase Lock Loop). Available only with the Transmit interface type. Specify the **PLL Input Clock Frequency** in megahertz and click **Calculate**. Actual Clock Frequency shows the result.
PLL Reference Clock From I/O Pin	Select if the PLL reference clock will come from an I/O pin. Then specify the CLKI Input Buffer Type (below). Only available when Generate PLL with this Module (above) is selected.
CLKI Input Buffer Type	Choose the buffer for CLKI, the input reference clock for the PLL, when the clock is coming from an I/O pin.
Reference Clock From I/O Pin	Select if the reference clock will come from an I/O pin. Then specify the Reference Clock Input Buffer Type (below). Available only with the Transmit interface type.
Reference Clock Input Buffer Type	Choose the buffer for the input reference clock when the clock is coming from an I/O pin.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

DDR_GENERIC Options (LatticeEC, LatticeECP, LatticeXP)

Table 159: DDR_GENERIC Dialog Box for LatticeEC, LatticeECP, and LatticeXP

Feature	Description
DDR Data Width	Specify the width of the DDR bus. Values: 1 to 64
Tristate Enable for DDR Data Output Registers	Specify if the DDR output is a tristate bus. In this case, a DDR tristate enable, implemented using output DDRs, is generated. Otherwise, it is treated as an output bus.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.

DDR_GENERIC Options (LatticeECP2/M, LatticeXP2)

Table 160: DDR_GENERIC Dialog Box for LatticeECP2/M, and LatticeXP2

Feature	Description
Mode	Specify the Mode of the DDR. The DDR can be used as an input, output, tristate, or bidirectional. A tristate mode consists of two output DDRs. A bidirectional mode has one input and two output DDRs. Values: Input, Output, Bidirectional, Tristate
DDR Data Width	Specify the width of the DDR bus. Values: 1 to 64
Gearing Ratio	Specify the gearing ratio. A 1x is the regular DDR where the output width is twice the input bus width. For gear ratio of 2x, the output width is 4 times the input width. The clock rate will be slower by the same amount. Values: 1x, 2x
Delay	Specify the Data Delay type. By default, Dynamic delay control is enabled. Values: Dynamic (default), Fixed XGMII, User Defined Note that availability of Delay control options are dependent upon Gearing Ratio selection. In 1x mode, you can select a fixed delay for the XGMII interface, a user-defined value between 0 and 15, or dynamic control using del[3:0]. In 2x mode, only the user-defined and dynamic control selections are available.
Multiplier for Fixed Delay	Specifies the delay in increments of approximately 50 ps. Values: 0 to 15
Use Single Clock for 1x	Specify that only one clock is required for the DDR module. This option is only available for Input and Bidirectional DDR with a gearing ratio of 1x.
Use CLKDIV for 2x	Specify the use of CLKDIV element to get the slower clock. Using the clock and reset from the CLKDIV will reduce the skew between the two. This is useful for high-speed interfaces that have gearing. This option is only available for Input DDR with a gearing ratio of 2x.

Table 160: DDR_GENERIC Dialog Box for LatticeECP2/M, and LatticeXP2 (Continued)

Feature	Description
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.

DDR_GENERIC Options (LatticeECP3)

The module dialog box has two tabs:

- Pre-Configuration, below
- Configuration, see Table 162 on page 1424

First, fill out the Pre-Configuration tab. The Configuration tab is automatically filled out based on the specifications in the Pre-Configuration tab. This is sufficient for most uses. Use the Configuration tab only if you want to further customize the module.

Table 161: DDR_GENERIC Dialog Box for LatticeECP3—Pre-Configuration Tab

Feature	Description
Interface Type	Specify whether the interface is for transmit or receive.
Enable Tri-state Control	Available only with the Transmit interface type.
I/O Standard for this Interface	Choose an I/O standard.
Number of these interfaces on a side of a device	You can specify more than one interface in the module. All of the interfaces will be placed on the same side of the FPGA.
Bus Width for this Interface	Specify the width of the bus in bits. The maximum possible bus width depends on the I/O standard and the number of interfaces specified above.
Clock Frequency for this Interface	Specify the frequency of the clock in megahertz.
Interface Bandwidth (Calculated)	Shows the resulting bandwidth in megabits/second. Bandwidth is the bus width multiplied by the clock frequency times 2. This field is read-only.

Table 161: DDR_GENERIC Dialog Box for LatticeECP3—Pre-Configuration Tab (Continued)

Feature	Description
Clock to Data Relationship at the Pins	Choose the clock-to-data relationship.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 162: DDR_GENERIC Dialog Box for LatticeECP3—Configuration Tab

Feature	Description
Interface selection based on pre-configuration	After filling out the Pre-Configuration tab, clear this option to further customize the module. Select this option to change the settings to match the Pre-Configuration tab.
Interface Type	Specify whether the interface is for transmit or receive.
Enable Tri-state Control	Available only with the Transmit interface type.
I/O Standard	Choose an I/O standard.
Clock Frequency	Specify the frequency of the clock in megahertz.
Gearing Ratio	Choose the gearing ratio. 2x is required for frequencies greater than 200 MHz. For a gearing ratio of 2x, the output width is four times the input width.
Alignment	Choose the clock-to-data relationship.
Number of interfaces	You can specify more than one interface in the module. All of the interfaces will be placed on the same side of the FPGA.
Bus Width	Specify the width of the bus in bits. The maximum possible bus width depends on the I/O standard and the number of interfaces specified above.
Phase Adjust	Choose whether to use a PLL or DLL to adjust the clock phase. Available only with a Receive interface, 1x gearing ratio, and edge-to-edge alignment. See “DELAYB” on page 1863 and “TRDLLB” on page 2395.
Clock Divider	Choose the FPGA library primitive to use as the clock divider (SCLK). Available only with a Receive interface, 2x gearing ratio, and edge-to-edge alignment. See “CLKDIVB” on page 1845 and “TRDLLB” on page 2395.
Input Clock Multiplier	Available only with a Transmit interface and with a 2x gearing ratio.
PLL Input Clock Frequency	Shows the frequency resulting from the Clock Frequency and the Input Clock Multiplier. Available only with a Transmit interface, a 2x gearing ratio, and PLL selected in the Phase Adjust box. Read only.
Interface	Shows the interface in terms of primitives. This field is read-only.

Table 162: DDR_GENERIC Dialog Box for LatticeECP3—Configuration Tab (Continued)

Feature	Description
Data Path Delay	Shows the delay type: ▶ Bypass means no delay. ▶ Dynamic adds a 4-bit control port, del[3:0]. The value on the control port specifies the number of fine delay increments. Each increment is 1/16 of the clock cycle. ▶ Fixed sets a fixed delay. Available only with the receive interface type. This field is read-only.
DQS Grouping	**Number of DQS** - Shows the number of DQS groups, which is equal to the number of interfaces in the module. This field is read-only. **DQS Group** - Choose the number of bits in the group to use.
ISI Calibration	Choose the ISI calibration type.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

DDR_GENERIC Options (MachXO2, MachXO3L, Platform Manager 2)

The module dialog box has two tabs:

- Pre-Configuration, below
- Configuration, see Table 164 on page 1426

First, fill out the Pre-Configuration tab. The Configuration tab is automatically filled out based on the specifications in the Pre-Configuration tab. This is sufficient for most uses. Use the Configuration tab only if you want to further customize the module.

Table 163: DDR_GENERIC Dialog Box for MachXO2, MachXO3L, and Platform Manager 2—Pre-Configuration Tab

Feature	Description
Interface Type	Specify whether the interface is for transmit or receive and regular or MIPI (Mobile Industry Processor Interface).
Enable Tri-state Control	Available only with the Transmit interface type.
Enable MIPI High Speed Mode Only	Available only with the MIPI interface types.
I/O Standard for this Interface	Choose an I/O standard. Not available with MIPI interface types.
Clock Frequency for this Interface	Specify the frequency of the clock in megahertz.
Bus Width for this Interface	Specify the width of the bus in bits. The maximum possible bus width depends on the I/O standard and the number of interfaces specified above.
Number of this interface	This read-only field is calculated based on the selected Interface Type, Clock Frequency for this Interface, and Bus Width for this Interface. All of the interfaces will be placed on the same side of the FPGA.
Interface Bandwidth	Shows the resulting bandwidth in megabits/second. Bandwidth is the bus width multiplied by the clock frequency times 2. This field is read-only.
Clock to Data Relationship at the Pins	Choose the clock-to-data relationship.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 164: DDR_GENERIC Dialog Box for MachXO2, MachXO3L, and Platform Manager 2—Configuration Tab

Feature	Description
Interface selection based on pre-configuration	After filling out the Pre-Configuration tab, clear this option to further customize the module. Select this option to change the settings to match the Pre-Configuration tab.
Interface Type	Specify whether the interface is for transmit or receive.
Enable Tri-state Control	Available only with the Transmit interface type.
Enable MIPI High Speed Mode Only	Available only with the MIPI interface types.
I/O Standard	Choose an I/O standard. Not available with MIPI interface types.
Clock Frequency	Specify the frequency of the clock in megahertz.
Gearing Ratio	Choose the gearing ratio. 2x is required for frequencies greater than 200 MHz. For a gearing ratio of 2x, the output width is four times the input width.

Table 164: DDR_GENERIC Dialog Box for MachXO2, MachXO3L, and Platform Manager 2—Configuration Tab (Continued)

Feature	Description
Alignment	Choose the clock-to-data relationship.
Bus Width	Specify the width of the bus in bits. The maximum possible bus width depends on the I/O standard and the number of interfaces specified above.

DDR_MEM Options (ECP5)

The module dialog box has three tabs:

- Configuration, below
- Clock/Address/Command, see Table 166 on page 1429
- Advanced Settings, for DDR2 only, Table 167 on page 1429

Table 165: DDR_MEM Dialog Box for ECP5—Configuration Tab

Feature	Description
Interface	Specify the mode of the DDR memory interface. This selection affects the I/O Buffer configuration, the frequency of DQS, and signaling of DQS.
I/O Buffer Configuration	Specify the I/O buffer type for the DDR memory interface.
DDR Memory Frequency	Select the frequency of operation of the DDR memory interface. The available values depend on the Interface type.
System Clock Frequency	Shows the required system clock frequency.
DQS Buffer Configuration for DDR2	If the interface is DDR2, specify whether the buffer is single-ended or differential.
Number of DQ per DQS	Select the number of DQ per DQS group.
Data Width	Specify the combined width of the DQS groups.
Total number of DQS Groups	Choose the number DQS groups based on the data width and the number of DQ.
Data Mask	Select this option to add a data mask port for each DQS group.
Clock/Address/Command	Select this option to fill in the Clock/Address/Command tab to further customize the module.

Table 165: DDR_MEM Dialog Box for ECP5—Configuration Tab (Continued)

Feature	Description
Enable Dynamic Margin Control on Clock Delay	Select to enable dynamic margin control on clock delay.
Generate PLL with this module	Select to include a PLL (Phase Lock Loop). Available only with the Transmit interface type. Specify the **PLL Input Clock Frequency** in megahertz and click **Calculate**. Actual Clock Frequency shows the result.
PLL Reference Clock From I/O Pin	Select if the PLL reference clock will come from an I/O pin. Then specify the CLKI Input Buffer Type (below). Only available when Generate PLL with this Module (above) is selected.
CLKI Input Buffer Type	Choose the buffer for CLKI, the input reference clock for the PLL.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 166: DDR_MEM Dialog Box for ECP5—Clock/Address/Command Tab

Feature	Description
Number of Clocks	Choose the number of clocks.
Address Width	Choose the width of the address in bits.
Bank Address Width	Choose the width of the bank address in bits.
Number of Chip Selects	Choose the number of bits in the chip select port.
Number of ODT	Choose the number of bits in the input and output on-die termination (ODT) ports.
Number of Clock Enables	Choose the number of bits in the input and output clock enable ports.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 167: DDR_MEM Dialog Box for ECP5—Advanced Settings Tab

Feature	Description
DQS Read Delay Adjustment DQS Write Delay Adjustment	Select whether the delay is PLUS or MINUS. Then select a delay value.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.

Table 167: DDR_MEM Dialog Box for ECP5—Advanced Settings Tab (Continued)

DDR_MEM Options (LatticeEC, LatticeECP, LatticeXP)

Table 168: DDR_MEM Dialog Box for LatticeEC, LatticeECP, and LatticeXP

Feature	Description
I/O Buffer Configuration	Specify the I/O buffer type for the DDR Memory interface. Values: SSTL25_I, SSTL25_II
DDR Data Width	Specify the width of the DDR bus. Values: 8, 16, 32, 64
Number of DQS	Specifies the number of DQS signals. There will be one DQS for every byte (8 bits) of data. Values: 1, 2, 4, 8
Frequency of DQS (MHz)	Select the frequency of operation of the DDR memory interface. Values: 100, 133, 166, 200
Lock/Jitter Sensitivity	Specify the Lock/Jitter Sensitivity for the Master DLL. Values: HIGH, LOW
LSR for DDR Input Registers	Specify if the input registers are of Reset or Set type. Values: SET, RESET
Create Clock Enable for DDR Data Input Registers	Specify if the clock enable port should be generated for the input DDR registers.
Tristate Enable for DDR Data Output Registers	Specify if the tristate enable signal of the output DDR (part of the bidirectional bus) data bus is DDR. Otherwise, this control signal is a single bit.
DDR Tristate Enable for DQS	Specify if the tristate enable signal of the DQS buffer is a DDR signal or a single bit.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.

DDR_MEM Options (LatticeECP2/M, LatticeXP2)

Table 169: DDR_MEM Dialog Box for LatticeECP2/M, and LatticeXP2

Feature	Description
Mode	Specify the mode of the DDR Memory interface. Specify if it is a DDR or DDR2 interface. This selection affects the I/O Buffer configuration, the frequency of DQS, and signaling of DQS.
I/O Buffer Configuration	Specify the I/O buffer type for the DDR Memory interface. Values: SSTL25_I, SSTL25_II (for DDR) Values: SSTL18_I, SSTL18_II (for DDR2)
DDR Data Width	Specify the width of the DDR bus. Values: 8, 16, 18, 32, 64
Number of DQS	Specifies the number of DQS signals. There will be one DQS for every byte (8 bits) of data. Values: 1, 2, 4, 8
Frequency of DQS (MHz)	Select the frequency of operation of the DDR memory interface. Values: 100, 133, 166, 200 (for DDR) Values: 166, 200, 266 (for DDR2)
Lock/Jitter Sensitivity	Specify the Lock/Jitter Sensitivity for the Master DLL. Values: HIGH, LOW
LSR for DDR Input Registers	Specify if the input registers are of Reset or Set type. Values: SET, RESET
DDR Tristate Enable for DDR Data Output Registers	Specify if the tristate enable signal of the output DDR (part of the bidirectional bus) data bus is DDR. Otherwise, this control signal is a single bit.
DDR Tristate Enable for DQS	Specify if the tristate enable signal of the DQS buffer is a DDR signal or a single bit.

Table 169: DDR_MEM Dialog Box for LatticeECP2/M, and LatticeXP2 (Continued)

Feature	Description
DQS Buffer Configuration for DDR2	This option allows you to select either Single-ended or Differential. If Differential is selected, SSTL18D_II will be applied. By default, this option is grayed-out. If DDR2 is selected for the mode, then the I/O Buffer Configuration drop down will show SSTL18_I and SSTL18_II. If the selected I/O buffer configuration is SSTL18_II then this option will be active.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

DDR_MEM Options (LatticeECP3, MachXO2, Platform Manager 2)

The module dialog box has two tabs:

- Configuration, below
- Clock/Address/Command, see Table 171 on page 1433

Table 170: DDR_MEM Dialog Box for LatticeECP3, MachXO2, and Platform Manager 2—Configuration Tab

Feature	Description
Interface	Specify the mode of the DDR Memory interface. This selection affects the I/O Buffer configuration, the frequency of DQS, and signaling of DQS.
I/O Buffer Configuration	Specify the I/O buffer type for the DDR Memory interface.
DDR Memory Frequency	Select the frequency of operation of the DDR memory interface.
Number of DQS	Specify the number of DQS signals. There should be one DQS for every byte (8 bits) of data.
DQS Group	Choose the number of bits in the group to use.
DQS Buffer Configuration	If the interface is DDR2, specify whether the buffer is single-ended or differential.

Table 170: DDR_MEM Dialog Box for LatticeECP3, MachXO2, and Platform Manager 2—Configuration Tab (Continued)

Feature	Description
Data Width	Shows the combined width of the DQS groups. This field is read-only. (MachXO2 and Platform Manager 2 only)
Clock/Address/Command	Select this option to fill in the Clock/Address/Command tab to further customize the module.
Data Mask	Select this option to add a data mask port for each DQS group.
Lock/Jitter Sensitivity	Specify the lock/jitter sensitivity for the Master DLL. (MachXO2 and Platform Manager 2 only)
ISI Calibration	When available, choose the ISI calibration type. (LatticeECP3 only)
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 171: DDR_MEM Dialog Box for LatticeECP3, MachXO2, and Platform Manager 2—Clock/Address/Command Tab

Feature	Description
Number of Clocks	Choose the number of clocks.
Number of Clock Enables	Choose the number of bits in the input and output clock enable ports.
Address Width	Choose the width of the address in bits.
Bank Address Width	Choose the width of the bank address in bits.
Number of ODT	Choose the number of bits in the input and output on-die termination (ODT) ports.
Number of Chip Selects	Choose the number of bits in the chip select port.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.

Digital CDR

The clock and data recovery logic takes a clock at approximately the same frequency as the incoming data, then produces this same data re-timed with the appropriate clock phase.

Table 172: Digital CDR Dialog Box

Feature	Description
Number of channel groups (3 channels per group)	The 18 channels supported by the Digital CDR are broken up into 6 groups (A, B, C, D, E, F) of 3 channels. By default these three channels share a common output clock (contact the factory for independent operation). This option selects how many 3-channel groups will be used.
Bus width of the channel output	This option selects the size of the data output bus. The output clock will be divided down to match the bus width.
REFCLK Frequency	The frequency of the clock connected to the REFCLK port of the CDR.
CDR Lock Mode	Sync mode is used for systems where there is 0ppm offset between the REFCLK and incoming data rate. Async mode is used for systems where there is an offset between the REFCLK rate and incoming data rate.
REFCLK source routing	This option selects either edge or primary clock routing for the connection to the CDR REFCLK.
GSR Enabled	Enables or disables the GSR from resetting the Digital CDR.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Distributed_DPRAM

A dual-port RAM using LUT logic. The module provides a variety of RAM organizations and is implemented as PFU-based, distributed memory. Ports, properties, and functionality are described in detail in the technical notes listed in the “See Also” section below.

Table 173: Distributed_DPRAM Dialog Box

Feature	Description
Address Depth	The Address Depth entry field is used to specify the address size in terms of the number of words in the ROM. The maximum address depth will vary depending on the device used.
Data Width	The Data Width entry field is used to specify the width of the data bus in bits. The data width will vary depending on the device used.
Enable Output Register	When selected the data outputs of the RAM are registered (separate controls for port A and B). Registering the output ports allows the module to run at a faster clock speed (higher f_{MAX}), but uses more area. Unchecking this box will cause the module to run slower, but will use less area in the device. The Enable Output Register option will add additional ports like RdClockEn, RdClock and Reset for the Output registers.
Memory file	(ECP5, LatticeECP3, LatticeSC/M, LatticeXP2, MachXO2, MachXO3L, and Platform Manager 2 only) Allows you to select a memory initialization (.mem) file for the module. A .mem file is not required. See “Creating a Memory Initialization File with Memory Generator” on page 202.
Memory File Format	(ECP5, LatticeECP3, LatticeSC/M, LatticeXP2, MachXO2, MachXO3L, and Platform Manager 2 only) Allows you to choose Binary, Hex, or Addressed Hex format.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

VHDL pmi_distributed_dpram Definition

```
component pmi_distributed_dpram is
     generic (
       pmi_addr_depth : integer := 32;
       pmi_addr_width : integer := 5;
       pmi_data_width : integer := 8;
       pmi_regmode : string := "reg";
       pmi_init_file : string := "none";
       pmi_init_file_format : string := "binary";
       pmi_family : string := "EC";
       module_type : string := "pmi_distributed_dpram"
    );
    port (
     WrAddress : in std_logic_vector((pmi_addr_width-1) downto
0);
     Data : in std_logic_vector((pmi_data_width-1) downto 0);
     WrClock: in std_logic;
     WE: in std_logic;
     WrClockEn: in std_logic;
     RdAddress : in std_logic_vector((pmi_addr_width-1) downto
0);
     RdClock: in std_logic;
     RdClockEn: in std_logic;
     Reset: in std_logic;
     Q : out std_logic_vector((pmi_data_width-1) downto 0)
   );
  end component pmi_distributed_dpram;
```

Parameter Names and Values

The following table contains the pmi_distributed_dpram module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_addr_depth	2 to 8192	32	
pmi_addr_width	1 to 13	5	
pmi_data_width	1 to 256	8	
pmi_regmode	“reg” | “noreg”	“reg”	
pmi_init_file	<string>	“none”	The pmi_init_file and pmi_initi_file_format parameters are only supported for LatticeECP3, LatticeSC/M, and LatticeXP2 device families in distributed mode.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_init_file_format	“binary”	“hex”	“binary”	The pmi_init_file and pmi_initi_file_format parameters are only supported for LatticeECP3, LatticeSC/M, and LatticeXP2 device families in distributed mode.
pmi_family	“EC”	“ECP”	“ECP2”	“ECP2M”	“ECP3”	“ECP5U”	“ECP5UM”	“SC”	“SCM”	“XP”	“XP2”	“XO”	“XO2”	“XO3L”	“LPTM”	“EC”

Distributed_ROM

A read-only memory using LUT logic. The ROM module provides a variety of ROM organizations and is implemented as PFU-based, distributed memory. Ports, properties, and functionality are described in detail in the technical notes in the “See Also” section below.

Table 174: Distributed_ROM Dialog Box

Feature	Description
Address Depth	The Address Depth entry field is used to specify the address size in terms of the number of words in the ROM. The maximum address depth will vary depending on the device used.
Data Width	The Data Width entry field is used to specify the width of the data bus in bits. The maximum data width will vary depending on the device used.
Enable Output Register	When selected, the data outputs of the ROM are registered. Registering the output ports allows the module to run at a faster clock speed (higher f_{MAX}), but uses more area. Unchecking this box will cause the module to run slower, but will use less area in the device. Enable Output Register option will add an additional port like OutClockEn and Reset for the Output registers. The default is checked.
Memory file	Allows you to select a memory initialization (.mem) file for the module. See “Creating a Memory Initialization File with Memory Generator” on page 202.
Memory File Format	Allows you to choose the format of the memory file. Supported formats are Binary, Hex, or Addressed Hex.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.

Table 174: Distributed_ROM Dialog Box (Continued)

Feature	Description
Generate	Builds the module as specified.

pmi_distributed_rom

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_distributed_rom.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	Address	Bus	(pmi_addr_width - 1):0
I	OutClock	Bit	N/A
I	OutClockEn	Bit	N/A
I	Reset	Bit	N/A
O	Q	Bus	(pmi_data_width - 1):0

Verilog pmi_distributed_rom Definition

```
module pmi_distributed_rom
  #(parameter pmi_addr_depth = 32,
    parameter pmi_addr_width = 5,
    parameter pmi_data_width = 8,
```

```
    parameter pmi_regmode = "reg",
    parameter pmi_init_file = "none",
    parameter pmi_init_file_format = "binary",
    parameter pmi_family = "EC",
    parameter module_type = "pmi_distributed_rom")
    (
     input [(pmi_addr_width-1):0] Address,
     input OutClock,
     input OutClockEn,
     input Reset,
     output [(pmi_data_width-1):0] Q)/* synthesis syn_black_box
*/;

endmodule // pmi_distributed_rom
```

VHDL pmi_distributed_rom Definition

```
component pmi_distributed_rom is
     generic (
       pmi_addr_depth : integer := 32;
       pmi_addr_width : integer := 5;
       pmi_data_width : integer := 8;
       pmi_regmode : string := "reg";
       pmi_init_file : string := "none";
       pmi_init_file_format : string := "binary";
       pmi_family : string := "EC";
       module_type : string := "pmi_distributed_rom"
    );
    port (
     Address : in std_logic_vector((pmi_addr_width-1) downto
0);
     OutClock: in std_logic;
     OutClockEn: in std_logic;
     Reset: in std_logic;
     Q : out std_logic_vector((pmi_data_width-1) downto 0)
   );
  end component pmi_distributed_rom;
```

Parameter Names and Values

The following table contains the pmi_distributed_rom module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value
pmi_addr_depth	2 to 8192	32
pmi_addr_width	1 to 13	5
pmi_data_width	1 to 128	8
pmi_regmode	“reg” | “noreg”	“reg”
pmi_init_file	<string>	“none”
pmi_init_file_format	“binary” | “hex”	“binary”
pmi_family	“EC” | “ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” | “ECP5UM” | “SC” | “SCM” | “XP” | “XP2” | “XO” | “XO2” | “XO3L” | “LPTM”	“EC”

Distributed_SPRAM

A single-port RAM using LUT logic. The RAM module provides a variety of RAM organizations and is implemented as PFU-based, distributed memory. Ports, properties, and functionality are described in detail in the technical notes in the "See Also" section below.

Table 175: Distributed_SPRAM Dialog Box

Feature	Description
Address Depth	The Address Depth entry field is used to specify the address size in terms of the number of words in the ROM. The maximum address depth will vary depending on the device used.
Data Width	The Data Width entry field is used to specify the width of the data bus in bits. The maximum data width will vary depending on the device used.
Enable Output Register	When selected, the data outputs of the RAM are registered. Registering the output ports allows the module to run at a faster clock speed (higher f_{MAX}), but uses more area. Unchecking this box will cause the module to run slower, but will use less area in the device. The Enable Output Register option will add an additional Reset port for the Output registers.
Memory file	(ECP5, LatticeECP3, LatticeSC/M, LatticeXP2, MachXO2, MachXO3L, and Platform Manager 2 only) Allows you to select a memory initialization (.mem) file for the module. A .mem file is not required. See "Creating a Memory Initialization File with Memory Generator" on page 202.
Memory File Format	(ECP5, LatticeECP3, LatticeSC/M, LatticeXP2, MachXO2, MachXO3L, and Platform Manager 2 only) Allows you to choose the format of the memory file. Supported formats are Binary, Hex, or Addressed Hex.
Bus Ordering Style	Specifies whether the numbers should begin at the high end ("Big Endian"- BusA[7 to 0]) or at the low end ("Little Endian"-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

pmi_distributed_spram

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_distributed_spram.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	Address	Bus	(pmi_addr_width - 1):0
I	Data	Bus	(pmi_data_width - 1):0
I	Clock	Bit	N/A
I	ClockEn	Bit	N/A
I	WE	Bit	N/A
I	Reset	Bit	N/A
O	Q	Bus	(pmi_data_width - 1):0

Verilog pmi_distributed_spram Definition

```
module pmi_distributed_spram
  #(parameter pmi_addr_depth = 32,
    parameter pmi_addr_width = 5,
    parameter pmi_data_width = 8,
    parameter pmi_regmode = "reg",
    parameter pmi_init_file = "none",
    parameter pmi_init_file_format = "binary",
    parameter pmi_family = "EC",
    parameter module_type = "pmi_distributed_spram")

    (
     input [(pmi_addr_width-1):0] Address,
     input [(pmi_data_width-1):0] Data,
     input Clock,
     input ClockEn,
     input WE,
     input Reset,
```

```
    output [(pmi_data_width-1):0] Q)/* synthesis syn_black_box
*/;

endmodule // pmi_distributed_spram
```

VHDL pmi_distributed_spram Definition

```
component pmi_distributed_spram is
    generic (
      pmi_addr_depth : integer := 32;
      pmi_addr_width : integer := 5;
      pmi_data_width : integer := 8;
      pmi_regmode : string := "reg";
      pmi_init_file : string := "none";
      pmi_init_file_format : string := "binary";
      pmi_family : string := "EC";
      module_type : string := "pmi_distributed_spram"
    );
    port (
     Address : in std_logic_vector((pmi_addr_width-1) downto
0);
     Data : in std_logic_vector((pmi_data_width-1) downto 0);
     Clock: in std_logic;
     ClockEn: in std_logic;
     WE: in std_logic;
     Reset: in std_logic;
     Q : out std_logic_vector((pmi_data_width-1) downto 0)
   );
  end component pmi_distributed_spram;
```

Parameter Names and Values

The following table contains the pmi_distributed_spram module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_addr_depth	2 to 8192	32	
pmi_addr_width	1 to 13	5	
pmi_data_width	1 to 128	8	
pmi_regmode	“reg” | “noreg”	“reg”	
pmi_init_file	<string>	“none”	The pmi_init_file and pmi_initi_file_format parameters are only supported for LatticeECP3, LatticeSC/M, and LatticeXP2 device families in distributed mode.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_init_file_format	“binary”	“hex”	“binary”	The pmi_init_file and pmi_initi_file_format parameters are only supported for LatticeECP3, LatticeSC/M, and LatticeXP2 device families in distributed mode.
pmi_family	“EC”	“ECP”	“ECP2”	“ECP2M”	“ECP3”	“ECP5U”	“ECP5UM”	“SC”	“SCM”	“XP”	“XP2”	“XO”	“XO2”	”XO3L”	“LPTM”	“EC”

DLL

DLLs (delayed lock loop) are used in a variety of applications such as clock injection removal, clock injection match, and time reference delay, which is used to adjust the DQS strobe delay setting for DDR memory applications.

Table 176: DLL Dialog Box

Feature	Description
Specify the DLL usage mode	By selecting the mode of operation, the generated netlist includes the appropriate library element so that the predefined settings are fixed.
CLKI Frequency	Specify the input frequency of the DLL in MHz. This is passed as an attribute to the netlist and is also used to determine the configuration of the DLL in Clock Injection Delay Removal mode (above).
CLKOS Divider	The frequency of CLKOS is CLKI divided by this value. This also affects the CLKOS phase shift (below) when the DLL usage mode (above) is “Time Reference Delay.”

Table 176: DLL Dialog Box (Continued)

Feature	Description
CLKOS Phase Shift (degree)	Choose the phase shift of the CLKOS output relative to CLKI. Available only when the DLL usage mode (above) is “Time Reference Delay.” **Note:** The amount of the phase shift is based on the period of CLKI, not CLKOS. The delay between CLKI and CLKOS stays the same regardless of changes in the CLKOS Divider, which changes the frequency and period of CLKOS. For example, a Phase Shift of 90 degrees is always 1/4 of the CLKI period regardless of the Divider value and the resulting CLKOS frequency: CLKFB	Specify the feedback input. If you choose User Clock, specify the frequency of the feedback clock in terms of CLKI. Not available when the DLL usage mode (above) is “Time Reference Delay.”
Provide SMI ports on DLL module	Select to generate SMI ports. The SMI port can be used to modify the settings of the DLL after configuration of the FPGA. (LatticeSC/M only)
Provide RSTN port	Select to add a reset port. A reset can shut off the output clock and have undesirable effects on the system.
Provide DIFF port	Select to add a DIFF signal that indicates when DCNTL is different from the internal setting and that an update is needed. Only available with LatticeECP3 when the DLL usage mode (above) is “Time Reference Delay.”
Provide GRAYI/O and INCI/O ports	Select to add a gray-coded control bus for other DLLs and an INC port. If the DLL usage mode (above) is “Clock Injection Delay Removal,” these will be input ports. If the mode is “Time Reference Delay,” these will be output ports. (LatticeECP3 only)
Provide DCNTL Ports	Select to add the DCNTL output ports. These ports can be connected to a Delay block (generated as part of a DDR or SDR module, or instantiated by you in the netlist) to match the delays in the DLL. Only available with LatticeECP3 when the DLL usage mode (above) is “Time Reference Delay,” or with LatticeSC/M when the DLL usage mode (above) is “Clock Injection Delay Removal.”
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

DQS

Data strobe used with DDR.

Table 177: DQS Dialog Box

Feature	Description
Number of DQS	Specifies the number of (bidirectional) DQS buffers. Values: 1, 2, 4, 8
Frequency of DQS (MHz)	Specify the frequency of operation of the DLL. The DQS input will be delayed (by T/4) based on the clock frequency. Values: 100, 133, 166, 200
DQS Postamble Solution	Specify if the postamble solution to shut off the DQS clock is to be generated. Values: Yes, No
DDR Tristate Enable for DQS Output	Specify if the tristate enable for the DQS output uses DDR registers. Without this option, the DQS tristate enable is generated without the output DDR registers.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Dynamic Bank Controller

Dynamic Bank Controller (INRD and LVDSO) allows you to turn off banks of referenced and differential I/O buffers (used to implement standards such as HSTL, SSTL, and LVDS) These I/Os consume more power than other I/O standards such as LVCMOS. Dynamic Bank Controller (SLEWRATE) allows you to turn off reference current for slewrate slow mode when they are not needed.

RTL or functional simulation is not supported. Only post-place-and-route simulation is supported.

Table 178: Dynamic Bank Controller Dialog Box

Feature	Description
Enable Dynamic InRD Control	Select the referenced and differential input banks to control. ECP5 only supports banks 2, 3, 6, and 7. MachXO2 supports banks 0 to 5 with MachXO2-2000 or larger. MachXO3L supports banks 0 to 5 with MachXO3L-1300 or larger. MachXO3D supports banks 0 to 5. Platform Manager 2 supports banks 0 to 3.
Enable Slew Rate Control (MachXO3D Only)	Select the output banks to control slew rate. MachXO3D supports banks 0 to 5.
Enable Dynamic LVDS Control	Select to control the LVDS output buffers for the bank. MachXO2 only supports bank 0 and only with MachXO2-1200 or larger. MachXO3L only supports bank 0. MachXO3D only supports bank 0. Platform Manager 2 only supports bank 0 and only with LPTM21.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

EFB

MachXO2, MachXO3L, MachXO3D, and Platform Manager 2 devices provide embedded hardened functions, such as SPI, I2C, and Timer/Counter. These embedded function blocks (EFB) interface with the user logic through a WISHBONE bus.

The module dialog box has several tabs. Start with the EFB Enables tab to select the function blocks that you want to include in the module. Regardless

of which blocks you select, always set the **Wishbone Clock Frequency** at the bottom of the tab. Then go to the other tabs to set options for the selected blocks.

- EFB Enables, below
- I2C, see Table 180 on page 1449
- SPI, see Table 181 on page 1450
- Timer/Counter, see Table 182 on page 1451
- UFM, see Table 183 on page 1451
- Tamper, see Table 190 on page 1455

Table 179: EFB Dialog Box—EFB Enables Tab

Feature	Description
I2C	The EFB contains three I2C endpoints: Primary Configuration, Primary User, and Secondary User. Select an option to add the ports required to access the specified endpoints. Then set options in the I2C tab (see Table 180 on page 1449).
SPI	Select to add an SPI block to the module. Then set options in the SPI tab (see Table 181 on page 1450).
Timer/Counter	Select to add a timer/counter block to the module. Then select a Timer/Counter Use (see next item) and set options in the Timer/Counter tab (see Table 182 on page 1451).
Timer/Counter Use	Access to the Timer/Counter block through the WISHBONE interface is optional. Using the WISHBONE interface allows you set registers to control the Timer/Counter. To use the WISHBONE interface, select **Dynamic register changes via WISHBONE**. Otherwise, select **Static settings only (no WISHBONE access)**. Then set options in the Timer/Counter tab (see Table 182 on page 1451).
PLL (Dynamic access)	Select to add dynamic access to one or two PLLs. Not available with MachXO2-256 or -640, MachXO3L-640, or Platform Manager 2-20.
Number of PLL's of dynamic access	If you selected PLL (above), select how many PLLs you want to access. The EFB module in MachXO2-4000 and larger and MachXO3L 2100 and larger can access one or two PLLs. Most other devices can access only one PLL.
User Flash Memory	Select to add access to the flash memory through the WISHBONE interface. Then set options in the UFM tab (see Table 183 on page 1451). Not available with MachXO2-256 or MachXO3L.

Table 179: EFB Dialog Box—EFB Enables Tab

Feature	Description
User Flash Memory (MachXO3D Only)	Internal Boot: ▶ Single Boot - Allows you to reserve to boot from Image-0:CFG0 and optionally, include UFM0. ▶ Dual Boot - Allows you to reserve to boot from Image-0:CFG0 and optionally, include UFM0. Also, allows you to reserve to boot from Image-1:CFG1 and optionally, include UFM1. External Boot - Boot from external flash memory. Total available UFM: 33590 pages(537440 bytes) and UFM used in EFB: 6 Pages (96 bytes). ▶ First number is total available UFM. ▶ Second number is the total UFM used as specified in the selected UFM tab(s).
WISHBONE	Select to have a WISHBONE interface without any of the other functions.
WISHBONE Clock Frequency	Specify the frequency of the clock that the module will run on.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 180: EFB Dialog Box—I2C Tab

Feature	Description
General Call Enable	Enables the generic call response in slave mode.
Wakeup Enable	Enables the I2C block to signal the on-chip power manager to wake up the part from standby/sleep mode when the slave address is called. If not selected, the I2C block is powered down during standby/sleep mode.
I2C Bus Performance	Select a frequency for the SCL clock.
Clock Prescale Value	Calculated from the WISHBONE Clock Frequency on the EFB Enables tab and the I2C Bus Performance. This field is read-only.
I2C Addressing	Choose to have a 7- or a 10-bit slave address.
Slave Address	Enter the slave address. The last two bits are fixed. The address of the primary I2C block always ends in 01 (xxxxx01). The address of the secondary I2C block always ends in 10 (xxxxx10).
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.

Table 180: EFB Dialog Box—I2C Tab

Feature	Description
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 181: EFB Dialog Box—SPI Tab

Feature	Description
SPI Mode	For slave mode only, select **Slave**. To dynamically control the mode, select **Slave & Master**.
Master Clock Rate	Enter the desired rate for the clock in MHz. The Actual box shows the actual rate based on the desired value and the WISHBONE clock frequency entered in the EFB Enables tab. Available only for master mode.
LSB First	Select to have the least-significant bit (LSB) first in the data.
Inverted Clock	Select to invert the clock polarity.
Phase Adjust	Select to allow changing the clock/data phase relationship.
Slave Handshake Mode	Select to include the Slave Handshake Mode, which can be useful when the SPI slave is running at high speed. In this mode, the SPI block signals to the external master when data can be sent.
Master Chip Selects	Select the number of chip select outputs desired. Available only for master mode.
Tx Ready	Select to add an interrupt signal that indicates when the SPI transmit data register is empty.
Rx Ready	Select to add an interrupt signal that indicates when the SPI receive data register contains valid data.
Tx Overrun	Select to add an interrupt signal that indicates when the slave SPI select signal is active.
Rx Overrun	Select to add an interrupt signal that indicates when receiving new data before reading the previous data.
Enable Port	Adds an interrupt output signal from the SPI block.
Wakeup Enable	Enables the SPI block to signal the on-chip power manager to wake up the part from low-power modes.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 182: EFB Dialog Box—Timer/Counter Tab

Feature	Description
Timer/Counter Mode	Select the mode: CTCM: Clear timer on compare match WATCHDOG FASTPWM: Fast PWM PFCPWM: Phase and frequency correct PWM
Output Function	Select the type of output.
Clock Edge Selection	Select the clock edge to use.
Use On-Chip Oscillator	Select to use the on-chip oscillator.
Prescale Divider Value	Select a value for the prescale divider.
Enable Interrupt Register	Select conditions that will trigger the interrupt signal. Overflow, Output Compare Match, and Input Capture are only available if “Dynamic register changes via WISHBONE” was selected in the EFB Enables tab. Standalone Overflow is only available if “Static settings only (no WISHBONE access)” was selected in the EFB Enables tab.
Set Top Counter Value	Select to set the maximum counter value.
Timer/Counter Top	Type in a maximum counter value.
Output Compare Value	Enter a value for the output comparison. Not available with the CTCM Timer/Counter mode.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.

FFT_Butterfly

Butterfly module for the popular Cooley-Tukey Fast Fourier Transform (FFT), which recursively breaks down the discrete Fourier transform (DTF) into smaller DTFs. The ultimate computation unit is the FFT_Butterfly module. This module offers radix-2 or radix-4 and decimation in time or decimation in frequency algorithms.

Table 192: FFT_Butterfly Dialog Box

Feature	Description
FFT Butterfly Mode	Specify the algorithm. Radix-2 and radix-4 are supported. For each, the implementation can be decimation in time (DIT) or decimation in frequency (DIF).
Use DSP Block	Select Use DSP block to implement the complex multiplier. This greatly increases performance and reduces the number of LUTs used. When this option is not selected, the multiplier is implemented in SLICE logic. This option is only available for architectures that have DSP blocks.
Treat Inputs as Complex Numbers	Specifies that the inputs are complex numbers and require the full complex multiplier to compute the results. If selected, both real and imaginary ports are used and it requires three multipliers and some adders to implement this function. If this option is not selected, both real and imaginary ports will still be generated; however, the imaginary ports will not be used. Two multipliers will be sufficient to implement this function.
Input Data Bit Width	Specify the width of the input data.
Twiddle Factor Bit Width	Specify the width of the sin-cos twiddle factors.

Table 192: FFT_Butterfly Dialog Box (Continued)

Feature	Description
Output Bit Width	Shows the bit width of each of the result buses. The output width is the sum of the input data and twiddle factor widths.
Specify the Number of Pipeline Stages	Specify the number of register stages inserted. More stages improves achievable frequency of operation, but the latency for the output increases.
Enable Input Registers	Specify if input registers are required.
Enable Output Registers	Specify if output registers are required.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

FIFO

A FIFO using EBR (Embedded Block RAM). The FIFO module provides a variety of FIFO memory organizations. This FIFO has only one clock. Binary counters are used in the generated netlist. Ports, properties, and functionality are described in detail in the technical notes listed in the “See Also” section below.

Table 193: FIFO Dialog Box

Feature	Description
FIFO Implementation	**EBR Based** (or **Only**) - Contains Embedded Block RAM implementation. **LUT Based** (or **Only**) – Contains LUTs and logic implementation. The LUT implementation has some limitations: ▶ The maximum address depth is 8192. ▶ The Enable ECC option (below) is not available.
Address_depth	Specifies the depth of the FIFO.
Data_width	Specifies the data width of the FIFO.
Enable Output Register	Specify that registers are used for the output data. There is no change to the flag logic.

Table 193: FIFO Dialog Box (Continued)

Feature	Description
Controlled by RdEn	Specify that the registers for the output data are controlled by the read enable. If the read enable is directly controlled by the Empty output, this will not release the final data. When this option is not selected, the output registers are always enabled. In this case, the final data will come out even when read enable is low. To enable this option, select **Enable Output Register**.
Flag Control	**Almost Empty Flag -** Specifies the threshold value for the partial empty flag. **Almost Full Flag -** Specifies the threshold value for the partial full flag. In the drop-down menus, choose the threshold options for each flag. Static thresholds are set at the time of module generation. Dynamic thresholds have additional ports to allow changing the thresholds during operation. A single threshold allows specifying one value to be used for both assert and deassert. This uses fewer resources, but has a latency for deassert. Dual thresholds allow different values to assert and deassert the flag. If you chose a static threshold, specify the Assert and, if needed, Deassert values.
Reset Mode	(ECP5 only) Asynchronous or synchronous reset supported. Reset release requires that reset assertion be asynchronous.
Data Count Options	Enables the data count output. This output is synchronized with Clock and shows the number of words in the FIFO. Since it is synchronized with the write clock, the changes due to reads will show a few cycles later.
Enable ECC (not supported for Data Width > 64)	Allows error correction of single errors and error detection of double errors. This is only available with the EBR implementation and is not supported for data widths greater than 64 bits.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

pmi_fifo

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_fifo.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	Data	Bus	(pmi_data_width - 1):0
I	Clock	Bit	N/A
I	WrEn	Bit	N/A
I	RdEn	Bit	N/A
I	Reset	Bit	N/A
O	Q	Bus	(pmi_data_width - 1):0
O	Empty	Bit	N/A
O	Full	Bit	N/A
O	AlmostEmpty	Bit	N/A
O	AlmostFull	Bit	N/A

Verilog pmi_fifo Definition

```
module pmi_fifo #(
         parameter pmi_data_width = 8,
         parameter pmi_data_depth = 256,
         parameter pmi_full_flag = 256,
         parameter pmi_empty_flag = 0,
         parameter pmi_almost_full_flag = 252,
         parameter pmi_almost_empty_flag = 4,
         parameter pmi_regmode = "reg",
         parameter pmi_family = "EC" ,
         parameter module_type = "pmi_fifo",
        parameter pmi_implementation = "LUT")

  (input  [pmi_data_width-1:0] Data,
   input Clock,
   input WrEn,
   input RdEn,
   input Reset,
   output [pmi_data_width-1:0] Q,
   output Empty,
   output Full,
   output AlmostEmpty,
   output AlmostFull)/*synthesis syn_black_box */;

endmodule // pmi_fifo
```

VHDL pmi_fifo Definition

```
component pmi_fifo is
     generic (
       pmi_data_width : integer := 8;
       pmi_data_depth : integer := 256;
       pmi_full_flag : integer := 256;
       pmi_empty_flag : integer := 0;
       pmi_almost_full_flag : integer := 252;
       pmi_almost_empty_flag : integer := 4;
       pmi_regmode : string := "reg";
       pmi_family : string := "EC" ;
       module_type : string := "pmi_fifo";
       pmi_implementation : string := "LUT"
    );
    port (
     Data : in std_logic_vector(pmi_data_width-1 downto 0);
     Clock: in std_logic;
     WrEn: in std_logic;
     RdEn: in std_logic;
     Reset: in std_logic;
     Q : out std_logic_vector(pmi_data_width-1 downto 0);
     Empty: out std_logic;
     Full: out std_logic;
     AlmostEmpty: out std_logic;
     AlmostFull: out std_logic
   );
  end component pmi_fifo;
```

Parameter Names and Values

The following table contains the pmi_fifo module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value
pmi_addr_depth	2 to 8192	256
pmi_data_width	1 to 256	8
pmi_almost_empty	1 to 512	4
pmi_almost_full	1 to 512	252
pmi_full_flag	1 to pmi_data_depth	256
pmi_empty_flag	0	0
pmi_regmode	“reg” | “noreg”	“reg”
pmi_implementation	“EBR” | “LUT”	“EBR”
pmi_family	“EC” | “ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” | “ECP5UM” | “SC” | “SCM” | “XP” | “XP2”	“EC”

FIFO_DC Options for ECP5

A dual-clock FIFO using EBR (Embedded Block RAM). The FIFO_DC module provides a variety of FIFO memory organizations. This FIFO has two clocks. The generated netlist has gray counters to handle clock domain transfer. Ports, properties, and functionality are described in detail in the “See Also” section below.

Table 194: FIFO_DC Dialog Box for ECP5

Feature	Description
FIFO Implementation	**EBR Only** – Contains only Embedded Block RAM implementation. **LUT Only** – Contains only LUT implementation. The LUT Only implementation has some limitations: ▶ The maximum address depth is 8192. ▶ The Read Address Depth is the same as for Write. ▶ ECC is not available.
Write	Specify the number of address locations and the data width for the input, Data. The Write Data Width is also the Read Data Width. With LUT Only implementations, the Write Address Depth is also the Read Address Depth.
Read	Specify the number of address locations and the data width for the output, Q. The Read Data Width is the same as the Write Data Width. With LUT Only implementations, the Read Address Depth is the same as the Write Address Depth.
Enable Output Register	Specify that registers are used for the output data. There is no change to the flag logic.
Controlled by RdEn	Specify that the registers for the output data are controlled by the read enable. Available only if Enable Output Register is selected. If the read enable is directly controlled by the Empty output, this will not release the final data. When this option is not selected, the output registers are always enabled. In this case, the final data will come out even when read enable is low.
Flag Control	**Almost Empty Flag -** Select to include an almost empty flag. **Almost Full Flag -** Select to include an almost full flag. In the drop-down menus, choose the threshold options for each flag. Static thresholds are set at the time of module generation. Dynamic thresholds have additional ports to allow changing the thresholds during operation. A single threshold allows specifying one value to be used for both assert and deassert. This uses fewer resources, but has a latency for deassert. Dual thresholds allow different values to assert and deassert the flag. If you chose a static threshold, specify the Assert and, if needed, Deassert values.
Reset Mode	Select whether the reset is asynchronous or synchronous. Reset release requires that reset assertion be asynchronous.

Table 194: FIFO_DC Dialog Box for ECP5 (Continued)

Feature	Description
Data Count Options	**Data Count (Synchronized with Write Clock) -** Enables the data count output. This output is synchronized with WrClock and shows the number of words in the FIFO. Since it is synchronized with the write clock, the changes due to reads will show a few cycles later. **Data Count (Synchronized with Read Clock) -** Enables the data count output. This output is synchronized with RdClock and shows the number of words in the FIFO. Since it is synchronized with the read clock, the changes due to writes will show a few cycles later.
Enable ECC	Allows error correction of single errors and error detection of double errors. This is not supported for data widths greater than 64 bits. (Not available with LUT Only implementation.)
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.

FIFO_DC Options for LatticeSC/M, MachXO

A dual-clock FIFO using EBR (Embedded Block RAM). The FIFO_DC module provides a variety of FIFO memory organizations. This FIFO has two clocks. The generated netlist has gray counters to handle clock domain transfer. Ports, properties, and functionality are described in detail in the “See Also” section below.

Table 196: FIFO_DC Dialog Box for LatticeSC/M and MachXO

Feature	Description
FIFO Implementation	**EBR Only** – Contains only Embedded Block RAM implementation. The EBR Only implementation has some limitations: ▶ Almost Empty and Almost Full flags are always included. ▶ Data Count Options are not available. **LUT Based** – Contains LUTs and logic implementation. The LUT Based implementation has some limitations: ▶ The maximum address depth is 8192. ▶ The Read Address Depth is the same as for Write. ▶ ECC is not available.
Write	Specify the number of address locations and the data width for the input, Data. The Write Data Width is also the Read Data Width. With LUT Based implementations, the Write Address Depth is also the Read Address Depth.
Read	Specify the number of address locations and the data width for the output, Q. The Read Data Width is the same as the Write Data Width. With LUT Based implementations, the Read Address Depth is the same as the Write Address Depth.
Enable Output Register	Specify that registers are used for the output data. There is no change to the flag logic.
Controlled by RdEn	Specify that the registers for the output data are controlled by the read enable. Available only if Enable Output Register is selected. If the read enable is directly controlled by the Empty output, this will not release the final data. When this option is not selected, the output registers are always enabled. In this case, the final data will come out even when read enable is low.
Flag Control	**Almost Empty Flag -** Select to include an almost empty flag. With EBR Only implementation, the flag is automatically included. **Almost Full Flag -** Select to include an almost full flag. With EBR Only implementation, the flag is automatically included. In the drop-down menus, choose the threshold options for each flag. Static thresholds are set at the time of module generation. Dynamic thresholds have additional ports to allow changing the thresholds during operation. A single threshold allows specifying one value to be used for both assert and deassert. This uses fewer resources, but has a latency for deassert. Dual thresholds allow different values to assert and deassert the flag. If you chose a static threshold, specify the Assert and, if needed, Deassert values.

Table 196: FIFO_DC Dialog Box for LatticeSC/M and MachXO (Continued)

Feature	Description
Reset Mode	Select whether the reset is asynchronous or synchronous.
Data Count Options	**Write Data Count (synchronized with Clock) -** Enables the data count output. This output is synchronized with WrClock and shows the number of words in the FIFO. Since it is synchronized with the write clock, the changes due to reads will show a few cycles later. (Not available with EBR Only implementation.) **Read Data Count (synchronized with Clock) -** Enables the data count output. This output is synchronized with RdClock and shows the number of words in the FIFO. Since it is synchronized with the read clock, the changes due to writes will show a few cycles later. (Not available with EBR Only implementation.)
Enable ECC	Allows error correction of single errors and error detection of double errors. This is not supported for data widths greater than 64 bits. (Not available with LUT Based implementation.)
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

FIFO_DC Options for MachXO2, MachXO3L, Platform Manager 2

A dual-clock FIFO using EBR (Embedded Block RAM). The FIFO_DC module provides a variety of FIFO memory organizations. This FIFO has two clocks. The generated netlist has gray counters to handle clock domain transfer. Ports, properties, and functionality are described in detail in the “See Also” section below.

Table 197: FIFO_DC Dialog Box for MachXO2, MachXO3L, and Platform Manager 2

Feature	Description
FIFO Implementation	**EBR Only** – (With MachXO2, requires 640 LUTs or larger.) Contains only Embedded Block RAM implementation. The EBR Only implementation has some limitations: ▶ Almost Empty and Almost Full flags are always included. ▶ Data Count Options are not available. **LUT Based** – Contains LUTs and logic implementation. The LUT Based implementation has some limitations: ▶ The maximum address depth is 8192. ▶ The Read Address Depth is the same as for Write. ▶ ECC is not available.
Write	Specify the number of address locations and the data width for the input, Data. The Write Data Width is also the Read Data Width. With LUT Based implementations, the Write Address Depth is also the Read Address Depth.
Read	Specify the number of address locations and the data width for the output, Q. The Read Data Width is the same as the Write Data Width. With LUT Based implementations, the Read Address Depth is the same as the Write Address Depth.
Enable Output Register	Specify that registers are used for the output data. There is no change to the flag logic.
Controlled by RdEn	Specify that the registers for the output data are controlled by the read enable. Available only if Enable Output Register is selected. If the read enable is directly controlled by the Empty output, this will not release the final data. When this option is not selected, the output registers are always enabled. In this case, the final data will come out even when read enable is low.
Enable Output ClockEn	Adds an output clock enable port. This is an input port. Requires that the Output Register (above) be enabled first.

Table 197: FIFO_DC Dialog Box for MachXO2, MachXO3L, and Platform Manager 2 (Continued)

Feature	Description
Flag Control	**Almost Empty Flag -** Select to include an almost empty flag. With EBR Only implementation, the flag is automatically included. **Almost Full Flag -** Select to include an almost full flag. With EBR Only implementation, the flag is automatically included. In the drop-down menus, choose the threshold options for each flag. Static thresholds are set at the time of module generation. Dynamic thresholds have additional ports to allow changing the thresholds during operation. A single threshold allows specifying one value to be used for both assert and deassert. This uses fewer resources, but has a latency for deassert. Dual thresholds allow different values to assert and deassert the flag. If you chose a static threshold, specify the Assert and, if needed, Deassert values.
Reset Mode	Select whether the reset is asynchronous or synchronous. The Output Register (above) must be enabled first. Reset release requires that reset assertion be asynchronous.
Data Count Options	**Data Count (Synchronized with Write Clock) -** Enables the data count output. This output is synchronized with WrClock and shows the number of words in the FIFO. Since it is synchronized with the write clock, the changes due to reads will show a few cycles later. (Not available with EBR Only implementation.) **Data Count (Synchronized with Read Clock) -** Enables the data count output. This output is synchronized with RdClock and shows the number of words in the FIFO. Since it is synchronized with the read clock, the changes due to writes will show a few cycles later. (Not available with EBR Only implementation.)
Enable ECC	Allows error correction of single errors and error detection of double errors. This is not supported for data widths greater than 64 bits.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

FIFO_DC Options for Platform Manager

A dual-clock FIFO using EBR (Embedded Block RAM). The FIFO_DC module provides a variety of FIFO memory organizations. This FIFO has two clocks. The generated netlist has gray counters to handle clock domain transfer. Ports, properties, and functionality are described in detail in the “See Also” section below.

Table 198: FIFO_DC Dialog Box for Platform Manager

Feature	Description
FIFO Implementation	**EBR Only** – Not available with Platform Manager. **LUT Based** – Contains LUTs and logic implementation.
Write	Specify the number of address locations and the data width for the input, Data. The Write and Read Data Widths and Address Depths are the same.
Read	Specify the number of address locations and the data width for the output, Q. The Read Data Width is the same as the Write Data Width. The Read Address Depth is the same as the Write Address Depth.
Enable Output Register	Specify that registers are used for the output data. There is no change to the flag logic.
Controlled by RdEn	Specify that the registers for the output data are controlled by the read enable. Available only if Enable Output Register is selected. If the read enable is directly controlled by the Empty output, this will not release the final data. When this option is not selected, the output registers are always enabled. In this case, the final data will come out even when read enable is low.
Flag Control	**Almost Empty Flag -** Select to include an almost empty flag. **Almost Full Flag -** Select to include an almost full flag. In the drop-down menus, choose the threshold options for each flag. Static thresholds are set at the time of module generation. Dynamic thresholds have additional ports to allow changing the thresholds during operation. A single threshold allows specifying one value to be used for both assert and deassert. This uses fewer resources, but has a latency for deassert. Dual thresholds allow different values to assert and deassert the flag. If you chose a static threshold, specify the Assert and, if needed, Deassert values.
Reset Mode	Select whether the reset is asynchronous or synchronous.
Data Count Options	**Write Data Count (synchronized with Clock) -** Enables the data count output. This output is synchronized with WrClock and shows the number of words in the FIFO. Since it is synchronized with the write clock, the changes due to reads will show a few cycles later. **Read Data Count (synchronized with Clock) -** Enables the data count output. This output is synchronized with RdClock and shows the number of words in the FIFO. Since it is synchronized with the read clock, the changes due to writes will show a few cycles later.
Enable ECC	Not available with Platform Manager.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.

pmi_fifo_dc

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_fifo_dc.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	Data	Bus	(pmi_data_width_w - 1):0
I	WrClock	Bit	N/A
I	RdClock	Bit	N/A
I	WrEn	Bit	N/A
I	RdEn	Bit	N/A
I	Reset	Bit	N/A
I	RPReset	Bit	N/A
O	Q	Bus	(pmi_data_width - 1):0
O	Empty	Bit	N/A
O	Full	Bit	N/A
O	AlmostEmpty	Bit	N/A
O	AlmostFull	Bit	N/A

Verilog pmi_fifo_dc Definition

```
module pmi_fifo_dc #(
        parameter pmi_data_width_w = 18,
        parameter pmi_data_width_r = 18,
        parameter pmi_data_depth_w = 256,
```

```
            parameter pmi_data_depth_r = 256,
            parameter pmi_full_flag = 256,
            parameter pmi_empty_flag = 0,
            parameter pmi_almost_full_flag = 252,
            parameter pmi_almost_empty_flag = 4,
            parameter pmi_regmode = "reg",
            parameter pmi_resetmode = "async",
            parameter pmi_family = "EC" ,
            parameter module_type = "pmi_fifo_dc",
           parameter pmi_implementation = "EBR"
            )

  (input  [pmi_data_width_w-1:0] Data,
   input WrClock,
   input RdClock,
   input WrEn,
   input RdEn,
   input Reset,
   input RPReset,
   output [pmi_data_width_r-1:0] Q,
   output Empty,
   output Full,
   output AlmostEmpty,
   output AlmostFull)/*synthesis syn_black_box */;

endmodule // pmi_fifo_dc
```

VHDL pmi_fifo_dc Definition

```
component pmi_fifo_dc is
     generic (
       pmi_data_width_w : integer := 18;
       pmi_data_width_r : integer := 18;
       pmi_data_depth_w : integer := 256;
       pmi_data_depth_r : integer := 256;
       pmi_full_flag : integer := 256;
       pmi_empty_flag : integer := 0;
       pmi_almost_full_flag : integer := 252;
       pmi_almost_empty_flag : integer := 4;
       pmi_regmode : string := "reg";
       pmi_resetmode : string := "async";
       pmi_family : string := "EC" ;

```

```
 );
end component pmi_fifo_dc;
```

Parameter Names and Values

The following table contains the pmi_fifo_dc module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_data_depth_w	2 to 131072	256	The device depth for the LUT based FIFO_DC range from 2 to 8192. The LatticeECP2/M, LatticeECP3, LatticeSC/M, and LatticeXP2 device family data depths range from 2 to 131072. The LatticeECP/EC and LatticeXP data depths range from 2 to 65536. The MachXO and Platform Manager data depths range from 2 to 16384. The LatticeSC/M, Platform Manager, and MachXO device families support different read/write depths and different read/write data widths.
pmi_data_depth_r	2 to 131072	256	The device depth for the LUT based FIFO_DC range from 2 to 8192. The LatticeECP2/M, LatticeECP3, LatticeSC/M, and LatticeXP2 device family data depths range from 2 to 131072. The LatticeECP/EC and LatticeXP data depths range from 2 to 65536. The MachXO and Platform Manager data depths range from 2 to 16384. The LatticeSC/M, Platform Manager, and MachXO device families support different read/write depths and different read/write data widths.
pmi_data_width_w	1 to 256	18	
pmi_data_width_r	1 to 256	18	
pmi_full_flag	1 to pmi_data_depth_r	256	
pmi_empty_flag	0	0	
pmi_almost_full_flag	1 to pmi_data_depth_w	252	
pmi_almost_empty_flag	1 to pmi_data_depth_r	4	
pmi_regmode	“reg” | “noreg”	“reg”	
pmi_resetmode	“async” | “sync”	“async”	The LatticeSC/M and MachXO device families support the pmi_resetmode parameter. The pmi_resetmode parameter applies to the EBR memory implementation.
pmi_implementation	“EBR” | “LUT”	“EBR”	
pmi_family	“EC” | “ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” | “SC” | “SCM” | “XP” | “XP2” | “XO” | “XO2” | “XO3L” |“LPTM”	“EC”

GDDR_7:1

ECP5, MachXO2, MachXO3L, and Platform Manager 2 devices have built-in 7:1 LVDS video interface support. The 7:1 LVDS is a source-synchronous interface for video applications that serialize the 7 bits of parallel data for each cycle of the low-speed clock.

Details of the 7:1 LVDS applications can be found in the MachXO2 Display Interface reference design (RD1093). For more information and to get the source code, go to the Lattice Web site at:

Products > Design Software & Intellectual Property > Intellectual Property > 7:1 LVDS Video Interface

A source code license agreement is required before accessing the source code.

Table 199: GDDR_7:1 Dialog Box

Feature	Description
Interface Type	Specify whether the DDR is for transmit or receive.
Data (or Bus) Width	Specify the width of the data bus in bits.
High-Speed Clock Frequency (pixel clock)	Specify the desired clock frequency in megahertz.
Enable Bit Alignment & Word Alignment Soft IP	Select to add bit and word alignment. Available only with ECP5 and the Receive interface type.
Reference Clock From I/O Pin	Select if the reference clock will come from an I/O pin. Then specify the Reference Clock Input Buffer Type (below). Available only with ECP5 and the Transmit interface type.
Reference Clock Input Buffer Type	Choose the buffer for the input reference clock when the clock is coming from an I/O pin. Available only with ECP5 and the Transmit interface type.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

I2C

A System Bus Interface (SBI) or FIFO Interface connects the Hard IP to the fabric. The system bus is connected to two I^2C Hard IPs. Select an option in the first tab to enable the other two tabs.

Table 200: I2C Dialog Box—Hard IP Enables Tab

Feature	Description
Enable Hard Users I2C0	Enables the I2C0 Settings and Interrupts.
System Bus Clock Frequency	Configures the divider settings of the I2C0.
Enable Hard Users I2C1	Enables the I2C1 Settings and Interrupts.
System Bus Clock Frequency	Configures the divider settings of the I2C1.
Configure	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 201: I2C Dialog Box—I2C Settings Tab

Feature	Description
General	**General Call Enable** – Enables I2C General call support. Sets a register based on the active mode (FIFO or System bus). **Include IO Buffers** – Include buffers for the I2C pins. The pins can be placed in any IO location, and will default to the IO LVCMOS standard. Includes the I2C pins I2Cx_SCL and I2Cx_SDA. **SDA Input Delay (ns)** – Add a 50 ns input delay. **SDA Output Delay (ns)** – Add a 50, 75, 125, 150, 200, 300, or 350 ns output delay.
Master Clock Rate	**Desired(KHz)** – Enter a desired clock rate in KHz to automatically determine a divider value and generate a clock close to this value based on the input clock. The frequency of this input System Bus clock is specified in the Hard IP Enables tab. The divider is rounded to the nearest integer after dividing the input System Bus clock by the value entered in this field. **Actual(KHz)** – Since the input System Bus clock cannot always be divided into the user's exact desired master clock, this field displays the actual value. This read-only value is calculated as follows: `Actual clock = rounded(System Bus clock / rounded(System Bus clock / Master clock) )` Divider values exactly halfway between two integers are rounded up (for example, a divider value of 108.5 is rounded to 109).
FIFO Mode	**Enable FIFO Mode** – Allows you change all bits of the I2C address. **CLK Stretch Enable** – Enables data setup time. **RxFIFO Almost Full** – Shows the actual almost full value (not the offset), determined by I2CFIFOTHRESHOLD[9:5] = 32 - I2C_FIFO_RxAlmostF. **TxFIFO Almost Empty** – Shows the actual almost empty value.
I2C Addressing	**Addressing mode** – Select 7-bit or 10-bit addressing. **Address** – Define the Hard I2C address. FIFO mode allows all bits to be programmed, but register mode fixes the lower two bits.
PMU Wake Options	**Address Match** – Wake up the PMU on Address Match. **RxFIFO Almost Full** – Only available for I2C0, as that is the only I2C block connected to the PMU. Enabling this option also enables the Glitchless Clock Switch.
Configure	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 202: I2C Dialog Box—I2C Interrupts Tab

Feature	Description
System Bus Interrupts	**Arbitration Lost** – This indicates when the master has lost its arbitration in master mode. **Tx/Rx Ready** – Enables Tx/Rx Ready status. **Overrun or NACK** – Enables Overrun or NACK status. **General Call IRQ Enable** – Enables the generic call response.
FIFO Interrupts	**General Call** – Enables I2C General call support. Sets a register based on the active mode (FIFO or System bus). **Receive NACK** – Allows the PMU to receive a NACK signal. **Master Read Complete** – Enables Master Read Complete. **Arbitration Lost** – This indicates when the master has lost its arbitration in master mode. **Tx FIFO Sync** – Enables Tx FIFO Sync. **Tx FIFO Underflow** – Enables Tx FIFO Underflow. **Rx FIFO Overflow** – Enables Tx FIFO Overflow.
Configure	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

LFSR

A linear feedback shift register (LFSR).

Table 203: LFSR Dialog Box

Feature	Description
LFSR Type	Specifies whether Fibonacci or Galois LFSR is implemented. Default is Fibonacci.
Gate Type	Gate type used in the feedback polynomial. The gate can be XOR or XNOR. Default is XOR.
Number of Bits	Size of LFSR that can be implemented. Number of bits ranges from 1 to 512. Default is 8.
Feedback Polynomial	Feedback polynomial that is handled by the LFSR. The polynomial limit is 64 bits. The default is 0x00.
Initial Value	Initial value of the LFSR. The initial value limit is 512 bits. Default is 0x01.
Enable Parallel Output	Enables parallel output when selected or serial output when not selected. Default is selected.

Table 203: LFSR Dialog Box (Continued)

Feature	Description
Use Reloadable Seed Values	If the check box is checked, the Din port is defined. The value on Din is a parallel value having the same number of bits as the shift register, and presents the value of the reloadable seed to the block. The reloadable seed is loaded at initialization, and whenever a new shift sequence is started. Default is not selected.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

MAC

Two-input multiply/accumulate (MAC) logic. The module provides a variety of multiply/accumulate organizations and is implemented as embedded sysDSP Blocks. Ports, properties, and functionality are described in detail in the “See Also” section below.

The options vary with the device family. See:

- “MAC Options (ECP5, LatticeECP3)” on page 1479
- “MAC Options (LatticeECP, LatticeECP2/M, LatticeXP2)” on page 1480

See Also

- TN1140, *LatticeXP2 sysDSP Usage Guide*.

MAC Options (ECP5, LatticeECP3)

Table 204: MAC Dialog Box for ECP5 and LatticeECP3

Feature	Description
Size of the DSPMAC Block	**Width** – Specify the size of the inputs. **Data Type** – Specify the data format of the inputs as signed, unsigned, or dynamic selection of the sign. **Source** – Specify if the source of the input is Parallel for generic routing, Shift for the shift outputs of an adjacent DSP block, or Dynamic for dynamic selection of the source of the input. **Accumulator** – Size of the output. This can be a number between product size + 16 and product size + 32. The product size is the sum of the multiplicand and multiplier bit sizes. The default size (product + 16) will use the accumulator in the DSP block (if possible). If the accumulator size is greater than 52, it will be implemented in PFUs. **Select Shift Out A** – Enables the shift-out port A of the DSP block. **Select Shift Out B** – Enables the shift-out port B of the DSP block. **Add/Sub Operation** – Specify addition or subtraction in the accumulator, or dynamic selection of the operation. In dynamic mode high = add, low = subtract.
Register Options	Enable or disable input, pipeline, and output registers. Then specify options for the registers. Choices for Clock, CE, and RST vary depending on which registers are enabled and whether or not a clock is selected. With some configurations, there is only one choice and it is selected automatically. **Reset Mode** – Specify whether the reset is synchronous or asynchronous. **Clock** – Selects the clock for the registers of the DSP block. If both input registers have a clock specified, the pipeline register must use the same clock as one of the input registers (InputA or InputB) or no clock (NONE). If the pipeline register has a clock specified, the output register will use that same clock (Pipeline). **CE** – Selects the clock enable pin to the registers of the DSP block. **RST** – Selects the reset pin to the registers of the DSP block. If both input registers have a clock specified, the pipeline and output resets automatically use the same sources as their clocks (InputA, InputB, or Pipeline).
Bus Ordering Style	Specify if the inputs and output are big endian (MSB:LSB) or little endian (LSB:MSB), or none.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

MAC Options (LatticeECP, LatticeECP2/M, LatticeXP2)

The module dialog box has two tabs:

- Basic, below
- Advanced, see Table 206 on page 1482

In the Basic tab, you can enable pipelining and set parameters such as the size and format of the data. In the Advanced tab, you can control each group of pipelining registers with independent clocks, clock enables, and resets.

Table 205: MAC Dialog Box for LatticeECP, LatticeECP2/M, and LatticeXP2—Basic Tab

Feature	Description
Size of the DSPMAC block	**Multiplicand A bit size** – Specify the size of the first term in the multiplication. **Multiplier B bit size** – Specify the size of the second term in the multiplication. **Accumulator bit size** – Size of the output. This can be a number between product size + 16 and product size + 32. The product size is the sum of the multiplicand and multiplier bit sizes. The default size (product + 16) will use the accumulator in the DSP block (if possible). If the accumulator size is greater than 52, it will be implemented in PFUs.
Select Block Options	**Area/Speed** – Specify if the implementation should minimize the number of DSP blocks (Area) or minimize the number of partial products to be added (Speed). In some cases, both the options will produce the same implementation. **Accumulator Implementation** – Specify if the accumulator is built using the built-in accumulator in the sysDSP block or using PFU logic. It is possible to use the built-in accumulator when using default output size and the size is less than 52. However, only two MACs fit in a DSP block. When using PFU logic, it is possible to have four MACs per DSP block, but it will use additional logic resources. **Add/Sub Operation** – Select if the Accumulator is in add, subtract, or dynamic mode. In dynamic mode high = add, low = subtract.
Data Format	**Note**: The shift options, input and out, are only available if both inputs are 18 or fewer bits. **Input A, B** – Specify if the source of input is from generic routing (Parallel) or the shift outputs of an adjacent DSP block (Shift). The Shift format enables a sample/shift register. Dynamic control is also allowed (not available in LatticeECP). **Signed/Unsigned** – Specify if the data format of the inputs is signed or unsigned. Dynamic selection using an additional input is also available (not available in LatticeECP). **Select Shift Out A, B** – Enables the shift out on port A or port B of the DSP block.

Table 205: MAC Dialog Box for LatticeECP, LatticeECP2/M, and LatticeXP2—Basic Tab (Continued)

Feature	Description
Select Pipelining	**Enable Input Registers** – Enables the input registers. This option is automatically selected if either of the inputs has a Shift or Dynamic data format specified. See above. **Enable Pipeline Registers** – Enables the pipeline registers. **Enable Output Register** – For the MAC, the output register is always enabled. This is used to implement the accumulator. **RST on all registers** – Connects a reset pin to all registers of the DSP block. **CE on all registers** – Connects a clock enable pin to all registers of the DSP block.
Bus Ordering Style	Specify if the inputs and output are big endian (MSB:LSB) or little endian (LSB:MSB), or none.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.

Table 206: MAC Dialog Box for LatticeECP, LatticeECP2/M, and LatticeXP2—Advanced Tab

Feature	Description
Select Pipelining	**Enable Input Register A, B** – Specify options for Input A or Input B registers. This option is disabled if the Enable Input Registers option on the Basic tab is not selected. **Enable Signed Register A, B –** (not available in LatticeECP) Specify options for signed registers A or B of the DSP block. **Enable Signed Pipeline Register A, B –** (not available in LatticeECP) Specify options for signed pipeline registers A or B of the DSP block. This option is disabled if the Enable Pipeline Registers option on the Basic tab is not selected. **Enable Accumulator Load Input Register** – Specify options for the accumulator load input register. This option is disabled if the Enable Input Registers option on the Basic tab is not selected. **Enable Accumulator Load Pipeline Register** – Specify options for the accumulator load pipeline register. This option is disabled if the Enable Pipeline Registers option on the Basic tab is not selected. **Enable Addsub Input Register** – Specify options for the ADDNSUB input register. This option is enabled only if Add/Sub Operation on the Basic tab is set to Dynamic mode. **Enable Addsub Pipeline Register** – Specify options for the ADDNSUB pipeline register. This option is enabled only if Add/Sub Operation on the Basic tab is set to Dynamic mode and the Enable Pipeline Registers option is selected. **Enable Pipeline Register** – Specify options for the pipeline registers of the multiplier. This option is disabled if the Enable Pipeline Registers option on the Basic tab is not selected. **Enable Output Register** – Specify options for the output accumulator registers. If the accumulator is implemented in the PFU, this option is used to implement the PFU registers.
Bus Ordering Style	Specify if the inputs and output are big endian (MSB:LSB) or little endian (LSB:MSB), or none.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

pmi_dsp_mac

The following table is intended to provide information for pmi_dsp_mac usage (pmi_dsp_mac.v).

pmi_dsp_mac Control and Data Signal Descriptions

RST Asynchronous reset of selected registers		
SignA Dynamic signal:	0 = unsigned,	1 = signed
SignB Dynamic signal:	0 = unsigned	1 = signed
ACCUMSLOAD Dynamic signal:	0 = accumulate	1 = load
ADDNSUB Dynamic signal:	0 = subtract	1 = add
SOURCEA Dynamic signal:	0 = parallel input	1 = shift input
SOURCEB Dynamic signal:	0 = parallel input	1 = shift input

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_dsp_mac.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	CLK0	Bit	N/A
I	CLK1	Bit	N/A
I	CLK2	Bit	N/A
I	CLK3	Bit	N/A
I	CE0	Bit	N/A
I	CE1	Bit	N/A
I	CE2	Bit	N/A
I	CE3	Bit	N/A
I	RST0	Bit	N/A
I	RST1	Bit	N/A
I	RST2	Bit	N/A
I	RST3	Bit	N/A
I	SignA	Bit	N/A
I	SignB	Bit	N/A
I	SourceA	Bit	N/A
I	SourceB	Bit	N/A
I	ADDNSUB	Bit	N/A
I	A	Bus	(pmi_dataa_width -1):0
I	B	Bus	(pmi_datab_width -1):0
I	LD	Bus	((pmi_dataa_width + pmi_datab_width - 1) + 16):0
I	ACCUMSLOAD	Bit	N/A
I	SRIA	Bus	17:0
I	SRIB	Bus	17:0
O	OVERFLOW	Bit	N/A
O	ACCUM	Bus	((pmi_dataa_width + pmi_datab_width - 1) + 16):0
O	SROA	Bus	17:0
O	SROB	Bus	17:0

Parameter Names and Values

The following table contains the pmi_dsp_mac module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_dataa_width	2 to 72	8	
pmi_datab_width	2 to 72	8	
pmi_gsr	“enable” | “disable”	“enable”	
pmi_additional_pipeline	0 to 1	0	
pmi_input_reg	“on” | “off”	“on”	
pmi_family	“ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” | “ECP5UM” | “XP2”	“ECP2”	

Parameter Name	Acceptable Values	Default Value	Notes
pmi_source_controla	“parallel”	“shift”	“parallel”	The pmi_source_controla and pmi_source_controlb parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.
pmi_source_controlb	“parallel”	“shift”	“parallel”	The pmi_source_controla and pmi_source_controlb parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.
pmi_reg_inputa_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”	
pmi_reg_inputa_ce	“CE0”	“CE1”	“CE2”	“CE3”	“CE0”	
pmi_reg_inputa_rst	“RST0”	“RST1”	“RST2”	“RST3”	“RST0”	
pmi_reg_inputb_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”	
pmi_reg_inputb_ce	“CE0”	“CE1”	“CE2”	“CE3”	“CE0”	
pmi_reg_inputb_rst	“RST0”	“RST1”	“RST2”	“RST3”	“RST0”	
pmi_reg_pipeline_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”	
pmi_reg_pipeline_ce	“CE0”	“CE1”	“CE2”	“CE3”	“CE0”	
pmi_reg_pipeline_rst	“RST0”	“RST1”	“RST2”	“RST3”	“RST0”	
pmi_reg_output_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”	
pmi_reg_output_ce	“CE0”	“CE1”	“CE2”	“CE3”	“CE0”	
pmi_reg_output_rst	“RST0”	“RST1”	“RST2”	“RST3”	“RST0”	
pmi_reg_signeda_0_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”	
pmi_reg_signeda_0_ce	“CE0”	“CE1”	“CE2”	“CE3”	“CE0”	
pmi_reg_signeda_0_rst	“RST0”	“RST1”	“RST2”	“RST3”	“RST0”	
pmi_reg_signeda_1_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”	
pmi_reg_signeda_1_ce	“CE0”	“CE1”	“CE2”	“CE3”	“CE0”	
pmi_reg_signeda_1_rst	“RST0”	“RST1”	“RST2”	“RST3”	“RST0”	

Parameter Name	Acceptable Values	Default Value	Notes
pmi_reg_signedb_0_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”	
pmi_reg_signedb_0_ce	“CE0”	“CE1”	“CE2”	“CE3”	“CE0”	
pmi_reg_signedb_0_rst	“RST0”	“RST1”	“RST2”	“RST3”	“RST0”	
pmi_reg_signedb_1_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”	
pmi_reg_signedb_1_ce	“CE0”	“CE1”	“CE2”	“CE3”	“CE0”	
pmi_reg_signedb_1_rst	“RST0”	“RST1”	“RST2”	“RST3”	“RST0”	
pmi_reg_accumsload_0_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”	
pmi_reg_accumsload_0_ce	“CE0”	“CE1”	“CE2”	“CE3”	“CE0”	
pmi_reg_accumsload_0_rst	“RST0”	“RST1”	“RST2”	“RST3”	“RST0”	
pmi_reg_accumsload_1_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”	
pmi_reg_accumsload_1_ce	“CE0”	“CE1”	“CE2”	“CE3”	“CE0”	
pmi_reg_accumsload_1_rst	“RST0”	“RST1”	“RST2”	“RST3”	“RST0”	
pmi_reg_addnsub_0_rst	“RST0”	“RST1”	“RST2”	“RST3”	“RST0”	
pmi_reg_addnsub_0_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”	
pmi_reg_addnsub_0_ce	“CE0”	“CE1”	“CE2”	“CE3”	“CE0”	
pmi_reg_addnsub_1_rst	“RST0”	“RST1”	“RST2”	“RST3”	“RST0”	
pmi_reg_addnsub_1_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”	
pmi_reg_addnsub_1_ce	“CE0”	“CE1”	“CE2”	“CE3”	“CE0”

MIPI_DPHY

MIPI DPHY uses a point-to-point differential interface, with modular architecture that supports multiple data lanes and a clock lane, allowing all possible configurations.

Table 207: MIPI_DPHY Dialog Box

Feature	Description
Interface Type	Select the Transmit or Receive interface type.
MIPI Interface Application	Select a DSI or CSI-2 application.
Receiver DPHY Module Type	In Hard MIPI DPHY mode, Scuba will generate the MIPI Hard DPHY Rx and Tx interface modules. In Soft MIPI DPHY mode, Scuba will generate the Soft MIPI DPHY Rx interface module.
Interface Clock Frequency	This sets the Frequency MIPI Input Clock, which determines the gearing ratio used for DPHY Soft and Hard modules.
Interface Data Rate	A read-only field displaying a calculated value based on the clock frequency.
Gearing Ratio	This value is set automatically based on the clock frequency. It can also be manually adjusted.
Bus Width	The desired bus width to generate.
DPHY PLL Input Reference Clock Frequency	Input Clock Frequency of the DPHY PLL. Based on this value and the divider settings, Scuba automatically calculates the output clock frequency. The CLKOUT frequency will be the interface Clock Frequency entered above.
Reference Clock from I/O Pin	Used to set the IO_TYPE for the reference clock input to the PLL so that the Planner can place the module.
Reference Clock Input Buffer Type	Used to set the IO_TYPE for the reference clock input to the PLL so that the Planner can place the module.
Include Start up Synchronization logic	Adds start-up synchronization logic.
Configure	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

MMAC

Multiplier Multiplier Accumulate provides a variety of multiply/accumulate organizations and is implemented as embedded sysDSP Blocks.

Table 208: MMAC Dialog Box

Feature	Description
Size of the DSPMMAC Block	**Width** – Specify the size of the inputs. **Data Type** – Specify the data format of the inputs as signed, unsigned, or dynamic selection of the sign. **Source** – Specify if the source of the input is Parallel for generic routing, Shift for the shift outputs of an adjacent DSP block, or Dynamic for dynamic selection of the source of the input. **Accumulator** – Size of the output. This is Input A0/A1 + Input B0/B1 + 16. The output uses the accumulator in the DSP block if possible. If the accumulator size is greater than 52, it is implemented in PFUs. **Select Shift Out A** – Enables the shift-out port A of the DSP block. **Select Shift Out B** – Enables the shift-out port B of the DSP block. **Operation** – Specify addition or subtraction of the two multiplication results, or dynamic selection of the operation. In dynamic mode high = add, low = subtract.
Register Options	**Reset Mode** – Specify whether the reset is synchronous or asynchronous. **Clock** – Selects the clock for the registers of the DSP block. **CE** – Selects the clock enable pin to the registers of the DSP block. **RST** – Selects the reset pin to the registers of the DSP block.
Bus Ordering Style	Specify if the inputs and output are big endian (MSB:LSB) or little endian (LSB:MSB), or none.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

MULT

Multiplier that provides a variety of multiplier organizations and is implemented as embedded sysDSP Blocks. Ports, properties, and functionality are described in detail in the technical notes listed in the “See Also” section below.

The options vary with the device family. See:

- “MULT Options (ECP5, LatticeECP3)” on page 1492
- “MULT Options (LatticeECP, LatticeECP2/M, LatticeXP2)” on page 1493

MULT Options (ECP5, LatticeECP3)

Table 209: MULT Dialog Box for ECP5 and LatticeECP3

Feature	Description
Size of the DSPMULT Block	**Width** – Specify the size of the inputs. **Data Type** – Specify the data format of the inputs as signed, unsigned, or dynamic selection of the sign. **Source** – Specify if the source of the input is Parallel for generic routing, Shift for the shift outputs of an adjacent DSP block, or Dynamic for dynamic selection of the source of the input. **Output** – Size of the output. The product size is the sum of the multiplicand and multiplier bit sizes. **Select Shift Out A** – Enables the shift-out port A of the DSP block. **Select Shift Out B** – Enables the shift-out port B of the DSP block.
Register Options	**Reset Mode** – Specify whether the reset is synchronous or asynchronous. **Clock** – Selects the clock for the registers of the DSP block. **CE** – Selects the clock enable pin to the registers of the DSP block. **RST** – Selects the reset pin to the registers of the DSP block.
Bus Ordering Style	Specify if the inputs and output are big endian (MSB:LSB) or little endian (LSB:MSB), or none.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

MULT Options (LatticeECP, LatticeECP2/M, LatticeXP2)

In the Basic tab you set most of the parameters including the size and format of the data, and enable pipelining. In the Advanced tab, you can control each group of pipelining registers with independent clocks, clock enables, and resets.

The module dialog box has two tabs:

- Basic, below
- Advanced, see Table 211 on page 1494

Table 210: MULT Dialog Box LatticeECP, LatticeECP2/M, and LatticeXP2—Basic Tab

Feature	Description
Size of the DSPMULT Block	**Multiplicand A bit size** – Specify the size of the first term in the multiplication. **Multiplier B bit size** – Specify the size of the second term in the multiplication. **Product bit size** – Size of the output. This is an automatically calculated value. The product size is the sum of the multiplicand and multiplier bit sizes.
Select Block Options	**Area/Speed** – Specify if the implementation should minimize the number of DSP blocks (Area) or minimize the number of partial products to be added (Speed). In some cases, both the options will produce the same implementation.
Data Format	**Note**: The shift options, input and out, are not available if either of the A and B inputs is larger than 18 bits. **Input A, B** – Specify if the source of input is from generic routing (Parallel) or the shift outputs of an adjacent DSP block (Shift). The Shift format enables a sample/shift register. Dynamic control is also allowed (not available in LatticeECP). **Signed/Unsigned** – Specify if the data format of the inputs is signed or unsigned. Dynamic selection of signed/unsigned using an additional input is also allowed (not available in LatticeECP). **Select Shift Out A, B** – Enables the shift-out on port A or port B of the DSP block.

Table 210: MULT Dialog Box LatticeECP, LatticeECP2/M, and LatticeXP2—Basic Tab (Continued)

Feature	Description
Select Pipelining	**Enable Input Registers** – Enables the input registers. This option is automatically selected if either of the inputs has a Shift or Dynamic data format specified. See above. **Enable Pipeline Registers** – Enables the pipeline registers. **Enable Output Register** – Enables the output register. **RST on all registers** – Connects a reset pin to all registers of the DSP block. **CE on all registers** – Connects a clock enable pin to all registers of the DSP block.
Bus Ordering Style	Specify if the inputs and output are big endian (MSB:LSB) or little endian (LSB:MSB), or none.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.

Table 211: MULT Dialog Box LatticeECP, LatticeECP2/M, and LatticeXP2—Advanced Tab

Feature	Description
Select Pipelining	**Enable Input Register A, B** – Specify options for Input A or Input B registers. This option is disabled if the Enable Input Registers option on the Basic tab is not selected. **Enable Signed Register A, B –** (not available in LatticeECP) Specify options for signed registers A or B of the DSP block. This option is disabled unless the Signed/ Unsigned A, B option on the Basic tab is set to Dynamic and the Enable Input Registers option is selected. **Enable Signed Pipeline Register A, B –** (not available in LatticeECP) Specify options for signed pipeline registers A or B of the DSP block. This option is disabled if the Enable Pipeline Registers option on the Basic tab is not selected. **Enable Pipeline Register** – Specify options for the pipeline registers of the multiplier. This option is disabled if the Enable Pipeline Registers option on the Basic tab is not selected. **Enable Output Register** – Specify options for the output accumulator registers. If the accumulator is implemented in the PFU, this option is used to implement the PFU registers. This option is disabled if the Enable Output Register option on the Basic tab is not selected.
Bus Ordering Style	Specify if the inputs and output are big endian (MSB:LSB) or little endian (LSB:MSB), or none.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.

pmi_dsp_mult

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_dsp_mult.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	CLK0	Bit	N/A
I	CLK1	Bit	N/A
I	CLK2	Bit	N/A
I	CLK3	Bit	N/A
I	CE0	Bit	N/A
I	CE1	Bit	N/A
I	CE2	Bit	N/A
I	CE3	Bit	N/A
I	RST0	Bit	N/A
I	RST1	Bit	N/A
I	RST2	Bit	N/A
I	RST3	Bit	N/A
I	SignA	Bit	N/A
I	SignB	Bit	N/A
I	SourceA	Bit	N/A
I	SourceB	Bit	N/A
I	A	Bus	(pmi_dataa_width - 1):0
I	B	Bus	(pmi_datab_width - 1):0
I	SRIA	Bus	17:0
I	SRIB	Bus	17:0
O	P	Bus	(pmi_dataa_width + pmi_datab_width - 1):0
O	SROA	Bus	17:0
O	SROB	Bus	17:0

Parameter Names and Values

The following table contains the pmi_dsp_mult module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_dataa_width	2 to 72	8	
pmi_datab_width	2 to 72	8	

Parameter Name	Acceptable Values	Default Value	Notes
pmi_gsr	“enable”	“disable”	“enable”	
pmi_additional_pipeline	0 to 1	0	
pmi_input_reg	“on”	“off”	“on”	
pmi_output_reg	“on”	“off”	“on”	
pmi_source_controla	“parallel”	“shift”	“parallel”	The pmi_source_controla and pmi_source_controlb parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.
pmi_source_controlb	“parallel”	“shift”	“parallel”	The pmi_source_controla and pmi_source_controlb parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.
pmi_family	“ECP”	“ECP2”	“ECP2M”	“ECP3”	“ECP5U”	“ECP5UM”	“XP2”	“ECP2”	
reg_inputa_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”	
reg_inputa_ce	“CE0”	“CE1”	“CE2”	“CE3”	“CE0”	
reg_inputa_rst	“RST0”	“RST1”	“RST2”	“RST3”	“RST0”	
reg_inputb_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”	
reg_inputb_ce	“CE0”	“CE1”	“CE2”	“CE3”	“CE0”	
reg_inputb_rst	“RST0”	“RST1”	“RST2”	“RST3”	“RST0”	
reg_pipeline_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”	
reg_pipeline_ce	“CE0”	“CE1”	“CE2”	“CE3”	“CE0”	
reg_pipeline_rst	“RST0”	“RST1”	“RST2”	“RST3”	“RST0”	
reg_output_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”

Mult_Add_Sub

Two-input MULTADDSUB block look-up table (LUT) implementation. For DSP devices, DSP implementation is also available.

Table 212: Mult_Add_Sub Dialog Box

Feature	Description
Block Implementation	Allows you to choose between LUT-based implementation and DSP. DSP is only available with ECP5, LatticeECP, LatticeECP2/M, LatticeECP3, and LatticeXP2.
Add/Sub Operation	Allows the implementation of adder or subtractor. Default is set to add.
Input A0/A1 Width	Size of multiplier inputs A0/A1. The size of the multiplier inputs can be any size between 2 and 36 bits. The default size is 9.
Input B0/B1 Width	Size of multiplicand inputs B0/B1. The size of the multiplicand inputs can be any size between 2 and 36 bits. The default size is 9.
Representation	Allows the operation of signed and unsigned multiplication. Default setting is signed.
Sum Width	Sum of the multiplier and multiplicand inputs + 1.
Specify the Number of Pipeline Stages	Allows the number of pipelined stages to be set. Default is set to 1.
Enable Input Registers	Allows the implementation of registers on the inputs. Default is input register is enabled.
Enable Output Registers	Allows the implementation of registers on the outputs. Default is output register is enabled.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.

pmi_multaddsub

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_multaddsub.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	DataA0	Bus	(pmi_dataa_width -1):0
I	DataA1	Bus	(pmi_dataa_width -1):0
I	DataB0	Bus	(pmi_datab_width -1):0
I	DataB1	Bus	(pmi_datab_width -1):0
I	Clock	Bit	N/A
I	ClkEn	Bit	N/A
I	Aclr	Bit	N/A
O	Result	Bus	(pmi_dataa_width + pmi_datab_width):0

Verilog pmi_multaddsub Definition

```
module pmi_multaddsub #(parameter pmi_dataa_width = 8,
         parameter pmi_datab_width = 8,
         parameter module_type = "pmi_multaddsub",
         parameter pmi_sign = "on",
         parameter pmi_additional_pipeline = 1,
         parameter pmi_add_sub = "add",
         parameter pmi_input_reg = "on",
         parameter pmi_output_reg = "on",
         parameter pmi_family = "EC",
         parameter pmi_implementation = "LUT")

        (input   [(pmi_dataa_width-1):0]  DataA0,
         input   [(pmi_dataa_width-1):0]  DataA1,
         input   [(pmi_datab_width-1):0]  DataB0,
         input   [(pmi_datab_width-1):0]  DataB1,
         input   Clock, ClkEn, Aclr,
```

```
        output  [(pmi_dataa_width + pmi_datab_width):0]
Result)/*synthesis syn_black_box*/;

endmodule // pmi_multaddsub
```

VHDL pmi_multaddsub Definition

```
component pmi_multaddsub is
     generic (
       pmi_dataa_width : integer := 8;
       pmi_datab_width : integer := 8;
       module_type : string := "pmi_multaddsub";
       pmi_sign : string := "on";
       pmi_additional_pipeline : integer := 1;
       pmi_add_sub : string := "add";
       pmi_input_reg : string := "on";
       pmi_output_reg : string := "on";
       pmi_family : string := "EC";
       pmi_implementation : string := "LUT"
    );
    port (
     DataA0 : in std_logic_vector((pmi_dataa_width-1) downto
0);
     DataA1 : in std_logic_vector((pmi_dataa_width-1) downto
0);
     DataB0 : in std_logic_vector((pmi_datab_width-1) downto
0);
     DataB1 : in std_logic_vector((pmi_datab_width-1) downto
0);
     Clock: in std_logic;
     Result : out std_logic_vector((pmi_dataa_width +
pmi_datab_width) downto 0)
   );
  end component pmi_multaddsub;
```

Parameter Names and Values

The following table contains the pmi_multaddsub module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_dataa_width	2 to 36	8	
pmi_datab_width	2 to 36	8	
pmi_sign	“on” | “off”	“on”	
pmi_additional_pipeline	0 to Maximum {pmi_dataa_width, pmi_datab_width}	1	The pmi_additional_pipeline parameter ranges from 0 to 1 for DSP implementation. For the LUT implementation the limit is set to Maximum {pmi_dataa_width, pmi_datab_width}.
pmi_add_sub	“add” | “sub”	“add”	
pmi_input_reg	“on” | “off”	“on”	
pmi_output_reg	“on” | “off”	“on”	

Parameter Name	Acceptable Values	Default Value	Notes
pmi_family	“EC” | “ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” | “ECP5UM” | “SC” | “SCM” | “XP” | “XP2” | “XO” | “XO2” | “XO3L” |“LPTM”	“EC”	
pmi_implementation	“DSP” | “LUT”	“LUT”

Mult_Add_Sub_Sum

Two-input MULTADDSUBSUM block look-up table (LUT) implementation. For DSP devices, DSP implementation is also available.

Table 213: Mult_Add_Sub_Sum Dialog Box

Feature	Description
Block Implementation	Allows you to choose between LUT-based implementation and DSP. DSP is only available with LatticeECP, LatticeECP2/M, LatticeECP3, ECP5, and LatticeXP2.
Add/Sub 0 Operation	Allows the implementation of adder or subtractor. Default is set to add.
Add/Sub 1 Operation	Allows the implementation of adder or subtractor. Default is set to add.
Input A0/A1/A3/A3 Width	Size of multiplier inputs A0/A1/A2/A3. The size of the multiplier inputs can be any size between 2 and 36 bits. The default size is 9.
Input B0/B1/B2/B3 Width	Size of multiplicand inputs B0/B1/B2/B3. The size of the multiplicand inputs can be any size between 2 and 36 bits. The default size is 9.
Representation	Allows the operation of signed and unsigned multiplication. Default setting is signed.
Product Bit Width	Sum of the multiplier and multiplicand inputs + 2.
Specify the Number of Pipeline Stages	Allows the number of pipelined stages to be set. Default is set to 1.
Enable Input Registers	Allows the implementation of registers on the inputs. Default is input register is enabled.
Enable Output Registers	Allows the implementation of registers on the outputs. Default is output register is enabled.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.

MULTADDSUB

Two-input MULTADDSUB block multiplier that provides a variety of multiplier add/subtract organizations and is implemented as embedded sysDSP Blocks. Ports, properties, and functionality are described in detail in the technical notes listed in the “See Also” section below.

The options vary with the device family. See:

- “MULTADDSUB Options (ECP5, LatticeECP3)” on page 1507
- “MULTADDSUB Options (LatticeECP, LatticeECP2/M, LatticeXP2)” on page 1508

MULTADDSUB Options (ECP5, LatticeECP3)

Table 214: MULTADDSUB Dialog Box for ECP5 and LatticeECP3

Feature	Description
Size of the DSPMULTADDSUB block	**Enable Cascade Input** – Select if this module will also get input from another MULTADDSUB module. Enabling cascade input reduces the number of bits available for the multiplier input buses (below). The output width is always 54 bits. This is needed to feed into the 54-bit CIN of the next slice. For the final slice of the chain, some lower bits may have to be ignored. Due to the alignment of the inputs to the primitives, the lower (36 - (A0/A1 width + B0/B1 width)) must be ignored. If both the input widths are less than or equal to 9, then the lower (18 - (A0/A1 width + B0/B1 width)) must be ignored. For example, if Input A0/A1 width = 12 and Input B0/B1 width = 16, the lower 36 - (12+16) = 8 bits should be ignored. **Input A0/A1 width** – Specify the size of the first term in the multiplication (for both multipliers). **Input B0/B1 width** – Specify the size of the second term in the multiplication (for both multipliers). **Sum output width** – Size of the output. This is one more than the product size (that is, it is equal to A0/A1 size + B0/B1 size + 1).
Select Options	**Select Shift Out A** - Enables the shift-out port A of the DSP block. **Cascade Match Register** – Enables the Cascade Match Register of the A multiplier. **Select Shift Out B** - Enables the shift-out port B of the DSP block. **Add/Sub Operation** - Select if the adder is adding, subtracting or dynamic mode. In dynamic mode high = add, low = subtract.
Data Options	**Input A0, A1, B0, B1 Source** – Specify if the source of the input is Parallel for generic routing, Shift for the shift outputs of an adjacent DSP block, or Dynamic for dynamic selection of the source of the input. **Data Type A, B** – Specify the data format of the inputs as signed, unsigned, or dynamic selection of the sign.
Register Options	**Reset Mode** – Specify whether the reset is synchronous or asynchronous. **Clock** – Selects the clock for the registers of the DSP block. **CE** – Selects the clock enable pin to the registers of the DSP block. **RST** – Selects the reset pin to the registers of the DSP block.

Table 214: MULTADDSUB Dialog Box for ECP5 and LatticeECP3 (Continued)

Feature	Description
Bus Ordering Style	Specify if the inputs and output are big endian (MSB:LSB) or little endian (LSB:MSB), or none.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

MULTADDSUB Options (LatticeECP, LatticeECP2/M, LatticeXP2)

The module dialog box has two tabs:

- Basic, below
- Advanced, see Table 216 on page 1510

In the Basic tab you set most of the parameters including the size and format of the data, and enable pipelining. In the Advanced tab, you can control each group of pipelining registers with independent clocks, clock enables, and resets.

Table 215: MULTADDSUB Dialog Box for LatticeECP, LatticeECP2/M, and LatticeXP2—Basic Tab

Feature	Description
Size of the DSPMADD Block	**Multiplicand A0/A1 bit size** – Specify the size of the first term in the multiplication (for both the multipliers). **Multiplier B0/B1 bit size** – Specify the size of the second term in the multiplication (for both multipliers). **Sum output bit size** – Size of the output. This is one more than the product size (that is, it is equal to A0/A1 size + B0/B1 size + 1).
Select Block Options	**Area/Speed** – Specify if the implementation should minimize the number of DSP blocks (Area) or minimize number of partial products to be added (Speed). In some cases, both the options will produce the same implementation. **Add/Sub Implementation** - (not available in LatticeECP) Specify if the ADDER is built using the add/sub block in the DSP block or using PFU logic. **Add/Sub Operation** - Select if the ADDER is in add, subtract, or dynamic mode. In dynamic mode high = add, low = subtract.
Data Format	**Note**: The shift options, input and out, are not available if either of the A and B inputs is larger than 18 bits. **Input A0** – Specify if the source of input A for multiplier 0 is input A0 from generic routing (Parallel) or SRIA, the shift outputs of adjacent DSP block (Shift). Dynamic selection of the input source is also allowed (not available in LatticeECP). **Input A1** – Specify if the source of input A for multiplier 1 is input A1 from generic routing (Parallel) or the registered input A0 (Shift). Dynamic selection of the input source is also allowed (not available in LatticeECP). **Select Shift Out A** - Enables the shift-out port A of the DSP block. **Input B0** – Specify if the source of input B for multiplier 0 is input B0 from generic routing (Parallel) or SRIB, the shift outputs of the adjacent DSP block (Shift). Dynamic selection of the input source is also allowed (not available in LatticeECP). **Input B1** – Specify if the source of input B for multiplier 1 is input B1 from generic routing (Parallel) or the registered input B0 (Shift). Dynamic selection of the input source is also allowed (not available in LatticeECP). **Select Shift Out B** - Enables the shift-out port B of the DSP block. **Signed/Unsigned** – Specify if the data format of the inputs is signed or unsigned. Dynamic selection of the sign is also allowed (not available in LatticeECP).
Select Pipelining	**Enable Input Registers** – Enables the input registers. This option is selected if any input is selected as a “Shift” input. **Enable Pipeline Register** - Enables the pipeline registers at the output of each multiplier. **Enable Output Register** - Enables the output register after the ADDER. **RST on all registers** - Connects a reset pin to all registers of the DSP block. **CE on all registers** - Connects a clock enable pin to all registers of the DSP block.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.

Table 215: MULTADDSUB Dialog Box for LatticeECP, LatticeECP2/M, and LatticeXP2—Basic Tab

Feature	Description
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 216: MULTADDSUB Dialog Box for LatticeECP, LatticeECP2/M, and LatticeXP2—Advanced Tab

Feature	Description
Select Pipelining	**Enable Input Register A0, A1, B0, B1** – Specify options for Input registers. This option is disabled if the Enable Input Registers option on the Basic tab is not selected. **Enable Signed Register A, B –** (not available in LatticeECP) Specify options for signed registers A or B of the DSP block. This option is disabled unless the Signed/ Unsigned A, B option on the Basic tab is set to Dynamic and the Enable Input Registers option is selected. **Enable Signed Pipeline Register A, B –** (not available in LatticeECP) Specify options for signed pipeline registers A or B of the DSP block. This option is disabled if the Enable Pipeline Registers option on the Basic tab is not selected. **Enable Addsub Input Register** – Specify options for the ADDNSUB input register. This option is enabled only if the ADDER is set to dynamic mode. **Enable Addsub Pipeline Register** – Specify options for the ADDNSUB pipeline register. This option is enabled only if the ADDER is set to dynamic mode. **Enable Multiplier Pipeline Register 0, 1** – (not available in LatticeECP) Specify options for the pipeline registers of multiplier 0 or 1. This option is disabled if the Enable Pipeline Registers option on the Basic tab is not selected. **Enable Pipeline Register 0, 1** – (LatticeECP only) Specify options for the pipeline registers of multiplier 0 or 1. This option is disabled if the Enable Pipeline Registers option on the Basic tab is not selected. **Enable Output Register** – Specify options for the output registers. If the ADDER is implemented in the PFU, this option is used for the multiplier blocks. There will be no register after the ADDER block. The ADDER will be built using PFU logic if the module does not fit into a single DSP element. This option is disabled if the Enable Output Register option on the Basic tab is not selected.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.

pmi_dsp_multaddsub

The following table is intended to provide information for pmi_dsp_multaddsub usage (pmi_dsp_multaddsub.v).

pmi_dsp_multaddsub Control and Data Signal Descriptions

RST Asynchronous reset of selected registers		
SignA Dynamic signal:	0 = unsigned,	1 = signed
SignB Dynamic signal:	0 = unsigned	1 = signed
ACCUMSLOAD Dynamic signal:	0 = accumulate	1 = load
ADDNSUB Dynamic signal:	0 = subtract	1 = add
SOURCEA Dynamic signal:	0 = parallel input	1 = shift input
SOURCEB Dynamic signal:	0 = parallel input	1 = shift input

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_dsp_multaddsub.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	CLK0	Bit	N/A
I	CLK1	Bit	N/A
I	CLK2	Bit	N/A
I	CLK3	Bit	N/A
I	CE0	Bit	N/A
I	CE1	Bit	N/A
I	CE2	Bit	N/A
I	CE3	Bit	N/A
I	RST0	Bit	N/A
I	RST1	Bit	N/A
I	RST2	Bit	N/A
I	RST3	Bit	N/A
I	SignA	Bit	N/A
I	SignB	Bit	N/A
I	ShiftA0	Bit	N/A
I	ShiftA1	Bit	N/A
I	ShiftB0	Bit	N/A
I	ShiftB1	Bit	N/A
I	ADDNSUB	Bit	N/A
I	A0	Bus	(pmi_dataa_width -1):0
I	SRIA	Bus	17:0
I	A1	Bus	(pmi_dataa_width -1):0
	B0	Bus	(pmi_datab_width - 1):0
I	SRIB	Bus	17:0
I	B1	Bus	(pmi_datab_width - 1):0
O	SUM	Bus	(pmi_dataa_width + pmi_datab_width):0
O	SROA	Bus	17:0
O	SROB	Bus	17:0

Parameter Names and Values

The following table contains the pmi_dsp_multaddsub module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_dataa_width	2 to 72	8	
pmi_datab_width	2 to 72	8	
pmi_gsr	“enable” | “disable”	“enable”	
pmi_additional_pipeline	0 to 1	0	
pmi_input_reg	“on” | “off”	“on”	
pmi_output_reg	“on” | “off”	“on”	
pmi_family	“ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” | “ECP5UM” | “XP2”	“ECP2”	

Parameter Name	Acceptable Values	Default Value	Notes
pmi_source_controla0	“parallel”	“shift”	“parallel”	The pmi_source_controla0, pmi_source_controla1, pmi_source_controlb0 and pmi_source_controlb1 parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.
pmi_source_controla1	“parallel”	“shift”	“parallel”	The pmi_source_controla0, pmi_source_controla1, pmi_source_controlb0 and pmi_source_controlb1 parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.
pmi_source_controlb0	“parallel”	“shift”	“parallel”	The pmi_source_controla0, pmi_source_controla1, pmi_source_controlb0 and pmi_source_controlb1 parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.
pmi_source_controlb1	“parallel”	“shift”	“parallel”	The pmi_source_controla0, pmi_source_controla1, pmi_source_controlb0 and pmi_source_controlb1 parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.
pmi_reg_inputa0_clk	“CLK0”	“CLK1”	“CLK2”	“CLK3”	“CLK0”

pmi_dsp_casmultaddsub

The following table is intended to provide information for pmi_dsp_casmultaddsub usage (pmi_dsp_multaddsub.v). This module is for LatticeECP3.

pmi_dsp_casmultaddsub Control and Data Signal Descriptions

RST Asynchronous reset of selected registers		
SignA Dynamic signal:	0 = unsigned	1 = signed
SignB Dynamic signal:	0 = unsigned	1 = signed
ADDNSUB Dynamic signal:	0 = subtract	1 = add

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_dsp_casmultaddsub.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	CLK0	Bit	N/A
I	CLK1	Bit	N/A
I	CLK2	Bit	N/A
I	CLK3	Bit	N/A
I	CE0	Bit	N/A
I	CE1	Bit	N/A
I	CE2	Bit	N/A
I	CE3	Bit	N/A
I	RST0	Bit	N/A
I	RST1	Bit	N/A
I	RST2	Bit	N/A
I	RST3	Bit	N/A
I	SignA	Bit	N/A
I	SignB	Bit	N/A
I	ShiftA0	Bit	N/A
I	ShiftA1	Bit	N/A
I	ShiftB0	Bit	N/A
I	ShiftB1	Bit	N/A
I	ADDNSUB	Bit	N/A
I	SignCIN	Bit	N/A
I	A0	Bus	(pmi_dataa_width -1):0
I	SRIA	Bus	17:0
I	A1	Bus	(pmi_dataa_width -1):0
I	B0	Bus	(pmi_datab_width - 1):0
I	SRIB	Bus	17:0
I	B1	Bus	(pmi_datab_width - 1):0
I	CIN	Bus	53:0
O	SUM	Bus	53:0
O	SROA	Bus	17:0
O	SROB	Bus	17:0

Verilog pmi_dsp_casmultaddsub Definition

MULTADDSUBSUM

Two-input MULTADDSUBSUM block multiplier that provides a variety of multiplier, add/subtract, and sum organizations and is implemented as embedded sysDSP Blocks. Ports, properties, and functionality are described in detail in the technical notes listed in the "See Also" section below.

The options vary with the device family. See:

- "MULTADDSUBSUM Options (ECP5, LatticeECP3)" on page 1525
- "MULTADDSUBSUM Options (LatticeECP)" on page 1526
- "MULTADDSUBSUM Options (LatticeECP2/M, LatticeXP2)" on page 1528

MULTADDSUBSUM Options (ECP5, LatticeECP3)

Table 217: MULTADDSUBSUM Dialog Box for ECP5 and LatticeECP3

Feature	Description
Size of DSPMULTADDSUBSUM block	**Input A0/A1/A2/A3 width** – Specify the size of the first term in the multiplication (for all multipliers). **Input B0/B1/B2/B3 width** – Specify the size of the second term in the multiplication (for all multipliers). **Sum output width** – Size of the output. This is two more than the product size. That is, it is equal to A size + B size + 2.
Select Options	**Select Shift Out A** - Enables the shift-out port A of the DSP block. **Select Shift Out B** - Enables the shift-out port B of the DSP block. **Add/Sub 0, 1 Operation** - Select if the adder is in add, subtract, or dynamic mode. In dynamic mode high = add, low = subtract.

Table 217: MULTADDSUBSUM Dialog Box for ECP5 and LatticeECP3 (Continued)

Feature	Description
Data Options	**Input A0, A1, A2, A3, B0, B1, B2, B3 Source** – Specify if the source of the input is Parallel for generic routing, Shift for the shift outputs of an adjacent DSP block, or Dynamic for dynamic selection of the source of the input. **Data Type A, B** – Specify the data format of the inputs as signed, unsigned, or dynamic selection of the sign.
Register Options	**Reset Mode** – Specify whether the reset is synchronous or asynchronous. **Clock** – Selects the clock for the registers of the DSP block. **CE** – Selects the clock enable pin to the registers of the DSP block. **RST** – Selects the reset pin to the registers of the DSP block.
Bus Ordering Style	Specify if the inputs and output are big endian (MSB:LSB) or little endian (LSB:MSB), or none.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

MULTADDSUBSUM Options (LatticeECP)

The module dialog box has two tabs:

- Basic, below
- Advanced, see Table 219 on page 1528

In the Basic tab, you can enable pipelining and set parameters such as the size and format of the data. In the Advanced tab, you can control each group of pipelining registers with independent clocks, clock enables, and resets.

Table 218: MULTADDSUBSUM Dialog Box for LatticeECP—Basic Tab

Feature	Description
Size of the DSPMADDSUM block	**Multiplicand A0/A1/A2/A3 bit size** – Specify the size of the first term in the multiplication (for all multipliers). **Multiplier B0/B1/B2/B3 bit size** – Specify the size of the second term in the multiplication (for all multipliers). **Sum output bit size** – Size of the output. This is 2 more than the product size. That is, it is equal to A size + B size + 2.
Select Block Options	**Area/Speed** - Specify if the implementation should minimize the number of DSP blocks (Area) or minimize number of partial products to be added (Speed). In some cases, both options will produce the same implementation. **Add/Sub 1, 3 Operation** - Select if the ADDER is in add, subtract, or dynamic mode. In dynamic mode high = add, low = subtract.
Data Format	**Note**: The shift options, input and out, are not available if either of the A and B inputs is larger than 18 bits. **Input A0, A1, A2, A3** – Specify if the source of input A for multiplier 0, 1, 2, or 3 is from generic routing (Parallel) or the shift outputs of the adjacent DSP block (Shift). **Select Shift Out A** - Enables the shift-out port A of the DSP block. **Input B0, B1, B2, B3** – Specify if the source of input B for multiplier 0, 1, 2, or 3 is from generic routing (Parallel) or the shift outputs of the adjacent DSP block (Shift). **Select Shift Out B** - Enables the shift-out port B of the DSP block. **Signed/Unsigned** - Specify if the data format of the inputs is signed or unsigned.
Select Pipelining	**Enable Input Registers** – Enables the input registers. **Enable Pipeline Register** - Enables the pipeline registers. **Enable Output Register** - Enables the output registers. **RST on all registers** - Connects a reset pin to all registers of the DSP block. **CE on all registers** - Connects a clock enable pin to all registers of the DSP block.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 219: MULTADDSUBSUM Dialog Box for LatticeECP—Advanced Tab

Feature	Description
Select Pipelining	**Enable Input Register A0, A1, A2, A3, B0, B1, B2, B3** – Specify options for Input registers. This option is disabled if the Enable Input Registers option on the Basic tab is not selected. **Enable Addsub1 Input Register** – Specify options for the ADDNSUB1 input register. This option is available only if the ADDER is set to dynamic mode. **Enable Addsub1 Pipeline Register** – Specify options for the ADDNSUB1 pipeline register. This option is enabled only if the ADDER is set to dynamic mode. **Enable Addsub3 Input Register** – Specify options for the ADDNSUB3 input register. This option is available only if the ADDER is set to dynamic mode. **Enable Addsub3 Pipeline Register** – Specify options for the ADDNSUB3 pipeline register. This option is available only if the ADDER is set to dynamic mode. **Enable Pipeline Register 0, 1, 2, 3** – Specify options for the pipeline registers of multipliers 0, 1, 2, or 3. This option is disabled if the Enable Pipeline Registers option on the Basic tab is not selected. **Enable Output Register** – Specify options for the output registers. If the Adders and Summer are implemented in the PFU, this option is used for the multiplier blocks. There will be no register after the ADDSUB/SUM block. If the size of the module exceeds one DSP element, the ADDERs and SUM will be implemented in PFU. This option is disabled if the Enable Output Register option on the Basic tab is not selected.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified and saves the files in the project folder.
Close	Cancels the dialog box without generating the module.
Help	Opens the Help Contents.

MULTADDSUBSUM Options (LatticeECP2/M, LatticeXP2)

The module dialog box has three tabs:

- Basic, below
- Advanced, see Table 221 on page 1530
- Advanced Cont., see Table 222 on page 1531

In the Basic tab you set most of the parameters including the size and format of the data, and enable pipelining. In the Advanced tab, you can control each group of pipelining registers with independent clocks, clock enables, and resets. Because of the number of registers, the advanced controls are on two tabs, Advanced and Advanced Cont.

Table 220: MULTADDSUBSUM Dialog Box for LatticeECP2/M, and LatticeXP2—Basic Tab

Feature	Description
Size of the DSPMADDSUM block	**Multiplicand A0/A1/A2/A3 bit size** – Specify the size of the first term in the multiplication (for all multipliers). **Multiplier B0/B1/B2/B3 bit size** – Specify the size of the second term in the multiplication (for all multipliers). **Sum output bit size** – Size of the output. This is 2 more than the product size. That is, it is equal to A size + B size + 2.
Select Block Options	**Area/Speed** - Specify if the implementation should minimize the number of DSP blocks (Area) or minimize number of partial products to be added (Speed). In some cases, both options will produce the same implementation. **Add/Sub Implementation -** Specify if the ADDER is built using a DSP block or Look Up Table (LUT) logic. **Sum Implementation -** Specify if this function is built using a DSP block or Look Up Table (LUT) logic. **Add/Sub 1, 3 Operation** - Select if the ADDER is in add, subtract, or dynamic mode. In dynamic mode high = add, low = subtract.
Data Format	**Note**: The shift options, input and out, are not available if either of the A and B inputs is larger than 18 bits. **Input A0, A1, A2, A3** – Specify if the source of input A for multiplier 0, 1, 2, or 3 is from generic routing (Parallel) or the shift outputs of the adjacent DSP block (Shift). The source can also have dynamic control. **Select Shift Out A** - Enables the shift-out port A of the DSP block. **Input B0, B1, B2, B3** – Specify if the source of input B for multiplier 0, 1, 2, or 3 is from generic routing (Parallel) or the shift outputs of the adjacent DSP block (Shift). The source can also have dynamic control. **Select Shift Out B** - Enables the shift-out port B of the DSP block. **Signed/Unsigned A, B** - Specify if the data format of the inputs is signed or unsigned. The data can also have dynamic control. **Special sign extension for unsigned subtract** - This option is available only when one or both of the add/sub operations is in subtract or dynamic mode and both of the Signed/Unsigned A and B options are set to Unsigned.
Select Pipelining	**Enable Input Registers** – Enables the input registers. **Enable Pipeline Registers** - Enables the pipeline registers. **Enable Output Register** - Enables the output registers. **RST on all registers** - Connects a reset pin to all registers of the DSP block. **CE on all registers** - Connects a clock enable pin to all registers of the DSP block.

Table 220: MULTADDSUBSUM Dialog Box for LatticeECP2/M, and LatticeXP2—Basic Tab

Feature	Description
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 221: MULTADDSUBSUM Dialog Box for LatticeECP2/M, and LatticeXP2—Advanced Tab

Feature	Description
Select Pipelining	**Enable Input Register A0, A1, A2, A3, B0, B1, B2, B3** – Specify options for Input registers. This option is disabled if the Enable Input Registers option on the Basic tab is not selected. **Enable Signed Register A, B –** Specify options for signed registers A or B of the DSP block. This option is disabled unless the Signed/Unsigned A, B option on the Basic tab is set to Dynamic and the Enable Input Registers option is selected. **Enable Signed Pipeline Register A, B –** Specify options for signed pipeline registers A or B of the DSP block. This option is disabled if the Enable Pipeline Registers option on the Basic tab is not selected.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.

Table 222: MULTADDSUBSUM Dialog Box for LatticeECP2/M, and LatticeXP2—Advanced Cont. Tab

Feature	Description
Select Pipelining	**Enable Addsub1 Input Register** – Specify options for the ADDNSUB1 input register. This option is enabled only if the ADDER is set to dynamic mode. **Enable Addsub1 Pipeline Register** – Specify options for the ADDNSUB1 pipeline register. This option is enabled only if the ADDER is set to dynamic mode. **Enable Addsub3 Input Register** – Specify options for the ADDNSUB3 input register. This option is enabled only if the ADDER is set to dynamic mode. **Enable Addsub3 Pipeline Register** – Specify options for the ADDNSUB3 pipeline register. This option is enabled only if the ADDER is set to dynamic mode. **Enable Multiplier Pipeline Register 0, 1, 2, 3** – Specify options for the pipeline registers of multipliers 0, 1, 2, or 3. This option is disabled if the Enable Pipeline Registers option on the Basic tab is not selected. **Enable Output Register** – Specify options for the output registers. If the Adders and Summer are implemented in the PFU, this option is used for the multiplier blocks. There will be no register after the ADDSUB/SUM block. If the size of the module exceeds one DSP element, the ADDERs and SUM will be implemented in PFU. This option is disabled if the Enable Output Register option on the Basic tab is not selected.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.

pmi_dsp_multaddsubsum

The following table is intended to provide information for pmi_dsp_multaddsubsum usage (pmi_dsp_multaddsubsum.v).

pmi_dsp_multaddsubsum Control and Data Signal Descriptions

RST Asynchronous reset of selected registers		
SignA Dynamic signal:	0 = unsigned	1 = signed
SignB Dynamic signal:	0 = unsigned	1 = signed
ADDNSUB1 Dynamic signal:	0 = subtract	1 = add
ADDNSUB3 Dynamic signal:	0 = subtract	1 = add

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_dsp_multaddsubsum.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	CLK0	Bit	N/A
I	CLK1	Bit	N/A
I	CLK2	Bit	N/A
I	CLK3	Bit	N/A
I	CE0	Bit	N/A
I	CE1	Bit	N/A
I	CE2	Bit	N/A
I	CE3	Bit	N/A
I	RST0	Bit	N/A
I	RST1	Bit	N/A
I	RST2	Bit	N/A
I	RST3	Bit	N/A
I	SignA	Bit	N/A
I	SignB	Bit	N/A
I	ShiftA0	Bit	N/A
I	ShiftA1	Bit	N/A
I	ShiftA2	Bit	N/A
I	ShiftA3	Bit	N/A
I	ShiftB0	Bit	N/A
I	ShiftB1	Bit	N/A
I	ShiftB2	Bit	N/A
I	ShiftB3	Bit	N/A
I	ADDNSUB1	Bit	N/A
I	ADDNSUB3	Bit	N/A
i	A0	Bus	(pmi_dataa_width - 1):0
I	SRIA	Bus	17:0

Parameter Names and Values

The following table contains the pmi_dsp_multaddsubsum module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_dataa_width	2 to 72	8	
pmi_datab_width	2 to 72	8	
pmi_additional_pipeline	0 to 1	0	
pmi_input_reg	“on”	“off”	“on”	
pmi_output_reg	“on”	“off”	“on”	
pmi_family	“ECP”	“ECP2”	“ECP2M”	“ECP3”	“ECP5U”	“ECP5UM”	“XP2”	“ECP2”	
pmi_gsr	“enable”	“disable”	“enable”	
pmi_source_controla0	“parallel”	“shift”	“parallel”	The pmi_source_controla0, pmi_source_controla1, pmi_source_controla2, pmi_source_controla3, pmi_source_controlb0, pmi_source_controlb1, pmi_source_controlb2 and pmi_source_controlb3 parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_source_controla1	“parallel” | “shift”	“parallel”	The pmi_source_controla0, pmi_source_controla1, pmi_source_controla2, pmi_source_controla3, pmi_source_controlb0, pmi_source_controlb1, pmi_source_controlb2 and pmi_source_controlb3 parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.
pmi_source_controla2	“parallel” | “shift”	“parallel”	The pmi_source_controla0, pmi_source_controla1, pmi_source_controla2, pmi_source_controla3, pmi_source_controlb0, pmi_source_controlb1, pmi_source_controlb2 and pmi_source_controlb3 parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.
pmi_source_controla3	“parallel” | “shift”	“parallel”	The pmi_source_controla0, pmi_source_controla1, pmi_source_controla2, pmi_source_controla3, pmi_source_controlb0, pmi_source_controlb1, pmi_source_controlb2 and pmi_source_controlb3 parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.
pmi_source_controlb0	“parallel” | “shift”	“parallel”	The pmi_source_controla0, pmi_source_controla1, pmi_source_controla2, pmi_source_controla3, pmi_source_controlb0, pmi_source_controlb1, pmi_source_controlb2 and pmi_source_controlb3 parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.
pmi_source_controlb1	“parallel” | “shift”	“parallel”	The pmi_source_controla0, pmi_source_controla1, pmi_source_controla2, pmi_source_controla3, pmi_source_controlb0, pmi_source_controlb1, pmi_source_controlb2 and pmi_source_controlb3 parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_source_controlb2	“parallel” | “shift”	“parallel”	The pmi_source_controla0, pmi_source_controla1, pmi_source_controla2, pmi_source_controla3, pmi_source_controlb0, pmi_source_controlb1, pmi_source_controlb2 and pmi_source_controlb3 parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.
pmi_source_controlb3	“parallel” | “shift”	“parallel”	The pmi_source_controla0, pmi_source_controla1, pmi_source_controla2, pmi_source_controla3, pmi_source_controlb0, pmi_source_controlb1, pmi_source_controlb2 and pmi_source_controlb3 parameters have options parallel/shift for LatticeECP. This option is for LatticeECP only.

Multiplier

Multiplier. Look-up table (LUT) implementation available. For DSP devices, DSP implementation is also available.

The signed or unsigned, n x m-bit multiplier module is an n and m input / n + m output device that performs electronically in a manner that can be interpreted as the binary multiplication of an n-bit word with the other m-bit word. The constant coefficient option allows you to specify a constant integer value for the multiplicand. A pipeline option introduces registered elements controlled by clock, clock enable, and reset ports.

Table 223: Multiplier Dialog Box

Feature	Description
Use a Constant Coefficient	Allows the operation of a constant multiplier when selected.
Constant Coefficient Value	The constant coefficient value range is -2^31 to 2^31-1. The default value is set to 2.
Use RAM Based Multiplier	Specifies RAM-based implementation of multiplier. Option only available when using Constant Coefficient feature.
Block Implementation	Allows you to choose between LUT or DSP Based Implementation.
Input A Width	Size of multiplier input. The size of the multiplier input can be any size between 2 and 36 bits. The default size is 9.
Input B Width	Size of multiplicand input. The size of the multiplicand input can be any size between 2 and 36 bits. The default size is 9.
Representation	Allows the operation of signed and unsigned multiplication. Default setting is signed.
Product Bit Width	Size of Product. The product bit width is the sum of the multiplier and multiplicand bit widths. The default size is 18.
Specify the Number of Pipeline Stages	Specifies the number of register stages inserted into the multiplier. More stages improves achievable frequency of operation, but the latency for the output increases.
Enable Input Registers	Allows the implementation of registers on the inputs. Default is input register is enabled.

Table 223: Multiplier Dialog Box (Continued)

Feature	Description
Enable Output Registers	Allows the implementation of registers on the outputs. Default is output register is enabled.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 224: Multiplier Ports

Name	Description
DataA[size-1..0]	Multiplicand input
DataB[size-1..0] (Optional)	Multiplier input
Result[size-1..0]	Multiplier output
Clock (Optional)	Positive, edge-triggered clock input for pipeline stages
ClkEn (Optional)	Clock enable input
Aclr (Optional)	Asynchronous clear input for pipeline stages

Table 225: Multiplier Properties

Feature	Description
Constant coefficient	Treat the multiplicand as an integer constant
Size	Width of the DataA, DataB, and Result ports.
Representation	Type of multiplication performed: Signed or unsigned.
Number of pipeline stages	Number of register stages inserted in the multiplier. For example, in an 8x8 multiplier: The value 1 inserts registers in one of the multiplication stages. The value 2 inserts registers in two of the multiplication stages, and so on for 4 and 8 values. Zero (0) indicates that the module should be implemented as a purely combinatorial function.

pmi_mult

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_mult.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	DataA	Bus	(pmi_dataa_width - 1):0
I	DataB	Bus	(pmi_datab_width - 1:):0
I	Clock	Bit	N/A
I	ClkEn	Bit	N/A
I	Aclr	Bit	N/A
O	Result	Bus	(pmi_dataa_width + pmi_datab_width - 1):0

Verilog pmi_mult Definition

```
module pmi_mult #(parameter pmi_dataa_width = 8,
         parameter pmi_datab_width = 8,
         parameter module_type = "pmi_mult",
         parameter pmi_sign = "on",
         parameter pmi_additional_pipeline = 1,
         parameter pmi_input_reg = "on",
         parameter pmi_output_reg = "on",
         parameter pmi_family = "EC",
         parameter pmi_implementation = "LUT")

        (input   [(pmi_dataa_width-1):0]  DataA,
         input   [(pmi_datab_width-1):0]  DataB,
         input   Clock, ClkEn, Aclr,
         output  [(pmi_dataa_width + pmi_datab_width - 1):0]
Result)/*synthesis syn_black_box*/;

endmodule // pmi_mult
```

VHDL pmi_mult Definition

```
component pmi_mult is
     generic (
       pmi_dataa_width : integer := 8;
       pmi_datab_width : integer := 8;
       module_type : string := "pmi_mult";
       pmi_sign : string := "on";
       pmi_additional_pipeline : integer := 1;
       pmi_input_reg : string := "on";
       pmi_output_reg : string := "on";
       pmi_family : string := "EC";
       pmi_implementation : string := "LUT"
    );
    port (
     DataA : in std_logic_vector((pmi_dataa_width-1) downto 0);
     DataB : in std_logic_vector((pmi_datab_width-1) downto 0);
```

```
    Clock: in std_logic;
    Result : out std_logic_vector((pmi_dataa_width +
pmi_datab_width - 1) downto 0)
   );
  end component pmi_mult;
```

Parameter Names and Values

The following table contains the pmi_mult module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_dataa_width	2 to 36	8	
pmi_datab_width	2 to 36	8	
pmi_additional_pipeline	0 to Maximum {pmi_dataa_width, pmi_datab_width}	1	The pmi_additional_pipeline parameter ranges from 0 to 1 for DSP implementation. For the LUT implementation the limit is set to Maximum {pmi_dataa_width, pmi_datab_width}.
pmi_input_reg	“on” | “off”	“on”	
pmi_output_reg	“on” | “off”	“on”	
pmi_sign	“on” | “off”	“on”	
pmi_family	“EC” | “XP” | “XP2” | “SC” | “SCM” | “ECP” | “ECP2” | “ECP2M” | “XO” | “XO2” | “XO3L” | “ECP3” | “ECP5U” | “ECP5UM” | “LPTM”	“EC”

pmi_constant_mult

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_constant_mult.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	DataA	Bus	(pmi_dataa_width - 1):0
I	Clock	Bit	N/A
I	ClkEn	Bit	N/A
I	Aclr	Bit	N/A
O	Result	Bus	(pmi_dataa_width + pmi_datab_width - 1):0

Verilog pmi_constant_mult Definition

```
module pmi_constant_mult #(parameter pmi_dataa_width = 8,
                 parameter pmi_datab_width = 8,
                 parameter module_type = "pmi_constant_mult",
                 parameter pmi_sign = "on",
                 parameter pmi_additional_pipeline = 1,
                 parameter pmi_constant_value = 2,
                 parameter pmi_input_reg = "on",
                 parameter pmi_output_reg = "on",
                 parameter pmi_family = "EC",
                 parameter pmi_implementation = "LUT")

              (input   [(pmi_dataa_width-1):0]  DataA,
               input   Clock, ClkEn, Aclr,
               output  [(pmi_dataa_width + pmi_datab_width -
1):0]  Result)/*synthesis syn_black_box*/;

endmodule // pmi_constant_mult
```

VHDL pmi_constant_mult Definition

```
component pmi_constant_mult is
     generic (
       pmi_dataa_width : integer := 8;
       pmi_datab_width : integer := 8;
       module_type : string := "pmi_constant_mult";
       pmi_sign : string := "on";
       pmi_additional_pipeline : integer := 1;
       pmi_constant_value : integer := 2;
       pmi_input_reg : string := "on";
       pmi_output_reg : string := "on";
       pmi_family : string := "EC";
       pmi_implementation : string := "LUT"
    );
    port (
     DataA : in std_logic_vector((pmi_dataa_width-1) downto 0);
     Clock: in std_logic;
     Result : out std_logic_vector((pmi_dataa_width +
pmi_datab_width - 1) downto 0)
   );
  end component pmi_constant_mult;
```

Parameter Names and Values

The following table contains the pmi_constant_mult module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_dataa_width	2 to 36	8	
pmi_datab_width	2 to 36	8	The pmi_datab_width parameter is implemented to calculate the data width for the constant value.
pmi_sign	“on” | “off”	“on”	
pmi_additional_pipeline	0 to Maximum {pmi_dataa_width, pmi_datab_width}	1	The pmi_additional_pipeline parameter ranges from 0 to 1 for DSP implementation. For the LUT implementation the limit is set to Maximum {pmi_dataa_width, pmi_datab_width}.
pmi_constant_value	-2^{31} to 2^{31} -1	2	
pmi_input_reg	“on” | “off”	“on”	
pmi_output_reg	“on” | “off”	“on”	
pmi_family	“EC” | “ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” | “ECP5UM” | “SC” | “SCM” | “XP” | “XP2” | “XO” | “XO2” | “XO3L” | “LPTM”	“EC”

Multiply_Accumulate

A two-input multiply/accumulate (MAC) logic. Look-up table (LUT) implementation is available. For DSP devices, DSP implementation is also available.

Table 226: Multiply_Accumulate Dialog Box

Feature	Description
Block Implementation	Allows you to choose between LUT based implementation and DSP. DSP is only available with ECP5, LatticeECP, LatticeECP2/M, LatticeECP3, and LatticeXP2.
Add/Sub Operation	Allows the implementation of adder or subtractor. Default is set to add.
Input A Width	Size of multiplier input. The size of the multiplier input can be any size between 2 and 36 bits. The default size is 18.
Input B Width	Size of multiplicand input. The size of the multiplicand input can be any size between 2 and 36 bits. The default size is 18.
Representation	Allows the operation of signed and unsigned multiplication. Default setting is signed.
Accumulator Width	Size of the accumulator. The accumulator can be set to any size between 1 and 32 bits. The default size is 16.
Sum Output Bit Width	Sum of the multiplier, multiplicand, and accumulator width.
Specify the Number of Pipeline Stages	Allows the number of pipelined stages to be set. Default is set to 1.
Enable Input Registers	Allows the implementation of registers on the inputs. Default is input register is enabled.
Enable Output Registers	Allows the implementation of registers on the outputs. For the Multiply Accumulate module, the output register is always enabled.
Bus Ordering Style	Specifies whether the numbers should begin at the high end ("Big Endian"- BusA[7 to 0]) or at the low end ("Little Endian"-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

pmi_mac

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_mac.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	DataA	Bus	(pmi_dataa_width - 1):0
I	DataB	Bus	(pmi_datab_width - 1):0
I	Clock	Bit	N/A
I	ClkEn	Bit	N/A
I	Aclr	Bit	N/A
O	Result	Bus	(pmi_accum_width - 1):0

Verilog pmi_mac Definition

```
module pmi_mac #(parameter pmi_dataa_width = 8,
         parameter pmi_datab_width = 8,
         parameter pmi_accum_width = 32,
         parameter module_type = "pmi_mac",
         parameter pmi_sign = "on",
         parameter pmi_additional_pipeline = 1,
         parameter pmi_add_sub = "add",
         parameter pmi_input_reg = "on",
         parameter pmi_family = "EC",
         parameter pmi_implementation = "LUT")

        (input   [(pmi_dataa_width - 1):0]  DataA,
         input   [(pmi_datab_width - 1):0]  DataB,
         input   Clock, ClkEn, Aclr,
         output  [(pmi_accum_width - 1):0]  Result)/*synthesis
syn_black_box*/;

endmodule // pmi_mac
```

VHDL pmi_mac Definition

```
component pmi_mac is
     generic (
       pmi_dataa_width : integer := 8;
       pmi_datab_width : integer := 8;
       pmi_accum_width : integer := 32;
       module_type : string := "pmi_mac";
       pmi_sign : string := "on";
       pmi_additional_pipeline : integer := 1;
       pmi_add_sub : string := "add";
       pmi_input_reg : string := "on";
       pmi_family : string := "EC";
       pmi_implementation : string := "LUT"
    );
    port (
```

```
     DataA : in std_logic_vector((pmi_dataa_width - 1) downto
0);
     DataB : in std_logic_vector((pmi_datab_width - 1) downto
0);
     Clock: in std_logic;
     Result : out std_logic_vector((pmi_accum_width - 1) downto
0)
   );
  end component pmi_mac;
```

Parameter Names and Values

The following table contains the pmi_mac module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_dataa_width	2 to 36	8	
pmi_datab_width	2 to 36	8	
pmi_sign	“on” | “off”	“on”	
pmi_accum_width	(pmi_dataa_width + pmi_datab_width + 1) to (pmi_dataa_width + pmi_datab_width + 32)	“32”	
pmi_additional_pipeline	0 to Maximum {pmi_dataa_width, pmi_datab_width}	1	The pmi_additional_pipeline parameter ranges from 0 to 1 for DSP implementation. For the LUT implementation the limit is set to Maximum {pmi_dataa_width, pmi_datab_width}.
pmi_add_sub	“add” | “sub”	“add”	
pmi_input_reg	“on” | “off”	“on”	
pmi_family	“EC” | “ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” | “ECP5UM” | “SC” | “SCM” | “XP” | “XP2” | “XO” | “XO2” | “XO2L” |“LPTM”	“EC”	
pmi_implementation	“DSP” | “LUT”	“LUT”

ORCAstra

The interface for the ORCAstra FPGA Bus Control Center (not available with Diamond). The module includes a JTAG port for external communication. For LatticeSC/M, internal communication is with the User Master Interface of a System Bus module. For LatticeECP2M, LatticeECP3, and LatticeXP2, internal communication is with a SERDES Client Interface (SCI).

Note

The ORCAstra module cannot be simulated. The usual practice is to add the module when your design is ready for on-chip debugging.

Also, you must use Synplify to synthesize the design when the ORCAstra module is included.

Table 227: ORCAstra Dialog Box

Feature	Description
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Ports The JTAG port is automatically connected to the JTAG pins, so the JTAG signals are not discussed here or shown in the ORCAstra Configuration dialog box. No user action is required.

Table 228:

Name	Description
clk	Free-running clock input. It is typically connected to the output of an OSCA clock library element but any stable clock will suffice. The frequency should be specified in the constraints file during place-and-route.
jcex	The scien port in the SCI bus.
rstn	Active-low, asynchronous reset. Its use is optional because the logic is self-starting and will start from any initial state.
sci<*name*>	All port names starting with “sci” are from an SCI bus and connect with an address decoder of your own design. See “References,” below.
umi_<*name*>	All port names starting with “umi_” connect with the User Master Interface of a LatticeSC/M System Bus module. See “References,” below.

PCS

PCS (Physical Coding Sub-layer) supports advanced system level standards including RapidIO, Sonet, Gigabit Ethernet, 10 Gb Ethernet, Fibre Channel and PCI Express.

In addition to the usual files, the PCS module includes a <*module_name*>.txt file. This file is used by simulation and bitgen to configure the modules. When you import the source files for this module into the design project, also import the <*module_name*>.txt file as a source. It will show up under Documents in the Files tab.

The options vary with the device family. See:

- “PCS Options (ECP5UM)” on page 1555
- “PCS Options (LatticeECP2M)” on page 1559
- “PCS Options (LatticeECP3)” on page 1564
- “PCS Options (LatticeSC/M)” on page 1570

PCS Options (ECP5UM)

PCS for ECP5UM is available through System Builder/Planner, not IPexpress.

The dialog box has several tabs:

- Instance Setup, see Table 229 on page 1556
- SerDes Setup, see Table 230 on page 1557
- PCS Setup, see Table 231 on page 1557
- Control Setup, see Table 232 on page 1558
- Advanced Setup, see Table 233 on page 1559

Table 229: PCS Dialog Box for ECP5UM—Instance Setup Tab

Feature	Description
Protocol	Specify the communication protocol.
Number of Channels	Specify the number of channels.
Mode	Specify if the channels are to both receive (RX) and transmit (TX), transmit only, or receive only.
Tx Max Data Rate	Specify the maximum transmit data rate in giga-bits per second (Gbps).
PLL Multiplier	Select a clock multiplier to achieve the transmit data rate. This value determines the required reference clock frequency (below).
Ref Clk Freq	Shows the reference clock frequency required to achieve the transmit data rate given the selected PLL multiplier (in MHz). Adjust the Tx Max Data Rate and the PLL Multiplier (above) until you are satisfied with the reference clock frequency.
Loss Of Lock Setting	Allowed loss of signal threshold selections for a selected protocol.
Receive Max Data Rate (CDR)	Specify the maximum receive data rate in giga-bits per second (Gbps).
CDR Multiplier	Select a clock multiplier to achieve the receive data rate. This value determines the required reference clock frequency (below).
Rx Rate	Specify if the receive rate is full speed or 1/2 of the Transmit Data Rate (above).
CDR Refclk	Shows the reference clock frequency required to achieve the receive data rate given the selected CDR multiplier (in MHz). Adjust the Receive Max Data Rate and the CDR Multiplier (above) until you are satisfied with the reference clock frequency.
Rx Line Rate	Shows the receive line rate based on the Receive Max Data Rate and the Rx Rate (above).
Rx FPGA Bus Width	Select the desired receive bus width.
Rx FPGA Bus Freq	Shows the receive bus frequency based on the Receive Max Data Rate and the Rx Bus Width (above).
Rx Low Data Rate Path	Select if the channel is to be low-speed.
CDR Loss Of Lock Range	Allowed loss of signal threshold selections for a selected protocol.
Tx Rate	Specify if the transmit rate is full speed or 1/2 of the Transmit Data Rate (above).
Tx Line Rate	Shows the transmit line rate based on the Tx Max Data Rate and the Tx Rate (above).
Tx FPGA Bus Width	Select the desired transmit bus width.
Tx FPGA Bus Freq	Shows the receive bus frequency based on the Tx Max Data Rate and the Tx Bus Width (above).
Tx Low Data Rate Path	Select if the channel is to be low-speed.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.

Table 229: PCS Dialog Box for ECP5UM—Instance Setup Tab (Continued)

Feature	Description
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 230: PCS Dialog Box for ECP5UM—SerDes Setup Tab

Feature	Description
I/O Standard	Select a SerDes standard.
Differential Amplitude	Select an amplitude level.
Output Termination	Select the amount of resistance for the termination.
De-emphasis Pre-cursor Select	Select a value or disable it.
De-emphasis Post-cursor Select	Select a value or disable it.
Input Termination	Select the amount of resistance for the termination.
AC/DC Couple	Choose either AC or DC coupling.
Linear Equalizer	Select a value or disable it.
Loss of Signal Threshold Select	Select a loss-of-signal threshold.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 231: PCS Dialog Box for ECP5UM—PCS Setup Tab

Feature	Description
Invert Tx Data Polarity	Choose whether to invert the signal. When enabled, the P data goes on the N output and the N data goes on the P output.
Enable 8B10B Encoder	Choose whether to use the 8b10b encoder.
FPGA Bridge Tx FIFO	Specify if you want a FIFO bridge.
Invert Rx Data Polarity	Choose whether to invert the signal. When enabled, the P data is expected on the N input and the N data is expected on the P input.
Enable 8B10B Decoder	Choose whether to use the 8b10b decoder.
FPGA Bridge Rx FIFO	Specify if you want a FIFO bridge.
Enable External Link State Machine	Adds External Link State Machine ports to control the word aligner.
Word Alignment (WA) Mode	Select a word alignment mode.

Table 231: PCS Dialog Box for ECP5UM—PCS Setup Tab (Continued)

Feature	Description
Specific Comma	Choose from K28P5 and K28P157. The fields below show the resulting comma A, B, and mask characters.
Comma A, B, Mask Char	Shows the comma A, B, and mask characters depending on the specific comma selected above.
Enable CTC FIFO	Select to include a CTC (clock tolerance compensation) block.
Match Pattern	Choose a CTC match pattern.
Byte N	Specify the10-bit CC register value. If K is selected, the two prefix bits (MSB) are 01. If K is cleared, the prefix bits are 00. Specify the remaining eight bits in the text box.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 232: PCS Dialog Box for ECP5UM—Control Setup Tab

Feature	Description
Loopback Mode	Choose a loopback mode.
Dynamic Rate Control Interface	Choose whether or not to enable the dynamic rate control interface.
Receive Loss-of-Signal Port	Choose whether or not to enable the receive loss-of-signal port.
CDR LOL Action	Choose the kind of recalibration following a loss-of-lock: none, simple, or full.
Select Reset Sequence	Select to include a reset sequence. Then enable the Tx Ready Port, Rx Ready Port, or both, and specify the wait times.
Import	1. If you are testing the serdes with Reveal Analyzer, click **Import**. This opens the Import Reveal SERDES Analyzer Setting dialog box. 2. Click the **...** button. 3. In the Open dialog box, browse to the .srv file. 4. Click **Open**. 5. Specify the DCU and channel. 6. Click **OK**.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 233: PCS Dialog Box for ECP5UM—Advanced Setup Tab

Feature	Description
SCI Port Enable	Select to add a SerDes Client Interface (SCI) to help with debugging SerDes.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

PCS Options (LatticeECP2M)

The dialog box has several tabs:

- Quad, see below
- Reference Clocks, see Table 235 on page 1560

  This tab is enabled if Quad-Based Protocol Mode is selected in the Quad tab.
- Reference Clocks (CM), see Table 236 on page 1561

  This tab is enabled if Channel-Based Protocol Mode is selected in the Quad tab.
- SerDes Advanced, see Table 237 on page 1561
- PCS Advanced, see Table 238 on page 1562
- Optional Port, see Table 239 on page 1563
- Generation, see Table 240 on page 1564

Table 234: PCS Dialog Box for LatticeECP2M—Quad Tab

Feature	Description
Protocol Setup	**Quad Based Protocol Mode** - Selecting this option enables the Reference Clocks tab. **Channel Based Protocol Mode** - Selecting this option enables the Reference Clocks (CM) tab. **Quad Protocol Mode** - Drop-down menu allows you to select protocol.
Channel Selection and Grouping	Controls group mode selection for Channel0, Channel1, Channel2 and Channel3. The supported group modes are: Single, MCA Group1, MCA Group2, and Disable. MCA Group 1 and 2 are only available in the Quad Based Protocol Mode and depending on the Quad Protocol Mode chosen. Setting the channel rate is only available in the Channel Based Protocol Mode.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 235: PCS Dialog Box for LatticeECP2M—Reference Clocks Tab

Feature	Description
Tx Reference Clock Source Selection	Use REFCLK for external clock source. Use CORE_TXREFCLK for internal clock source.
Rx Reference Clock Source Selection	Use REFCLK for external clock source. Use CORE_RXREFCLK for internal clock source.
Serial Bit Clock Rate	Required serial bit clock rate for application (in GHz).
Reference Clock Multiplier	Allowed PCS reference clock multiplier values for given serial bit clock rate.
Calculated Reference Clock Rate	Resulting input reference clock required for the supplied serial bit rate given the selected reference clock multiplier (in MHz). The value is calculated automatically based on the Serial Bit Clock Rate and the Reference Clock Multiplier (above).
FPGA Interface Data Bus Width	Allowed bus width selections for the selected PCS Quad protocol (single or double bus width).
Calculated FPGA Interface Clock Rate	Resulting FPGA interface clock required for the supplied serial bit rate given the selected FPGA interface data bus width. The value is calculated automatically based on the Serial Bit Clock Rate and the FPGA Interface Data Bus Width (above).
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 236: PCS Dialog Box for LatticeECP2M—Reference Clocks (CM) Tab

Feature	Description
Tx Reference Clock Source Selection	Use REFCLK for external clock source. Use CORE_TXREFCLK for internal clock source.
Rx Reference Clock Source Selection	Selections available for Channel0, Channel1, Channel2, and Channel3. Use REFCLK for external clock source. Use CORE_RXREFCLK for internal clock source.
Serial Bit Clock Rate	Required serial bit clock rate for application (in GHz). Specify the Full Rate Channel. The Half Rate Channel is calculated automatically.
Reference Clock Multiplier	Allowed PCS reference clock multiplier values for given serial bit clock rate. The Half Rate Channel is always the same as the Full Rate Channel.
Calculated Reference Clock Rate	Resulting input reference clock required for the supplied serial bit rate given the selected reference clock multiplier (in MHz). The value is calculated automatically based on the Serial Bit Clock Rate and the Reference Clock Multiplier (above).
FPGA Interface Data Bus Width	Allowed bus width selections for the selected PCS Quad protocol (single or double bus width). Specify the Full Rate Channel and the Half Rate Channel. They can have different values.
Calculated FPGA Interface Clock Rate	Resulting FPGA interface clock required for the supplied serial bit rate given the selected FPGA interface data bus width. The value is calculated automatically based on the Serial Bit Clock Rate and the FPGA Interface Data Bus Width (above).
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 237: PCS Dialog Box for LatticeECP2M—SerDes Advanced Tab

Feature	Description
Differential Output Voltage	Allowed differential output voltage selections for a selected protocol. This is a channel-level transmit setting.
PreEmphasis	Allowed pre-emphasis selections for a selected protocol. This is a channel-level transmit setting.
TX I/O Termination(Ohms)	Allowed transmit I/O termination selections for a selected protocol. This is a channel-level transmit setting.
Equalization	Allowed equalization selections for a selected protocol. This is a channel-level receive setting.
RX I/O Termination(Ohms)	Allowed receive I/O termination selections for a selected protocol. This is a channel-level receive setting.
RX I/O Coupling	Allowed receive I/O coupling selections for a selected protocol. This is a channel-level receive setting.
Loss of Signal Threshold	Allowed loss of signal threshold selections for a selected protocol. This is a quad-level receive setting.

Table 237: PCS Dialog Box for LatticeECP2M—SerDes Advanced Tab (Continued)

Feature	Description
TX PLL Reference Clock IO Termination(Ohms)	Allowed transmit PLL reference clock I/O termination selections for a selected protocol. This is a quad-level setting.
TX Reference Clock IO Coupling	Allowed transmit PLL reference clock I/O coupling selections for a selected protocol. This is a quad-level setting.
PLL Loss of Lock	Allowed PLL loss of lock selections for a selected protocol. This is a quad-level setting.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 238: PCS Dialog Box for LatticeECP2M—PCS Advanced Tab

Feature	Description
Rx_Tx 8B10B Mode	This setting is for 8B/10B decoder bypass control and is set automatically depending on the Quad Protocol Mode set in the Quad tab. In NORMAL mode the 8B/10B decoder is not bypassed and in BYPASS mode the 8B/10B decoder will be bypassed. This is a channel level setting.
TxInvert	This setting is for controlling the inversion of transmit data. In NORMAL mode, data is not inverted. In INV mode, data is inverted. This is a channel level setting.
RxInvert	This setting is for controlling the inversion of receive data. In NORMAL mode, data is not inverted. In INV mode, data is inverted. This is a channel level setting.
Plus Comma Value	Set the positive disparity 10-bit code. This value is shown as LSb:MSb (that is, with the least significant bit to the left and the most significant bit to the right). For a selected protocol the default value will be populated. This is a quad level receive setting.
Minus Comma Value	Set the negative disparity 10-bit code. This value is shown as LSb:MSb (that is, with the least significant bit to the left and the most significant bit to the right). For a selected protocol the default value will be populated. This is a quad level receive setting.
Comma Mask	Set the10-bit comma mask value. This value is shown as LSb:MSb (that is, with the least significant bit to the left and the most significant bit to the right). For a selected protocol the default value will be populated. This is a quad level receive setting.
Comma Align	Allowed comma align selections for a selected protocol. This is a quad level receive setting.
CTC	Allowed CTC (clock tolerance compensation) selections for a selected protocol. This is a channel level receive setting.
CC_MATCH	Set the10-bit CC1, CC2, CC3, or CC4 register value. This value is shown as MSb:LSb (that is, with the most significant bit to the left and the least significant bit to the right). For a selected protocol the default value will be will populated. This is a quad level receive setting.

Table 238: PCS Dialog Box for LatticeECP2M—PCS Advanced Tab (Continued)

Feature	Description
CC_MATCH_MODE	Allowed cc match mode selections for a selected protocol. This is a quad level receive setting.
RX CTC Min IPG	Allowed CTC IPG (Inter-Packet Gap) selections for a selected protocol. This is a quad level receive setting.
High Watermark	Allowed high watermark setting on the CTC FIFO (Rx Elastic Buffer) selections for a selected protocol. This is a quad level receive setting.
Low Watermark	Allowed low watermark setting on the CTC FIFO (Rx Elastic Buffer) selections for a selected protocol. This is a quad level receive setting.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 239: PCS Dialog Box for LatticeECP2M—Optional Port Tab

Feature	Description
Dynamic Inversion of Received Data	This setting controls the inclusion of Dynamic Inversion of Received Data ports in the wrapper top-level port list. Select this option to include these ports. **Note:** This setting is different from the “Rx Invert” setting in the PCS Advanced Tab.
External Link State Machine	Adds External Link State Machine ports in the wrapper top-level port list.
Transmitter Electrical Idle	This setting controls the inclusion of Transmitter Electrical Idle ports in the wrapper top-level port list. Select this option to include these ports. Available only when the Quad Protocol Mode is Generic 8B10B.
Loopback Mode (Rx to Tx)	This setting controls Loopback options for selection.
Serial Loopback (Rx Equalization to Tx, No Clock)	This setting controls Serial Loopback selection.
SerDes Parallel Loopback	The channel-specific SerDes Parallel Loopback will be included in the wrapper top-level port list.
PCS Parallel Loopback	The channel-specific PCS Parallel Loopback will be included in the wrapper top-level port list.
Reference Clock to FPGA Core	The Reference Clock to FPGA Core Port will be included in the wrapper top-level port list.
PLL Quarter Clock	The PLL Quarter Clock Port will be included in the wrapper top-level port list.
SCI (SerDes Client Interface)	The SCI Ports will be included in the wrapper top-level port list.
SCI Interrupt	The SCI Interrupt Port will be included in the wrapper top-level port list.
Error Status	The Error Status Ports will be included in the wrapper top-level port list.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.

Table 239: PCS Dialog Box for LatticeECP2M—Optional Port Tab (Continued)

Feature	Description
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 240: PCS Dialog Box for LatticeECP2M—Generation Tab

Feature	Description
Automatic	Automatically generates the HDL and attributes (.txt) files as needed. Some changes do not require regenerating both files. **Force Place & Route Process Reset** - Select to reset the Place & Route Design process. **Force Place & Route Trace Process Reset** - Select to reset the Place & Route Trace process.
Force Module and Settings Generation	Generates both the HDL and attributes files.
Force Settings Generation Only (error if module generation is required)	Generates only the attributes file. You get an error message if the HDL file also needs to be generated. **Force Place & Route Process Reset** - Select to reset the Place & Route Design process. **Force Place & Route Trace Process Reset** - Select to reset the Place & Route Trace process.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

PCS Options (LatticeECP3)

The dialog box has several tabs:

- Quad, see below
- Reference Clocks, see Table 242 on page 1566

- SerDes Advanced, see Table 243 on page 1567
- PCS Advanced1, see Table 244 on page 1567
- PCS Advanced2, see Table 245 on page 1568
- Control Setup, see Table 246 on page 1569
- Generation Options, see Table 247 on page 1569

Table 241: PCS Dialog Box for LatticeECP3—Quad Tab

Feature	Description
RX and TX, RX only, TX only, Disable Channel	Specify if the channel is to both receive (RX) and transmit (TX), receive only, transmit only, or be disabled.
Protocol	Specify the channel's communication protocol.
Low Speed Data Ports	Specify if the channel is to be low-speed.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 242: PCS Dialog Box for LatticeECP3—Reference Clocks Tab

Feature	Description
Transmit	**Max Data Rate** - Specify the transmit data rate for all channels in Gbps. The range is 0.25 - 3.2. **Tx Refclk Source** - Specify if the transmit reference clock is internal or external to the FPGA. **Tx/Rx Multiplier** - Select a multiplier for the transmit reference clock rate (see next item) and the receive reference clock rate (see the Receive row following). **Tx Reference Clock Rate** - Shows the required input reference clock rate. The rate is the Transmit Data Rate divided by the Tx/Rx Multiplier. In most cases, you can use the calculated value. **Protocol** - Shows the receive/transmit choices made in the Quad tab. **Tx Rate** - Specify if the transmit rate for this channel is full speed, or 1/2 or 1/11 of the Transmit Data Rate (above). **FPGA Bus Width** - Specify the width of the parallel bus to be transmitted on this channel. **FPGA Interface Clock** - Shows the required FPGA interface clock rate. The rate depends on the Transmit Data Rate and the transmit FPGA Bus Width of the channel.
Receive	**Max Data Rate** - Specify the receive data rate in Gbps. The range is 0.25 - 3.2. **Protocol** - Shows the receive/transmit choices made in the Quad tab. **Reference Clock Source** - Specify if the receive reference clock for this channel is internal or external to the FPGA. **Multiplier** - Shows the multiplier for the Rx reference clock rate (see below). The multiplier is selected in Tx/Rx Multiplier (see the Transmit row above). **Rx Rate** - Specify if the receive rate for this channel is full speed, or 1/2 or 1/11 of the Transmit Data Rate (above). **Rx Reference Clock Rate** - Shows the required input reference clock rate. The rate is the same as Tx Reference Clock Rate, which is the Transmit Data Rate divided by the Tx/Rx Multiplier (see the Transmit row above). **FPGA Bus Width** - Specify the width of the parallel bus to be transmitted from this channel. **FPGA Interface Clock** - Shows the required FPGA interface clock rate. The rate depends on the Transmit Data Rate (see the Transmit row above) and the receive FPGA Bus Width of the channel.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 243: PCS Dialog Box for LatticeECP3—SerDes Advanced Tab

Feature	Description
Transmit Settings	**Differential Output Voltage** - Select the differential output voltage for this channel. **PreEmphasis** - Select the pre-emphasis setting for this channel. **TX I/O Termination (Ohms)** - Select the transmit I/O termination for this channel.
Receive Settings	**Equalization Setting** - Select the equalization setting for this channel. **RX I/O Termination (Ohms)** - Select the receive I/O termination for this channel. **RX I/O Coupling** - Select the receive I/O coupling for this channel. **Loss of Signal Threshold Setting** - Select the loss of signal threshold for this channel.
Clock and PLL Settings	**Reference Clock IO Termination (Ohms)** - Allowed transmit PLL reference clock I/O termination selections for a selected protocol. **Reference Clock IO Coupling** - Allowed transmit PLL reference clock I/O coupling selections for a selected protocol. **TX PLL Loss of Lock** - Allowed PLL loss of lock selections for a selected protocol.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 244: PCS Dialog Box for LatticeECP3—PCS Advanced1 Tab

Feature	Description
Transmit Settings	**Invert the Transmit Signal** - Choose whether to invert the signal. When enabled, the P data goes on the N output and the N data goes on the P output. **Enable 8B10B Encoder** - Choose whether to use the 8b10b encoder. **FPGA FIFO Bridge** - Specify if you want a FIFO bridge on this channel.
Receive Settings	**Invert the Receive Signal** - Choose whether to invert the signal. When enabled, the P data is expected on the N input and the N data is expected on the P input. **Dynamically Invert Port** - Specify whether to dynamically invert the receive signal. When enabled, a ffc_sb_inv_rx_ch port is added to control inverting this channel. **Enable 8B10B Decoder** - This setting is for 8b10b decoder bypass control. In NORMAL mode the 8b10b decoder is not bypassed and in BYPASS mode the 8b10b decoder will be bypassed. **FPGA FIFO Bridge** - Specify if you want a FIFO bridge on this channel.

Table 244: PCS Dialog Box for LatticeECP3—PCS Advanced1 Tab (Continued)

Feature	Description
Word Alignment	**Word Alignment Block** - Choose whether to use the word alignment block. **Internal Link State Machine** - Choose whether to use the internal link state machine. **Specific Comma** - Choose from User Defined, 1111111111 (K28.5), 1111111100 (K28.157), and DISABLED. Choose User Defined to specify the plus and minus comma value, and the comma mask (following) for this channel. **Plus Comma Value** - Specify the positive disparity 10-bit code for this channel. **Minus Comma Value** - Specify the negative disparity 10-bit code for this channel. **Comma Mask** - Specify the10-bit comma mask for this channel.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 245: PCS Dialog Box for LatticeECP3—PCS Advanced2 Tab

Feature	Description
CTC block	Choose whether to include a CTC (clock tolerance compensation) block for this channel. CTC blocks are not available with LatticeECP3-150TW.
Size of the ordered set to match (Bytes)	Choose the number of bytes to match for this channel: 1, 2, or 4.
ByteN(Hex)	Specify the10-bit CC register value for this channel. If K is selected, the two prefix bits (MSB) are 01. If K is cleared, the prefix bits are 00. Specify the remaining eight bits in the text box.
Inter packet gap to enforce	Choose the minimum inter-packet gap for this channel. The minimum number of bytes after a deletion is this value plus one times the size of the ordered set (above). For example, if you choose 3 for the gap and 2 for the ordered set, the minimum gap is (3 + 1) x 2 = 8 bytes.
Deletion Threshold	Specify the point in the FIFO at which CTC block deletes an ordered set. The deletion threshold must be larger than the insertion threshold.
Insertion Threshold	Specify the point in the FIFO at which CTC block inserts an ordered set.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 246: PCS Dialog Box for LatticeECP3—Control Setup Tab

Feature	Description
Loopback Selection	Select the desired mode for each enabled channel: ▶ Disabled ▶ Loopback serial data after equalizer ▶ Loopback serial data after transmit driver ▶ Loopback parallel data after de-serializer
Transmitter Electrical Idle	This setting controls the inclusion of Transmitter Electrical Idle ports in the wrapper top-level port list. If the check box is enabled the ports will be included in the wrapper top-level port list.
Reset Sequence Generation	The PCS module for LatticeECP3 requires a reset sequence after system reset and when a receiver is reconnected. Select **Include Reset Sequence Generation** to add logic that produces the reset sequence. Highly recommended. **Note:** If you are upgrading a PCS module for an existing design and the design provides separate logic for the reset sequence, clear **Include Reset Sequence Generation**. The regenerated module will still work with the separate reset sequence logic.
Provide SerDes Client Interface (SCI)	Select to include the SerDes Client Interface (SCI).
Provide the SerDes Client Interface (SCI) Interrupt Port	Select to include the SCI Interrupt Port.
Reference Clock to FPGA Core	Select to include the refclk2fpga output.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 247: PCS Dialog Box for LatticeECP3—Generation Options Tab

Feature	Description
Automatic (Generate Module and Settings as needed)	Automatically generates the HDL and attributes (.txt) files as needed. Some changes do not require regenerating both files. **Force Place & Route Process Reset** - Select to reset the Place & Route Design process. **Force Place & Route Trace Process Reset** - Select to reset the Place & Route Trace process.
Force Module and Settings Generation	Generates both the HDL and attributes files.

Table 247: PCS Dialog Box for LatticeECP3—Generation Options Tab (Continued)

Feature	Description
Force Settings Generation Only (error if module generation required)	Generates only the attributes file. You get an error message if the HDL file also needs to be generated. **Force Place & Route Process Reset** - Select to reset the Place & Route Design process. **Force Place & Route Trace Process Reset** - Select to reset the Place & Route Trace process.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

PCS Options (LatticeSC/M)

The dialog box has several tabs:

- PCS, see below
- Setup, see Table 249 on page 1571
- Multi-Channel Alignment, see Table 250 on page 1571

  Available only when one of the Align Channels options is selected in the PCS tab.

Table 248: PCS Dialog Box for LatticeSC/M—PCS Tab

Feature	Description
Quad Mode	PCS protocol selection for one PCS quad (all four channels).
Channel 0, 1, 2, 3 Enabled	Select which channels to enable. In the autoconfig file, any channel that is enabled will be powered up. Channels can later be powered down using the run time memory map.
Align Channels	Select a static multi-channel alignment mode. This alignment mode can be later changed using the run time memory map. Go to the Multi-Channel Alignment tab to set options including multi-quad alignment.
Optional Direct Control & Status Register Access	Include control and status pins on the PCS block interface.

Table 248: PCS Dialog Box for LatticeSC/M—PCS Tab (Continued)

Feature	Description
Optional System Bus Interface	Include System BUS Interface pins on the PCS block interface. Required if System bus control of the PCS is desired.
Use internal 10G (XAUI) Link State Machine	Uses a 10G (XAUI) link state machine to control the word aligner. Available only with the Generic 8b10b Quad Mode.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 249: PCS Dialog Box for LatticeSC/M—Setup Tab

Feature	Description
Reference Clock Source Selection	Select the source of the reference clock for the Tx and Rx clocks to the SERDES. If “All Reference Clocks” is selected, set the autoconfig file to the correct default for reference clock selection in quad register 0x29. The default value written in the autoconfig file is 0x00, which is the external reference clock.
Serial Bit Clock Rate (GHz)	Required serial bit clock rate for the application (in GHz).
Reference Clock Multiplier	Multiplier for the reference clock to reach the serial bit clock rate.
Calculated Reference Clock Rate (MHz)	Required input reference clock rate (in MHz) given the serial bit clock rate and the reference clock multiplier set above.
FPGA Interface Data Bus Width	Width of the data buses for each channel (single or double bus width).
FPGA Interface Clock Rate (MHz)	Required FPGA interface clock and data bus rate given the serial bit clock rate and interface data bus width set above.
Amplitude Boost	Provides an additional 100-150 mV differential amplitude for a 20% power increase.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 250: PCS Dialog Box for LatticeSC/M—Multi-Channel Alignment Tab

Feature	Description
Multi-channel Alignment Settings	Select the channel alignment character. If only one alignment word is needed, set “A” and “B” to the same value.
Enable Multi-Quad Alignment	Select Multi-Quad Alignment. Available if “Optional Direct Control & Status Register Access,” in the PCS tab, has been selected for two or more PCS Quads.

Table 250: PCS Dialog Box for LatticeSC/M—Multi-Channel Alignment Tab (Continued)

Feature	Description
Select Multi-Quad Alignment Group	Select one of four Multi-Quad Alignment input clocks (Group 0, Group 1, Group 2, or Group 3) for all quads that require Multi-Quad alignment. All Quads to be aligned to each other must use the same Multi-Quad Alignment input clock.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

PLL

A phase-locked loop (PLL) that provides a variety of sysCLOCK PLL implementations. Ports, properties, and functionality are described in detail in the technical notes listed in the “See Also” section below.

Frequency preferences on the output clocks are generated automatically. After generating the PLL module, you can modify the FREQUENCY preference with keywords such as PAR_ADJ and HOLD_MARGIN. See FREQUENCY.

The options vary with the device family. See:

- “PLL Options (ECP5)” on page 1573
- “PLL Options (LatticeECP/EC, LatticeXP, MachXO)” on page 1576

PLL Options (ECP5)

The module dialog box has three tabs:

- Frequency, see below
- Phase, see Table 252 on page 1575
- Optional Ports, see Table 253 on page 1575

Output frequencies depend on the input frequency, the desired output frequencies, and the tolerances. To see what the actual output frequencies will be, set the options and then click **Calculate**. If the results are not satisfactory, adjust the values and recalculate before generating the module.

After setting up the Frequency tab, go to the other tabs to specify phase shifts for the output clocks and optional ports such as for dynamic phase shift, clock enable, and PLL reset.

Table 251: PLL Dialog Box for ECP5—Frequency Tab

Feature	Description
CLKI	**Frequency** – CLKI is the input reference clock for the PLL. Specify its frequency in megahertz. **Refclk Divider** – After clicking Calculate, this shows the divider value used to achieve the desired output frequency. **Enable High Bandwidth** – Select to have a higher PLL bandwidth. After clicking Calculate, the bandwidth is shown in the Info box. **PLL Reference Clock from Pin** – Select to get the reference clock directly from one of the FPGA's pins. Then choose the pin's buffer type.
CLKFB	**Feedback Mode** – Specify the feedback clock source. Choices are internal and external CLKOP, CLKOS, CLKOS2, CLKOS3, and external user clock. To use CLKOS, CLKOS2, or CLKOS3, select the clock's **Enable** option and clear the **Bypass** option. Then choose the feedback mode. If you select Bypass for CLKOP, the CLKOP, INT_OP, and UserClock options are disabled. **Feedback Divider** – The divider in the feedback path is shown after clicking Calculate.
Info	These values are shown after filling in the other fields and clicking Calculate.
CLKOP, CLKOS, CLKOS2, CLKOS3	The PLL can produce up to four different clock signals. Select **Enable** for the clocks you want to use (CLKOP is always enabled). Then use the following options to specify the form of the clocks. **Enable** – Select to add the clock to the module. CLKOP is the standard output and is always enabled. **Bypass** – The bypass option connects the output to the input, bypassing the PLL circuit. **Output Divider** – Shows the calculated divider to produce the actual frequency. **Desired Frequency** – Specify the desired output clock frequency. **Tolerance %** – Specify a tolerance for the frequency as a percentage of the requested frequency. Since the dividers can only take a certain set of values, not all frequencies can be generated. The tolerance value is used to guide the tool to select a suitable divider value. **Actual Frequency** – The actual frequency that the PLL will produce is after clicking Calculate.
Calculate	Software calculates divider settings and actual output frequencies based on CLKI and desired frequencies.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 252: PLL Dialog Box for ECP5—Phase Tab

Feature	Description
Desired Phase	Specify the desired phase shift in degrees.This option is available if the clock is enabled but the Bypass option has not been selected and the clock has not been selected in Feedback Mode.
Actual Phase	Shows the actual phase shift after clicking Calculate. Not all phase shifts are possible.
Calculate	After entering the desired phase shifts, click **Calculate** to see what actual phase shift will be implemented.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 253: PLL Dialog Box for ECP5—Optional Ports Tab

Feature	Description
Enable Clock Select	Adds a second input clock port, CLKI2, and a select port.
Dynamic Phase Ports	Adds phase controls.
Clock Enable OP, OS, OS2, OS3	Adds an enable input port for each selected clock. This option is available if the clock is enabled but the Bypass option has not been selected and the clock has not been selected in Feedback Mode. The PHASESEL port selects a clock with the following code: CLKOP: 11 CLKOS: 00 CLKOS2: 01 CLKOS3: 10
Provide Standby Port	Adds a STDBY port to power down the PLL.
Provide PLL Reset	Adds a port to reset the PLL.
Provide PLL Lock Signal	Adds an active-high output signal that indicates PLL lock. Select **PLL Lock is Sticky** to make the lock signal sticky.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

PLL Options (LatticeECP/EC, LatticeXP, MachXO)

Output frequencies depend on the input frequency and the divider values. To see what the actual output frequencies will be, set the options and then click **Calculate**. If the results are not satisfactory, adjust the values and recalculate before generating the module.

Table 254: PLL Dialog Box for LatticeEC, LatticeECP, LatticeXP, and MachXO

Feature	Description
Frequency Mode	Default mode. When input and clock frequencies are entered in this mode, divider settings are automatically calculated.
Divider Mode	Advanced mode. This mode is for advanced users. Enter input clock frequency and divider values to achieve expected output frequency.
CLKI	CLKI is the input reference clock for the PLL. Specify its frequency in MHz. If in Divider mode, also choose a divider value to achieve the desired output frequency.
CLKOP	**Divider** – In the Frequency mode, divider values cannot be selected. Clicking the “Calculate” button displays the actual values used by the generated module. In the Divider mode, the user can select the CLKOP divider from the drop-down. The listed divider values are not limited when the other clock outputs are enabled. **Desired Frequency** – In the Frequency mode, specify the output clock (CLKOP) frequency. **Tolerance** – Specify a tolerance for the CLKOP frequency, as a percentage of requested frequency. Since the dividers can only take a certain set of values, not all frequencies can be generated. The tolerance value is used to guide the tool to select a suitable divider value. **Actual Frequency** – Clicking the “Calculate” button displays the actual frequency used by the generated module.
CLKFB	**Feedback Mode** – Specify the feedback mode to be internal feedback, CLKOP/CLKOS feedback (to compensate the output clock), or an external user clock. **Divider** – In the divider mode, the divider in the feedback path can be selected from the drop-down list. In the Frequency mode, clicking the “Calculate” button displays the divider value.
CLKOS	**Enable CLKOS** – Selecting this option will produce the CLKOS port in the generated module. This clock has the same frequency as CLKOP and it has the specified phase relation with CLKOP. **PhaseADJ (degree)** – Select the phase difference between CLKOP and CLKOS. **Duty Cycle (*1/8)** – Specify a duty cycle of CLKOS in terms of 1/8th of the period. The legal values are 1 – 7.
Delay Adjust	**Dynamic Delay Control** – Specify if Dynamic delay control is required for the PLL. Selecting this option will generate input ports to control the delay.

Table 254: PLL Dialog Box for LatticeEC, LatticeECP, LatticeXP, and MachXO (Continued)

Feature	Description
CLKOK	**Enable CLKOK** – Selecting this option will produce the CLKOK port in the generated module. This clock is a slower clock than CLKOP. In the Frequency mode, select the desired frequency. In the Divider mode, select the divider value for the desired frequency. **Divider** – In the Frequency mode, divider values cannot be selected. Clicking the "Calculate" button displays the actual values used by the generated module. In the Divider mode, the user can select the CLKOK divider from the drop-down. The listed divider values are not limited when the other clock outputs are enabled. **Desired Frequency** – In the Frequency mode, specify the CLKOK frequency. This is disabled in the divider mode. **Tolerance** – Specify a tolerance for the CLKOK frequency, as a percentage of requested frequency. Since the dividers can only take a certain set of values, not all frequencies can be generated. The tolerance value is used to guide the tool to select a suitable divider value. **Actual Frequency** – Clicking the "Calculate" button displays the actual frequency that the PLL can produce.
Calculate	**Frequency Mode**: Software calculates Divider settings based on input/output frequency. **Divider Mode**: Software calculates output frequencies based on divider values.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

PLL Options (LatticeECP2/M)

Output frequencies depend on the input frequency and the divider values. To see what the actual output frequencies will be, set the options and then click **Calculate**. If the results are not satisfactory, adjust the values and recalculate before generating the module.

Table 255: PLL Dialog Box for LatticeECP2 and LatticeECP2M

Feature	Description
Frequency Mode	**Default mode** – When input and clock frequencies are entered in this mode, divider settings are automatically calculated.
Divider Mode	**Advanced mode** – This mode is for advanced users. Enter input clock frequency and divider values to achieve expected output frequency.
CLKI	CLKI is the input reference clock for the PLL. Specify its frequency in MHz. If in Divider mode, also choose a divider value to achieve the desired output frequency.
CLKFB	**Feedback Mode** – Specify the feedback mode to be internal feedback, CLKOP feedback (to compensate the output clock), or an external user clock. **Divider** – In the divider mode, select the divider in the feedback path from the drop-down list. In the frequency mode, the divider value is shown when the “Calculate” button is clicked.
PLL Phase & Duty Options	Allows you to select **Static Mode** or **Dynamic Mode**.
Delay Adjust	Specify if you need dynamic, static, or no delay. If no delay, also specify whether the PLL should go on a GPLL or SPLL site. This choice, in combination with the CLKI setting (above), may require an external capacitor (see External Capacitor Pin following). Check the PAR report for the PLL placement and external capacitor requirement information. ▶ GPLL (Dynamic Delay): Select this option if you require dynamic fine delay adjustment. This configuration will be placed on a GPLL site using an EHXPLLD primitive. ▶ GPLL (Static Delay): Select this option if you require static fine delay adjustment. This configuration will be placed on a GPLL site using an EHXPLLD primitive. ▶ GPLL (No Delay): Select this option if you do not require fine delay adjustment and want the PLL to be placed on a GPLL. This configuration will be placed on a GPLL site using an EHXPLLD primitive. ▶ SPLL (No Delay): Select this option if you do not require fine delay adjustment and want the PLL to be placed on an SPLL. This configuration will be placed on an SPLL site using an EPLLD primitive. ▶ SPLL or GPLL (No Delay): Select this option if you do not require fine delay adjustment. This configuration can be placed on either an SPLL or a GPLL site using an EPLLD primitive.
External Capacitor Pin	The need for an external capacitor is decided automatically depending on the Delay Adjust and CLKI settings (above).

Table 255: PLL Dialog Box for LatticeECP2 and LatticeECP2M (Continued)

Feature	Description
CLKOP	**Bypass (CLKOP=CLKI)** – The bypass option will connect the output to the input, bypassing the PLL circuit. Bypassing CLKOP disables its frequency and tolerance and removes it as a feedback mode option. If both CLKOP and CLKOS are in BYPASS, everything is disabled except the CLKI frequency option. **Divider** – In the Frequency mode, divider values cannot be selected. Clicking the "Calculate" button displays the actual values used by the generated module. In the Divider mode, the user can select the CLKOP divider from the drop-down. The listed divider values are not limited when the other clock outputs are enabled. **Desired Frequency** – In the Frequency mode, specify the output clock (CLKOP) frequency. **Tolerance** – Specify a tolerance for the CLKOP frequency, as a percentage of requested frequency. Since the dividers can only take a certain set of values, not all frequencies can be generated. The tolerance value is used to guide the tool to select a suitable divider value. **Actual Frequency** – Clicking the "Calculate" button displays the actual frequency that the PLL can produce.
CLKOS	**Enable CLKOS** – Selecting this option will produce the CLKOS port in the generated module and allow you to select Phase and Duty Options. This clock has the same frequency as CLKOP and it has the specified phase relation with CLKOP. **Bypass (CLKOS=CLKI)** – The bypass option will connect the output to the input, bypassing the PLL circuit. Bypassing CLKOS disables its frequency, tolerance, and phase shift and removes it as a feedback option. CLKOS's frequency automatically matches CLKOP's frequency. If both CLKOP and CLKOS are in BYPASS, then everything is disabled except the CLKI frequency option. **Phase & Duty Options (Static Mode)** ▶ **Phase Shift (degree)** – Allows phase shift selection in 22.5-degree increments from 0 to 360. ▶ **Duty Cycle (*1/16)** – Allows duty cycle selection in 1/16 increments. **Phase & Duty Options (Dynamic Mode)** See TN1103, "LatticeECP2/M sysCLOCK PLL/DLL Design and Usage Guide." ▶ **Dynamic Phase with 50% Duty** – Implements dynamic phase shift with 50% duty option. ▶ **Dynamic Phase with Dynamic Duty** – Implements dynamic phase shift with dynamic duty option.

Table 255: PLL Dialog Box for LatticeECP2 and LatticeECP2M (Continued)

Feature	Description
CLKOK	**Enable CLKOK** – Selecting this option will produce the CLKOK port in the generated module. This clock is a slower clock than CLKOP. In the Frequency mode, select the desired frequency. In the Divider mode, select the divider value for the desired frequency. **Bypass (CLKOK=CLKI)** – The bypass option will connect the output to the input, bypassing the PLL circuit. **Divider** – In the Frequency mode, divider values cannot be selected. Clicking the "Calculate" button displays the actual values used by the generated module. In the Divider mode, the user can select the CLKOK divider from the drop-down. The listed divider values are not limited when the other clock outputs are enabled. **Desired Frequency** – In the Frequency mode, specify the CLKOK frequency. This is disabled in the Divider mode. **Tolerance** – Specify a tolerance for the CLKOK frequency, as a percentage of requested frequency. Since the dividers can only take a certain set of values, not all frequencies can be generated. The tolerance value is used to guide the tool to select a suitable divider value. **Actual Frequency** – Clicking the "Calculate" button displays the actual frequency that the PLL can produce. **Provide CLKOK Divider Reset** – Specify if CLKOK Divider Reset is required as an input port. Selecting this option and enabling CLKOK generates an RSTK input port.
Provide PLL Reset	Provides a reset pin to reset the PLL.
Calculate	**Frequency Mode** – Software calculates Divider settings based on input/output frequency. **Divider Mode** – Software calculates output frequencies based on divider values.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

PLL Options (LatticeECP3)

Output frequencies depend on the input frequency and the divider values. To see what the actual output frequencies will be, set the options and then click **Calculate**. If the results are not satisfactory, adjust the values and recalculate before generating the module.

Table 256: PLL Dialog Box for LatticeECP3

Feature	Description
Frequency Mode	**Default mode** – In this mode, entering input and clock frequencies will automatically calculate divider settings.
Divider Mode	**Advanced mode** – This mode is for advanced users. Enter input clock frequency and divider values to achieve expected output frequency.
CLKI	CLKI is the input reference clock for the PLL. Specify its frequency in MHz. If in Divider mode, also choose a divider value to achieve the desired output frequency. After clicking Calculate, the approximate bandwidth is calculated and displayed here.
CLKFB	**Feedback Mode** – Specify the feedback mode to be internal feedback, CLKOP feedback (to compensate the output clock), CLKOS, or an external user clock. **Divider** – In Divider mode, the divider in the feedback path can be selected from the drop-down list. In Frequency mode, the divider value is shown when the “Calculate” button is clicked.
PLL Phase & Duty Options	Allows you to select **Static Mode** or **Dynamic Mode**.
Provide PLL Reset	Provides a reset pin to reset the PLL.
Provide FINDELA Port	Specify a dynamic single-step delay adjustment signal for CLKOS.
Enable CLKOK2(CLKOP/3)	Specify a clock that is equal to CLKOP/3.
CLKOP/CLKOS (Non Bypass Mode)	These features are not available when both CLKOP and CLKOS are in Bypass mode (below). **Divider** – In Frequency mode, divider values cannot be selected. Clicking the “Calculate” button displays the actual values used by the generated module. In Divider mode, select the CLKOP divider from the drop-down. The listed divider values are not limited when the other clock outputs are enabled. **Desired Frequency** – In Frequency mode, specify the output clock (CLKOP) frequency. **Tolerance** – Specify a tolerance for the CLKOP frequency, as a percentage of requested frequency. Since the dividers can only take a certain set of values, not all frequencies can be generated. The tolerance value is used to guide the tool to select a suitable divider value. **Actual Frequency** – Clicking the “Calculate” button displays the actual frequency that the PLL can produce.

Table 256: PLL Dialog Box for LatticeECP3 (Continued)

Feature	Description
CLKOP	**Bypass (CLKOP=CLKI)** – The bypass option connects the output to the input, bypassing the PLL circuit. Bypassing CLKOP and CLKOS disables the CLKOP desired frequency and tolerance fields and removes CLKOP as a feedback mode option. If both CLKOP and CLKOS are in BYPASS, then everything is disabled except the CLKI frequency option. **Duty Trim Option (Dynamic Mode)** ▶ **Rising** – This selection applies to the rising edge. ▶ **Falling** – This selection applies to the falling edge. ▶ **Delay Multiplier** – This selection provides delay multiplier for the rising edge or falling edge duty trim option.
CLKOS	**Enable CLKOS** – Selecting this option will produce the CLKOS port in the generated module. This clock has the same frequency as CLKOP and it has the specified phase relation with CLKOP. **Bypass (CLKOS=CLKI)** – The bypass option will connect the output to the input, bypassing the PLL circuit. Bypassing CLKOS disables its frequency, tolerance, and phase shift fields and removes it as a feedback option. CLKOS's frequency automatically matches CLKOP's frequency. **Phase & Duty Options (Static Mode)** ▶ **Phase Shift (degree)** – Allows phase shift selection in 22.5-degree increments from 0 to 360. ▶ **Duty Cycle (*1/16)** – Allows duty cycle selection in 1/16 increments. ▶ **Delay Multiplier** – This selection is the delay multiplier for the rising edge or falling edge. **Phase & Duty Options (Dynamic Mode)** See TN1103, "LatticeECP2/M sysCLOCK PLL/DLL Design and Usage Guide." ▶ **Dynamic Phase with 50% Duty** – Implements dynamic phase shift with 50% duty option. ▶ **Dynamic Phase with Dynamic Duty** – Implements dynamic phase shift with dynamic duty option. **Duty Trim Options (Dynamic Mode)** ▶ **Rising** – This selection applies to the rising edge. ▶ **Falling** – This selection applies to the falling edge. ▶ **Delay Multiplier** – This selection is the delay multiplier for the rising edge or falling edge duty trim option.

Table 256: PLL Dialog Box for LatticeECP3 (Continued)

Feature	Description
CLKOK	**Enable CLKOK** – Selecting this option produces the CLKOK port in the generated module. This clock is a slower clock than CLKOP. In frequency mode, select the desired frequency. In divider mode, select the divider value for the desired frequency. **Bypass (CLKOK=CLKI)** – The bypass option connects the output to the input, bypassing the PLL circuit. **CLKOP as Input/CLKOS as Input** – If CLKOS is enabled (above), you have a choice between using CLKOP or CLKOS as the input for CLKOK. If CLKOS is not enabled, CLKOP is used as the input. **Divider** – In Frequency mode, this divider value cannot be selected. Clicking the "Calculate" button displays the actual values used by the generated module. In Divider mode, select the CLKOK divider from the drop-down list. The listed divider values are not limited when the other clock outputs are enabled. **Desired Frequency** – In Frequency mode, specify the CLKOK Frequency. This is disabled in Divider mode. **Tolerance** – Specify a tolerance for the CLKOK frequency, as a percentage of requested frequency. Since the dividers can only take a certain set of values, not all frequencies can be generated. The tolerance value is used to guide the tool to select a suitable divider value. **Actual Frequency** – Clicking the "Calculate" button displays the actual frequency that the PLL can produce. **Provide CLKOK Divider Reset** – Specify if CLKOK Divider Reset is required as an input port. When this is selected and CLKOK is enabled, an input port RSTK is generated.
Calculate	**Frequency Mode**: Software calculates Divider settings based on input/output frequency. **Divider Mode**: Software calculates output frequencies based on divider values.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

PLL Options (LatticeSC/M)

Output frequencies depend on the input frequency and the divider values. To see what the actual output frequencies will be, set the options and then click **Calculate**. If the results are not satisfactory, adjust the values and recalculate before generating the module.

Table 257: PLL Dialog Box for LatticeSC/M

Feature	Description
CLKI	Specify the frequency of the input clock in MHz. This should be in the range of 2 - 1000 MHz.
CLKFB	**Feedback Mode** – Specify the feedback mode to be internal feedback, CLKOP/ CLKOS feedback (to compensate the output clock), or an external user clock. **Frequency** – If the CLKFB Feedback Mode is set to User Clock, specify the frequency in MHz.
Provide RSTN Port	Specify if a RSTN port is required in the generated PLL. A reset port can shut off the output clock and have undesirable effects on the system.
Provide SMI Ports on PLL Module	Specify if the SMI port that allows runtime reconfiguration of the PLL block using the SMI ports is required in the generated PLL.
Enable High Bandwidth	Use the Enable High Bandwidth option to increase the bandwidth of the PLL and reduce the noise floor of the PLL. The trade-off is that this will cause more jitter peaking of the PLL.
CLKOP	**Bypass (CLKOP=CLKI)** – The bypass option will connect the output to the input, bypassing the PLL circuit. Bypassing CLKOP disables its frequency and tolerance fields and removes it as a feedback mode option. **Desired Frequency** – In the frequency mode, specify the output clock (CLKOP) Frequency. **Tolerance** – Specify a tolerance for the CLKOP frequency, as a percentage of requested frequency. Since the dividers can only take a certain set of values, not all frequencies can be generated. The tolerance value is used to guide the tool to select a suitable divider value. **Actual Frequency** – Specify the desired frequency of the output clock, CLKOP. This can be in the range of 1.5625 MHz to 1 GHz. The tolerance is specified as a percentage of the desired frequency. The actual frequency that the PLL can produce is shown when the “Calculate” button is clicked.

Table 257: PLL Dialog Box for LatticeSC/M (Continued)

Feature	Description
CLKOS	**Bypass (CLKOS=CLKI)** – The bypass option will connect the output to the input, bypassing the PLL circuit. Bypassing CLKOS disables its frequency, tolerance, and phase shift fields, and removes it as a feedback option. If both CLKOP and CLKOS are in BYPASS, then everything is disabled except the CLKI frequency option. **Desired Frequency** – In the Frequency mode, specify the output clock (CLKOP) Frequency. **Tolerance** – Specify a tolerance for the CLKOP frequency, as a percentage of requested frequency. Since the dividers can only take a certain set of value, not all frequencies can be generated. The tolerance value is used to guide the tool to select a suitable divider value. **Actual Frequency** – Specify the desired frequency of the output clock, CLKOP. This can be in the range of 1.5625 MHz to 1 GHz. The tolerance is specified as a percentage of the desired frequency. Clicking the “Calculate” button displays the actual frequency that the PLL can produce. **Phase shift (degree)** – Specify the desired phase shift of the CLKOS output compared to the CLKOP output. The CLKOS output will be delayed this amount from the CLKOP output. Two attributes determine the total phase shift (PHASEADJ and CLKOS_VCODEL). These attributes are based on the VCO rate of the PLL. IPexpress will perform the calculations and set these attributes to correctly produce the specified phase shift on the CLKOS output.
Info	**VCO Rate (MHz)** – The VCO rate in MHz is automatically updated by clicking the Calculate button. **Approximate PLL Bandwidth (MHz)** – The approximate PLL bandwidth in MHz is automatically updated by clicking the Calculate button.
Calculate	The Calculate button updates the actual frequency the PLL will generate. Not all values can be generated, due to a limited set of divider values and other hardware limitations. This also updates the VCO Rate and Approximate PLL Bandwidth boxes.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

PLL Options (LatticeXP2)

Output frequencies depend on the input frequency and the divider values. To see what the actual output frequencies will be, set the options and then click **Calculate**. If the results are not satisfactory, adjust the values and recalculate before generating the module.

Table 258: PLL Dialog Box for LatticeXP2

Feature	Description
Frequency Mode	**Default mode** – In this mode, entering input and clock frequencies automatically calculates the divider settings.
Divider Mode	**Advanced mode** – This mode is for advanced users. Enter input clock frequency and divider values to achieve expected output frequency.
CLKI	CLKI is the input reference clock for the PLL. Specify its frequency in MHz. If in Divider mode, also choose a divider value to achieve the desired output frequency.
CLKFB	**Feedback Mode** – Specify the feedback mode to be internal feedback, CLKOP feedback (to compensate the output clock), or an external user clock. **Divider** – In the Divider mode, you can select the divider in the feedback path from the drop-down list. In the Frequency mode, clicking the “Calculate” button displays the divider values.
PLL Phase & Duty Options	Allows you to select **Static Mode** or **Dynamic Mode**.
Enable CLKOK2(CLKOP/3)	Enables the CLKOK2 PLL output. The frequency of CLKOK2 is one-third the frequency of CLKOP. The CLKOK2 is in phase with CLKOP.
Provide PLL Reset	Provides a reset pin to reset the PLL.
Provide Dynamic Power Down Port	Adds a signal that starts the powerdown routine.
Calculate	**Frequency Mode**: Software calculates Divider settings based on input/output frequency. **Divider Mode**: Software calculates output frequencies based on divider values.
CLKOP	**Bypass (CLKOP=CLKI)** – The bypass option will connect the output to the input, bypassing the PLL circuit. **Divider** – You cannot select divider values in Frequency mode. Clicking the “Calculate” button displays the actual values used by the generated module. In Divider mode, you can select the CLKOP divider from the drop-down menu. **Desired Frequency** – In Frequency mode, specify the output clock frequency. **Tolerance** – Specify a tolerance for the frequency, as a percentage of the requested frequency. Since the dividers can only take a certain set of values, not all frequencies can be generated. The tolerance value is used to guide the tool to select a suitable divider value. **Actual Frequency** – Clicking the “Calculate” button displays the actual frequency that the PLL will produce. **Duty Trim Option (Dynamic Mode)** – Choose a delay multiplier for the rising edge or falling edge duty trim option.

Table 258: PLL Dialog Box for LatticeXP2

Feature	Description
CLKOS	**Enable CLKOS** – Selecting this option will produce the CLKOS port in the generated module. This clock has the same frequency as CLKOP and it has the specified phase relation with CLKOP. **Bypass (CLKOS=CLKI)** – The bypass option will connect the output to the input, bypassing the PLL circuit. **Phase & Duty Options (Static Mode)** ▶ **Phase Shift (degree)** – Allows phase shift selection in 22.5-degree increments from 0 to 360. ▶ **Duty Cycle (*1/16)** – Allows duty cycle selection in 1/16 increments. **Phase & Duty Options (Dynamic Mode)** ▶ **Dynamic Phase Shift with 50% Duty** – Implements dynamic phase shift with 50% duty option. See tech note, “LatticeXP2 sysCLOCK PLL/DLL Design and Usage Guide” for details. ▶ **Dynamic Phase with Dynamic Duty** – Implements dynamic phase shift with dynamic duty option. See tech note, “LatticeXP2 sysCLOCK PLL/DLL Design and Usage Guide” for details. **Duty Trim Options (Dynamic Mode)** ▶ **Rising** – This selection applies to the rising edge. ▶ **Falling** – This selection applies to the falling edge. ▶ **Delay Multiplier** – This selection provides delay multiplier for the rising edge or falling edge duty trim option. **Provide CLKOS Fine Delay** – Adds a signal to add approximately 70 ps of delay.
CLKOK	**Enable CLKOK** – Selecting this option will produce the CLKOK port in the generated module. This clock is a slower clock than CLKOP. In the Frequency mode, select the desired frequency. In the Divider mode, select the divider value for the desired frequency. **Bypass (CLKOK=CLKI)** – The bypass option will connect the output to the input, bypassing the PLL circuit. **Divider** – In the Frequency mode, divider values cannot be selected. Clicking the “Calculate” button displays the actual values used by the generated module. In the Divider mode, the user can select the CLKOK divider from the drop-down. The listed divider values are not limited when the other clock outputs are enabled. **Desired Frequency** – In the Frequency mode, specify the CLKOK Frequency. This is disabled in the Divider mode. **Tolerance** – Specify a tolerance for the CLKOK frequency, as a percentage of requested frequency. Since the dividers can only take a certain set of values, not all frequencies can be generated. The tolerance value is used to guide the tool to select a suitable divider value. **Actual Frequency** – Clicking the “Calculate” button displays the actual frequency that the PLL can produce. **Provide CLKOK Divider Reset** – Specify if CLKOK Divider Reset is required as an input port. Selecting this option and enabling CLKOK generates an RSTK input port.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.

PLL Options (MachXO2, MachXO3L, Platform Manager 2)

Available with MachXO2 with 1200 LUTs or larger, MachXO2-640UHC, MachXO3L, and Platform Manager 2-21.

Output frequencies depend on the input frequency and the divider values. To see what the actual output frequencies will be, set the options and then click **Calculate**. If the results are not satisfactory, adjust the values and recalculate before generating the module.

The Calculate button is just below the CLKOS3 box. If you do not see the Calculate button, scroll down.

Table 259: PLL Dialog Box for MachXO2, MachXO3L, and Platform Manager 2

Feature	Description
Frequency Mode	**Default mode** – In this mode, entering input and clock frequencies automatically calculates Divider settings.
Divider Mode	**Advanced mode** – This mode is for advanced users. Enter input clock frequency and divider values to achieve expected output frequency.
CLKI	CLKI is the input reference clock for the PLL. Specify its frequency in MHz. If in Divider mode, also choose a divider value to achieve the desired output frequency. After clicking Calculate, the approximate bandwidth and VCO frequency are calculated and displayed here.
CLKFB	**FBK Mode** – Specify the feedback clock source. Choices are internal and external CLKOP, CLKOS, CLKOS2, CLKOS3, and external user clock. To use CLKOS, CLKOS2, or CLKOS3, select the clock's Enable option and then choose the FBK mode. If you select Bypass for CLKOP, the CLKOP, INT_OP, and UserClock options are disabled. **FBK Divider** – In the Divider mode, the divider in the feedback path can be selected from the drop-down list. In the Frequency mode, clicking the "Calculate" button displays the divider value. **Fractional-N Divider** – To finely divide the feedback clock frequency, select **Enable** and enter a divider value. Available in both Frequency and Divider modes.

Table 259: PLL Dialog Box for MachXO2, MachXO3L, and Platform Manager 2 (Continued)

Feature	Description
Optional Port Selections	Select additional ports for the module. **Dynamic Phase Ports** – Adds phase controls. The PHASESEL port selects a clock with the following code: CLKOP: 11 CLKOS: 00 CLKOS2: 01 CLKOS3: 10 **Clock Enable Ports** – Adds an enable input port for each selected clock. **Standby Ports** – Adds a STDBY port to power down the PLL. **Enable Clock Select** – Adds a second clock and a signal to select which one to use.
PLL Reset Options	Select reset options for the PLL. Each of the following adds an active-high input port that resets a different clock: **Provide PLL Reset** – Resets CLKOP. **Provide PLLM Reset** – Resets CLKOP and the CLKI divider. **PLL CLKOS2 Reset** – Resets the CLKOS2 divider. **PLL CLKOS3 Reset** – Resets the CLKOS3 divider.
Lock Settings	Adds an active-high output signal that indicates PLL lock. Select **PLL Lock is Sticky** to make the lock signal sticky.
Wishbone BUS	Adds ports allowing you to configure the PLL through a Wishbone bus: PLLADDR[4:0]: Address (input) PLLCLK: Clock (input) PLLDATI[7:0]: Data (input) PLLRST: Reset for data bus, not any registers (input) PLLSTB: Strobe (input) PLLWE: write enable (input) PLLACK: Acknowledge (output) PLLDATO[7:0]: Data (output) Use with an EFB module with the PLL (Dynamic access) option. See “EFB” on page 1447.

Table 259: PLL Dialog Box for MachXO2, MachXO3L, and Platform Manager 2 (Continued)

Feature	Description
CLKOP, CLKOS, CLKOS2, CLKOS3	The PLL can produce up to four different clock signals. Select **Enable** for the clocks you want to use (CLKOP is always enabled). Then use the following options to specify the form of the clocks. The duty trim option is only available with CLKOP and CLKOS. **Enable** – Select to add the clock to the module. CLKOP is the standard output and is always enabled. **Bypass** – The bypass option connects the output to the input, bypassing the PLL circuit. However, you can still apply a divider to the frequency. See “Clock Divider” below. **Clock Divider** – If you are applying the bypass option to the clock, you can still apply a divider to the frequency. But you must be using Divider mode for the PLL. To apply a divider, select **Clock Divider** and then choose a value from the Divider drop-down menu. **Desired Frequency** – In Frequency mode, specify the output clock frequency. **Tolerance %** – Specify a tolerance for the frequency as a percentage of the requested frequency. Since the dividers can only take a certain set of values, not all frequencies can be generated. The tolerance value is used to guide the tool to select a suitable divider value. **Divider** – Select a value to divide the input frequency by. Only available in Divider mode. To see the actual output frequency, click “Calculate” and check the Actual Frequency box. **Actual Frequency** – Clicking “Calculate” displays the actual frequency that the PLL will produce. **Static Phase Shift (degree)** – Choose a phase shift to build into the PLL. **Duty Trim Options** – (CLKOP and CLKOS only) Choose a delay multiplier for the rising edge or falling edge duty trim option.
Calculate	**Frequency Mode** – Software calculates divider settings based on input/output frequency. **Divider Mode** – Software calculates output frequencies based on divider values.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

PLL Options (LIFMD)

The module dialog box has three tabs:

- Frequency, see below
- Phase, see Table 252 on page 1575
- Optional Ports, see Table 253 on page 1575

Output frequencies depend on the input frequency, the desired output frequencies, and the tolerances. To see what the actual output frequencies will be, set the options and then click **Calculate**. If the results are not satisfactory, adjust the values and recalculate before generating the module.

After setting up the Frequency tab, go to the other tabs to specify phase shifts for the output clocks and optional ports such as for dynamic phase shift, clock enable, and PLL reset.

Table 260: PLL Dialog Box for LIFMD—Frequency Tab

Feature	Description
CLKI	**Frequency** – CLKI is the input reference clock for the PLL. Specify its frequency in megahertz. **Refclk Divider** – After clicking Calculate, this shows the divider value used to achieve the desired output frequency. **Enable High Bandwidth** – Select to have a higher PLL bandwidth. After clicking Calculate, the bandwidth is shown in the Info box. **PLL Reference Clock from Pin** – Select to get the reference clock directly from one of the FPGA's pins. Then choose the pin's buffer type.
CLKFB	**Feedback Mode** – Specify the feedback clock source. Choices are internal and external CLKOP, CLKOS, CLKOS2, CLKOS3, INT_OP, INT_OS, INT_OS2, INT_OS3, UserClock. To use CLKOS, CLKOS2, or CLKOS3, select the clock's **Enable** option and clear the **Bypass** option. Then choose the feedback mode. If you select Bypass for CLKOP, the CLKOP, INT_OP, and UserClock options are disabled. **Feedback Divider** – The divider in the feedback path is shown after clicking Calculate.
Info	These values are shown after filling in the other fields and clicking Calculate.

Table 260: PLL Dialog Box for LIFMD—Frequency Tab (Continued)

Feature	Description
CLKOP, CLKOS, CLKOS2, CLKOS3	The PLL can produce up to four different clock signals. Select **Enable** for the clocks you want to use (CLKOP is always enabled). Then use the following options to specify the form of the clocks. **Enable** – Select to add the clock to the module. CLKOP is the standard output and is always enabled. **Bypass** – The bypass option connects the output to the input, bypassing the PLL circuit. **Output Divider** – Shows the calculated divider to produce the actual frequency. **Desired Frequency** – Specify the desired output clock frequency. **Tolerance %** – Specify a tolerance for the frequency as a percentage of the requested frequency. Since the dividers can only take a certain set of values, not all frequencies can be generated. The tolerance value is used to guide the tool to select a suitable divider value. **Actual Frequency** – The actual frequency that the PLL will produce is after clicking Calculate.
Calculate	Software calculates divider settings and actual output frequencies based on CLKI and desired frequencies.
Configure	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 261: PLL Dialog Box for LIFMD—Phase Tab

Feature	Description
Desired Phase	Specify the desired phase shift in degrees.This option is available if the clock is enabled but the Bypass option has not been selected and the clock has not been selected in Feedback Mode.
Actual Phase	Shows the actual phase shift after clicking Calculate. Not all phase shifts are possible.
Calculate	After entering the desired phase shifts, click **Calculate** to see what actual phase shift will be implemented.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 262: PLL Dialog Box for LIFMD—Optional Ports Tab

Feature	Description
Enable Clock Select	Adds a second input clock port, CLKI2, and a select port.
Dynamic Phase Ports	Adds phase controls.
Clock Enable OP, OS, OS2, OS3	Adds an enable input port for each selected clock. This option is available if the clock is enabled but the Bypass option has not been selected and the clock has not been selected in Feedback Mode. The PHASESEL port selects a clock with the following code: CLKOP: 11 CLKOS: 00 CLKOS2: 01 CLKOS3: 10
Provide Standby Port	Adds a STDBY port to power down the PLL.
Provide PLL Reset	Adds a port to reset the PLL.
Provide PLL Lock Signal	Adds an active-high output signal that indicates PLL lock. Select **PLL Lock is Sticky** to make the lock signal sticky.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Spmi_pll

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_pll.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)	Notes
I	CLKI	Bit	N/A	
I	CLKFB	Bit	N/A	
I	RESET	Bit	N/A	Inverted sense in LatticeSC/M.

Input/Output	Port Name	Type	Size (Buses Only)	Notes
O	LOCK	Bit	N/A	
O	CLKOP	Bit	N/A	
O	CLKOS	Bit	N/A	
O	CLKOK	Bit	N/A	Not applicable for LatticeSC/M.
O	CLKOK2	Bit	N/A	LatticeECP3 and LatticeXP only.

Verilog pmi_pll Definition

```
module pmi_pll
 #(parameter pmi_freq_clki = 100,
   parameter pmi_freq_clkfb = 100,
   parameter pmi_freq_clkop = 100,
   parameter pmi_freq_clkos = 100,
   parameter pmi_freq_clkok = 100,
   parameter pmi_family = "SC",
   parameter pmi_phase_adj = 0,
   parameter pmi_duty_cycle = 50,
   parameter pmi_clkfb_source = "CLKOP",
   parameter pmi_fdel = "off",     // ECP2 Only
   parameter pmi_fdel_val = 0,
   parameter module_type = "pmi_pll")

  (input       CLKI,
   input       CLKFB,
   input       RESET,
   output      CLKOP,
   output      CLKOS,
   output      CLKOK,
   output      CLKOK2,
   output      LOCK)/*synthesis syn_black_box */;

endmodule //pmi_pll
```

VHDL pmi_pll Definition

```
component pmi_pll is
     generic (
       pmi_freq_clki : integer := 100;
       pmi_freq_clkfb : integer := 100;
       pmi_freq_clkop : integer := 100;
       pmi_freq_clkos : integer := 100;
       pmi_freq_clkok : integer := 100;

    CLKOK2: out std_logic;
    LOCK: out std_logic
  );
end component pmi_pll;
```

Parameter Names and Values

The following table contains the pmi_pll module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_freq_clki	15 to 1000 MHz (LatticeSC/M) 1 to 420 MHz (LatticeECP2, LatticeXP2) 25 to 420 MHz (LatticeECP/EC, LatticeXP) 5 to 500 MHz (LatticeECP3)	100	
pmi_freq_clkfb	15 to 1000 MHz (LatticeSC/M) 1 to 420 MHz (LatticeECP2, LatticeXP2) 25 to 420 MHz (LatticeECP/EC, LatticeXP) 5 to 500 MHz (LatticeECP3)	100	
pmi_freq_clkop	1.562 to 1000 MHz (LatticeSC/M) 1 to 420 MHz (LatticeECP2, LatticeXP2) 25 to 420 MHz (LatticeECP/EC, LatticeXP) 5 to 500 MHz (LatticeECP3)	100	
pmi_freq_clkok	1 to 420 MHz (LatticeECP2, LatticeXP2) 25 to 420 MHz (LatticeECP/EC, LatticeXP) 5 to 500 MHz (LatticeECP3)	50	Not available for LatticeSC/M.
pmi_freq_clkos	1 to 840 MHz (LatticeSC/M)	100	LatticeSC/M only.
pmi_phase_adj	0, 22.5, 45, 90, …, 315, 337.5 (LatticeECP2, LatticeECP3, LatticeXP2) 0, 45, 90, …, 315 (LatticeECP/EC, LatticeSC/M, MachXO)	0	
pmi_duty_cycle	12.5, 25, 37.5, 62.5, 75, 87.5 (LatticeECP/EC, MachXO) 12.5, 18.75, 25, 31.25, 37.5, 43.75, 50, 56.25, 62.5, 68.75, 75, 81.25, 87.5 (LatticeECP2, LatticeECP3, LatticeXP)	50	▶ Listed as a percentage. ▶ Does not apply to LatticeSC/M.
pmi_clkfb_source	INTERNAL, CLKOP, USERCLOCK, CLKOS	CLKOP	The CLKOS option is only applicable for LatticeECP3.
pmi_fdel	“on” | “off”	“off”	LatticeECP2 only.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_fdel_val	-8 to 8	0	LatticeECP/EC, LatticeECP2/M, and LatticeXP only.
pmi_family	“EC” | “ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” | “ECP5UM” | “SC” | “SCM” | “XP” | “XP2” | “XO” | “XO2” | “XO3L | “LPTM”	“EC”

pmi_pll_fp

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_pll_fp (PLL Floating Point).

Port Description

Input/Output	Port Name	Type	Size (Buses Only)	Notes
I	CLKI	Bit	N/A	
I	CLKFB	Bit	N/A	
I	RESET	Bit	N/A	Inverted sense in LatticeSC/M.
O	LOCK	Bit	N/A	
O	CLKOP	Bit	N/A	
O	CLKOS	Bit	N/A	
O	CLKOK	Bit	N/A	Not applicable for LatticeSC/M.
O	CLKOK2	Bit	N/A	LatticeXP2, and LatticeECP3 only.

Verilog pmi_pll_fp Definition

```
module pmi_pll_fp
 #(parameter pmi_freq_clki = "100.0",
   parameter pmi_freq_clkfb = "100.0",
   parameter pmi_freq_clkop = "100.0",
   parameter pmi_freq_clkos = "100.0",
   parameter pmi_freq_clkok = "50.0",
   parameter pmi_family = "EC",
   parameter pmi_phase_adj = "0.0",
   parameter pmi_duty_cycle = "50.0",
   parameter pmi_clkfb_source = "CLKOP",
   parameter pmi_fdel = "off",     // ECP2 Only
   parameter pmi_fdel_val = 0,
   parameter module_type = "pmi_pll_fp")

  (input       CLKI,
```

```
   input       CLKFB,
   input       RESET,
   output      CLKOP,
   output      CLKOS,
   output      CLKOK,
   output      CLKOK2,
   output      LOCK)/*synthesis syn_black_box */;
endmodule //pmi_pll_fp
```

VHDL pmi_pll_fp Definition

```
component pmi_pll_fp is
     generic (
       pmi_freq_clki : string := "100.0";
       pmi_freq_clkfb : string := "100.0";
       pmi_freq_clkop : string := "100.0";
       pmi_freq_clkos : string := "100.0";
       pmi_freq_clkok : string := "50.0";
       pmi_family : string := "EC";
       pmi_phase_adj : string := "0.0";
       pmi_duty_cycle : string := "50.0";
       pmi_clkfb_source : string := "CLKOP";
       pmi_fdel : string := "off";
       pmi_fdel_val : integer := 0;
       module_type : string := "pmi_pll_fp"
    );
    port (
     CLKI: in std_logic;
     CLKFB: in std_logic;
     RESET: in std_logic;
     CLKOP: out std_logic;
     CLKOS: out std_logic;
     CLKOK: out std_logic;
     CLKOK2: out std_logic;
     LOCK: out std_logic
   );
  end component pmi_pll_fp;
```

Parameter Names and Values

The following table contains the pmi_pll module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_freq_clki	15 to 1000 MHz (LatticeSC/M) 1 to 420 MHz (LatticeECP2, LatticeXP2) 25 to 420 MHz (LatticeECP/EC, LatticeXP) 5 to 500 MHz (LatticeECP3)	100	
pmi_freq_clkfb	15 to 1000 MHz (LatticeSC/M) 1 to 420 MHz (LatticeECP2, LatticeXP2) 25 to 420 MHz (LatticeECP/EC, LatticeXP) 5 to 500 MHz (LatticeECP3)	100	

Parameter Name	Acceptable Values	Default Value	Notes
pmi_freq_clkop	1.562 to 1000 MHz (LatticeSC/M) 1 to 420 MHz (LatticeECP2, LatticeXP2) 25 to 420 MHz (LatticeECP/EC, LatticeXP) 5 to 500 MHz (LatticeECP3)	100	
pmi_freq_clkok	1 to 420 MHz (LatticeECP2, LatticeXP2) 25 to 420 MHz (LatticeECP/EC, LatticeXP) 5 to 500 MHz (LatticeECP3)	50	Not available for LatticeSC/M.
pmi_freq_clkos	1 to 840 MHz (LatticeSC/M)	100	LatticeSC/M only.
pmi_phase_adj	0, 22.5, 45, 90, …, 315, 337.5 (LatticeECP2, LatticeECP3, LatticeXP2) 0, 45, 90, …, 315 (LatticeECP/EC, LatticeSC/M, MachXO)	0	
pmi_duty_cycle	12.5, 25, 37.5, 62.5, 75, 87.5 (LatticeECP/EC, MachXO) 12.5, 18.75, 25, 31.25, 37.5, 43.75, 50, 56.25, 62.5, 68.75, 75, 81.25, 87.5 (LatticeECP2, LatticeECP3, LatticeXP)	50	▶ Listed as a percentage. ▶ Does not apply to LatticeSC/M.
pmi_clkfb_source	INTERNAL, CLKOP, USERCLOCK, CLKOS	CLKOP	The CLKOS option is only applicable for LatticeECP3.
pmi_fdel	“on” | “off”	“off”	LatticeECP2 only
pmi_fdel_val	-8 to 8	0	LatticeECP/EC, LatticeECP2/M, and LatticeXP only.
pmi_family	“EC” | “ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” |”ECP5UM” | “SC” | “SCM” | “XP” | “XP2” | “XO” | “XO2” | “XO3L” | “LPTM”	“EC”

PMU

The Power Management Unit (PMU) can reduce power consumption for Lattice FPGA products.

Table 263: PMU Dialog Box

Feature	Description
Device Wake Up(Sleep Mode to Normal Mode) Options	**External User Wake Up** – Allows signals from an external pin to wake up the PMU. **User I2C Wake Up** – Allows signals from an I2C0 component to wake up the PMU. **Watch Dog Timer (WDT) Expiry Wake Up** – Allows signals from a Watch Dog Timer to wake up the PMU.
Watch Dog Timer Expiry Wake Up Options	Select which Watch Dog Timer should wake up the PMU.
Watch Dog Timer Initialization Options	Enter the time interval in hours (HH), minutes (MM), and seconds (SS) after which the Watch Dog Timer will wake the PMU.
Watch Dog Timer(WDT) User Mode Options	**Enable User Mode for Watch Dog Timer in Normal State** – Allows you to use Watch Dog Timers in Normal State. **Mode Selection** – Select Count Once to complete a single countdown, or Count Repetitively to start a new timer every time the current one finishes. **Select the Watch Dog Timer (WDT) Counter that will be used in User Mode** – Select which Watch Dog Timer should wake up the PMU in User Mode. **Interrupt Enable** – Adds a Watch Dog Timer Interrupt port to a Normal State design.
Configure	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Power Controller

Power Controller ensures smooth transitions into and out of standby mode.

Table 264: Power Controller Dialog Box

Feature	Description
Entry Signals	Select entry options. Options include User, Configuration, and User & Configuration. Configuration includes JTAG, SPI, and I2C.
Stop to Standby Delay	Select how to control the delay between the STOP and STDBY signals: User: Adds the USERTIMEOUT enable signal for Power Controller's timer counter. Counter: Adds the clock signal for Power Controller's timer counter. Bypass: No delay.

Table 264: Power Controller Dialog Box

Feature	Description
Wake Signals	Specify the source of the wake-up signal. Choose User for user logic, or choose Configuration to use an internal JTAG, SPI, or I2C block (see "EFB" on page 1447).
Enable Standby Flags	Includes standby flags.
Turn off POR when in Standby	Turns off the Power-On-Reset circuit when in standby mode. Recommended only for applications with reliable power supply rails.
Turn off Bandgap when in Standby	Turning off Bandgap also turns off POR. Bandgap is required for use of the oscillator, PLL, and referenced I/Os.
Bus Ordering Style	Specifies whether the numbers should begin at the high end ("Big Endian"- BusA[7 to 0]) or at the low end ("Little Endian"-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Power Guard

Power Guard controls dynamic power consumption by blocking signals at the input buffers. This feature can be used in both clock and data paths. Power Guard's biggest impact is in standby mode when it can be used to switch off clock inputs that are distributed using general routing resources.

Table 265: Power Guard Dialog Box

Feature	Description
Specify the width of the Power Guard bus	Enter the number of bits in the bus to be controlled by the Power Guard module.
Bus Ordering Style	Specifies whether the numbers should begin at the high end ("Big Endian"- BusA[7 to 0]) or at the low end ("Little Endian"-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.

RAM_Based_Shift_Register

A shift register using RAM.

Table 266: RAM_Based_Shift_Register Dialog Box

Feature	Description
Data Width	Specify the width of the data.
Ram Type	**LUT Based** – Contains LUTs and logic implementation. **EBR Based** – Contains Embedded Block RAM implementation.
Shift Register Type	Specify the type of shift register. The output data is the input data delayed by a certain number of clock cycles. **Fixed Length** –The delay is fixed and is always equal to the number of shifts. **Number of Shifts** – Specify the number of shifts for a fixed-length shift register. **Variable Length (Lossy)** – The delay is controlled by the Addr input. When the "Addr" changes, the current input data will appear at the output Addr cycles later. The output for the next Addr cycles is not defined. **Variable Length (Lossless)** – The delay is controlled by the Addr input. When the "Addr" changes, the current output data is what was at the input Addr cycles earlier. **Max Number of Shifts** – Specify the maximum number of shifts for a variable length shift register. This will determine the size of the Addr input.
Enable Output Register	Specify that registers are used for the output data. This will produce an additional clock cycle delay for the output.
Memory File	(ECP5, LatticeECP3, LatticeSC/M, LatticeXP2, MachXO2, MachXO3L, and Platform Manager 2 only) Allows you to select a memory initialization (.mem) file for the module. See "Creating a Memory Initialization File with Memory Generator" on page 202.
Memory File Format	(ECP5, LatticeECP3, LatticeSC/M, LatticeXP2, MachXO2, MachXO3L, and Platform Manager 2 only) Allows you to choose Binary, Hex, or Addressed Hex format.
Bus Ordering Style	Specifies whether the numbers should begin at the high end ("Big Endian"- BusA[7 to 0]) or at the low end ("Little Endian"-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.

pmi_distributed_shift_reg

Note

The module name pmi_distributed_shift_reg will change when the configuration is implemented.

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_distributed_shift_reg.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	Din	Bus	(pmi_data_width - 1):0
I	Addr	Bus	(pmi_max_width - 1):0
I	Clock	Bit	N/A
I	ClockEn	Bit	N/A
O	Q	Bus	(pmi_data_width - 1):0

Verilog pmi_distributed_shift_reg Definition

```
module pmi_distributed_shift_reg
  #(parameter pmi_data_width = 16,
    parameter pmi_regmode = "reg",
    parameter pmi_shiftreg_type = "fixed",
    parameter pmi_num_shift = 16,
    parameter pmi_num_width = 4,
    parameter pmi_max_shift = 16,
    parameter pmi_max_width = 4,
```

```
    parameter pmi_init_file = "none",
    parameter pmi_init_file_format = "binary",
    parameter pmi_family = "EC",
    parameter module_type = "pmi_distributed_shift_reg")

    (
     input [(pmi_data_width-1):0] Din,
     input [(pmi_max_width-1):0] Addr,
     input Clock,
     input ClockEn,
     input Reset,
     output [(pmi_data_width-1):0] Q)/*synthesis
syn_black_box*/;

endmodule // pmi_distributed_shift_reg
```

VHDL pmi_distributed_shift_reg Definition

```
component pmi_distributed_shift_reg is
     generic (
       pmi_data_width : integer := 16;
       pmi_regmode : string := "reg";
       pmi_shiftreg_type : string := "fixed";
       pmi_num_shift : integer := 16;
       pmi_num_width : integer := 4;
       pmi_max_shift : integer := 16;
       pmi_max_width : integer := 4;
       pmi_init_file : string := "none";
       pmi_init_file_format : string := "binary";
       pmi_family : string := "EC";
       module_type : string := "pmi_distributed_shift_reg"
    );
    port (
     Din : in std_logic_vector((pmi_data_width-1) downto 0);
     Addr : in std_logic_vector((pmi_max_width-1) downto 0);
     Clock: in std_logic;
     ClockEn: in std_logic;
     Reset: in std_logic;
     Q : out std_logic_vector((pmi_data_width-1) downto 0)
   );
  end component pmi_distributed_shift_reg;
```

Parameter Names and Values

The following table contains the pmi_distributed_shift_reg module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_data_width	1 to 256	16	
pmi_regmode	“reg” | “noreg”	“reg”	
pmi_shiftreg_type	“fixed” | “variable” | “lossless”	“fixed”	
pmi_num_shift	2 to 1024	16	
pmi_num_width	0 to 10	4	

Parameter Name	Acceptable Values	Default Value	Notes
pmi_max_shift	2 to 1024	16	
pmi_max_width	0 to 10	4	
pmi_init_file	<string>	“none”	The pmi_init_file and pmi_initi_file_format parameters are only supported for LatticeSC/M, LatticeECP3, and LatticeXP2 device families in distributed mode.
pmi_init_file_format	“binary” | “hex”	“binary”	The pmi_init_file and pmi_initi_file_format parameters are only supported for LatticeSC/M, LatticeECP3, and LatticeXP2 device families in distributed mode.
pmi_family	“EC” | “ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” | “ECP5UM” | “SC” | “SCM” | “XP” | “XP2” | “XO” | “XO2” | “XO3L” |“LPTM”	“EC”

RAM_DP Options (ECP5, MachXO2, MachXO3L, Platform Manager 2)

A pseudo-dual-port RAM that provides a variety of RAM organizations and is implemented as sysMEM EBR memory. Ports, properties, and functionality are described in detail in the technical note listed in the “See Also” section below.

Table 267: RAM_DP Dialog Box for ECP5, MachXO2, MachXO3L, and Platform Manager 2

Feature	Description
Specify the Size of the RAM_DP	Both Read and Write port width can be specified. Enter number of address locations times data width. The two ports can be of different widths. In such cases, the memory initialization file corresponds to the Write Port. For example, for a RAM_DP with Write Port = 1024x36 and Read Port = 2048x18, the initialization file should be of size 1024x36.
Provide Byte Enables	Allows for byte enables at a size of 8 or 9 bytes. Choose the byte size from the drop-down menu.
Enable Output Register	When selected, the output register is enabled (separate controls for Read Port and Write Port).
Enable Output ClockEn	Adds an output clock enable port. This is an input port. Requires that the Output Register (above) be enabled first.
Optimization	Select whether to optimize the module for minimum area or maximum speed.
Reset Mode	Asynchronous or synchronous reset supported. The Output Register (above) must be enabled first. Reset release requires that reset assertion be asynchronous.
Initialization	Select how to initialize the memory: all zeros, all ones, or from a memory file (see below). If you select Memory File, you may allow updates of the initialization file that is stored in the user flash memory (UFM) (not available with ECP5 and MachXO3L).
Memory File	Allows you to select a memory initialization (.mem) file for the module. See “Creating a Memory Initialization File with Memory Generator” on page 202.
Memory File Format	Allows you to choose Binary, Hex, or Addressed Hex format.
Allow update of initialization file stored in UFM	If you select Memory File (above), you may allow updates of the initialization file that is stored in the user flash memory (UFM). (Not available with ECP5 and MachXO3L)
Enable ECC	Allows error correction of single errors and detection of 2-bit errors. This is not supported for data widths greater than 64 bits.
Pipeline Stages for Q and Error Outputs	If ECC is enabled, the output can be pipelined. Choose the number of stages from the drop-down menu.

Table 267: RAM_DP Dialog Box for ECP5, MachXO2, MachXO3L, and Platform Manager 2

Feature	Description
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

RAM_DP Options (LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeSC/M, LatticeXP, LatticeXP2, MachXO)

A pseudo-dual-port RAM that provides a variety of RAM organizations and is implemented as sysMEM EBR memory. Ports, properties, and functionality are described in detail in the technical notes listed in the “See Also” section below.

Table 268: RAM_DP Dialog Box

Feature	Description
Specify the Size of RAM_DP	Both Read and Write port width can be specified. Enter number of address locations times data width. The two ports can be of different widths. In such cases, the memory initialization file corresponds to the Write Port. For example, for a RAM_DP with Write Port = 1024x36 and Read Port = 2048x18, the initialization file should be of size 1024x36.
Provide Byte Enables	Allows for byte enables at a size of 8 or 9 bytes. Choose the byte size from the drop-down menu. (Not available with LatticeEC, LatticeECP, LatticeXP, or MachXO.)
Enable Output Register	When selected, output register is enabled (separate controls for Read Port and Write Port).
Reset Mode	Asynchronous or synchronous reset supported. (Not available with LatticeECP3.)
Optimization	Select whether to optimize the module for minimum area or maximum speed.

Table 268: RAM_DP Dialog Box (Continued)

Feature	Description
Memory File	Allows you to select a memory initialization (.mem) file for the module. If a memory file is not used, all the RAM contents are initialized to 0. See "Creating a Memory Initialization File with Memory Generator" on page 202.
Memory File Format	Allows you to choose Binary, Hex, or Addressed Hex format.
Enable ECC	Allows error correction of single errors and detection of 2-bit errors. This is not supported for data widths greater than 64 bits.
Pipeline Stages for Q and Error Outputs	If ECC is enabled, the output can be pipelined. Choose the number of stages from the drop-down menu.
Bus Ordering Style	Specifies whether the numbers should begin at the high end ("Big Endian"- BusA[7 to 0]) or at the low end ("Little Endian"-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.

Parameter Names and Values

The following table contains the pmi_ram_dp module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_rd_addr_depth	2 to 65536	512	The LatticeECP2 and LatticeSC/M device families read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
pmi_rd_addr_width	1 to 16	9	The LatticeECP2 and LatticeSC/M device families read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
pmi_rd_data_width	1 to 256	18	
pmi_wr_addr_depth	2 to 65536	512	The LatticeECP2 and LatticeSC/M device families read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
pmi_wr_addr_width	1 to 16	9	The LatticeECP2 and LatticeSC/M device families read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
pmi_wr_data_width	1 to 256	18	
pmi_regmode	“reg” | “noreg”	“reg”	

Parameter Name	Acceptable Values	Default Value	Notes
pmi_gsr	“enable”	“disable”	“disable”	
pmi_resetmode	“async”	“sync”	“sync”	The “async” option is not valid for LatticeECP3 devices.
pmi_init_file	<string>	“none”	
pmi_init_file_format	“binary”	“hex”	“binary”	
pmi_family	“EC”	“ECP”	“ECP2”	“ECP2M”	“ECP3”	“ECP5U”	“ECP5UM”	“SC”	“SCM”	“XP”	“XP2”	“XO”	“XO2”	“XO3L”	“LPTM”	“EC”

pmi_ram_dp_be

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_ram_dp_be, which is similar to pmi_ram_dp but with a byte enable.

Port Description

Input/ Output	Port Name	Type	Size (Buses Only)
I	WrAddress	Bus	(pmi_wr_addr_width - 1):0
I	RdAddress	Bus	(pmi_rd_addr_width - 1):0
I	Data	Bus	(pmi_wr_data_width - 1):0
I	RdClock	Bit	N/A
I	RdClockEn	Bit	N/A
I	Reset	Bit	N/A
I	WrClock	Bit	N/A
I	WrClockEn	Bit	N/A
I	WE	Bit	N/A
I	ByteEn	Bit	((pmi_wr_data_width + pmi_byte_size-1) / pmi_byte_size-1):0
O	Q	Bus	(pmi_rd_data_width - 1):0

Verilog pmi_ram_dp_be Definition

```
module pmi_ram_dp_be
 #(parameter pmi_wr_addr_depth = 512,
   parameter pmi_wr_addr_width = 9,
   parameter pmi_wr_data_width = 18,
   parameter pmi_rd_addr_depth = 512,
   parameter pmi_rd_addr_width = 9,
   parameter pmi_rd_data_width = 18,
   parameter pmi_regmode = "reg",
   parameter pmi_gsr = "disable",

RAM_DP_TRUE

A true dual-port RAM that provides a variety of RAM organizations and is implemented as sysMEM EBR memory. Ports, properties, and functionality are described in detail in the technical notes listed in the “See Also” section below.

The options vary with the device family. See:

- “RAM_DP_TRUE Options (ECP5, MachXO2, MachXO3L, Platform Manager 2)” on page 1614
- “RAM_DP_TRUE Options (LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeSC/M, LatticeXP, LatticeXP2, MachXO)” on page 1616

RAM_DP_TRUE Options (ECP5, MachXO2, MachXO3L, Platform Manager 2)

The module dialog box has two tabs:

- Configuration, below
- Advanced, see Table 270 on page 1615

Table 269: RAM_DP_TRUE Dialog Box for ECP5, MachXO2, MachXO3L, and Platform Manager 2—Configuration Tab

Feature	Description
Specify the Size of the RAM_DP_TRUE	Both Read and Write port widths can be specified. Enter the number of address locations and the data width. The size of the memory initialization file corresponds to the port A. For example, for a RAM_DP_TRUE with port A = 1024x36 and port B = 2048x18, the initialization file should be of size 1024x36.
Enable Output Register	When selected, the output registered is enabled (separate controls for ports A and B).
Enable Output ClockEn	Adds an output clock enable port. This is an input port. Requires that the Output Register (above) be enabled first.
Provide Byte Enables	Allows for byte enables at a size of 8 or 9 bytes. Choose the byte size from the drop-down menu.
Optimization	Select whether to optimize the module for minimum area or maximum speed.
Reset Mode	Asynchronous or synchronous reset supported. The Output Register (above) must be enabled first. Reset release requires that reset assertion be asynchronous.

Table 269: RAM_DP_TRUE Dialog Box for ECP5, MachXO2, MachXO3L, and Platform Manager 2—Configuration Tab (Continued)

Feature	Description
Initialization	Select how to initialize the memory: all zeros, all ones, or from a memory file (see below). If you select Memory File, you may allow updates of the initialization file that is stored in the user flash memory (UFM) (not available with ECP5 and MachXO3L).
Memory File	Allows you to select a memory initialization (.mem) file for the module. See “Creating a Memory Initialization File with Memory Generator” on page 202.
Memory File Format	Allows you to choose Binary, Hex, or Addressed Hex format.
Allow update of initialization file stored in UFM	If you select Memory File (above), you may allow updates of the initialization file that is stored in the user flash memory (UFM). (Not available with ECP5 and MachXO3L)
Enable ECC	Allows error correction of single errors and detection of 2-bit errors. Ports A and B must have the same data width and the data width cannot be greater than 64 bits.
Pipeline Stages for Q and Error Outputs	If ECC is enabled, the output can be pipelined. Choose the number of stages from the drop-down menu.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 270: RAM_DP_TRUE Dialog Box for ECP5, MachXO2, MachXO3L, and Platform Manager 2—Advanced Tab

Feature	Description
Port A, B Write Mode	Supports: ▶ Normal ▶ Write Through ▶ Read Before Write. A memory configuration can only use read-before-write if its data width is a multiple of 9. Set Data Width in the Configuration tab to match this requirement.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

RAM_DP_TRUE Options (LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeSC/M, LatticeXP, LatticeXP2, MachXO)

The module dialog box has two tabs:

- Configuration, below
- Advanced, see Table 272 on page 1617

Table 271: RAM_DP_TRUE Dialog Box—Configuration Tab

Feature	Description
Specify the Size of RAM_DP_TRUE	Both Read and Write port width can be specified. Enter the number of address locations and the data width. The size of the memory initialization file corresponds to the port A. For example, for a RAM_DP_TRUE with port A = 1024x36 and port B = 2048x18, the initialization file should be of size 1024x36.
Enable Output Register	When selected, output register is enabled (separate controls for port A and B).
Provide Byte Enables	Allows for byte enables at a size of 8 or 9 bytes. Choose the byte size from the drop-down menu. (Not available with LatticeEC, LatticeECP, LatticeXP, or MachXO.)
Reset Mode	Asynchronous or synchronous reset supported. (Not available with LatticeECP3.)
Optimization	Select whether to optimize the module for minimum area or maximum speed.
Memory File	Allows you to select a memory initialization (.mem) file for the module. If a memory file is not used, all the RAM contents are initialized to 0. See “Creating a Memory Initialization File with Memory Generator” on page 202.
Memory File Format	Allows you to choose Binary, Hex, or Addressed Hex format.
Enable ECC	Allows error correction of single errors and detection of 2-bit errors.
Pipeline Stages for Q and Error Outputs	If ECC is enabled, the output can be pipelined. Choose the number of stages from the drop-down menu.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.

Parameter Names and Values

The following table contains the pmi_ram_dp_true module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_addr_depth_a	2 to 65536	512	The LatticeECP2 and LatticeSC/M device families read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
pmi_addr_width_a	1 to 16	9	The LatticeECP2 and LatticeSC/M device families read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
pmi_data_width_a	1 to 256	18	
pmi_addr_depth_b	2 to 65536	512	The LatticeECP2 and LatticeSC/M device families read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
pmi_addr_width_b	1 to 16	9	The LatticeECP2 and LatticeSC/M device families read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
pmi_data_width_b	1 to 256	18	
pmi_regmode_a	“reg” | “noreg”	“reg”	
pmi_regmode_b	“reg” | “noreg”	“reg”	
pmi_gsr	“enable” | “disable”	“disable”	
pmi_resetmode	“async” | “sync”	“sync”	The “async” option is not valid for LatticeECP3 devices.
pmi_init_file	<string>	“none”	
pmi_init_file_format	“binary” | “hex”	“binary”	
pmi_write_mode_a	“normal” | “writethrough” | “readbeforewrite”	“normal”	The “readbeforewrite” option is not supported for the LatticeECP2/M, LatticeSC/M, and LatticeXP device families.
pmi_write_mode_b	“normal” | “writethrough” | “readbeforewrite”	“normal”	The “readbeforewrite” option is not supported for the LatticeECP2/M, LatticeSC/M, and LatticeXP device families.
pmi_family	“EC” | “ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” | “ECP5UM” | “SC” | “SCM” | “XP” | “XP2” | “XO” | “| “XO2” | “XO3L” | “LPTM”	“EC”

Parameter Names and Values

The following table contains the pmi_ram_dp_true module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_addr_depth_a	2 to 65536	512	The LatticeECP2 and LatticeSC/M device families read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
pmi_addr_width_a	1 to 16	9	The LatticeECP2 and LatticeSC/M device families read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
pmi_data_width_a	1 to 256	18	
pmi_addr_depth_b	2 to 65536	512	The LatticeECP2 and LatticeSC/M device families read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
pmi_addr_width_b	1 to 16	9	The LatticeECP2 and LatticeSC/M device families read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
pmi_data_width_b	1 to 256	18	
pmi_regmode_a	“reg” | “noreg”	“reg”	
pmi_regmode_b	“reg” | “noreg”	“reg”	
pmi_gsr	“enable” | “disable”	“disable”	
pmi_resetmode	“async” | “sync”	“sync”	The “async” option is not valid for LatticeECP3 devices.
pmi_optimization	“area” | “speed”	“speed”	
pmi_init_file	<string>	“none”	

Parameter Name	Acceptable Values	Default Value	Notes
pmi_init_file_format	“binary”	“hex”	“binary”	
pmi_write_mode_a	“normal”	“writethrough”	“readbeforewrite”	“normal”	The “readbeforewrite” option is not supported for the LatticeECP2/M, LatticeSC/M, and LatticeXP device families.
pmi_write_mode_b	“normal”	“writethrough”	“readbeforewrite”	“normal”	The “readbeforewrite” option is not supported for the LatticeECP2/M, LatticeSC/M, and LatticeXP device families.
pmi_byte_size	8	9	9	
pmi_family	“ECP2”	“ECP2M”	“ECP3”	“ECP5U”	“ECP5UM”	“SC”	“SCM”	“XP2”	“XO2”| “XO2”	“XO3L”	“ECP2”

RAM_DQ

A RAM that can support registered and unregistered outputs. The module provides a variety of RAM organizations and is implemented as sysMEM EBR memory. Ports, properties, and functionality are described in detail in the technical notes listed in the “See Also” section below.

The options vary with the device family. See:

- “RAM_DQ Options (ECP5, MachXO2, MachXO3L, Platform Manager 2)” on page 1625
- “RAM_DQ Options (LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeSC/M, LatticeXP, LatticeXP2, MachXO)” on page 1626

RAM_DQ Options (ECP5, MachXO2, MachXO3L, Platform Manager 2)

The module dialog box has two tabs:

- Configuration, below
- Advanced, see Table 274 on page 1626

Table 273: RAM_DQ Dialog Box for ECP5, MachXO2, MachXO3L, and Platform Manager 2—Configuration Tab

Feature	Description
Specify the size of the RAM_DQ	Specify the number of address locations and the data width.
Provide Byte Enables	Allows for byte enables at a size of 8 or 9 bytes. Choose the byte size from the drop-down menu. The data width must be at least 9 bits.
Enable Output Register	When selected, output registered is enabled.
Enable Output ClockEn	Adds an output clock enable port. This is an input port. Requires that the Output Register (above) be enabled first.
Optimization	Select whether to optimize the module for minimum area or maximum speed.
Reset Mode	Asynchronous or synchronous reset supported. The Output Register (above) must be enabled first. Reset release requires that reset assertion be asynchronous.
Initialization	Select how to initialize the memory: all zeros, all ones, or from a memory file (see below). If you select Memory File, you may allow updates of the initialization file that is stored in the user flash memory (UFM) (not available with ECP5 or MachXO3L).
Memory File	Allows you to select a memory initialization (.mem) file for the module. See “Creating a Memory Initialization File with Memory Generator” on page 202.
Memory File Format	Allows you to choose Binary, Hex, or Addressed Hex format.
Allow update of initialization file stored in UFM	If you select Memory File (above), you may allow updates of the initialization file that is stored in the user flash memory (UFM). (Not available with ECP5 or MachXO3L)
Enable ECC	Allows error correction of single errors and detection of 2-bit errors. This is not supported for data widths greater than 64 bits.
Pipeline Stages for Q and Error Outputs	If ECC is enabled, the output can be pipelined. Choose the number of stages from the drop-down menu.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.

Table 273: RAM_DQ Dialog Box for ECP5, MachXO2, MachXO3L, and Platform Manager 2—Configuration Tab (Continued)

Feature	Description
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 274: RAM_DQ Dialog Box for ECP5, MachXO2, MachXO3L, and Platform Manager 2—Advanced Tab

Feature	Description
Write Mode	Supports: ▶ Normal ▶ Write Through ▶ Read before Write. A memory configuration can only use read-before-write if its data width is a multiple of 9. Set Data Width in the Configuration tab to match this requirement.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

RAM_DQ Options (LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeSC/M, LatticeXP, LatticeXP2, MachXO)

The module dialog box has two tabs:

- Configuration, below
- Advanced, see Table 276 on page 1627

Table 275: RAM_DQ Dialog Box—Configuration Tab

Feature	Description
Specify the size of RAM_DQ	Specify the number of address locations and the data width.
Enable Output Register	When selected, output register is enabled.
Provide Byte Enables	Allows for byte enables at a size of 8 or 9 bytes. Choose the byte size from the drop-down menu. The data width must be at least 9 bits. (Not available with LatticeEC, LatticeECP, LatticeXP, or MachXO.)
Reset Mode	Asynchronous or synchronous reset supported. (Not available with LatticeECP3.)
Optimization	Select whether to optimize the module for minimum area or maximum speed.
Memory File	Allows you to select a memory initialization (.mem) file for the module. If a memory file is not used, all the RAM contents are initialized to 0. See “Creating a Memory Initialization File with Memory Generator” on page 202.
Memory File Format	Allows you to choose Binary, Hex, or Addressed Hex format.
Enable ECC (not supported for Data Width > 64)	Allows error correction of single errors and detection of 2-bit errors. This is not supported for data widths greater than 64 bits.
Pipeline Stages for Q and ERROR Outputs	If ECC is enabled, the output can be pipelined. Choose the number of stages from the drop-down menu.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

ROM Options (ECP5, MachXO2, MachXO3L, Platform Manager 2)

A ROM that provides a variety of ROM organizations and is implemented as sysMEM EBR memory. Ports, properties, and functionality are described in detail in the technical notes listed in the “See Also” section below.

Table 277: ROM Dialog Box for ECP5, MachXO2, MachXO3L, and Platform Manager 2

Feature	Description
Specify the size of the ROM	Specify the number of address locations and the data width.
Enable Output Register	When selected, output registered is enabled.
Optimization	Select whether to optimize the module for minimum area or maximum speed.
Reset Mode	Asynchronous or synchronous reset supported. The Output Register (above) must be enabled first. Reset release requires that reset assertion be asynchronous.
Memory File	Allows you to select a memory initialization (.mem) file for the module. See “Creating a Memory Initialization File with Memory Generator” on page 202.
Memory File Format	Allows you to choose Binary, Hex, or Addressed Hex format.
Allow update of initialization file stored in UFM	Allow updates of the initialization file that is stored in the user flash memory (UFM). (Not available with ECP5 and MachXO3L)
Enable ECC	Allows error correction of single errors and detection of 2-bit errors. This is not supported for data widths greater than 64 bits.
Pipeline Stages for Q and ERROR Outputs	If ECC is enabled, the output can be pipelined. Choose the number of stages from the drop-down menu.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

pmi_rom

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_rom.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	Address	Bus	(pmi_addr_width - 1):0
I	OutClock	Bit	N/A
I	OutClockEn	Bit	N/A
I	Reset	Bit	N/A
O	Q	Bus	(pmi_data_width - 1):0

Verilog pmi_rom Definition

```
module pmi_rom
  #(parameter pmi_addr_depth = 512,
    parameter pmi_addr_width = 9,
    parameter pmi_data_width = 8,
    parameter pmi_regmode = "reg",
    parameter pmi_gsr = "disable",
    parameter pmi_resetmode = "sync",
    parameter pmi_optimization = "speed",
    parameter pmi_init_file = "none",
    parameter pmi_init_file_format = "binary",
    parameter pmi_family = "EC",
    parameter module_type = "pmi_rom")

    (input [(pmi_addr_width-1):0]Address,
     input OutClock,
     input OutClockEn,
     input Reset,
     output [(pmi_data_width-1):0] Q)/*synthesis
syn_black_box*/;

endmodule // pmi_rom
```

VHDL pmi_rom Definition

```
component pmi_rom is
     generic (
       pmi_addr_depth : integer := 512;
       pmi_addr_width : integer := 9;
       pmi_data_width : integer := 8;
       pmi_regmode : string := "reg";
       pmi_gsr : string := "disable";
       pmi_resetmode : string := "sync";
       pmi_optimization : string := "speed";
       pmi_init_file : string := "none";
       pmi_init_file_format : string := "binary";
       pmi_family : string := "EC";
       module_type : string := "pmi_rom"
    );
```

```
    port (
     Address : in std_logic_vector((pmi_addr_width-1) downto
0);
     OutClock: in std_logic;
     OutClockEn: in std_logic;
     Reset: in std_logic;
     Q : out std_logic_vector((pmi_data_width-1) downto 0)
   );
  end component pmi_rom;
```

Parameter Names and Values

The following table contains the pmi_rom module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_addr_depth	2 to 65536	512	The LatticeECP2 and LatticeSC/M device families read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
pmi_addr_width	1 to 16	9	The LatticeECP2 and LatticeSC/M device families read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
pmi_data_width	1 to 256	8	
pmi_regmode	“reg” | “noreg”	“reg”	
pmi_gsr	“enable” | “disable”	“disable”	
pmi_resetmode	“async” | “sync”	“sync”	The “async” option is not valid for LatticeECP3 devices.
pmi_init_file	<string>	“none”	
pmi_init_file_format	“binary” | “hex”	“binary”	
pmi_family	“EC” | “ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” | “ECP5UM” | “SC” | “SCM” | “XP” | “XP2” | “XO” | “ XO2” | “XO3L” | “LPTM”	“EC”

SDR

Single data-rate registers of specified width and mode. Although an SDR generated for a specific width can be used for other widths, it usually requires extra care in specifying the connection while instantiating.

The options vary with the device family. See:

- “SDR Options (ECP5)” on page 1638
- “SDR Options (LatticeECP3, MachXO2, MachXO3L, Platform Manager 2)” on page 1639
- “SDR Options (LatticeSC/M)” on page 1640

SDR Options (ECP5)

Table 279: SDR Dialog Box for ECP5

Feature	Description
Interface Type	Specify whether the interface is for transmit or receive.
Enable Tri-state Control	Available only with the Transmit interface type.
I/O Standard for this Interface	Choose an I/O standard.
Bus Width for this Interface	Specify the width of the bus in bits.
Clock Frequency for this Interface	Specify the frequency of the clock in megahertz.
Interface Bandwidth	Shows the resulting bandwidth in megabits/second. Bandwidth is the bus width multiplied by the clock frequency. This field is read-only.
Interface	Shows the interface in terms of primitives. Depends on the Interface Type above.
Clock Inversion	Specify whether or not to enable clock inversion. Available only with the receive interface type.
Data Path Delay	Choose a delay type. The delay types depend on the Interface Type. - Bypass means no delay. - Static sets a fixed delay. - Dynamic adds a data_direction, data_loadn, data_move, and data_cflag ports each of which is as wide as the Bus Width. - User Defined allows you to set a delay value in the Delay Value for User Defined field.
Delay Value for User Defined	If Data Path Delay is “User Defined,” specify the number of fine delay increments. Refer to the device datasheet to see the delay value for each increment.

Table 279: SDR Dialog Box for ECP5

Feature	Description
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

SDR Options (LatticeECP3, MachXO2, MachXO3L, Platform Manager 2)

Table 280: SDR Dialog Box for LatticeECP3, MachXO2, MachXO3L, and Platform Manager 2

Feature	Description
Interface Type	Specify whether the interface is for transmit or receive.
I/O Standard for this Interface	Choose an I/O standard.
Bus Width for this Interface	Specify the width of the bus in bits.
Clock Frequency for this Interface	Specify the frequency of the clock in megahertz.
Bandwidth (calculated)	Shows the resulting bandwidth in megabits/second. Bandwidth is the bus width multiplied by the clock frequency. This field is read-only.
Interface	Shows the interface. Depends on the Interface Type above.
Clock Inversion	Specify whether to enable clock inversion.

Table 280: SDR Dialog Box for LatticeECP3, MachXO2, MachXO3L, and Platform Manager 2

Feature	Description
Data Path Delay	Choose a delay type. The delay types depend on the device. Available only with the receive interface type. LatticeECP3: ▶ Bypass means no delay. ▶ Dynamic adds a 4-bit control port, del[3:0]. The value on the control port specifies the number of fine delay increments. Each increment is 1/16 of the clock cycle. ▶ User Defined sets a fixed delay. See FDEL for User Defined to set the amount. ▶ Fixed Delay adds a 4-bit control port, del[3:0]. The value on the control port specifies the number of fine delay increments. Each increment is 1/16 of the clock cycle. MachXO2, MachXO3L, or Platform Manager 2: ▶ Bypass means no delay. ▶ SCLK_ZEROHOLD sets zero hold for the register. ▶ User Defined sets a fixed delay. See FDEL for User Defined to set the amount.
FDEL for User Defined	If Data Path Delay is “User Defined,” specify the number of fine delay increments. Refer to the device datasheet to see the delay value for each increment. Available only with the receive interface type.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

SDR Options (LatticeSC/M)

The module dialog box has two tabs:

- Configuration, below
- Advanced, see Table 282 on page 1642

Table 281: SDR Dialog Box for LatticeSC/M—Configuration Tab

Feature	Description
Mode	Specify the Mode of the SDR. The SDR can be used as an input, output, tristate, or bidirectional. A tristate mode consists of two output SDRs. A bidirectional mode has one input and two output SDRs. Values: Input, Output, Bidirectional, Tristate
Bus Width	Specify the bus width. Values: 1 to 64
Gearing Ratio	Specify the gearing ratio. A 1x is an IO register. For gear ratio of 2x and 4x, the output width is 2 or 4 times the input width. The clock rate will be slower by the same amount. Values: 1x, 2x, 4x
Input, Output Clock Mode	Specifies the type of clock to use for the modes where no gearing is used. Values: Edge, Primary/Secondary
Data Delay	Specify the Data Delay type. By default, there is no delay in the data path. The delay may be set at configuration to values specified by CDEL and FDEL, set to match the primary or edge clock, or set to match the DLL Delay Controls (DCNTL bus). Values: None, DLL, Edge Clock, Primary Clock, ECLK Injection, User Defined
CDEL	Specify the coarse delay setting. Values: 0, 1, 2, 3
FDEL	Specify the fine delay setting. Values: 0 to 47
Use CLKDIV	Specify the use of CLKDIV element to get the slower clock. Using the clock and reset from the CLKDIV will reduce the skew between the two. This is useful for high-speed interfaces that have gearing.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 282: SDR Dialog Box for LatticeSC/M—Advanced Tab

Feature	Description
Use AIL	Specify that the Adaptive Input Logic (AIL) is used. This is available for configurations that contain an Input SDR. The AIL allows the I/O logic to automatically control coarse and fine delay settings to guarantee setup and hold times for a single I/O by sliding the data to a particular clock edge. The AIL features are not bus-based, but rather, per input port. Since the AIL will slide the data to a particular clock edge, the bits of a bus may not be latched on the same clock edge. This requires a training pattern to realign the individual bits of the input data bus to the same clock edge. For single bit instances, this training pattern is not required. An AIL deskew reference design is available from Lattice Semiconductor that provides an example of the circuitry and training pattern required to align the bits of a bus. Please contact Lattice Semiconductor for more information on this reference design.
AIL Acquisition Window (ps)	Specify the window size in ps where data transitions are not allowed. The AIL continuously delays data to keep the AIL Acquisition Window within the data pulse width away from the transition edges. Values: 400, 720, 1040, 1360
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Sin-Cos_Table

Look-up table for trigonometric sine and cosine values for an angle. The angle, Theta, is given in radians: 360º = 2π radians or 1 radian = 180º/π.

Table 283: Sin-Cos_Table Dialog Box

Feature	Description
Block Implementation	Specify if the module is implemented using EBR memory or LUTs. With Platform Manager, only LUT is available.
Input Theta Bit Width	Specify the width of the Theta input bus. This determines the precision with which the angle can be specified. The value of Theta will be in radians, from 0 to something less than 2π, depending on the width, and in the form of unsigned fixed-point data. The data will have a scaling factor of $\pi/2^{(width - 1)}$. For example, with an 8-bit Theta, π radians (180º) is given as $\pi \times 2^{(8 - 1)}/\pi = \pi \times 128/\pi$ = h'80.

Table 283: Sin-Cos_Table Dialog Box (Continued)

Feature	Description
Output Result Bit Width	Specify the width of the Sine and Cosine output buses.
Output Mode	Specify the outputs that are needed. More memory resources may be used when the Sin-Cos option is selected, but in some cases, this may be better than two independent Sin and Cos modules.
Use Tables for Quarter-wave Only	Select to reduce memory by only storing a quarter wave and deriving the rest of it with additional logic. If selected, see “Specify the number of pipeline stages” below to improve performance.
Use 1-bit for Signed Integer	Specify if the output values should be in twos complement format or sign-and-magnitude format. If this option is selected, the values will be in twos complement format with a scaling factor of $1/2^{(width - 1)}$. If this option is cleared, the values will be in sign-and-magnitude format with a scaling factor of $1/2^{(width - 2)}$.
Enable Input Registers	Specify if input registers are required.
Enable Output Registers	Specify if output registers are required. Output registers are automatically included in the LUT implementation.
Specify the number of pipeline stages	If Use Tables for Quarter-wave Only is selected (above), specify the number of register stages to insert to improve performance.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

SLICE

Generic module used to generate custom configurations. Provides a variety of multiply/accumulate organizations and is implemented as embedded sysDSP blocks. The full SLICE configuration is recommended only if MULT, MAC, MULTADDSUB, and MULTADDSUBSUM configurations cannot satisfy the application requirement.

The module dialog box has two tabs:

- Configuration, below
- Register Setup, see Table 285 on page 1646

Slice includes optional input and output registers. There are also optional pipeline registers between the multipliers and the ALU.

In the Register Setup tab you can choose to enable or to bypass any of these registers. Normally you would leave them all enabled and instead use the Enable Input/Pipeline/Output Registers check boxes in the Configuration tab. Normally you want all registers of the same type set the same for the sake of timing.

In the Register Setup tab, you can also specify the clock, clock enable, and reset signal for each register.

Table 284: SLICE Dialog Box—Configuration Tab

Feature	Description
Mult and ALU Selection	**Enable MultA** – Enable the A multiplier and the AA and AB inputs. MultA must be disabled to do logical combinations of the ALU's B and C inputs (see "Operation" following), or to use some options for the ALU's A input (see "Input A (A Mux)" following). **Enable MultB** – Enable the B multiplier and the BA and BB inputs. MultB must be disabled to use some options for the ALU's B input (see "Input B (B Mux)" following). **Cascade Match Register** – Enable the Cascade Match Register of the B multiplier. **Select Shift Out B** – Enable the shift-out port B of the DSP block. **Enable ALU** – Enable the arithmetic logic unit that combines the results of multipliers A and B. Disable the ALU to get the results of the multipliers on separate output buses. **Operation** – Specify an arithmetic combination of the ALU's A, B, and C inputs; a logical combination of the B and C inputs; or dynamic selection of the operation. For the B and C logical combinations, clear **Enable MultA** (above). Inputs are defined below the Operation box. A DYNAMIC setting is available for all inputs. Dynamic mode settings for Opcode[3:0]: A + B + C: 0100 A - B + C: 0101 A + B - C: 0110 A - B - C: 0111 B XNOR C: 1100 B XOR C: 1110 B NAND C: 0000 B AND C: 1000 B OR C: 0011 B NOR C: 1011

Table 284: SLICE Dialog Box—Configuration Tab (Continued)

Feature	Description
	Input A (A Mux) – Specify the A input for the ALU. For the MultA option, select **Enable MultA** (above). Dynamic mode settings for Amuxsel[1:0]: ALU Feedback: 00 MultA: 01 A_ALU: 10 0: 11 **Input B (B Mux)** – Specify the B input for the ALU. For the MultB Shift 18 L and MultB options, select **Enable MultB** (above). Dynamic mode settings for Bmuxsel[1:0]: MultB Shift 18 L: 00 MultB: 01 B_ALU: 10 0: 11
	Input C (C Mux) – Specify the C input for the ALU. Dynamic mode settings for Cmuxsel[2:0]: 0: 000 CIN Shift 18 R: 001 CIN: 010 C_ALU: 011 A_ALU: 100 ALU Feedback: 101 RNDtoPN: 110 RNDtoPNM1: 111
	MCPAT_SOURCE – Specify whether the source of the MEM cell pattern is static or dynamic. If static, specify the pattern in the MCPAT box. If dynamic, send the pattern through the C bus. MCPAT_SOURCE and MASKPAT_SOURCE cannot both be dynamic. Not available when Input C is set to C_ALU or A_ALU. **MASKPAT_SOURCE** – Specify whether the source of the mask for EQPAT/EQPATB is static or dynamic. If static, specify the mask in the MASKPAT box. If dynamic, send the mask through the C bus. MCPAT_SOURCE and MASKPAT_SOURCE cannot both be dynamic. Available only when Input C is set to C_ALU or A_ALU. **MCPAT** – Specify the MEM cell pattern in hexadecimal. **MASKPAT** – Specify the mask for EQPAT/EQPATB in hexadecimal. **MASK01** – Specify the mask for EQZM/EQOM in hexadecimal. **RNDPAT** – Specify the rounding pattern in hexadecimal. **n for RNDPAT** – Available only when Input C is set to RNDtoPN, RNDtoPNM1, or DYNAMIC.
	Reset Mode – Specify whether the reset is synchronous or asynchronous.

Table 284: SLICE Dialog Box—Configuration Tab (Continued)

Feature	Description
Input Selection	**Width** – Specify the size of the inputs. C's width can be set only when Input C is set to C_ALU, A_ALU, or DYNAMIC. **Source** – Specify if the source of the input is Parallel for generic routing, Shift for the shift outputs of an adjacent DSP block, or Dynamic for dynamic selection of the source of the input. **Sign** – Specify the data format of the inputs as signed, unsigned, or dynamic selection of the sign.
	Enable Input Registers – Enable the input registers as specified in the Register Setup tab. **Enable Pipeline Registers** – Enable the pipeline registers as specified in the Register Setup tab. **Enable Output Registers** – Enable the output registers and the flag register as specified in the Register Setup tab.
Bus Ordering Style	Specify if the inputs and output are big endian (MSB:LSB) or little endian (LSB:MSB), or none.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 285: SLICE Dialog Box—Register Setup Tab

Feature	Description
Enable Input Register AA, AB, BA, BB, C Enable ALU Opcode Register	Input registers for the A and B multipliers, the C ALU, and the ALU Opcode signal.
Enable MultA Pipeline Register Enable MultB Pipeline Register Enable ALU Opcode Pipeline Register	Pipeline registers from the multiplier outputs to the ALU and from the ALU Opcode (or the Opcode register if enabled) to the ALU. If the ALU is disabled (by clearing Enable ALU in the Configuration tab), the multiplier pipeline registers go to the PA and PB outputs of the Slice module.
Enable MultA Output Register Enable MultB Output Register Enable ALU Output and Flag Register	Output registers for the multipliers and the ALU.
Bus Ordering Style	Specify if the inputs and output are big endian (MSB:LSB) or little endian (LSB:MSB), or none.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.

Subtractor

A two-input subtractor that performs signed or unsigned subtraction of the data from input ports DataA and DataB. If the optional port Cin is used, the subtraction result DataA - DataB + Cin is returned to the output port Result. The optional Cout port represents carry-out and the optional Overflow port detects overflow conditions when operating on signed data.

Table 286: Subtractor Dialog Box

Feature	Description
Specify the Data Width of the Subtractor	Specifies the input bus width of the module.
Specify the Representation of the Subtractor	Selections can be either signed or unsigned. Choosing the signed representation will keep the signed bit on the output. Unsigned will remove the signed bit from the output.
Complex Inputs	Allows implementation of complex subtractor.
Use Carry-in port	Adds a carry-in port to the module. This port will be Active Low.
Specify the Carry-out Port	Uses the carry-out port, overflow port, or none at all. Overflow port is allowed only when the representation is signed.
Enable Output Register	Allows the implementation of registers on the outputs.
Specify number of pipeline stages	Specifies the number of register stages inserted into the subtractor. More stages improves achievable frequency of operation, but the latency for the output increases.
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.

Table 286: Subtractor Dialog Box (Continued)

Feature	Description
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 287: Subtractor Ports

Name	Description
Cin (optional)	Carry-in to the low-order bit.
DataA[size-1..0]	Minuend
DataB[size-1..0]	Subtrahend
Result[size-1..0]	DataA[size-1..0] - DataB[size-1..0] + Cin - 1
Cout (optional)	Carry-out of the MSB to detect overflow in unsigned representation. When Cout is prepended to the Result, the result is a vector that always has sufficient precision to represent the result of the operation, {Cout, Result} = DataA + DataB + Cin. Appears as a port of the module when representation is set to unsigned and appears as an internal signal of the module when representation is set to signed. The signal is active low.
Overflow (optional)	Result exceeds available precision when used with signed representation. XOR of the carry into the MSB and Cout. The Overflow port only produces meaningful output if representation is set to signed.

pmi_sub

The following are port descriptions, Verilog and VHDL definitions, and parameter descriptions for pmi_sub.

Port Description

Input/Output	Port Name	Type	Size (Buses Only)
I	DataA	Bus	(pmi_data_width - 1):0
I	DataB	Bus	(pmi_data_width - 1):0
I	Cin	Bit	N/A
O	Result	Bus	(pmi_data_width - 1):0
O	Cout	Bit	N/A
O	Overflow	Bit	N/A

Verilog pmi_sub Definition

```
module pmi_sub
  #(parameter pmi_data_width = 8,
    parameter pmi_result_width = 8,
    parameter pmi_sign = "off",
    parameter pmi_family = "EC",
    parameter module_type = "pmi_sub"
    )

    (
     input [pmi_data_width-1:0] DataA,
     input [pmi_data_width-1:0] DataB,
     input Cin,
     output [pmi_data_width-1:0] Result,
     output Cout,
     output Overflow)/*synthesis syn_black_box */;
endmodule // pmi_sub
```

VHDL pmi_sub Definition

     Result : out std_logic_vector(pmi_data_width-1 downto 0);
     Cout: out std_logic;
     Overflow: out std_logic
   );
  end component pmi_sub;
```

Parameter Names and Values

The following table contains the pmi_sub module parameters, acceptable values, and default value.

Parameter Name	Acceptable Values	Default Value	Notes
pmi_data_width	1 to 64	8	The LatticeSC/M device families data and result widths range from 1 to 256.
pmi_result_width	1 to 64	8	The LatticeSC/M device families data and result widths range from 1 to 256.
pmi_sign	“on” | “off”	“off”	
pmi_family	“EC” | “ECP” | “ECP2” | “ECP2M” | “ECP3” | “ECP5U” | “ECP5UM” | “SC” | “SCM” | “XP” | “XP2” | “XO” | “XO2” | “XO3L” | “LPTM”	“EC”

System_Bus

A LatticeSC/M system bus.

In addition to the usual files, the System Bus module includes a <*module_name*>.txt file. This file is used by simulation and bitgen to configure the modules. When you import the source files for this module into the design project, also import the <*module_name*>.txt file as a source. It will show up under Documents in the Files tab.

The module dialog box has seven tabs:

- MPI, below
- User Master, see Table 289 on page 1659
- User Slave, see Table 290 on page 1659
- SMI, Table 291 on page 1660
- PCS, see Table 292 on page 1660
- Global, see Table 293 on page 1661
- Advanced, see Table 294 on page 1661

Table 288: System_Bus Dialog Box—MPI Tab

Feature	Description
Enable MPI	Provides pins for the MPI interface on the system bus module. Selecting this option generates top-level MPI ports. Any tristate output ports and bidirectional buffers are also instantiated in the netlist. MPI is not available with the smallest LatticeSC/M packages.
Bus Width	Sets the bus width of the MPI data/parity buses. The width of the MPI data bus can be 8, 16, or 32. This determines the number of I/O pads locked for the MPI.
Parity Enable	Enables the creation of the parity pins on the MPI bus. When selected, the parity bits are connected to the top-level ports. The number of parity bits is determined by the MPI data bus width.
DMA Interface	Provides ports for the DFA interface on the system bus module.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 289: System_Bus Dialog Box—User Master Tab

Feature	Description
Enable User Master Interface	Provides ports for the user master interface (UMI) on the system bus module.
User Master Sync. to Systembus Clock (HCLK)	The system bus uses two modes of clocking: synchronous and asynchronous. This option will select the UMI to be a synchronous transaction. The asynchronous interface uses a small internal FIFO to cross clock domains from the UMI to the system bus.
Automatic Retry	Enables the UMI to automatically retry a transaction if necessary.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 290: System_Bus Dialog Box—User Slave Tab

Feature	Description
Enable User Slave Interface	Provides ports for the user slave interface (USI) on the system bus module.
User Slave Sync. to Systembus Clock (HCLK)	The system bus uses two modes of clocking: synchronous and asynchronous. This option will select the USI to be a synchronous transaction. The asynchronous interface uses a small internal FIFO to cross clock domains from the USI to the system bus.

Table 290: System_Bus Dialog Box—User Slave Tab (Continued)

Feature	Description
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 291: System_Bus Dialog Box—SMI Tab

Feature	Description
Enable Serial Management Interface	Provides ports for the user slave interface (USI) on the system bus module.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 292: System_Bus Dialog Box—PCS Tab

Feature	Description
Enable PCS Control/Status Ports	Include PCS Interface pins on the System Bus clock interface for the selected PCS quads. Select those PCS Quads which require System Bus control and/or monitoring.
Select Multi-Quad Alignment	Select **Enable Multi-Quad Alignment**. Available if “Enable PCS Control/Status Ports” is selected for two or more PCS quads. Then choose one of four Multi-Quad Alignment input clocks (0, 1, 2, or 3) for each quad that requires multi-quad alignment. All quads to be aligned to each other must use the same Multi-Quad Alignment input clock. Select “-” for any PCS quad that does not require Multi-Quad Alignment.
Enable Multi-Chip Alignment	Enable PCS Control/Status Ports has been selected for at least one PCS Quad. All PCS Quads which are to be multi-chip aligned must be set to the Group 0 clock.
Local Device	If Enable Multi-Chip Alignment is selected, specify if the local device is a slave or the master.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 293: System_Bus Dialog Box—Global Tab

Feature	Description
Parity	This selection controls the parity that is generated and checked by the system bus.
MPI Priority	The system bus can be configured as a multi-master bus. This selection sets the priority of the MPI. To select this option, first select Enable MPI in the MPI tab and Enable user Master Interface in the User_Master tab.
User Master Priority	The system bus can be configured as a multi-master bus. This selection sets the priority of the UMI. To select this option, first select Enable MPI in the MPI tab and Enable user Master Interface in the User_Master tab.
Systembus Reset by MPI	Allows the user to reset the system bus through a run time register only accessible from the MPI. To select this option, first select **Enable MPI** in the MPI tab.
Systembus Reset by User Master	Allows the user to reset the system bus through a run time register only accessible from the UMI. To select this option, first select **Enable User Master Interface** in the User_Master tab.
Systembus Clock	Selects the source of the internal system bus clock.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Table 294: System_Bus Dialog Box—Advanced Tab

Feature	Description
Read Only Word #1-6	Read only words that are set in the FPGA bitstream. These values are written to specific read-only registers in the system bus for run time access.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

Tag Memory

A one-page FLASH non-volatile memory accessible by the hard-wired Serial Peripheral Interface port or the JTAG port. This stand-alone TAG memory is ideal for scratch pad memory for mission critical data, board serialization, board revision log, and programmed pattern identification.

Table 295: Tag Memory Dialog Box

Feature	Description
Tag Memory Size	Displays the available memory, in bytes, for the selected device. This number cannot be changed by the user.
Memory File	Allows you to select a memory initialization (.mem) file for the module. See "Creating a Memory Initialization File with Memory Generator" on page 202.
Memory File Format	Allows you to choose Binary, Hex, or Addressed Hex format.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

WIDE_MUX

Multiplexes several input buses onto a single output bus.

Table 296: WIDE_MUX Dialog Box

Feature	Description
Width	Specifies the width of the input data buses and the Result bus.
Number of Inputs	Specifies the number of input data buses. The size of the Sel (select) bus adjusts automatically.
Reset Mode	Specify either a synchronous or asynchronous reset.
Enable Fully Pipelined Mode	Enables the output registers of all stages.
Enable Input Register	Enables the registers on the inputs.
Enable Output Register	Enables the registers on the output.

Table 296: WIDE_MUX Dialog Box (Continued)

Feature	Description
Bus Ordering Style	Specifies whether the numbers should begin at the high end (“Big Endian”- BusA[7 to 0]) or at the low end (“Little Endian”-BusA[0 to 7]). Selecting None prevents any bus notation and writes out all individual pins.
Import IPX to Diamond project	Adds the customized module to the currently open project. Not available if running IPexpress as a stand-alone tool. Not available in Clarity Designer.
Generate	Builds the module as specified.
Close	Closes the dialog box without generating the module.
Help	Opens the online Help.

FPGA Libraries Reference Guide

Lattice supports some libraries used in designing FPGAs with different device architectures in a number of CAE synthesis, schematic capture, and simulation platforms. These libraries are the main front-end design libraries for Lattice FPGAs. Logic design primitives in these libraries offer flexibility and efficiency to facilitate building specific applications with Lattice devices. Many primitives can be used in multiple Lattice device architectures. With Schematic Editor, you can place the primitive symbols from the Lattice Symbol Library, lattice.lib, which is composed of primitives compatible with most Lattice FPGA device families. For macro-sized primitives like architectural blocks, arithmetic, or memories, use IPexpress™ to configure and generate schematic symbols and files for implementation. You can also use physical macros that you create in EPIC. See the appropriate topic in the online help system for more information.

A specific primitive can be found according to the device family and functional category. Primitives available to each of the following device families are listed according to appropriate functional categories.

The “Alphanumeric Primitives List” section contains descriptions of all available primitives in their alphanumeric order. The following information is provided for each primitive, where applicable:

Table 297: Information Provided for Each Primitive

Fields	Description
Name	Primitive name
Definition	Brief description of primitive
Architectures Supported	Index of FPGA families supported by the primitive
Port Interface Symbol	Graphic to represent the primitive port interface. Data, address, clock, clock enable type ports appear on the left-hand side of the block. Synchronous control ports appear on the top of the symbol, asynchronous control ports on the bottom, and output ports on the right-hand side of the block. Some of the graphic symbols are shown in bus notation for proper layout. Those primitives must be instantiated in expanded bus notation format with each individual bit.
Attributes	Index of attributes compatible with the primitive. The first value is usually the default value, if it is not explicitly indicated. Attribute function, range, and port-to-attribute or attribute-to-attribute relationships for the primitive are noted. For descriptions of all the attributes used in primitives, see “List of Primitive-Specific HDL Attributes” on page 2413.
Description	Detailed description of primitive function. Exceptions are identified by device family. This section sometimes includes truth table, waveform, state diagram, or other graphical methods to illustrate behavior. References to appropriate Lattice technical notes are listed.
Port Description	Index of port names, polarity, and function.
Connectivity Rules	Some primitive ports, such as DDR and DSP blocks, are connected to dedicated routing with source or loads related to other primitives. This section describes connection rules.

Naming Conventions

The table shows the convention for naming all of the sequential primitives. Each primitive is identified using up to seven characters.

Flip-Flop/Latch Naming Conventions (name = abcdef)

Table 298: Naming Conventions

a=	F - Static implementation
b=	D - D type flip-flop
	J - J/K type flip-flop
	L - Cells contain a positive select front end (loadable)
	N - Cells contain a negative select front end (loadable)
	S - R-S type flip-flop
	T - Toggle type flip-flop
c=	Value - Number of clocks
d=	This parameter identifies the enable capability.
	S - No enable input
	P - Positive-level enable
	N - Negative-level enable
e=	This parameter identifies the clock capability
	1 - Positive-level sense (latch)
	2 - Negative edge-triggered (flip-flop)
	3 - Positive edge-triggered (flip-flop)
	4 - Negative-level sense (latch)
f=	A - No clear or preset inputs
	B - Positive-level asynchronous preset
	D - Positive-level asynchronous clear
	I - Positive-level synchronous clear
	J - Positive-level synchronous preset
	X - Standard primitive where GSR asynchronously clears or presets the flip-flop depending upon the function of the local clear or preset. If no local clear or preset is present (f=A), then GSR clears the register element.
	Y - Primitive is preset using GSR rather than cleared
	Z - Primitive not compatible with similar primitives available in the standard cell library

Example:

FD1P3BX is a single clock, positive edge-triggered, static, D-type flip-flop with a positive-level enable and a positive-level asynchronous preset.

Table 299: Example: FD1P3BX

FD1P3BX	a = F	Static cell
	b = D	D type
	c = 1	Single clock
	d = P	Positive-level enable
	e = 3	Positive edge-triggered
	f = B	Positive-level asynchronous preset

When creating designs from schematic or synthesis, please observe the following rules:

- Component, net, site, or instance names should be unique and independent of case. For example, if a net in a design is named "d0", then you cannot have an instance of AND2 named "D0".
- Component, net, site, or instance names cannot be any cell name.
- Component, net, site, or instance names cannot be GND, PWR, VSS, VDD, GSR, GSRNET, TSALL, TSALLNET, and so forth.
- Component, net, site, or instance names cannot contain preference keywords such as DIN, DOUT, SITE, COMP, and so forth.
- Component, net, site, or instance names cannot contain names starting with 0–9, /, \, +, –, and other special characters.
- Component, net, site, or instance names cannot be named using VHDL or Verilog keywords such as IN, OUT, INOUT, and so forth.

Note the following about numbering used throughout this Help:

- Least significant bits (LSBs) on a primitive are always determined by the lowest integer value (usually zero) expressed in a pin name input or output in a pin grouping just as most significant bits (MSBs) are always determined by the highest integer value.

For example, out of the pin group containing pins A0, A1, A2, and A3, A0 is the LSB and A3 is the MSB. The LSB or MSB is not affected by the order in which pins are numbered (that is, whether or not they are in ascending or descending order).

Memory Primitives Overview

The architectures of various Lattice FPGAs provide resources for on-chip memory intensive applications. The sysMEM™ embedded block RAM (EBR) complements the distributed PFU-based memory. Single-port RAM, dual-port

RAM, FIFO, and ROM memories can be constructed using the EBR. LUTs and PFU can implement distributed single-port RAM, dual-port RAM, and ROM. The Lattice Diamond software enables you to integrate the EBR- and PFU-based memories in various device families.

The EBR-based and PFU-based memory primitives are listed in this document. Designers can utilize the memory primitives in several ways via the IPexpress tool in the Diamond software. IPexpress allows you to specify the attributes of the memory application, such as required type and size. IPexpress takes the customized specification and constructs a netlist to implement the desired memory, using one or more of the memory primitives.

The available memory primitives include:

RAM_DP (Dual Port RAM)

Implementation: EBR

Table 300: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	WrAddress	Bus	(pmi_wr_addr_width – 1) : 0
I	RdAddress	Bus	(pmi_rd_addr_width – 1) : 0
I	Data	Bus	(pmi_wr_data_width – 1) : 0
I	RdClock	Bit	N/A
I	RdClockEn	Bit	N/A
I	Reset	Bit	N/A

Table 300: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	WrClock	Bit	N/A
I	WrClockEn	Bit	N/A
I	WE	Bit	N/A
O	Q	Bus	(pmi_rd_data_width – 1) : 0

Table 301: Parameters

Name	Value	Default
pmi_rd_addr_depth [1]	2 to 65536	512
pmi_rd_addr_width [1]	1 to 16	9
pmi_rd_data_width	1 to 256	18
pmi_wr_addr_depth [1]	2 to 65536	512
pmi_wr_addr_width [1]	1 to 16	9
pmi_wr_data_width	1 to 256	18
pmi_regmode	"reg" | "noreg"	"reg"
pmi_gsr	"enable" | "disable"	"disable"
pmi_resetmode [2]	"async" | "sync"	"sync"
pmi_optimization	"area" | "speed"	"speed"
pmi_init_file	*<string>*	"none"
pmi_init_file_format	"binary" | "hex"	"binary"
pmi_family	"EC" | "XP" | "XP2" | "SC" | "SCM" | "ECP" | "ECP2" | "ECP2M" | "XO" | "XO2" | "XO3L" | "XO3LF" | "ECP3" | "ECP5U" | "ECP5UM" | "LPTM" | "LPTM2"	"EC"

Note

1. For SC, SCM, ECP2, ECP2M, XP2, and ECP3 FPGA device families, the read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
2. For ECP3, "async" is not a valid option.

RAM_DP_BE (Dual Port RAM with Byte Enable)

Implementation: EBR

Table 302: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	WrAddress	Bus	(pmi_wr_addr_width – 1) : 0
I	RdAddress	Bus	(pmi_rd_addr_width – 1) : 0
I	Data	Bus	(pmi_wr_data_width – 1) : 0
I	RdClock	Bit	N/A
I	RdClockEn	Bit	N/A
I	Reset	Bit	N/A
I	WrClock	Bit	N/A
I	WrClockEn	Bit	N/A
I	WE	Bit	N/A
O	Q	Bus	(pmi_rd_data_width – 1) : 0
I	ByteEn	Bus	((pmi_wr_data_width + pmi_byte_size – 1) / pmi_byte_size – 1) : 0

Table 303: Parameters

Name	Value	Default
pmi_rd_addr_depth[1]	2 to 65536	512
pmi_rd_addr_width[1]	1 to 16	9
pmi_rd_data_width	1 to 256	18
pmi_wr_addr_depth[1]	2 to 65536	512
pmi_wr_addr_width[1]	1 to 16	9
pmi_wr_data_width	1 to 256	18
pmi_regmode	"reg" | "noreg"	"reg"
pmi_gsr	"enable" | "disable"	"disable"
pmi_resetmode[2]	"async" | "sync"	"sync"
pmi_optimization	"area" | "speed"	"speed"
pmi_init_file	*<string>*	"none"
pmi_init_file_format	"binary" | "hex"	"binary"

Table 303: Parameters (Continued)

Name	Value	Default
pmi_family	"XP2" | "SC" | "SCM" | "ECP2" | "ECP2M" | "XO2" | "ECP3" | "ECP5U" | "ECP5UM" | "LPTM2"	"ECP2"
pmi_byte_size	8 | 9	9

Note

1. For SC, SCM, ECP2, ECP2M, XP2, and ECP3 FPGA device families, the read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
2. For ECP3, "async" is not a valid option.

RAM_DP_TRUE (True Dual Port RAM)

Implementation: EBR

Table 304: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	DataInA	Bus	(pmi_data_width_a – 1) : 0
I	DataInB	Bus	(pmi_data_width_b – 1) : 0
I	AddressA	Bus	(pmi_addr_width_a – 1) : 0
I	AddressB	Bus	(pmi_addr_width_b – 1) : 0
I	ClockA	Bit	N/A
I	ClockB	Bit	N/A
I	ClockEnA	Bit	N/A
I	ClockEnB	Bit	N/A
I	WrA	Bit	N/A
I	WrB	Bit	N/A
I	ResetA	Bit	N/A
I	ResetB	Bit	N/A
O	QA	Bus	(pmi_data_width_a – 1) : 0
O	QB	Bus	(pmi_data_width_b – 1) : 0

Table 305: Parameters

Name	Value	Default
pmi_addr_depth_a[1]	2 to 65536	512
pmi_addr_width_a[1]	1 to 16	9
pmi_data_width_a	1 to 256	18
pmi_addr_depth_b[1]	2 to 65536	512
pmi_addr_width_b[1]	1 to 16	9
pmi_data_width_b	1 to 256	18
pmi_regmode_a	"reg" | "noreg"	"reg"
pmi_regmode_b	"reg" | "noreg"	"reg"
pmi_gsr	"enable" | "disable"	"disable"
pmi_resetmode[2]	"async" | "sync"	"sync"
pmi_optimization	"area" | "speed"	"speed"
pmi_init_file	*<string>*	"none"
pmi_init_file_format	"binary" | "hex"	"binary"
pmi_write_mode_a[3]	"normal" | "writethrough" | "readbeforewrite"	"normal"
pmi_write_mode_b[3]	"normal" | "writethrough" | "readbeforewrite"	"normal"
pmi_family	"EC" | "XP" | "XP2" | "SC" | "SCM" | "ECP" | "ECP2" | "ECP2M" | "XO" | "XO2" | "XO3L" | "XO3LF" | "ECP3" | "ECP5U" | "ECP5UM" | "LPTM" | "LPTM2"	"EC"

Note

1. For SC, SCM, ECP2, ECP2M, XP2, and ECP3 FPGA device families, the read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
2. For ECP3, "async" is not a valid option.
3. The "Readbeforewrite" option is not supported by ECP2, ECP2M, XP2, SC, SCM, or ECP3.

RAM_DP_TRUE_BE (True Dual Port RAM with Byte Enable)

Implementation: EBR

Table 306: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	DataInA	Bus	(pmi_data_width_a – 1) : 0
I	DataInB	Bus	(pmi_data_width_b – 1) : 0
I	AddressA	Bus	(pmi_addr_width_a – 1) : 0
I	AddressB	Bus	(pmi_addr_width_b – 1) : 0
I	ClockA	Bit	N/A
I	ClockB	Bit	N/A
I	ClockEnA	Bit	N/A
I	ClockEnB	Bit	N/A
I	WrA	Bit	N/A
I	WrB	Bit	N/A
I	ResetA	Bit	N/A
I	ResetB	Bit	N/A
O	QA	Bus	(pmi_data_width_a – 1) : 0
O	QB	Bus	(pmi_data_width_b – 1) : 0
I	ByteEnA	Bus	((pmi_data_width_a + pmi_byte_size – 1) / pmi_byte_size – 1) : 0
I	ByteEnB	Bus	((pmi_data_width_b + pmi_byte_size – 1) / pmi_byte_size – 1) : 0

Table 307: Parameters

Name	Value	Default
pmi_addr_depth_a[1]	2 to 65536	512
pmi_addr_width_a[1]	1 to 16	9
pmi_data_width_a	1 to 256	18
pmi_addr_depth_b[1]	2 to 65536	512
pmi_addr_width_b[1]	1 to 16	9
pmi_data_width_b	1 to 256	18
pmi_regmode_a	"reg" | "noreg"	"reg"

Table 307: Parameters (Continued)

Name	Value	Default
pmi_regmode_b	"reg" | "noreg"	"reg"
pmi_gsr	"enable" | "disable"	"disable"
pmi_resetmode[2]	"async" | "sync"	"sync"
pmi_optimization	"area" | "speed"	"speed"
pmi_init_file	*<string>*	"none"
pmi_init_file_format	"binary" | "hex"	"binary"
pmi_write_mode_a[3]	"normal" | "writethrough" | "readbeforewrite"	"normal"
pmi_write_mode_b[3]	"normal" | "writethrough" | "readbeforewrite"	"normal"
pmi_family	"XP2" | "SC" | "SCM" | "ECP2" | "ECP2M" | "XO2" | "LPTM2" | "ECP3" | "ECP5U" | "ECP5UM"	"ECP2"
pmi_byte_size	8 | 9	9

Note

1. For SC, SCM, ECP2, ECP2M, XP2, and ECP3 FPGA device families, the read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
2. For ECP3, "async" is not a valid option.
3. The "Readbeforewrite" option is not supported by ECP2, ECP2M, XP2, SC, SCM, or ECP3.

RAM_DQ (Single Port RAM)

Implementation: EBR

Table 308: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	Data	Bus	(pmi_data_width – 1) : 0
I	Address	Bus	(pmi_addr_width – 1) : 0
I	Clock	Bit	N/A
I	ClockEn	Bit	N/A
I	Reset	Bit	N/A
I	WE	Bit	N/A
O	Q	Bus	(pmi_data_width – 1) : 0

Table 309: Parameter

Name	Value	Default
pmi_addr_depth[1]	2 to 65536	512
pmi_addr_width[1]	1 to 16	9
pmi_data_width	1 to 256	18
pmi_regmode	"reg" | "noreg"	"reg"
pmi_gsr	"enable" | "disable"	"disable"
pmi_resetmode[2]	"async" | "sync"	"sync"
pmi_optimization	"area" | "speed"	"speed"
pmi_init_file	*<string>*	"none"
pmi_init_file_format	"binary" | "hex"	"binary"
pmi_write_mode[3]	"normal" | "writethrough" | "readbeforewrite"	"normal"
pmi_family	"EC" | "XP" | "XP2" | "SC" | "SCM" | "ECP" | "ECP2" | "ECP2M" | "XO" | "XO2" | "XO3L" | "XO3LF" | "ECP3" | "ECP5U" | "LPTM" | "LPTM2"	"EC"

Note

1. For SC, SCM, ECP2, ECP2M, XP2, and ECP3 FPGA device families, the read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
2. For ECP3, "async" is not a valid option.
3. The "Readbeforewrite" option is not supported by ECP2, ECP2M, XP2, SC, SCM, or ECP3.

RAM_DQ_BE (Single Port RAM with Byte Enable)

Implementation: EBR

Table 310: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	Data	Bus	(pmi_data_width – 1) : 0
I	Address	Bus	(pmi_addr_width – 1) : 0
I	Clock	Bit	N/A
I	ClockEn	Bit	N/A
I	Reset	Bit	N/A
I	WE	Bit	N/A

Table 310: Pins

Input/Output	Port Name	Type	Size (Buses Only)
O	Q	Bus	(pmi_data_width – 1) : 0
I	ByteEn	Bus	((pmi_data_width + pmi_byte_size – 1) / pmi_byte_size – 1) : 0

Table 311: Parameters

Name	Value	Default
pmi_addr_depth[1]	2 to 65536	512
pmi_addr_width[1]	1 to 16	9
pmi_data_width	1 to 256	18
pmi_regmode	"reg" | "noreg"	"reg"
pmi_gsr	"enable" | "disable"	"disable"
pmi_resetmode[2]	"async" | "sync"	"sync"
pmi_optimization	"area" | "speed"	"speed"
pmi_init_file	<*string*>	"none"
pmi_init_file_format	"binary" | "hex"	"binary"
pmi_write_mode[3]	"normal" | "writethrough" | "readbeforewrite"	"normal"
pmi_family	"XP2" | "SC" | "SCM" | "ECP2" | "ECP2M" | "XO2" | "LPTM2" | "ECP3" | "ECP5U"	"ECP2"
pmi_byte_size	8 | 9	9

Note

1. For SC, SCM, ECP2, ECP2M, XP2, and ECP3 FPGA device families, the read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
2. For ECP3, "async" is not a valid option.
3. The "Readbeforewrite" option is not supported by ECP2, ECP2M, XP2, SC, SCM, or ECP3.

ROM (Read Only Memory)

Implementation: EBR

Table 312: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	Address	Bus	(pmi_addr_width – 1) : 0
I	OutClock	Bit	N/A
I	OutClockEn	Bit	N/A
I	Reset	Bit	N/A
O	Q	Bus	(pmi_data_width – 1) : 0

Table 313: Parameters

Name	Value	Default
pmi_addr_depth[1]	2 to 65536	512
pmi_addr_width[1]	1 to 16	9
pmi_data_width	1 to 256	18
pmi_regmode	"reg" | "noreg"	"reg"
pmi_gsr	"enable" | "disable"	"disable"
pmi_resetmode[2]	"async" | "sync"	"sync"
pmi_optimization	"area" | "speed"	"speed"
pmi_init_file	*<string>*	"none"
pmi_init_file_format	"binary" | "hex"	"binary"
pmi_family	"EC" | "XP" | "XP2" | "SC" | "SCM" | "ECP" | "ECP2" | "ECP2M" | "XO" | "XO2" | "XO3L" | "XO3LF" | "ECP3" | "ECP5U" | "ECP5UM" | "LPTM" | "LPTM2"	"EC"

Note

1. For SC, SCM, ECP2, ECP2M, XP2, and ECP3 FPGA device families, the read/write address depth ranges from 2 to 131072. The address width ranges from 1 to 17.
2. For ECP3, "async" is not a valid option.

Distributed_DPRAM (Distributed Dual Port RAM)

Implementation: LUT

Table 314: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	WrAddress	Bus	(pmi_addr_width – 1) : 0
I	Data	Bus	(pmi_data_width – 1) : 0
I	WrClock	Bit	N/A
I	WrClockEn	Bit	N/A
I	WE	Bit	N/A
I	RdAddress	Bus	(pmi_addr_width – 1) : 0
I	RdClock	Bit	N/A
I	RdClockEn	Bit	N/A
I	Reset	Bit	N/A
O	Q	Bus	(pmi_data_width – 1) : 0

Table 315: Parameters

Name	Value	Default
pmi_addr_depth	2 to 8192	32
pmi_addr_width	1 to 13	5
pmi_data_width	1 to 256	8
pmi_regmode	"reg" | "noreg"	"reg"
pmi_init_file[1]	*<string>*	"none"
pmi_init_file_format[1]	"binary" | "hex"	"binary"
pmi_family	"EC" | "XP" | "XP2" | "SC" | "SCM" | "ECP" | "ECP2" | "ECP2M" | "XO" | "XO2" | "XO3L" | "XO3LF" | "ECP3" | "ECP5U" | "ECP5UM" | "LPTM" | "LPTM2"	"EC"

Note

1. The pmi_init_file and pmi_init_file_format parameters are not supported for EC, XP, ECP, ECP2, ECP2M, LPTM, and XO device families in distributed mode.

Distributed_ROM (Distributed Read Only Memory)

Implementation: LUT

Table 316: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	Address	Bus	(pmi_addr_width – 1) : 0
I	OutClock	Bit	N/A
I	OutClockEn	Bit	N/A
I	Reset	Bit	N/A
O	Q	Bus	(pmi_data_width – 1) : 0

Table 317: Parameters

Name	Value	Default
pmi_addr_depth	2 to 8192	32
pmi_addr_width	1 to 13	5
pmi_data_width	1 to 128	8
pmi_regmode	"reg" | "noreg"	"reg"
pmi_init_file	*<string>*	"none"
pmi_init_file_format	"binary" | "hex"	"binary"
pmi_family	"EC" | "XP" | "XP2" | "SC" | "SCM" | "ECP" | "ECP2" | "ECP2M" | "XO" | "XO2" | "XO3L" | "XO3LF" | "ECP3" | "ECP5U" | "ECP5UM" | "LPTM" | "LPTM2"	"EC"

Distributed_SPRAM (Distributed Single Port RAM)

Implementation: LUT

Table 318: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	Address	Bus	(pmi_addr_width – 1) : 0
I	Data	Bus	(pmi_data_width – 1) : 0
I	Clock	Bit	N/A
I	ClockEn	Bit	N/A
I	WE	Bit	N/A

Table 318: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	Reset	Bit	N/A
O	Q	Bus	(pmi_data_width – 1) : 0

Table 319: Parameters

Name	Value	Default
pmi_addr_depth	2 to 8192	32
pmi_addr_width	1 to 13	5
pmi_data_width	1 to 128	8
pmi_regmode	"reg" | "noreg"	"reg"
pmi_init_file[1]	*<string>*	"none"
pmi_init_file_format[1]	"binary" | "hex"	"binary"
pmi_family	"EC" | "XP" | "XP2" | "SC" | "SCM" | "ECP" | "ECP2" | "ECP2M" | "XO" | "XO2" | "XO3L" | "XO3LF" | "ECP3" | "ECP5U" | "ECP5UM" | "LPTM" | "LPTM2"	"EC"

Note

1. The pmi_init_file and pmi_init_file_format parameters are not supported for EC, XP, ECP, ECP2, ECP2M, LPTM, and XO device families in distributed mode.

FIFO (First In First Out Single Clock)

Implementation: EBR, LUT

Table 320: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	Data	Bus	(pmi_data_width – 1) : 0
I	Clock	Bit	N/A
I	WrEn	Bit	N/A
I	RdEn	Bit	N/A
I	Reset	Bit	N/A
O	Q	Bus	(pmi_data_width – 1) : 0
O	Empty	Bit	N/A
O	Full	Bit	N/A

Table 320: Pins

Input/Output	Port Name	Type	Size (Buses Only)
O	AlmostEmpty	Bit	N/A
O	AlmostFull	Bit	N/A

Table 321: Parameters

Name	Value	Default
pmi_data_depth[1]	2 to 65536	256
pmi_data_width	1 to 256	8
pmi_almost_empty_flag	1 to 512	4
pmi_almost_full_flag	1 to 512	252
pmi_full_flag	1 to pmi_data_depth	256
pmi_empty_flag	0	0
pmi_regmode	"reg" | "noreg" | "outreg" | "outreg_rden"	"reg"
pmi_implementation	"EBR" | "LUT"	"EBR"
pmi_family	"EC" | "XP" | "XP2" | "SC" | "SCM" | "ECP" | "ECP2" | "ECP2M" | "XO" | "XO2" | "XO3L" | "XO3LF" | "ECP3" | "ECP5U" | "ECP5UM" | "LPTM" | "LPTM2"	"EC"

Note

1. The device depth for the LUT based FIFO ranges from 2 to 8192. The XP2, ECP2, ECP2M, SC, SCM, and ECP3 device family address depths range from 2 to 131072. The EC, ECP, and XP families range from 2 to 65536.

FIFO_DC (First In First Out Dual Clock)

Implementation: EBR, LUT

Table 322: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	Data	Bus	(pmi_data_width_w – 1) : 0
I	WrClock	Bit	N/A
I	RdClock	Bit	N/A
I	WrEn	Bit	N/A
I	RdEn	Bit	N/A

Table 322: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	Reset	Bit	N/A
I	RPReset	Bit	N/A
O	Q	Bus	(pmi_data_width_r – 1) : 0
O	Empty	Bit	N/A
O	Full	Bit	N/A
O	AlmostEmpty	Bit	N/A
O	AlmostFull	Bit	N/A

Table 323: Parameters

Name	Value	Default
pmi_data_depth_w[1]	2 to 131072	256
pmi_data_depth_r[1]	2 to 131072	256
pmi_data_width_w	1 to 256	18
pmi_data_width_r	1 to 256	18
pmi_full_flag	1 to pmi_data_depth_r	256
pmi_empty_flag	0	0
pmi_almost_full_flag	1 to pmi_data_depth_w	252
pmi_almost_empty_flag	1 to pmi_data_depth_r	4
pmi_regmode	"reg" | "noreg" | "outreg" | "outreg_rden"	"reg"
pmi_resetmode[2]	"async" | "sync"	"async"
pmi_implementation	"EBR" | "LUT"	"EBR"
pmi_family	"EC" | "XP" | "XP2" | "SC" | "SCM" | "ECP" | "ECP2" | "ECP2M" | "XO" | "XO2" | "XO3L" | "XO3LF" | "ECP3" | "ECP5U" | "LPTM" | "LPTM2"	"EC"

Note

1. The device depth for the LUT-based FIFO_DC ranges from 2 to 8192. The XP2, ECP2, ECP2M, SC, SCM, and ECP3 device family data depths range from 2 to 131072. The EC, ECP, and XP families range from 2 to 65536. The XO, LPTM, LPTM2 and XO2 data depths range from 2 to 16384. The SC, SCM, XO, XO2, LPTM2, and LPTM device families support different read/write depths and different read/write data widths. The depth settings of SC and SCM are 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096, 8192, 16384, 32768, 65535, and 131072. The depth settings for XO and LPTM are 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096, 8192, and 16384.
2. The SC, SCM, XO, XO2, LPTM2 and LPTM device families support the pmi_resetmode parameter. The pmi_resetmode applies to the EBR memory implementation.

Shift Registers (Distributed RAM Shift Register)

Implementation: LUT, EBR[1]

Table 324: Pins

Input/Output	Port Name	Type	Size (Buses Only)
I	Din	Bus	(pmi_data_width – 1) : 0
I	Addr	Bus	(pmi_max_width – 1) : 0
I	Clock	Bit	N/A
I	ClockEn	Bit	N/A
O	Q	Bus	(pmi_data_width – 1) :0

Table 325: Parameters

Name	Value	Default
pmi_data_width	1 to 256	16
pmi_regmode	"reg" | "noreg"	"reg"
pmi_shiftreg_type[2]	"fixed" | "variable" | "lossless"	"fixed"
pmi_num_shift	2 to 1024	16
pmi_num_width	0 to 10	4
pmi_max_shift	2 to 1024	16
pmi_max_width	0 to 10	4
pmi_init_file[3]	<*string*>	"none"

Table 325: Parameters

Name	Value	Default
pmi_init_file_format[3]	"binary" | "hex"	"binary"
pmi_family	"EC" | "XP" | "XP2" | "SC" | "SCM" | "ECP" | "ECP2" | "ECP2M" | "XO" | "XO2" | "XO3L" | "XO3LF" | "ECP3" | "ECP5U" | "ECP5UM" | "LPTM" | "LPTM2"	"EC"

Note

1. EBR implementation is not available in ispLEVER 6.0 or earlier.
2. The lossless mode is not supported in ispLEVER 6.0 or earlier.
3. The pmi_init_file and pmi_init_file_format parameters are not supported for EC, XP, ECP, ECP2, ECP2M, LPTM, and XO device families in distributed mode.

Primitive Library - ECP5

This library includes compatible FPGA primitives supported by the ECP5 device family.

- Adder Subtractors
- Flip-Flops
- Input/Output Buffers
- ECP5 Memory Primitives
- Logic Gates
- Miscellaneous Logic
- Multiplexers
- Multipliers in DSP Blocks
- PIC Cells
  - PIC Flip-Flops (Input)
  - PIC Flip-Flops (Output)
  - PIC Latches (Input)
- Read-Only Memory
- Special Cells
  - Clock Manager/PLL/DLL
  - Combinatorial Primitives
  - Dual Data Rate Cells
  - Miscellaneous

References

For further information on individual primitives, a variety of technical notes for the ECP5 family are available on the Lattice Web site.

XOR21	21 Input Exclusive OR Gate

Table 331: Miscellaneous Logic

INV	Inverter
VHI	Logic High Generator
VLO	Logic Low Generator

Table 332: Multiplexers

L6MUX21	LUT-6 2 to 1 Multiplexer
MUX161	16-Input Mux within the PFU (4 Slices)
MUX21	2 to 1 Mux
MUX321	32-Input Mux within the PFU (8 Slices)
MUX41	4 to 1 Mux
MUX81	8 to 1 Mux

Table 333: Multipliers in DSP Blocks

MULT18X18C	18x18 Multiplier in DSP blocks
MULT18X18D	DSP Multiplier
MULT9X9C	9x9 Multiplier Multipliers in DSP blocks
MULT9X9D	DSP Multiplier

PIC Cells

Table 334: PIC Flip-Flops (Input)

IFS1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and System Clock (used in input PIC area only)
IFS1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and System Clock (used in input PIC area only)
IFS1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable, and System Clock (Clear overrides Enable) (used in input PIC area only)
IFS1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable, and System Clock (Preset overrides Enable) (used in input PIC area only)

Table 335: PIC Flip-Flops (Output)

OFS1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and System Clock (used in output PIC area only)
OFS1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and System Clock (used in output PIC area only)
OFS1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable (Clear overrides Enable), and System Clock (used in output PIC area only)
OFS1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable (Preset overrides Enable), and System Clock (used in output PIC area only)

Table 336: PIC Latches (Input)

IFS1S1B	Positive Level Data Latch with Positive Level Asynchronous Preset and System Clock (used in input PIC area only)
IFS1S1D	Positive Level Data Latch with Positive Level Asynchronous Clear and System Clock (used in input PIC area only)
IFS1S1I	Positive Level Data Latch with Positive Level Synchronous Clear and System Clock (used in input PIC area only)
IFS1S1J	Positive Level Data Latch with Positive Level Synchronous Preset and System Clock (used in input PIC area only)

Table 337: Read-Only Memory

ROM128X1A	128 Word by 1 Bit Positive Edge Triggered Read-Only Memory with Registered Data Outputs
ROM16X1A	16 Word by 1 Bit Read-Only Memory
ROM256X1A	256 Word by 1 Bit Positive Edge Triggered Read-Only Memory with Registered Data Outputs
ROM32X1A	32 Word by 1 Bit Read-Only Memory
ROM64X1A	64 Word by 1 Bit Positive Edge Triggered Read-Only Memory with Registered Data Outputs

Special Cells

Table 338: Clock Manager/PLL/DLL

CLKDIVF	Clock Divider
DCCA	Dynamic Clock Control Block
DCSC	Dynamic Clock Selection
DLLDELD	Slave Delay
ECLKBRIDGECS	ECLK Bridge Block Clock Select
EHXPLLL	GPLL for ECP5.
OSCG	Oscillator for Configuration Clock
PLLREFCS	PLL Dynamic Reference Clock Switching

Table 339: Combinatorial Primitives

LUT4	4-Input Look Up Table
LUT5	5-Input Look Up Table
LUT6	6-Input Look Up Table
LUT7	7-Input Look Up Table
LUT8	8-Input Look Up Table

Table 340: Dual Data Rate Cells

DDRDLLA	90 degree delay for the DQS Input during a memory interface or the clock input for a generic DDR interface
DQSBUFM	DQS circuit for DDR Memory.
ECLKSYNCB	ECLK Stop Block
IDDR71B	7:1 LVDS Input Supporting 1:7 Gearing
IDDRX1F	Generic Input DDR primitive
IDDRX2DQA	Implements DDR2 memory input interface at higher speeds and DDR3 memory interface.
IDDRX2F	Generic Input DDR primitive
ODDRX1F	Generic X1 ODDR implementation.
ODDRX2F	Generic X2 ODDR implementation.
ODDRX2DQA	Memory Output DDR Primitive for DQ outputs.
ODDRX2DQSB	Generates DQS clock output for DDR2 and DDR3 memory.
ODDR71B	7:1 LVDS ODDR implementation
OSHX2A	Generates the address and command for DDR3 memory with X2 gearing and write leveling.
TSHX2DQA	Generates the tristate control for DQ data output for DDR2 memory with X2 gearing and DDR3 memory.
TSHX2DQSA	Generate the tristate control for DQS output.

Table 341: Miscellaneous

ALU24A	24 Bit Ternary Adder/Subtractor
ALU24B	24-bit Ternary Adder/Subtractor for 9x9 Mode
ALU54A	54 Bit Ternary Adder/Subtractor
ALU54B	54 Bit Ternary Adder/Subtractor for Highspeed
BCINRD	Dynamic Bank Controller InRD
BCLVDSOB	Dynamic Bank Controller LVDS
CCU2C	Carry-Chain
DELAYF	Delay
DELAYG	Delay
DTR	Digital temperature readout
EXTREFB	External Reference Clock

Table 341: Miscellaneous (Continued)

GSR	Global Set/Reset
IMIPI	Special Primitive for MIPI Input Support
INRDB	Input Reference and Differential Buffer
LVDSOB	LVDS Output Buffer
PFUMX	2-Input Mux within the PFU, C0 used for Selection with Positive Select
PUR	Power Up Set/Reset
SEDGA	Soft Error Detect
SGSR	Synchronous Release Global Set/Reset Interface
START	Startup Controller
USRMCLK	Primitive to allow the user function to access the SPI PROM

Primitive Library - LatticeECP/EC and LatticeXP

This library includes compatible FPGA primitives supported by the LatticeXP and LatticeECP/EC device families.

- Adders Subtractors
- Comparators
- Counters
- Loadable Counters
- Flip-Flops
- Input/Output Buffers
- Latches
- LatticeECP DSP Block
- LatticeXP and LatticeEC Memory Primitives
- Logic Gates
- Miscellaneous Logic
- Multiplexer
- Multipliers (Not DSP)
- PIC Cells
  - PIC Flip-Flops (Input)
  - PIC Flip-Flops (Output)
  - PIC Latches (Input)
- Read Only memory
- Special Cells
  - Clock/PLL
  - Combinatorial Primitives
  - Dual Data Rate Cells
  - Miscellaneous

- TN1050 - LatticeECP/EC and XP DDR Usage Guide
- TN1051 - Memory Usage Guide for LatticeECP/EC and LatticeXP Devices
- TN1052 - Estimating Power Using Power Calculator for LatticeECP/EC and LatticeXP Devices
- TN1053 - LatticeECP/EC sysCONFIG Usage Guide

- TN1056 - LatticeECP/EC and LatticeXP sysIO Usage Guide
- TN1057 - LatticeECP sysDSP Usage Guide
- TN1082 - LatticeXP sysCONFIG Usage Guide

Table 342: Adders Subtractors

FADD2	2 Bit Fast Adder
FSUB2	2 Bit Fast Subtractor (two's complement)
FADSU2	2 Bit Fast Adder/Subtractor (two's complement)

Table 343: Comparators

AGEB2	A Greater Than Or Equal To B (2 bit)
ALEB2	A Less Than Or Equal To B (2 bit)
ANEB2	A Not Equal To B (2 bit)

Table 344: Counters

CB2	Combinational Logic for 2-Bit Bidirectional Counter
CD2	Combinational Logic for 2 Bit Down Counter
CU2	Combinational Logic for 2 Bit Up Counter

Table 345: Loadable Counters

LB2P3AX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Clear
LB2P3AY	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Preset
LB2P3BX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LB2P3DX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LB2P3IX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LB2P3JX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)

Table 345: Loadable Counters (Continued)

LB4P3AX	4 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Clear
LB4P3AY	4 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Preset
LB4P3BX	4 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LB4P3DX	4 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LB4P3IX	4 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LB4P3JX	4 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)
LD2P3AX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable, GSR Used for Clear
LD2P3AY	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable, GSR Used for Preset
LD2P3BX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LD2P3DX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LD2P3IX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LD2P3JX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)
LD4P3AX	4 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable, GSR Used for Clear
LD4P3AY	4 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable, GSR Used for Preset
LD4P3BX	4 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LD4P3DX	4 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LD4P3IX	4 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LD4P3JX	4 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)
LU2P3AX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable, GSR Used for Clear

Table 345: Loadable Counters (Continued)

LU2P3AY	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable, GSR Used for Preset
LU2P3BX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LU2P3DX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LU2P3IX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LU2P3JX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)
LU4P3AX	4 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable, GSR Used for Clear
LU4P3AY	4 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable, GSR Used for Preset
LU4P3BX	4 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LU4P3DX	4 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LU4P3IX	4 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LU4P3JX	4 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)

Table 346: Flip-Flops

FD1P3AX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, GSR used for Clear
FD1P3AY	Positive Edge Triggered D Flip-Flop with Positive Level Enable, GSR used for Preset
FD1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable and Positive Level Asynchronous Preset
FD1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable and Positive Level Asynchronous Clear
FD1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear and Positive Level Enable (Clear overrides Enable)
FD1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset and Positive Level Enable (Preset overrides Enable)

Table 346: Flip-Flops (Continued)

FD1S3AX	Positive Edge Triggered D Flip-Flop, GSR Used for Clear
FD1S3AY	Positive Edge Triggered D Flip-Flop, GSR Used for Preset
FD1S3BX	Positive Edge Triggered D Flip-Flop with Positive Level Asynchronous Preset
FD1S3DX	Positive Edge Triggered D Flip-Flop with Positive Level Asynchronous Clear
FD1S3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear
FD1S3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset
FL1P3AY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, and Positive Level Enable, GSR used for Preset
FL1P3AZ	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, and Positive Level Enable, GSR used for Clear
FL1P3BX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Asynchronous Preset, and Positive Level Enable
FL1P3DX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Asynchronous Clear, and Positive Level Enable
FL1P3IY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Synchronous Clear, and Positive Level Enable (Clear overrides Enable)
FL1P3JY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Synchronous Preset, and Positive Level Enable (Preset overrides Enable)
FL1S3AX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, GSR used for Clear
FL1S3AY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, GSR used for Preset

Table 347: Input/Output Buffers

BB	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional
BBPD	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate and Pull-down BiDirectional
BBPU	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate and Pull-up BiDirectional

Table 347: Input/Output Buffers

BBW	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional in keepermode
IB	CMOS Input Buffer
IBM	CMOS Input Buffer
IBMPD	CMOS Input Buffer with Pull-down
IBMPDS	CMOS Input Buffer with Pull-down and Delay
IBMPU	CMOS Input Buffer with Pull-up
IBMPUS	CMOS Input Buffer with Pull-up and Delay
IBMS	CMOS Input Buffer with Delay
IBPD	Input Buffer with Pull-down
IBPU	Input Buffer with Pull-up
ILVDS	LVDS Input Buffer
OB	Output Buffer
OBCO	Output Complementary Buffer
OBZ	6mA Sink 3mA Source Sinklim Output Buffer
OBZPD	12mA Sink 6mA Source Slewlim Output Buffer
OBZPU	12mA Sink 6mA Source Fast Output Buffer
OBW	6mA Sink 3mA Source Sinklim Output Buffer with Tristate
OLVDS	LVDS Output Buffer

Table 348: Latches

FD1S1A	Positive Level Data Latch with GSR Used for Clear
FD1S1AY	Positive Level Data Latch with GSR Used for Preset
FD1S1B	Positive Level Data Latch with Positive Level Asynchronous Preset
FD1S1D	Positive Level Data Latch with Positive Level Asynchronous Clear
FD1S1I	Positive Level Data Latch with Positive Level Synchronous Clear
FD1S1J	Positive Level Data Latch with Positive Level Synchronous Preset
FL1S1A	Positive Level Loadable Latch with Positive Select and GSR Used for Clear
FL1S1AY	Positive Level Loadable Latch with Positive Select and GSR Used for Preset
FL1S1B	Positive Level Loadable Latch with Positive Select and Positive Level Asynchronous Preset

Table 348: Latches (Continued)

FL1S1D	Positive Level Loadable Latch with Positive Select and Positive Level Asynchronous Clear
FL1S1I	Positive Level Loadable Latch with Positive Select and Positive Level Synchronous Clear
FL1S1J	Positive Level Loadable Latch with Positive Select and Positive Level Synchronous Preset

Table 349: LatticeECP DSP Block

MULT18X18	ECP 18X18 DSP Multiplier
MULT18X18ADDSUB	ECP 18X18 DSP Adder/Subtractor
MULT18X18ADDSUBSUM	ECP 18X18 DSP Adder/Subtractor/Sum
MULT18X18MAC	ECP 18X18 DSP MAC
MULT36X36	ECP 36X36 DSP Multiplier
MULT9X9	ECP 9X9 DSP Multiplier
MULT9X9ADDSUB	ECP 9X9 DSP Adder/Subtractor
MULT9X9ADDSUBSUM	ECP 9X9 DSP Adder/Subtractor/Sum
MULT9X9MAC	ECP 9X9 DSP MAC

Table 350: LatticeXP and LatticeEC Memory Primitives

DP8KA	8K Dual Port Block RAM
DPR16X2B	16 Word by 2 Dual Port RAM (within PFU)
PDP8KA	8K Pseudo Dual Port Block RAM
SP8KA	8K Single Port Block RAM
SPR16X2B	16 Word by 2 Single Port RAM (within PFU)

Table 351: Logic Gates

AND2	2 Input AND Gate
AND3	3 Input AND Gate
AND4	4 Input AND Gate
AND5	5 Input AND Gate
ND2	2 Input NAND Gate

Table 351: Logic Gates (Continued)

ND3	3 Input NAND Gate
ND4	4 Input NAND Gate
ND5	5 Input NAND Gate
OR2	2 Input OR Gate
OR3	3 Input OR Gate
OR4	4 Input OR Gate
OR5	5 Input OR Gate
NR2	2 Input NOR Gate
NR3	3 Input NOR Gate
NR4	4 Input NOR Gate
NR5	5 Input NOR Gate
XNOR2	2 Input Exclusive NOR Gate
XNOR3	3 Input Exclusive NOR Gate
XNOR4	4 Input Exclusive NOR Gate
XNOR5	5 Input Exclusive NOR Gate
XOR11	11 Input Exclusive OR Gate
XOR2	2 Input Exclusive OR Gate
XOR21	21 Input Exclusive OR Gate
XOR3	3 Input Exclusive OR Gate
XOR4	4 Input Exclusive OR Gate
XOR5	5 Input Exclusive OR Gate

Table 352: Miscellaneous Logic

INV	Inverter
VHI	Logic High Generator
VLO	Logic Low Generator

Table 353: Multiplexer

L6MUX21	2 to 1 Mux
MUX161	16-Input Mux within the PFU (4 Slices)
MUX21	2 to 1 Mux

Table 353: Multiplexer

MUX321	32-Input Mux within the PFU (8 Slices)
MUX4	4-bit Multiplexer
MUX41	4 to 1 Mux
MUX81	8 to 1 Mux

Table 354: Multipliers (Not DSP)

MULT2	2X2 Multiplier

PIC Cells

Table 355: PIC Flip-Flops (Input)

IFS1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and System Clock (used in input PIC area only)
IFS1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and System Clock (used in input PIC area only)
IFS1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable, and System Clock (Clear overrides Enable) (used in input PIC area only)
IFS1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable, and System Clock (Preset overrides Enable) (used in input PIC area only)

Table 356: PIC Flip-Flops (Output)

OFE1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and Edge Clock (used in output PIC area only)
OFE1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and Edge Clock (used in output PIC area only)
OFE1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable (Clear overrides Enable), and Edge Clock (used in output PIC area only)
OFE1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable (Preset overrides Enable), and Edge Clock (used in output PIC area only)

Table 356: PIC Flip-Flops (Output)

OFS1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and System Clock (used in output PIC area only)
OFS1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and System Clock (used in output PIC area only)
OFS1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable (Clear overrides Enable), and System Clock (used in output PIC area only)
OFS1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable (Preset overrides Enable), and System Clock (used in output PIC area only)

Table 357: PIC Latches (Input)

IFS1S1B	Positive Level Data Latch with Positive Level Asynchronous Preset and System Clock (used in input PIC area only)
IFS1S1D	Positive Level Data Latch with Positive Level Asynchronous Clear and System Clock (used in input PIC area only)
IFS1S1I	Positive Level Data Latch with Positive Level Synchronous Clear and System Clock (used in input PIC area only)
IFS1S1J	Positive Level Data Latch with Positive Level Synchronous Preset and System Clock (used in input PIC area only)

Table 358: Read Only memory

ROM16X1	16 Word by 1 Bit Read-Only Memory
ROM32X1	32 Word by 1 Bit Read-Only Memory
ROM64X1	64 Word by 1 Bit Read-Only Memory
ROM128X1	128 Word by 1 Bit Read-Only Memory
ROM256X1	256 Word by 1 Bit Read-Only Memory

Special Cells

Table 359: Clock/PLL

DCS	Dynamic Clock Selection Multiplexer

Table 359: Clock/PLL

EPLLB	Enhanced PLL
EHXPLLB	Enhanced High Performance with Dynamic Input Delay Control PLL

Table 360: Combinatorial Primitives

ORCALUT4	4-Input Look Up Table
ORCALUT5	5-Input Look Up Table
ORCALUT6	6-Input Look Up Table
ORCALUT7	7-Input Look Up Table
ORCALUT8	8-Input Look Up Table

Table 361: Dual Data Rate Cells

DQSBUFB	DDR DQS Buffer used as DDR memory DQS generator
DQSDLL	DLL used as DDR memory DQS DLL
IDDRXB	DDRX Input Cell
ODDRXB	Output DDR

Table 362: Miscellaneous

CCU2	Carry Chain
DELAY	Delay
GSR	Global Set/Reset
IBDDC	Dynamic Delay
JTAGB	JTAG (Joint Test Action Group) Controller
JTAGG	JTAG (Joint Test Action Group) Controller
PFUMX	2-Input Mux within the PFU, C0 used for Selection with Positive Select
PUR	Power Up Set/Reset
SGSR	Synchronous Release Global Set/Reset Interface
STRTUP	Startup Controller

Primitive Library - LatticeECP2/M

This library includes compatible FPGA primitives supported by the LatticeECP2/M (including the “S-Series” LatticeECP2S and LatticeECP2MS) device families.

- Adders/Subtractors
- Comparators
- Counters
- Loadable Counters
- Flip-Flops
- Input/Output Buffer
- LatticeECP2/M Memory Primitive
- Logic Gates
- Miscellaneous Logic
- Multiplexers
- PIC Cells
  - PIC Flip-Flops (Input)
  - PIC Flip-Flops (Output)
  - PIC Latches (Input)
- Read-only Memory
- Special Cells
  - Clock Manager/PLL/DLL
  - Combinatorial Primitives
  - Dual Data Rate Cells
  - Miscellaneous

DLLDELA	Slave Delay
EHXPLLD	Complex PLL
EPLLD	Enhanced PLL
OSCD	Oscillator for configuration clock
TRDLLA	Time Reference Delay

Table 379: Combinatorial Primitives

ORCALUT4	4-Input Look Up Table
ORCALUT5	5-Input Look Up Table
ORCALUT6	6-Input Look Up Table
ORCALUT7	7-Input Look Up Table
ORCALUT8	8-Input Look Up Table

Table 380: Dual Data Rate Cells

DQSBUFC	DQS Delay Function and Clock Polarity Selection Logic
DQSDLL	DLL Used as DDR Memory DQS DLL
IDDRFXA	DDR Generic Input with Full Clock Transfer (x1 Gearbox)
IDDRMFX1A	DDR Input and DQS to System Clock Transfer Registers with Full Clock Cycle Transfer
IDDRMX1A	DDR Input and DQS to System Clock Transfer Registers with Half Clock Cycle Transfer
IDDRX2B	DDR Generic Input with 2x Gearing Ratio
IDDRXC	DDR Generic Input
ODDRMXA	DDR Output Registers
ODDRX2B	DDR Generic Output with 2x Gearing Ratio
ODDRXC	DDR Generic Output

Table 381: Miscellaneous

CCU2B	Carry-Chain
DELAYB	Dynamic Delay in PIO
GSR	Global Set/Reset
JTAGC	JTAG (Joint Test Action Group) Controller
MULT2	2X2 Multiplier (not DSP)
PFUMX	2-Input Mux within the PFU, C0 used for Selection with Positive Select
PUR	Power Up Set/Reset
SEDAA	SED BASIC
SGSR	Synchronous Release Global Set/Reset Interface
SPIM	SPIM Primitive
STRTUP	Startup Controller

Primitive Library - LatticeECP3

This library includes compatible FPGA primitives supported by the LatticeECP3 device family.

- Adders/Subtractors
- Comparators
- Counters
- Loadable Counters
- Flip-Flops
- Input/Output Buffers
- LatticeECP3 Memory Primitives
- Logic Gates
- Miscellaneous Logic
- Multiplexer
- Multipliers in DSP Blocks
- PIC Cells
  - PIC Flip-Flops (Input)
  - PIC Flip-Flops (Output)
  - PIC Latches (Input)
- Read-Only Memory
- Special Cells
  - Clock Manager/PLL/DLL
  - Combinatorial Primitives
  - Dual Data Rate Cells
  - Miscellaneous

References

Table 382: Adders/Subtractors

FADD2B	2 Bit Fast Adders/Subtractors
FADSU2	2 Bit Fast Adder/Subtractor (two's complement)
FSUB2B	2 Bit Subtractor

Table 383: Comparators

AGEB2	A Greater Than Or Equal To B (2 bit)
ALEB2	A Less Than Or Equal To B (2 bit)
ANEB2	A Not Equal To B (2 bit)

Table 384: Counters

CB2	Combinational Logic for 2-Bit Bidirectional Counter
CD2	Combinational Logic for 2 Bit Down Counter
CU2	Combinational Logic for 2 Bit Up Counter

Table 385: Loadable Counters

LB2P3AX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Clear
LB2P3AY	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Preset
LB2P3BX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LB2P3DX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LB2P3IX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LB2P3JX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)
LD2P3AX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable, GSR Used for Clear

Table 385: Loadable Counters (Continued)

LD2P3AY	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable, GSR Used for Preset
LD2P3BX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LD2P3DX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LD2P3IX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LD2P3JX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)
LU2P3AX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable, GSR Used for Clear
LU2P3AY	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable, GSR Used for Preset
LU2P3BX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LU2P3DX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LU2P3IX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LU2P3JX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)

Table 386: Flip-Flops

FD1P3AX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, GSR used for Clear
FD1P3AY	Positive Edge Triggered D Flip-Flop with Positive Level Enable, GSR used for Preset
FD1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable and Positive Level Asynchronous Preset
FD1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable and Positive Level Asynchronous Clear
FD1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear and Positive Level Enable (Clear overrides Enable)
FD1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset and Positive Level Enable (Preset overrides Enable)

Table 386: Flip-Flops (Continued)

FD1S3AX	Positive Edge Triggered D Flip-Flop, GSR Used for Clear
FD1S3AY	Positive Edge Triggered D Flip-Flop, GSR Used for Preset
FD1S3BX	Positive Edge Triggered D Flip-Flop with Positive Level Asynchronous Preset
FD1S3DX	Positive Edge Triggered D Flip-Flop with Positive Level Asynchronous Clear
FD1S3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear
FD1S3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset
FL1P3AY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, and Positive Level Enable, GSR used for Preset
FL1P3AZ	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, and Positive Level Enable, GSR used for Clear
FL1P3BX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Asynchronous Preset, and Positive Level Enable
FL1P3DX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Asynchronous Clear, and Positive Level Enable
FL1P3IY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Synchronous Clear, and Positive Level Enable (Clear overrides Enable)
FL1P3JY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Synchronous Preset, and Positive Level Enable (Preset overrides Enable)
FL1S3AX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, GSR used for Clear
FL1S3AY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, GSR used for Preset

Table 387: Input/Output Buffers

BB	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional
BBPD	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional and Pull-down
BBPU	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional and Pull-up

Table 387: Input/Output Buffers (Continued)

BBW	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional in keepermode
IB	CMOS Input Buffer
IBPD	Input Buffer with Pull-down
IBPU	Input Buffer with Pull-up
ILVDS	LVDS Input Buffer
OB	Output Buffer
OBCO	Output Complementary Buffer
OBZ	Output Buffer with Tristate
OBZPU	Output Buffer with Tristate and Pull-up
OLVDS	LVDS Output Buffer

Table 388: LatticeECP3 Memory Primitives

DP16KC	True Dual Port Block RAM
DPR16X4C	Distributed Pseudo Dual Port RAM
PDPW16KC	Pseudo Dual Port Block RAM
SP16KC	Single Port Block RAM
SPR16X4C	Distributed Single Port RAM

Table 389: Logic Gates

AND2	2 Input AND Gate
AND3	3 Input AND Gate
AND4	4 Input AND Gate
AND5	5 Input AND Gate
ND2	2 Input NAND Gate
ND3	3 Input NAND Gate
ND4	4 Input NAND Gate
ND5	5 Input NAND Gate
OR2	2 Input OR Gate
OR3	3 Input OR Gate
OR4	4 Input OR Gate

Table 389: Logic Gates (Continued)

OR5	5 Input OR Gate
NR2	2 Input NOR Gate
NR3	3 Input NOR Gate
NR4	4 Input NOR Gate
NR5	5 Input NOR Gate
XNOR2	2 Input Exclusive NOR Gate
XNOR3	3 Input Exclusive NOR Gate
XNOR4	4 Input Exclusive NOR Gate
XNOR5	5 Input Exclusive NOR Gate
XOR2	2 Input Exclusive OR Gate
XOR3	3 Input Exclusive OR Gate
XOR4	4 Input Exclusive OR Gate
XOR5	5 Input Exclusive OR Gate
XOR11	11 Input Exclusive OR Gate
XOR21	21 Input Exclusive OR Gate

Table 390: Miscellaneous Logic

INV	Inverter
VHI	Logic High Generator
VLO	Logic Low Generator

Table 391: Multiplexer

L6MUX21	LUT-6 2 to 1 Multiplexer
MUX161	16-Input Mux within the PFU (4 Slices)
MUX21	2 to 1 Mux
MUX321	32-Input Mux within the PFU (8 Slices)
MUX41	4 to 1 Mux
MUX81	8 to 1 Mux

Table 392: Multipliers in DSP Blocks

MULT18X18C	18x18 Multiplier in DSP blocks
MULT9X9C	9x9 Multiplier Multipliers in DSP blocks

PIC Cells

Table 393: PIC Flip-Flops (Input)

IFS1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and System Clock (used in input PIC area only)
IFS1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and System Clock (used in input PIC area only)
IFS1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable, and System Clock (Clear overrides Enable) (used in input PIC area only)
IFS1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable, and System Clock (Preset overrides Enable) (used in input PIC area only)

Table 394: PIC Flip-Flops (Output)

OFD1S3AX	Positive Edge Triggered D Flip-Flop, GSR Used for Clear. Used to Tri-State DDR/DDR2
OFS1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and System Clock (used in output PIC area only)
OFS1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and System Clock (used in output PIC area only)
OFS1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable (Clear overrides Enable), and System Clock (used in output PIC area only)
OFS1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable (Preset overrides Enable), and System Clock (used in output PIC area only)

Table 395: PIC Latches (Input)

IFS1S1B	Positive Level Data Latch with Positive Level Asynchronous Preset and System Clock (used in input PIC area only)
IFS1S1D	Positive Level Data Latch with Positive Level Asynchronous Clear and System Clock (used in input PIC area only)
IFS1S1I	Positive Level Data Latch with Positive Level Synchronous Clear and System Clock (used in input PIC area only)
IFS1S1J	Positive Level Data Latch with Positive Level Synchronous Preset and System Clock (used in input PIC area only)

Table 396: Read-Only Memory

ROM128X1A	128 Word by 1 Bit Positive Edge Triggered Read-Only Memory with Registered Data Outputs
ROM16X1A	16 Word by 1 Bit Read-Only Memory
ROM256X1A	256 Word by 1 Bit Positive Edge Triggered Read-Only Memory with Registered Data Outputs
ROM32X1A	32 Word by 1 Bit Read-Only Memory
ROM64X1A	64 Word by 1 Bit Positive Edge Triggered Read-Only Memory with Registered Data Outputs

Special Cells

Table 397: Clock Manager/PLL/DLL

CIDDLLB	Clock Injection Delay Removal
CLKDIVB	Clock Divider
DCCA	*(For internal use only)* Dynamic Quadrant Clock Enable/Disable
DCS	Dynamic Clock Selection Multiplexer
DLLDELB	Slave Delay
EHXPLLF	Complex PLL
OSCF	Oscillator for Configuration Clock
TR1DLLB	Time Reference DLL with Dynamic Delay Adjustment
TRDLLB	Time Reference DLL

Table 398: Combinatorial Primitives

LUT4	4-Input Look Up Table
LUT5	5-Input Look Up Table
LUT6	6-Input Look Up Table
LUT7	7-Input Look Up Table
LUT8	8-Input Look Up Table

Table 399: Dual Data Rate Cells

DQSBUFD	DDR DQS Buffer Used for DDR3_MEM and DDR3_MEMGEN
DQSBUFE	DDR DQS Buffer Used for DDR_GENX2
DQSBUFE1	DDR DQS Buffer Used for DDR_GENX2
DQSBUFF	DDR DQS Buffer Used for DDR_MEM, DDR2_MEM, and DDR2_MEMGEN
DQSBUFG	DDR DQS Buffer Used for DDR_GENX1
DQSDLLB	DQS DLL for DDR_MEM, DDR2_MEM, and DDR3_MEM
ECLKSYNCA	ECLK Stop Block
IDDRX2D	Input DDR for DDR3_MEM, DDR_GENX2, and DDR3_MEMGEN
IDDRX2D1	Input DDR for DDR_GENX2
IDDRXD	Input DDR for DDR_MEM, DDR2_MEM, DDR_GENX1, and DDR2_MEMGEN
IDDRXD1	Input DDR for DDR_GENX1
ODDRTDQA	Tri-State for DQ: DDR3_MEM and DDR_GENX2
ODDRTDQSA	Tri-State for Single-Ended and Differential DQS: DDR_MEM, DDR2_MEM, and DDR3_MEM
ODDRX2D	Output DDR for DDR3_MEM and DDR_GENX2
ODDRX2DQSA	Output for Differential DQS: DDR3_MEM
ODDRXD	Output DDR for DDR_MEM, DDR2_MEM, DDR_GENX1, and DDR2_MEMGEN
ODDRXD1	Output DDR for DDR_GENX1
ODDRXDQSA	Output for Single-Ended and Differential DQS: DDR_MEM, DDR2_MEM, and DDR2_MEMGEN

Table 400: Miscellaneous

ALU24A	24 Bit Ternary Adder/Subtractor
ALU54A	54 Bit Ternary Adder/Subtractor
CCU2C	Carry-Chain
DELAYB	Dynamic Delay in PIO
DELAYC	Fixed Delay in PIO
GSR	Global Set/Reset
JTAGE	JTAG (Joint Test Action Group) Controller
MULT2	2X2 Multiplier (not DSP)
PERREGA	Persistent User Register
PFUMX	2-Input Mux within the PFU, C0 used for Selection with Positive Select
PUR	Power Up Set/Reset
SEDCA	Basic SED (Soft Error Detect)
SGSR	Synchronous Release Global Set/Reset Interface
SPIM	SPIM Primitive
START	Startup Controller

Primitive Library - LatticeSC/M

This library includes compatible FPGA primitives supported by the LatticeSC and LatticeSCM device families.

- Adders/Subtractors
- Comparators
- Counters
- Loadable Counters
- Flip-Flops
- Input/Output Buffers
- Latches
- LatticeSC/M Memory Primitives
- Logic Gates
- Miscellaneous Logic
- Multiplexers
- PIC Cells
  - PIC Flip-Flops (Input)
  - PIC Flip-Flops (Output)
  - PIC Flip-Flops (Latched)
  - PIC Latches (Input)
  - PIC Shift Registers
- Read-Only Memory
- Special Cells
  - Clock Manager/PLL/DLL
  - Dual Data Rate Cells
  - Miscellaneous

LB2P3AX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Clear
LB2P3AY	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Preset
LB2P3BX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LB2P3DX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LB2P3IX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LB2P3JX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)
LB4P3AX	4 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Clear
LB4P3AY	4 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Preset

Table 404: Loadable Counters (Continued)

LB4P3BX	4 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LB4P3DX	4 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LB4P3IX	4 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LB4P3JX	4 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)
LD2P3AX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable, GSR Used for Clear
LD2P3AY	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable, GSR Used for Preset
LD2P3BX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LD2P3DX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LD2P3IX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LD2P3JX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)
LD4P3AX	4 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable, GSR Used for Clear
LD4P3AY	4 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable, GSR Used for Preset
LD4P3BX	4 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LD4P3DX	4 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LD4P3IX	4 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LD4P3JX	4 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)
LU2P3AX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable, GSR Used for Clear
LU2P3AY	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable, GSR Used for Preset
LU2P3BX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Asynchronous Preset

Table 404: Loadable Counters (Continued)

LU2P3DX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LU2P3IX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LU2P3JX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)
LU4P3AX	4 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable, GSR Used for Clear
LU4P3AY	4 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable, GSR Used for Preset
LU4P3BX	4 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LU4P3DX	4 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LU4P3IX	4 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LU4P3JX	4 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)

Table 405: Flip-Flops

FD1P3AX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, GSR used for Clear
FD1P3AY	Positive Edge Triggered D Flip-Flop with Positive Level Enable, GSR used for Preset
FD1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable and Positive Level Asynchronous Preset
FD1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable and Positive Level Asynchronous Clear
FD1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear and Positive Level Enable (Clear overrides Enable)
FD1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset and Positive Level Enable (Preset overrides Enable)
FD1S3AX	Positive Edge Triggered D Flip-Flop, GSR Used for Clear
FD1S3AY	Positive Edge Triggered D Flip-Flop, GSR Used for Preset

Table 405: Flip-Flops (Continued)

FD1S3BX	Positive Edge Triggered D Flip-Flop with Positive Level Asynchronous Preset
FD1S3DX	Positive Edge Triggered D Flip-Flop with Positive Level Asynchronous Clear
FD1S3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear
FD1S3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset
FL1P3AY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, and Positive Level Enable, GSR used for Preset
FL1P3AZ	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, and Positive Level Enable, GSR used for Clear
FL1P3BX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Asynchronous Preset, and Positive Level Enable
FL1P3DX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Asynchronous Clear, and Positive Level Enable
FL1P3IY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Synchronous Clear, and Positive Level Enable (Clear overrides Enable)
FL1P3JY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Synchronous Preset, and Positive Level Enable (Preset overrides Enable)
FL1S3AX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, GSR used for Clear
FL1S3AY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, GSR used for Preset

Table 406: Input/Output Buffers

BB	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional
BBPD	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional and Pull-down
BBPU	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional and Pull-up
BBW	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional in keepermode
IB	Input Buffer

Table 406: Input/Output Buffers (Continued)

IBPD	Input Buffer with Pull-down
IBPU	Input Buffer with Pull-up
ILVDS	LVDS Input Buffer
OB	Output Buffer
OBW	Output Buffer with Tristate
OBZ	Output Buffer with Tristate
OBZPD	Output Buffer with Tristate and Pull-down
OBZPU	Output Buffer with Tristate and Pull-up
OLVDS	LVDS Output Buffer

Table 407: Latches

FD1S1A	Positive Level Data Latch with GSR Used for Clear
FD1S1AY	Positive Level Data Latch with GSR Used for Preset
FD1S1B	Positive Level Data Latch with Positive Level Asynchronous Preset
FD1S1D	Positive Level Data Latch with Positive Level Asynchronous Clear
FD1S1I	Positive Level Data Latch with Positive Level Synchronous Clear
FD1S1J	Positive Level Data Latch with Positive Level Synchronous Preset
FL1S1A	Positive Level Loadable Latch with Positive Select and GSR Used for Clear
FL1S1AY	Positive Level Loadable Latch with Positive Select and GSR Used for Preset
FL1S1B	Positive Level Loadable Latch with Positive Select and Positive Level Asynchronous Preset
FL1S1D	Positive Level Loadable Latch with Positive Select and Positive Level Asynchronous Clear
FL1S1I	Positive Level Loadable Latch with Positive Select and Positive Level Synchronous Clear
FL1S1J	Positive Level Loadable Latch with Positive Select and Positive Level Synchronous Preset

Table 408: LatticeSC/M Memory Primitives

DP16KA	16K Dual Port Block RAM
DPR16X2	16 Word by 2 Distributed Dual Port RAM (within PFU)

Table 408: LatticeSC/M Memory Primitives (Continued)

FIFO16KA	16K FIFO
PDP16KA	16K Pseudo Dual Port Block RAM
SP16KA	16 Word by 16 Bit Single Port Block RAM
SPR16X2	16 Word by 2 Distributed Single Port RAM (within PFU)

Table 409: Logic Gates

AND2	2 Input AND Gate
AND3	3 Input AND Gate
AND4	4 Input AND Gate
AND5	5 Input AND Gate
ND2	2 Input NAND Gate
ND3	3 Input NAND Gate
ND4	4 Input NAND Gate
ND5	5 Input NAND Gate
OR2	2 Input OR Gate
OR3	3 Input OR Gate
OR4	4 Input OR Gate
OR5	5 Input OR Gate
NR2	2 Input NOR Gate
NR3	3 Input NOR Gate
NR4	4 Input NOR Gate
NR5	5 Input NOR Gate
XNOR2	2 Input Exclusive NOR Gate
XNOR3	3 Input Exclusive NOR Gate
XNOR4	4 Input Exclusive NOR Gate
XNOR5	5 Input Exclusive NOR Gate
XOR2	2 Input Exclusive OR Gate
XOR3	3 Input Exclusive OR Gate
XOR4	4 Input Exclusive OR Gate
XOR5	5 Input Exclusive OR Gate
XOR11	11 Input Exclusive OR Gate
XOR21	21 Input Exclusive OR Gate

Table 410: Miscellaneous Logic

INV	Inverter
VHI	Logic High Generator
VLO	Logic Low Generator

Table 411: Multiplexers

L6MUX21	LUT-6 2 to 1 Multiplexer
MUX161	16-Input Mux within the PFU (4 Slices)
MUX21	2 to 1 Mux
MUX321	32-Input Mux within the PFU (8 Slices)
MUX41	4 to 1 Mux
MUX81	8 to 1 Mux

PIC Cells

Table 412: PIC Flip-Flops (Input)

IFS1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and System Clock (used in input PIC area only)
IFS1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and System Clock (used in input PIC area only)
IFS1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable, and System Clock (Clear overrides Enable) (used in input PIC area only)
IFS1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable, and System Clock (Preset overrides Enable) (used in input PIC area only)

Table 413: PIC Flip-Flops (Output)

OFE1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and Edge Clock (used in output PIC area only)
OFE1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and Edge Clock (used in output PIC area only)
OFE1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable (Clear overrides Enable), and Edge Clock (used in output PIC area only)
OFE1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable (Preset overrides Enable), and Edge Clock (used in output PIC area only)
OFS1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and System Clock (used in output PIC area only)
OFS1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and System Clock (used in output PIC area only)
OFS1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable (Clear overrides Enable), and System Clock (used in output PIC area only)
OFS1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable (Preset overrides Enable), and System Clock (used in output PIC area only)

Table 414: PIC Flip-Flops (Latched)

ILF2P3BX	Negative Level Edge Clocked (ECLK) Latch, Feeding Positive Edge Triggered System Clocked (SCLK) Flip-Flop, and Positive Level Asynchronous Preset (used in input PIC area only)
ILF2P3DX	Negative Level Edge Clocked (ECLK) Latch, Feeding Positive Edge Triggered System Clocked (SCLK) Flip-Flop, and Positive Level Asynchronous Clear (used in input PIC area only)
ILF2P3IX	Negative Level Edge Clocked (ECLK) Latch, Feeding Positive Edge Triggered System Clocked (SCLK) Flip-Flop, and Positive Level Synchronous Clear (Clear overrides Enable) (used in input PIC area only)
ILF2P3JX	Negative Level Edge Clocked (ECLK) Latch, Feeding Positive Edge Triggered System Clocked (SCLK) Flip-Flop, and Positive Level Synchronous Preset (Preset overrides Enable) (used in input PIC area only)

Table 415: PIC Latches (Input)

IFS1S1B	Positive Level Data Latch with Positive Level Asynchronous Preset and System Clock (used in input PIC area only)
IFS1S1D	Positive Level Data Latch with Positive Level Asynchronous Clear and System Clock (used in input PIC area only)
IFS1S1I	Positive Level Data Latch with Positive Level Synchronous Clear and System Clock (used in input PIC area only)
IFS1S1J	Positive Level Data Latch with Positive Level Synchronous Preset and System Clock (used in input PIC area only)

Table 416: PIC Shift Registers

ISRX1A	Input 1-Bit Shift Register
ISRX2A	Input 2-Bit Shift Register
ISRX4A	Input 4-Bit Shift Register
OSRX1A	Output 1-Bit Shift Register
OSRX2A	Output 2-Bit Shift Register
OSRX4A	Output 4-Bit Shift Register

Table 417: Read-Only Memory

ROM16X1	16 Word by 1 bit read-only memory
ROM32X1	32 Word by 1 bit read-only memory
ROM32X4	32 Word by 4 bit read-only memory
ROM64X1	64 Word by 1 bit read-only memory
ROM128X1	128 Word by 1 bit read-only memory
ROM256X1	256 Word by 1 bit read-only memory

Special Cells

Table 418: Clock Manager/PLL/DLL

CIDDLLA	Clock Injection Delay Removal
CIMDLLA	Clock Injection Match
CLKCNTL	Clock Controller
CLKDET	Clock Detect
CLKDIV	Clock Divider
DCS	Dynamic Clock Selection Multiplexer
EHXPLLA	Enhanced High Performance with Dynamic Input Delay Control PLL
OSCA	Internal Oscillator
SDCDLLA	Single Delay Cell DLL
TRDLLA	Time Reference Delay

Table 419: Dual Data Rate Cells

IDDRA	Input DDR
IDDRX1A	Input DDR
IDDRX2A	Input DDR
IDDRX4A	Input DDR
ODDRA	Output DDR
ODDRXA	Output DDR
ODDRX2A	Output DDR
ODDRX4A	Output DDR

Table 420: Miscellaneous

DELAY	Delay
GSR	Global Set/Reset
JTAGA	JTAG Logic Control Circuit
PFUMX	2-Input Mux within the PFU, C0 used for Selection with Positive Select
PUR	Power Up Set/Reset
PVTIOCTRL	PVT Monitor Circuit Controller

Table 420: Miscellaneous (Continued)

RDBK	Readback Controller
SGSR	Synchronous Release Global Set/Reset Interface
STRTUP	Startup Controller
TSALL	Global Tristate Interface

Primitive Library - LatticeXP2

This library includes compatible FPGA primitives supported by the LatticeXP2 device family

- Arithmetic Functions
- Comparators
- Counters
- Loadable Counters
- Flip-Flops
- Input/Output Buffers
- LatticeXP2 Memory Primitives
- Logic Gates
- Miscellaneous Logic
- Multiplexers
- Multipliers in DSP Blocks

Table 421: Arithmetic Functions

FADD2B	2 Bit Fast Adders/Subtractors
FADSU2	2 Bit Fast Adder/Subtractor (two's complement)
FSUB2B	2 Bit Subtractor
MULT2	2X2 Multiplier (not DSP)

Table 422: Comparators

AGEB2	A Greater Than Or Equal To B (2 bit)
ALEB2	A Less Than Or Equal To B (2 bit)
ANEB2	A Not Equal To B (2 bit)

Table 423: Counters

CB2	Combinational Logic for 2-Bit Bidirectional Counter
CD2	Combinational Logic for 2 Bit Down Counter
CU2	Combinational Logic for 2 Bit Up Counter

Table 424: Loadable Counters

LB2P3AX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Clear
LB2P3AY	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Preset
LB2P3BX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LB2P3DX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LB2P3IX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LB2P3JX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)
LD2P3AX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable, GSR Used for Clear

Table 424: Loadable Counters (Continued)

LD2P3AY	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable, GSR Used for Preset
LD2P3BX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LD2P3DX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LD2P3IX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LD2P3JX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)
LU2P3AX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable, GSR Used for Clear
LU2P3AY	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable, GSR Used for Preset
LU2P3BX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LU2P3DX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LU2P3IX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LU2P3JX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)

Table 425: Flip-Flops

FD1P3AX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, GSR used for Clear
FD1P3AY	Positive Edge Triggered D Flip-Flop with Positive Level Enable, GSR used for Preset
FD1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable and Positive Level Asynchronous Preset
FD1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable and Positive Level Asynchronous Clear
FD1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear and Positive Level Enable (Clear overrides Enable)
FD1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset and Positive Level Enable (Preset overrides Enable)

Table 425: Flip-Flops (Continued)

FD1S3AX	Positive Edge Triggered D Flip-Flop, GSR Used for Clear
FD1S3AY	Positive Edge Triggered D Flip-Flop, GSR Used for Preset
FD1S3BX	Positive Edge Triggered D Flip-Flop with Positive Level Asynchronous Preset
FD1S3DX	Positive Edge Triggered D Flip-Flop with Positive Level Asynchronous Clear
FD1S3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear
FD1S3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset
FL1P3AY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, and Positive Level Enable, GSR used for Preset
FL1P3AZ	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, and Positive Level Enable, GSR used for Clear
FL1P3BX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Asynchronous Preset, and Positive Level Enable
FL1P3DX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Asynchronous Clear, and Positive Level Enable
FL1P3IY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Synchronous Clear, and Positive Level Enable (Clear overrides Enable)
FL1P3JY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Synchronous Preset, and Positive Level Enable (Preset overrides Enable)
FL1S3AX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, GSR used for Clear
FL1S3AY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, GSR used for Preset

Table 426: Input/Output Buffers

BB	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional
BBPD	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional and Pull-down
BBPU	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional and Pull-up

Table 426: Input/Output Buffers (Continued)

BBW	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional in keepermode
IB	CMOS Input Buffer
IBPD	Input Buffer with Pull-down
IBPU	Input Buffer with Pull-up
ILVDS	LVDS Input Buffer
OB	Output Buffer
OBCO	Output Complementary Buffer
OBW	Output Buffer with Tristate
OBZ	Output Buffer with Tristate
OBZPD	Output Buffer with Tristate and Pull-down
OBZPU	Output Buffer with Tristate and Pull-up
OLVDS	LVDS Output Buffer

Table 427: LatticeXP2 Memory Primitives

DP16KB	True Dual Port Block RAM
DPR16X4A	Distributed Pseudo Dual Port RAM (within PFU)
DPR16X4B	Distributed Pseudo Dual Port RAM (within PFU)
PDPW16KB	Pseudo Dual Port Block RAM
SP16KB	Single Port Block RAM
SPR16X4A	Distributed Single Port RAM (within PFU)
SPR16X4B	Distributed Single Port RAM (within PFU)
SSPIA	SSPI TAG Memory
STFA	Store to Flash Primitive

Table 428: Logic Gates

AND2	2 Input AND Gate
AND3	3 Input AND Gate
AND4	4 Input AND Gate
AND5	5 Input AND Gate
ND2	2 Input NAND Gate

Table 428: Logic Gates (Continued)

ND3	3 Input NAND Gate
ND4	4 Input NAND Gate
ND5	5 Input NAND Gate
OR2	2 Input OR Gate
OR3	3 Input OR Gate
OR4	4 Input OR Gate
OR5	5 Input OR Gate
NR2	2 Input NOR Gate
NR3	3 Input NOR Gate
NR4	4 Input NOR Gate
NR5	5 Input NOR Gate
XNOR2	2 Input Exclusive NOR Gate
XNOR3	3 Input Exclusive NOR Gate
XNOR4	4 Input Exclusive NOR Gate
XNOR5	5 Input Exclusive NOR Gate
XOR2	2 Input Exclusive OR Gate
XOR3	3 Input Exclusive OR Gate
XOR4	4 Input Exclusive OR Gate
XOR5	5 Input Exclusive OR Gate
XOR11	11 Input Exclusive OR Gate
XOR21	21 Input Exclusive OR Gate

Table 429: Miscellaneous Logic

INV	Inverter
VHI	Logic High Generator
VLO	Logic Low Generator

Table 430: Multiplexers

L6MUX21	LUT-6 2 to 1 Multiplexer
MUX161	16-Input Mux within the PFU (4 Slices)
MUX21	2 to 1 Mux

Table 430: Multiplexers (Continued)

MUX321	32-Input Mux within the PFU (8 Slices)
MUX41	4 to 1 Mux
MUX81	8 to 1 Mux

Table 431: Multipliers in DSP Blocks

MULT18X18ADDSUBB	18x18 Multiplier Add/Subtract Multipliers in DSP blocks
MULT18X18ADDSUBSUMB	18x18 Multiplier Add/Subtract and SUM Multipliers in DSP blocks
MULT18X18B	18x18 Multiplier in DSP blocks
MULT18X18MACB	18x18 Multiplier Accumulate Multipliers in DSP blocks
MULT36X36B	36x36 Multiplier Multipliers in DSP blocks
MULT9X9ADDSUBB	9x9 Multiplier Add/Subtract Multipliers in DSP blocks
MULT9X9ADDSUBSUMB	9x9 Multiplier Add/Subtract and SUM Multipliers in DSP blocks
MULT9X9B	9x9 Multiplier Multipliers in DSP blocks

PIC Cells

Table 432: PIC Flip-Flops (Input)

IFS1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and System Clock (used in input PIC area only)
IFS1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and System Clock (used in input PIC area only)
IFS1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable, and System Clock (Clear overrides Enable) (used in input PIC area only)
IFS1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable, and System Clock (Preset overrides Enable) (used in input PIC area only)

Table 433: PIC Flip-Flops (Output)

OFE1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and Edge Clock (used in output PIC area only)
OFE1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and Edge Clock (used in output PIC area only)
OFE1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable (Clear overrides Enable), and Edge Clock (used in output PIC area only)
OFE1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable (Preset overrides Enable), and Edge Clock (used in output PIC area only)
OFS1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and System Clock (used in output PIC area only)
OFS1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and System Clock (used in output PIC area only)
OFS1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable (Clear overrides Enable), and System Clock (used in output PIC area only)
OFS1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable (Preset overrides Enable), and System Clock (used in output PIC area only)

Table 434: PIC Latches (Input)

IFS1S1B	Positive Level Data Latch with Positive Level Asynchronous Preset and System Clock (used in input PIC area only)
IFS1S1D	Positive Level Data Latch with Positive Level Asynchronous Clear and System Clock (used in input PIC area only)
IFS1S1I	Positive Level Data Latch with Positive Level Synchronous Clear and System Clock (used in input PIC area only)
IFS1S1J	Positive Level Data Latch with Positive Level Synchronous Preset and System Clock (used in input PIC area only)

Table 435: Read-Only Memory

ROM16X1	16 Word by 1 bit read-only memory
ROM32X1	32 Word by 1 bit read-only memory
ROM64X1	64 Word by 1 bit read-only memory
ROM128X1	128 Word by 1 bit read-only memory
ROM256X1	256 Word by 1 bit read-only memory

Special Cells

Table 436: Clock Manager/PLL/DLL

CLKDIVB	Clock Divider
DCS	Dynamic Clock Selection Multiplexer
EHXPLLE	Complex PLL
EHXPLLE1	Complex PLL
EPLLD	Enhanced PLL
EPLLD1	Enhanced PLL
OSCE	Oscillator for configuration clock

Table 437: Combinatorial Primitives

ORCALUT4	4-Input Look Up Table
ORCALUT5	5-Input Look Up Table
ORCALUT6	6-Input Look Up Table

Table 437: Combinatorial Primitives (Continued)

ORCALUT7	7-Input Look Up Table
ORCALUT8	8-Input Look Up Table

Table 438: Dual Data Rate Cells

DQSBUFC	DQS Delay Function and Clock Polarity Selection Logic
DQSDLL	DLL Used as DDR Memory DQS DLL
IDDRFXA	DDR Generic Input with Full Clock Transfer (x1 Gearbox)
IDDRMFX1A	DDR Input and DQS to System Clock Transfer Registers with Full Clock Cycle Transfer
IDDRMX1A	DDR Input and DQS to System Clock Transfer Registers with Half Clock Cycle Transfer
IDDRX2B	DDR Generic Input with 2x Gearing Ratio
IDDRXC	DDR Generic Input
ODDRMXA	DDR Output Registers
ODDRX2B	DDR Generic Output with 2x Gearing Ratio
ODDRXC	DDR Generic Output

Table 439: Miscellaneous

CCU2B	Carry-Chain
DELAYB	Dynamic Delay in PIO
GSR	Global Set/Reset
IOWAKEUPA	XP2 Wake-up Controller
JTAGE	JTAG (Joint Test Action Group) Controller
PFUMX	2-Input Mux within the PFU, C0 used for Selection with Positive Select
PUR	Power Up Set/Reset
SEDBA	XP2 SED BASIC
SEDBB	XP2 SED BASIC for One Shot Mode
SGSR	Synchronous Release Global Set/Reset Interface
SSPIA	XP2 SSPI TAG Memory
START	Startup Controller
STFA	XP2 Store to Flash Primitive

Primitive Library - LIFMD

This library includes compatible FPGA primitives supported by the LIFMD device family.

- Flip-Flops
- Input/Output Buffers
- Memory Primitives
- Logic Gates
- Miscellaneous Logic
- Multiplexers
- PIC Cells
  - PIC Flip-Flops (Input)
  - PIC Flip-Flops (Output)
  - PIC Latches (Input)
- Read-Only Memory
- Special Cells
  - Clock Manager/PLL/DLL
  - Combinatorial Primitives
  - Miscellaneous

References

For further information on individual primitives, a variety of technical notes for the LIFMD family are available on the Lattice web site.

Table 452: Dual Data Rate Cells

DDRDLLA	90-degree delay for the DQS Input during a memory interface or the clock input for a generic DDR interface
ECLKSYNCB	ECLK Stop Block
IDDR71B	7:1 LVDS Input Supporting 1:7 Gearing
IDDRX1F	Generic Input DDR primitive
IDDRX2F	Generic Input DDR primitive
IDDRX4C	DDR primitive
IDDR141A	DDR primitive
IDDRX8A	DDR primitive
ODDRX1F	Generic X1 ODDR implementation
ODDRX2F	Generic X2 ODDR implementation

Table 452: Dual Data Rate Cells

ODDRX4C	ODDR primitive
ODDR141A	ODDR primitive
ODDRX8A	ODDR primitive
ODDR71B	7:1 LVDS ODDR implementation

Table 453: Miscellaneous

BCINRD	Dynamic Bank Controller InRD
BCLVDSOB	Bank Controller for LVDS Outut Buffers
CCU2C	Carry-Chain
DELAYF	Delay
DELAYG	Delay
GSR	Global Set/Reset
INRDB	Input Reference and Differential Buffer
I2CA	I2C Primitive
LVDSOB	LVDS Output Buffer
MIPI	Special Primitive for MIPI Input Support
MIPIDPHYA	Primitive
PFUMX	2-Input mux within the PFU, C0 used for Selection with Positive Select
PMUA	Power Management Unit
PUR	Power Up Set/Reset
SGSR	Synchronous Release Global Set/Reset Interface

Primitive Library - MachXO and Platform Manager

This library includes compatible primitives supported by the MachXO and Platform Manager devices.

- Adders/Subtractors
- Comparators
- Counters
- Loadable Counters
- Flip-Flops
- Input/Output Buffers
- Latches
- Logic Gates
- MachXO and Platform Manager Memory Primitives
- Miselleaneous Logic
- Multiplexers
- Multipliers
- Read-Only Memory
- Combinatorial Primitives
- Miscellaneous

FADD2	2 Bit Fast Adder
FSUB2	2 Bit Fast Subtractor (two's complement)
FADSU2	2 Bit Fast Adder/Subtractor (two's complement)

Table 455: Comparators

AGEB2	A Greater Than Or Equal To B (2 bit)
ALEB2	A Less Than Or Equal To B (2 bit)
ANEB2	A Not Equal To B (2 bit)

Table 456: Counters

CB2	Combinational Logic for 2-Bit Bidirectional Counter
CD2	Combinational Logic for 2 Bit Down Counter
CU2	Combinational Logic for 2 Bit Up Counter

Table 457: Loadable Counters

LB2P3AX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Clear
LB2P3AY	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Preset
LB2P3BX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LB2P3DX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LB2P3IX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LB2P3JX	2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)
LD2P3AX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable, GSR Used for Clear
LD2P3AY	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable, GSR Used for Preset
LD2P3BX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LD2P3DX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LD2P3IX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)

Table 457: Loadable Counters (Continued)

LD2P3JX	2 Bit Positive Edge Triggered Loadable Down Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)
LU2P3AX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable, GSR Used for Clear
LU2P3AY	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable, GSR Used for Preset
LU2P3BX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Asynchronous Preset
LU2P3DX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Asynchronous Clear
LU2P3IX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)
LU2P3JX	2 Bit Positive Edge Triggered Loadable Up Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)

Table 458: Flip-Flops

FD1P3AX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, GSR used for Clear
FD1P3AY	Positive Edge Triggered D Flip-Flop with Positive Level Enable, GSR used for Preset
FD1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable and Positive Level Asynchronous Preset
FD1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable and Positive Level Asynchronous Clear
FD1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear and Positive Level Enable (Clear overrides Enable)
FD1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset and Positive Level Enable (Preset overrides Enable)
FD1S3AX	Positive Edge Triggered D Flip-Flop, GSR Used for Clear
FD1S3AY	Positive Edge Triggered D Flip-Flop, GSR Used for Preset
FD1S3BX	Positive Edge Triggered D Flip-Flop with Positive Level Asynchronous Preset
FD1S3DX	Positive Edge Triggered D Flip-Flop with Positive Level Asynchronous Clear
FD1S3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear

Table 458: Flip-Flops (Continued)

FD1S3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset
FL1P3AY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, and Positive Level Enable, GSR used for Preset
FL1P3AZ	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, and Positive Level Enable, GSR used for Clear
FL1P3BX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Asynchronous Preset, and Positive Level Enable
FL1P3DX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Asynchronous Clear, and Positive Level Enable
FL1P3IY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Synchronous Clear, and Positive Level Enable (Clear overrides Enable)
FL1P3JY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Synchronous Preset, and Positive Level Enable (Preset overrides Enable)
FL1S3AX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, GSR used for Clear
FL1S3AY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, GSR used for Preset

Table 459: Input/Output Buffers

BB	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional
BBPD	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional and Pull-down
BBPU	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional and Pull-up
BBW	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional in keepermode
IB	Input Buffer
IBPD	Input Buffer with Pull-down
IBPU	Input Buffer with Pull-up
ILVDS	LVDS Input Buffer

Table 459: Input/Output Buffers

OB	Output Buffer
OBW	Output Buffer with Tristate
OBZ	Output Buffer with Tristate
OBZPD	Output Buffer with Tristate and Pull-down
OBZPU	Output Buffer with Tristate and Pull-up
OLVDS	LVDS Output Buffer

Table 460: Latches

FD1S1A	Positive Level Data Latch with GSR Used for Clear
FD1S1AY	Positive Level Data Latch with GSR Used for Preset
FD1S1B	Positive Level Data Latch with Positive Level Asynchronous Preset
FD1S1D	Positive Level Data Latch with Positive Level Asynchronous Clear
FD1S1I	Positive Level Data Latch with Positive Level Synchronous Clear
FD1S1J	Positive Level Data Latch with Positive Level Synchronous Preset
FL1S1A	Positive Level Loadable Latch with Positive Select and GSR Used for Clear
FL1S1AY	Positive Level Loadable Latch with Positive Select and GSR Used for Preset
FL1S1B	Positive Level Loadable Latch with Positive Select and Positive Level Asynchronous Preset
FL1S1D	Positive Level Loadable Latch with Positive Select and Positive Level Asynchronous Clear
FL1S1I	Positive Level Loadable Latch with Positive Select and Positive Level Synchronous Clear
FL1S1J	Positive Level Loadable Latch with Positive Select and Positive Level Synchronous Preset

Table 461: Logic Gates

AND2	2 Input AND Gate
AND3	3 Input AND Gate
AND4	4 Input AND Gate
AND5	5 Input AND Gate
ND2	2 Input NAND Gate

Table 461: Logic Gates (Continued)

ND3	3 Input NAND Gate
ND4	4 Input NAND Gate
ND5	5 Input NAND Gate
OR2	2 Input OR Gate
OR3	3 Input OR Gate
OR4	4 Input OR Gate
OR5	5 Input OR Gate
NR2	2 Input NOR Gate
NR3	3 Input NOR Gate
NR4	4 Input NOR Gate
NR5	5 Input NOR Gate
XNOR2	2 Input Exclusive NOR Gate
XNOR3	3 Input Exclusive NOR Gate
XNOR4	4 Input Exclusive NOR Gate
XNOR5	5 Input Exclusive NOR Gate
XOR2	2 Input Exclusive OR Gate
XOR3	3 Input Exclusive OR Gate
XOR4	4 Input Exclusive OR Gate
XOR5	5 Input Exclusive OR Gate
XOR11	11 Input Exclusive OR Gate
XOR21	21 Input Exclusive OR Gate

Table 462: MachXO and Platform Manager Memory Primitives

DP8KB	8K Dual Port Block RAM
DPR16X2B	16 Word by 2 Dual Port RAM (within PFU)
FIFO8KA	8K FIFO
PDP8KB	8K Pseudo Dual Port Block RAM
SP8KB	8 Word by 8 Bit Single Port Block RAM
SPR16X2B	16 Word by 2 Bit Positive Edge Triggered Write Synchronous Single Port RAM Memory with Positive Write Enable and Positive Write Port Enable (1-Slice)

Table 463: Miselleaneous Logic

INV	Inverter
VHI	Logic High Generator
VLO	Logic Low Generator

Table 464: Multiplexers

L6MUX21	LUT-6 2 to 1 Multiplexer
MUX161	16-Input Mux within the PFU (4 Slices)
MUX21	2 to 1 Mux
MUX321	32-Input Mux within the PFU (8 Slices)
MUX41	4 to 1 Mux
MUX81	8 to 1 Mux

Table 465: Multipliers

MULT2	2x2 Multiplier

Table 466: Read-Only Memory

ROM16X1	16 Word by 1 bit read-only memory
ROM32X1	32 Word by 1 bit read-only memory
ROM64X1	64 Word by 1 bit read-only memory
ROM128X1	128 Word by 1 bit read-only memory
ROM256X1	256 Word by 1 bit read-only memory

ORCALUT4	4-Input Look Up Table
ORCALUT5	5-Input Look Up Table
ORCALUT6	6-Input Look Up Table
ORCALUT7	7-Input Look Up Table
ORCALUT8	8-Input Look Up Table

Table 468: Miscellaneous

CCU2	Carry Chain
EHXPLLC	Enhanced Extended Performance PLL
GSR	Global Set/Reset
JTAGD	JTAG (Joint Test Action Group) Controller
OSCC	Internal Oscillator
PFUMX	2-Input Mux within the PFU, C0 used for Selection with Positive Select
PUR	Power Up Set/Reset
TSALL	Global Tristate Interface

Primitive Library - MachXO2 and Platform Manager 2

This library includes compatible primitives supported by the MachXO2 device family.

- Adders/Subtractors
- Comparators
- Counters
  - Bi-Directional Loadable Counters
  - Loadable Down Counters
  - Loadable Up Counters
- Flip-Flops
- Input/Output Buffer
- Latches
- Logic Gates
- PIC Cells
  - Flip-Flops (Input)
  - Flip-Flops (Output)
  - PIC Latches (Input)
- MachXO2/Platform Manager 2 Memory Primitives
- Miscellaneous Logic
- Multiplexers
- Multipliers
- Read-Only Memory
- Special Cells
  - Clock/PLL/DLL
  - Combinatorial Primitives
  - Dual Data Rate Cells
  - Miscellaneous

PIC Cells

Table 479: Flip-Flops (Input)

IFS1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and System Clock (used in input PIC area only)
IFS1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and System Clock (used in input PIC area only)
IFS1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable, and System Clock (Clear overrides Enable) (used in input PIC area only)
IFS1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable, and System Clock (Preset overrides Enable) (used in input PIC area only)

Table 480: Flip-Flops (Output)

OFS1P3BX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and System Clock (used in output PIC area only)
OFS1P3DX	Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and System Clock (used in output PIC area only)
OFS1P3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable (Clear overrides Enable), and System Clock (used in output PIC area only)
OFS1P3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable (Preset overrides Enable), and System Clock (used in output PIC area only)

Table 481: PIC Latches (Input)

IFS1S1B	Positive Level Data Latch with Positive Level Asynchronous Preset and System Clock (used in input PIC area only)
IFS1S1D	Positive Level Data Latch with Positive Level Asynchronous Clear and System Clock (used in input PIC area only)

Table 481: PIC Latches (Input) (Continued)

IFS1S1I	Positive Level Data Latch with Positive Level Synchronous Clear and System Clock (used in input PIC area only)
IFS1S1J	Positive Level Data Latch with Positive Level Synchronous Preset and System Clock (used in input PIC area only)

Table 482: MachXO2/Platform Manager 2 Memory Primitives

DP8KC	8K True Dual Port Block RAM
DPR16X4C	Distributed Pseudo Dual Port RAM
FIFO8KB	8K FIFO Block RAM
PDPW8KC	Pseudo Dual Port Block RAM
SP8KC	8K Single Port Block RAM
SPR16X4C	Distributed Single Port RAM

Table 483: Miscellaneous Logic

INV	Inverter
VHI	Logic High Generator
VLO	Logic Low Generator

Table 484: Multiplexers

L6MUX21	LUT-6 2 to 1 Multiplexer
MUX161	16-Input Mux within the PFU (4 Slices)
MUX21	2 to 1 Mux
MUX321	32-Input Mux within the PFU (8 Slices)
MUX41	4 to 1 Mux
MUX81	8 to 1 Mux

Table 485: Multipliers

MULT2	2x2 Multiplier

Table 486: Read-Only Memory

ROM128X1A	128 Word by 1 Bit Positive Edge Triggered Read-Only Memory with Registered Data Outputs
ROM16X1A	16 Word by 1 Bit Read-Only Memory
ROM256X1A	256 Word by 1 Bit Positive Edge Triggered Read-Only Memory with Registered Data Outputs
ROM32X1A	32 Word by 1 Bit Read-Only Memory
ROM64X1A	64 Word by 1 Bit Positive Edge Triggered Read-Only Memory with Registered Data Outputs

Special Cells

Table 487: Clock/PLL/DLL

CLKDIVC	Clock Divider
DCCA	Dynamic Quadrant Clock Enable/Disable
DCMA	Dynamic Clock Mux
DLLDELC	Clock Shifting for ECLK or PCLK
ECLKBRIDGECS	ECLK Bridge Block Clock Select
ECLKSYNCA	ECLK Stop Block
EHXPLLJ	GPLL for MachXO2
OSCH	Oscillator for MachXO2
PLLREFCS	PLL Dynamic Reference Clock Switching

Table 488: Combinatorial Primitives

LUT4	4-Input Look Up Table
LUT5	5-Input Look Up Table
LUT6	6-Input Look Up Table
LUT7	7-Input Look Up Table
LUT8	8-Input Look Up Table

Table 489: Dual Data Rate Cells

DQSBUFH	DQS Circuit for DDR Memory
DQSDLLC	Master DLL for Generating Required Delay
IDDRXE	Input for Generic DDR X1 Using 1:2 Gearing
IDDRX2E	Input for Generic DDR X2 Using 1:4 Gearing
IDDRX4B	Input for Generic DDR X4 Using 1:8 Gearing
IDDRDQSX1A	Input for DDR1/2 Memory
IDDRX71A	7:1 LVDS Input Supporting 1:7 Gearing
ODDRXE	Output for Generic DDR X1 Using 2:1 Gearing
ODDRX2E	Output for Generic DDR X2 Using 4:1 Gearing
ODDRX4B	Output for Generic DDR X4 Using 8:1 Gearing
ODDRDQSX1A	Output for DDR1/2 Memory
ODDRX71A	7:1 LVDS Output
TDDRA	Tristate for DQ/DQS of PIC Cell

Table 490: Miscellaneous

BCINRD	Dynamic Bank Controller InRD
BCLVDSO	Dynamic Bank Controller LVDS
CCU2D	Carry Chain
CLKFBBUFA	Dummy Feedback Delay Between PLL clk Output and PLL fb Port
DELAYD	Dynamic Delay for Bottom Bank
DELAYE	Fixed Delay in PIO
EFB	Embedded Function Block
GSR	Global Set/Reset
INRDB	Input Reference and Differential Buffer
JTAGF	JTAG (Joint Test Action Group) Controller
LVDSOB	LVDS Output Buffer
PCNTR	Power Controller
PFUMX	2-Input Mux within the PFU, C0 used for Selection with Positive Select
PG	Power Guard

Table 490: Miscellaneous (Continued)

PUR	Power Up Set/Reset
SEDFA	Soft Error Detect in Basic Mode
SEDFB	Soft Error Detect in One Shot Mode
SGSR	Synchronous Release Global Set/Reset Interface
START	Startup Controller
TSALL	Global Tristate Interface

Primitive Library - MachXO3D

This library includes compatible primitives supported by the MachXO3D device family.

FD1S3AX	Positive Edge Triggered D Flip-Flop, GSR Used for Clear
FD1S3AY	Positive Edge Triggered D Flip-Flop, GSR Used for Preset
FD1S3BX	Positive Edge Triggered D Flip-Flop with Positive Level Asynchronous Preset
FD1S3DX	Positive Edge Triggered D Flip-Flop with Positive Level Asynchronous Clear
FD1S3IX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear
FD1S3JX	Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset
FL1P3AY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, and Positive Level Enable, GSR used for Preset
FL1P3AZ	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, and Positive Level Enable, GSR used for Clear
FL1P3BX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Asynchronous Preset, and Positive Level Enable
FL1P3DX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Asynchronous Clear, and Positive Level Enable
FL1P3IY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Synchronous Clear, and Positive Level Enable (Clear overrides Enable)
FL1P3JY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Synchronous Preset, and Positive Level Enable (Preset overrides Enable)
FL1S3AX	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, GSR used for Clear
FL1S3AY	Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, GSR used for Preset

Table 498: Input/Output Buffer

BB	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional
BBI3C	I3C Bidirectional Buffer
BBPD	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional and Pull-down

Table 498: Input/Output Buffer

BBPU	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional and Pull-up
BBW	CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate BiDirectional in keepermode
IB	Input Buffer
IBPD	Input Buffer with Pull-down
IBPU	Input Buffer with Pull-up
ILVDS	LVDS Input Buffer
OB	Output Buffer
OBCO	Output Complementary Buffer
OBZ	Output Buffer with Tristate
OBZPU	Output Buffer with Tristate and Pull-up
OLVDS	LVDS Output Buffer

IDDRXE	Input for Generic DDR X1 Using 1:2 Gearing
IDDRX2E	Input for Generic DDR X2 Using 1:4 Gearing
IDDRX4B	Input for Generic DDR X4 Using 1:8 Gearing
IDDRX71A	7:1 LVDS Input Supporting 1:7 Gearing
ODDRXE	Output for Generic DDR X1 Using 2:1 Gearing
ODDRX2E	Output for Generic DDR X2 Using 4:1 Gearing
ODDRX4B	Output for Generic DDR X4 Using 8:1 Gearing
ODDRX71A	7:1 LVDS Output

Table 512: Miscellaneous

BCINRD	Dynamic Bank Controller InRD
BCLVDSO	Dynamic Bank Controller LVDS
BCSLEWRATEA	Bank Controller for Slew Rate
CCU2D	Carry Chain
CLKFBBUFA	Dummy Feedback Delay Between PLL clk Output and PLL fb Port
DELAYD	Dynamic Delay for Bottom Bank
DELAYE	Fixed Delay in PIO

Table 512: Miscellaneous (Continued)

EFBB	Embedded Function Block for MachXO3D
ESBA	Embedded Security Block for MachXO3D
GSR	Global Set/Reset
INRDB	Input Reference and Differential Buffer
JTAGF	JTAG (Joint Test Action Group) Controller
LVDSOB	LVDS Output Buffer
PCNTR	Power Controller
PFUMX	2-Input Mux within the PFU, C0 used for Selection with Positive Select
PG	Power Guard
PUR	Power Up Set/Reset
SEDFA	Soft Error Detect in Basic Mode
SEDFB	Soft Error Detect in One Shot Mode
SGSR	Synchronous Release Global Set/Reset Interface
START	Startup Controller
TSALL	Global Tristate Interface

Primitive Library - MachXO3L

This library includes compatible primitives supported by the MachXO3L device family.

- Adders/Subtractors
- Comparators
- Counters
  - Bi-Directional Loadable Counters
  - Loadable Down Counters
  - Loadable Up Counters
- Flip-Flops
- Input/Output Buffer
- Latches
- Logic Gates
- PIC Cells
  - Flip-Flops (Input)
  - Flip-Flops (Output)
  - PIC Latches (Input)
- MachXO2 Memory Primitives
- Miscellaneous Logic
- Multiplexers
- Multipliers
- Read-Only Memory
- Special Cells
  - Clock/PLL/DLL
  - Combinatorial Primitives
  - Dual Data Rate Cells
  - Miscellaneous

Alphanumeric Primitives List

This section lists all the Lattice library primitives in alphanumeric order.

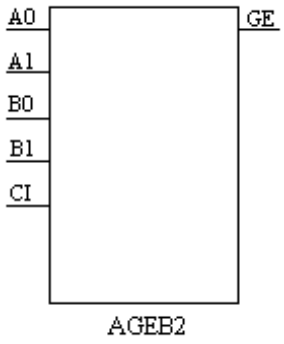
A

AGEB2

"A" Greater Than Or Equal To "B"

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A0, A1, B0, B1, CI

OUTPUT: GE

Description

AGEB2 is a 2-bit comparator that can be cascaded together to build larger comparators. It has two 2-bit inputs and a carry-in input. The carry-in (CI) on the first stage should be tied HIGH. The compare-out (GE) output is HIGH if A[1:0] >= B[1:0] and LOW if A[1:0] < B[1:0]. To build larger comparators, tie the GE on the lower stage to CI on the upper stage.

Note

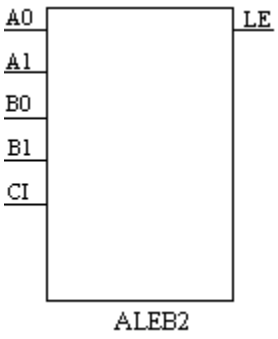
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

ALEB2

"A" Less Than Or Equal To "B"

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A0, A1, B0, B1, CI

OUTPUT: LE

Description

ALEB2 is a 2-bit comparator that can be cascaded together to build larger comparators. It has two 2-bit inputs and a carry-in input. The carry-in (CI) on the first stage should be tied HIGH. The compare-out (LE) output is HIGH if A[1:0] <= B[1:0] and LOW if A[1:0] > B[1:0]. To build larger comparators, tie the LE on the lower stage to CI on the upper stage.

Note

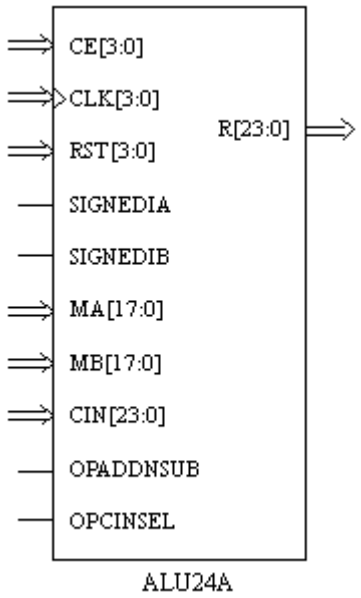
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

ALU24A

24 Bit Ternary Adder/Subtractor

Architectures Supported:

- ECP5
- LatticeECP3



INPUTS: MA17, MA16, MA15, MA14, MA13, MA12, MA11, MA10, MA9, MA8, MA7, MA6, MA5, MA4, MA3, MA2, MA1, MA0, MB17, MB16, MB15, MB14, MB13, MB12, MB11, MB10, MB9, MB8, MB7, MB6, MB5, MB4, MB3, MB2, MB1, MB0, CIN23, CIN22, CIN21, CIN20, CIN19, CIN18, CIN17, CIN16, CIN15, CIN14, CIN13, CIN12, CIN11, CIN10, CIN9, CIN8, CIN7, CIN6, CIN5, CIN4, CIN3, CIN2, CIN1, CIN0, CE3, CE2, CE1, CE0, CLK3, CLK2, CLK1,

CLK0, RST3, RST2, RST1, RST0, SIGNEDIA, SIGNEDIB, OPADDNSUB, OPCINSEL

OUTPUTS: R23, R22, R21, R20, R19, R18, R17, R16, R15, R14, R13, R12, R11, R10, R9, R8, R7, R6, R5, R4, R3, R2, R1, R0

ATTRIBUTES:

REG_OUTPUT_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_OUTPUT_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_OUTPUT_RST: "RST0" (default), "RST1", "RST2", "RST3"

REG_OPCODE_0_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_OPCODE_0_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_OPCODE_0_RST: "RST0" (default), "RST1", "RST2", "RST3"

REG_OPCODE_1_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_OPCODE_1_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_OPCODE_1_RST: "RST0" (default), "RST1", "RST2", "RST3"

GSR: "ENABLED" (default), "DISABLED"

RESETMODE: "SYNC" (default), "ASYNC"

ALU24A Attribute Description

Table 535:

Name	Description
REG_OUTPUT_CLK	ALU register for output clock selection
REG_OUTPUT_CLK	ALU register for output clock enable selection
REG_OUTPUT_RST	ALU register for output reset selection
REG_OPCODE_0_CLK	OPCODE register clock selection
REG_OPCODE_0_CE	OPCODE register clock enable selection
REG_OPCODE_0_RST	OPCODE register reset selection
REG_OPCODE_1_CLK	OPCODE pipeline register clock selection
REG_OPCODE_1_CE	OPCODE pipeline register clock enable selection
REG_OPCODE_1_RST	OPCODE pipeline register reset selection
GSR	Global set reset selection
RESETMODE	Reset mode selection

ALU24A Port Description

Table 536:

Input/Output	Port Name	Capture Name	Type	Size (Buses Only)	Description
I	CLK0	CLK0	Bit	N/A	Clock Input
I	CLK1	CLK1	Bit	N/A	Clock Input
I	CLK2	CLK2	Bit	N/A	Clock Input
I	CLK3	CLK3	Bit	N/A	Clock Input
I	CE0	CE0	Bit	N/A	Clock Enable Input
I	CE1	CE1	Bit	N/A	Clock Enable Input
I	CE2	CE2	Bit	N/A	Clock Enable Input
I	CE3	CE3	Bit	N/A	Clock Enable Input
I	RST0	RST0	Bit	N/A	Reset Input
I	RST1	RST1	Bit	N/A	Reset Input
I	RST2	RST2	Bit	N/A	Reset Input
I	RST3	RST3	Bit	N/A	Reset Input
I	SIGNEDIA[1]	SIGNEDIA	Bit	N/A	Input A Sign Selection
I	SIGNEDIB[1]	SIGNEDIB	Bit	N/A	Input A Sign Selection

Table 536:

Input/Output	Port Name	Capture Name	Type	Size (Buses Only)	Description
I	MA[1]	MA[35:18]	Bus	17:0	Input A from Multiplier
I	MB[1]	MB[35:18]	Bus	17:0	Input B from Multiplier
I	CIN	CIN[50:27]	Bus	23:0	CIN Input
I	OPCINSEL	OP5	Bit	N/A	CIN Select selects CIN (010) or GND (000)
I	OPADDNSUB	OP7	Bit	N/A	Add/Subtract selection
O	R	R[43:34]	Bus	23:0	Output

Notes:
1. A and B refer to the first and second multiplier of the slice and not the Ax and Bx inputs to multiplier x.

Note

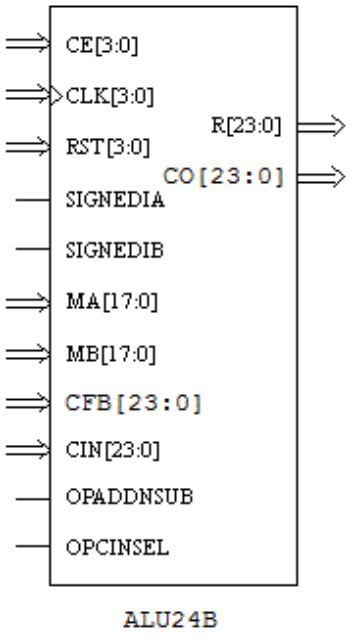
The synthesis tool will not use this block to inference DSP function.

ALU24B

24-bit Ternary Adder/Subtractor for 9x9 Mode

Architectures Supported:

- ECP5



INPUTS: MA17, MA16, MA15, MA14, MA13, MA12, MA11, MA10, MA9, MA8, MA7, MA6, MA5, MA4, MA3, MA2, MA1, MA0, MB17, MB16, MB15, MB14, MB13, MB12, MB11, MB10, MB9, MB8, MB7, MB6, MB5, MB4, MB3, MB2, MB1, MB0, CIN23, CIN22, CIN21, CIN20, CIN19, CIN18, CIN17, CIN16, CIN15, CIN14, CIN13, CIN12, CIN11, CIN10, CIN9, CIN8, CIN7, CIN6, CIN5, CIN4, CIN3, CIN2, CIN1, CIN0, CBF23, CBF22, CBF21, CBF20, CBF19, CBF18, CBF17, CBF16, CBF15, CBF14, CBF13, CBF12, CBF11, CBF10, CBF9, CBF8, CBF7, CBF6, CBF5, CBF4, CBF3, CBF2, CBF1, CBF0, CE3, CE2, CE1, CE0, CLK3, CLK2, CLK1, CLK0, RST3, RST2, RST1, RST0, SIGNEDIA, SIGNEDIB, OPADDNSUB, OPCINSEL

OUTPUTS: R23, R22, R21, R20, R19, R18, R17, R16, R15, R14, R13, R12, R11, R10, R9, R8, R7, R6, R5, R4, R3, R2, R1, R0, CO23, CO22, CO21, CO20, CO19, CO18, CO17, CO16, CO15, CO14, CO13, CO12, CO11, CO10, CO9, CO8, CO7, CO6, CO5, CO4, CO3, CO2, CO1, CO0

ATTRIBUTES:

REG_OUTPUT_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_OUTPUT_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_OUTPUT_RST: "RST0" (default), "RST1", "RST2", "RST3"

REG_OPCODE_0_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_OPCODE_0_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_OPCODE_0_RST: "RST0" (default), "RST1", "RST2", "RST3"

REG_OPCODE_1_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_OPCODE_1_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_OPCODE_1_RST: "RST0" (default), "RST1", "RST2", "RST3"

REG_INPUTCFB_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_INPUTCFB_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_INPUTCFB_RST: "RST0" (default), "RST1", "RST2", "RST3"

CLK0_DIV: "ENABLED" (default), "DISABLED"

CLK1_DIV: "ENABLED" (default), "DISABLED"

CLK2_DIV: "ENABLED" (default), "DISABLED"

CLK3_DIV: "ENABLED" (default), "DISABLED"

GSR: "ENABLED" (default), "DISABLED"

RESETMODE: "SYNC" (default), "ASYNC"

* When REG_INPUTCFB_CLK = NONE, then it means that the CFB ports are not used, and C -> Cr using the C0/C1_CLK attributes.

* When REG_INPUTCFB_CLK != NONE, then the CFB ports are being used and CFB -> CO is using these attributes. C -> Cr is unregistered and a DRC can check to make sure C0/C1_CLK = NONE

ALU24B Attribute Description

Table 537:

Attribute Name	Values	Default Value	GUI Access
REG_OUTPUT_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y
REG_OUTPUT_CE	CE0, CE1, CE2, CE3	CE0	Y
REG_OUTPUT_RST	RST0, RST1, RST2, RST3	RST0	Y
REG_OPCODE_0_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y
REG_OPCODE_0_CE	CE0, CE1, CE2, CE3	CE0	Y
REG_OPCODE_0_RST	RST0, RST1, RST2, RST3	RST0	Y
REG_OPCODE_1_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y
REG_OPCODE_1_CE	CE0, CE1, CE2, CE3	CE0	Y
REG_OPCODE_1_RST	RST0, RST1, RST2, RST3	RST0	Y
REG_INPUTCFB_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y
REG_INPUTCFB_CE	CE0, CE1, CE2, CE3	CE0	Y
REG_INPUTCFB_RST	RST0, RST1, RST2, RST3	RST0	Y
CLK0_DIV	ENABLED, DISABLED	ENABLED	Y
CLK1_DIV	ENABLED, DISABLED	ENABLED	Y
CLK2_DIV	ENABLED, DISABLED	ENABLED	Y
CLK3_DIV	ENABLED, DISABLED	ENABLED	Y
RESETMODE	SYNC, ASYNC	SYNC	Y
GSR	ENABLED, DISABLED	ENABLED	N

ALU24B Port Description

Table 538:

Port Name	I/O	Description
CE[3:0]	I	Clock Enable Inputs
CLK[3:0]	I	Clock Input
RST[3:0]	I	Reset inputs
SIGNEDIA	I	Sign Bit for Input A

Table 538:

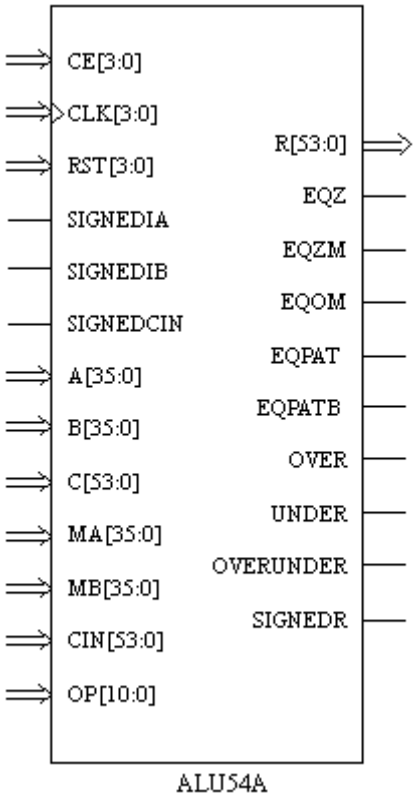
Port Name	I/O	Description
SIGNEDIB	I	Sign Bit for Input B
MA[17:0]	I	Input A
MB[17:0]	I	Input B
CFB[23:0]	I	C Input for Highspeed
CIN[23:0]	I	Carry In Input
OPADDNSUB	I	Add/Sub Selector
OPCINSEL	I	CarryIn Selector
R[23:0]	O	Sum
CO[23:0]	O	Sum – Special Routing output used for Highspeed option

ALU54A

54 Bit Ternary Adder/Subtractor

Architectures Supported:

- ECP5
- LatticeECP3



INPUTS: A35, A34, A33, A32, A31, A30, A29, A28, A27, A26, A25, A24, A23, A22, A21, A20, A19, A18, A17, A16, A15, A14, A13, A12, A11, A10, A9, A8, A7, A6, A5, A4, A3, A2, A1, A0, B35, B34, B33, B32, B31, B30, B29, B28, B27, B26, B25, B24, B23, B22, B21, B20, B19, B18, B17, B16, B15, B14, B13, B12, B11, B10, B9, B8, B7, B6, B5, B4, B3, B2, B1, B0, C53, C52, C51, C50, C49, C48, C47, C46, C45, C44, C43, C42, C41, C40, C39, C38, C37, C36, C35, C34, C33, C32, C31, C30, C29, C28, C27, C26, C25, C24, C23, C22, C21, C20, C19, C18, C17, C16, C15, C14, C13, C12, C11, C10, C9, C8, C7, C6, C5, C4, C3, C2, C1, C0, MA35, MA34, MA33, MA32, MA31, MA30, MA29, MA28, MA27, MA26, MA25, MA24, MA23, MA22, MA21, MA20, MA19, MA18, MA17, MA16, MA15, MA14, MA13, MA12, MA11, MA10, MA9, MA8, MA7, MA6, MA5, MA4, MA3, MA2, MA1, MA0, MB35, MB34, MB33, MB32, MB31, MB30, MB29, MB28, MB27, MB26, MB25, MB24, MB23, MB22, MB21, MB20, MB19, MB18, MB17, MB16, MB15, MB14, MB13, MB12, MB11, MB10, MB9, MB8, MB7, MB6, MB5, MB4, MB3, MB2, MB1, MB0, CIN53, CIN52, CIN51, CIN50, CIN49, CIN48, CIN47, CIN46, CIN45, CIN44, CIN43, CIN42, CIN41, CIN40, CIN39, CIN38, CIN37, CIN36, CIN35, CIN34, CIN33, CIN32, CIN31, CIN30, CIN29, CIN28, CIN27, CIN26, CIN25, CIN24, CIN23, CIN22, CIN21, CIN20, CIN19, CIN18, CIN17, CIN16, CIN15, CIN14, CIN13, CIN12, CIN11, CIN10, CIN9, CIN8, CIN7, CIN6, CIN5, CIN4, CIN3, CIN2, CIN1, CIN0, CE3, CE2, CE1, CE0, CLK3, CLK2, CLK1, CLK0, RST3, RST2, RST1, RST0, SIGNEDIA, SIGNEDIB, SIGNEDCIN, OP10, OP9, OP8, OP7, OP6, OP5, OP4, OP3, OP2, OP1, OP0

OUTPUTS: R53, R52, R51, R50, R49, R48, R47, R46, R45, R44, R43, R42, R41, R40, R39, R38, R37, R36, R35, R34, R33, R32, R31, R30, R29, R28, R27, R26, R25, R24, R23, R22, R21, R20, R19, R18, R17, R16, R15, R14, R13, R12, R11, R10, R9, R8, R7, R6, R5, R4, R3, R2, R1, R0, EQZ, EQZM, EQOM, EQPAT, EQPATB, OVER, UNDER, OVERUNDER, SIGNEDR

ATTRIBUTES:

REG_INPUTC0_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_INPUTC0_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_INPUTC0_RST: "RST0" (default), "RST1", "RST2", "RST3"

REG_INPUTC1_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_INPUTC1_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_INPUTC1_RST: "RST0" (default), "RST1", "RST2", "RST3"

REG_OPCODEOP0_0_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_OPCODEOP0_0_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_OPCODEOP0_0_RST: "RST0" (default), "RST1", "RST2", "RST3"

REG_OPCODEOP1_0_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_OPCODEOP0_1_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_OPCODEOP0_1_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_OPCODEOP0_1_RST: "RST0" (default), "RST1", "RST2", "RST3"

REG_OPCODEOP1_1_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_OPCODEIN_0_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_OPCODEIN_0_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_OPCODEIN_0_RST: "RST0" (default), "RST1", "RST2", "RST3"

REG_OPCODEIN_1_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_OPCODEIN_1_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_OPCODEIN_1_RST: "RST0" (default), "RST1", "RST2", "RST3"

REG_OUTPUT0_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_OUTPUT0_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_OUTPUT0_RST: "RST0" (default), "RST1", "RST2", "RST3"

REG_OUTPUT1_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_OUTPUT1_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_OUTPUT1_RST: "RST0" (default), "RST1", "RST2", "RST3"

REG_FLAG_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_FLAG_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_FLAG_RST: "RST0" (default), "RST1", "RST2", "RST3"

MCPAT_SOURCE: "STATIC" (default), "DYNAMIC"

MASKPAT_SOURCE: "STATIC" (default), "DYNAMIC"

MASK01: any 14-bit hexadecimal value (default: all zeros)

MCPAT: any 14-bit hexadecimal value (default: all zeros)

MASKPAT: any 14-bit hexadecimal value (default: all zeros)

RNDPAT: any 14-bit hexadecimal value (default: all zeros)

GSR: "ENABLED" (default), "DISABLED"

RESETMODE: "SYNC" (default), "ASYNC"

MULT9_MODE: "DISABLED" (default), "ENABLED"

FORCE_ZERO_BARREL_SHIFT: "DISABLED" (default), "ENABLED"

LEGACY: "DISABLED" (default), "ENABLED"

ALU54A Attribute Description

Table 539:

Name	Description
REG_INPUTC0_CLK	Input C register selection for C[26:0]
REG_INPUTC0_CE	Input C clock enable selection for C[26:0]
REG_INPUTC0_RST	Input C reset selection for C[26:0]
REG_INPUTC1_CLK	Input C register selection for C[53:27]
REG_INPUTC1_CE	Input C clock enable selection for C[53:27]
REG_INPUTC1_RST	Input C reset selection for C[53:27]
REG_OPCODEOP0_0_CLK	OPCODE register clock selection for oper [0]
REG_OPCODEOP0_0_CE	OPCODE register clock enable selection for oper [3:0]
REG_OPCODEOP0_0_RST	OPCODE register reset selection for oper [3:0]
REG_OPCODEOP1_0_CLK	OPCODE register clock selection for oper [3:1]
REG_OPCODEOP0_1_CLK	OPCODE pipeline register clock selection for oper [3:1]
REG_OPCODEOP0_1_CE	OPCODE pipeline register clock enable selection for oper [3:0]
REG_OPCODEOP0_1_RST	OPCODE pipeline register reset selection for oper [3:0]
REG_OPCODEOP1_1_CLK	OPCODE pipeline register clock selection for oper [3:1]
REG_OPCODEIN_0_CLK	OPCODE input register clock for InA[1:0], InB[1:0], InC[2:0]
REG_OPCODEIN_0_CE	OPCODE input register clock enable for InA[1:0], InB[1:0], InC[2:0]
REG_OPCODEIN_0_RST	OPCODE input register reset for InA[1:0], InB[1:0], InC[2:0]
REG_OPCODEIN_1_CLK	OPCODE input pipeline register clock for InA[1:0], InB[1:0], InC[2:0]
REG_OPCODEIN_1_CE	OPCODE input pipeline register clock enable for InA[1:0], InB[1:0], InC[2:0]
REG_OPCODEIN_1_RST	OPCODE input pipeline register reset for InA[1:0], InB[1:0], InC[2:0]
REG_OUTPUT0_CLK	ALU register for LSB output 17:0 clock selection
REG_OUTPUT0_CE	ALU register for LSB output 17:0 clock enable selection
REG_OUTPUT0_RST	ALU register for LSB output 17:0 reset selection
REG_OUTPUT1_CLK	ALU register for MSB output 53:18 clock selection

Table 539:

Name	Description
REG_OUTPUT1_CE	ALU register for MSB output 53:18 clock enable selection
REG_OUTPUT1_RST	ALU register for MSB output 53:18 reset selection
REG_FLAG_CLK	Flag register clock selection
REG_FLAG_CE	Flag register clock enable selection
REG_FLAG_RST	Flag pipeline register reset selection
MASKPAT_SOURCE[1]	EQPAT/EQPATB source setting
MCPAT_SOURCE[1]	MEM Cell Pattern source setting
MASK01	Mask for EQZM/EQOM
MASKPAT	Mask for EQPAT/EQPATB
MCPAT	MEM Cell Pattern
RNDPAT	Rounding Pattern
GSR	Global set reset selection
RESETMODE	Reset mode selection
MULT9_MODE	Operation in Mult9 mode
FORCE_ZERO_BARREL_SHIFT	Forces zeros to 18 MSB of shift for barrel shift
LEGACY	Required to support LatticeECP2 backward compatibility

Notes:
1. MASKPAT_SOURCE and MCPAT_SOURCE cannot be DYNAMIC at the same time since both use C[53:0]. There should be a DRC in the software to check this.

ALU54A Port Description

Table 540:

Input/Output	Port Name	Capture Name	Type	Size (Buses Only)	Description
I	CLK0	CLK0	Bit	N/A	Clock Input
I	CLK1	CLK1	Bit	N/A	Clock Input
I	CLK2	CLK2	Bit	N/A	Clock Input
I	CLK3	CLK3	Bit	N/A	Clock Input
I	CE0	CE0	Bit	N/A	Clock Enable Input
I	CE1	CE1	Bit	N/A	Clock Enable Input
I	CE2	CE2	Bit	N/A	Clock Enable Input
I	CE3	CE3	Bit	N/A	Clock Enable Input

Table 540:

Input/Output	Port Name	Capture Name	Type	Size (Buses Only)	Description
I	RST0	RST0	Bit	N/A	Reset Input
I	RST1	RST1	Bit	N/A	Reset Input
I	RST2	RST2	Bit	N/A	Reset Input
I	RST3	RST3	Bit	N/A	Reset Input
I	SIGNEDIA[1]	SIGNEDIA	Bit	N/A	Input A Sign Selection
I	SIGNEDIB[1]	SIGNEDIB	Bit	N/A	Input A Sign Selection
I	A[1]	A	Bus	35:0	Input A from Multiplier
I	B[1]	B	Bus	35:0	Input B from Multiplier
I	C	C	Bus	53:0	C Input
I	MA[1]	MA	Bus	35:0	Input A from Multiplier
I	MB[1]	MB	Bus	35:0	Input B from Multiplier
I	CIN	CIN	Bus	53:0	CIN Input
I	OP	OP	Bus	10:0	Opcode for ALU Operation Selection
I	SIGNEDCIN	SIGNEDCIN	Bit	N/A	CIN Right Shift, Signed or Unsigned Control
O	R	R	Bus	53:0	Output
O	EQZ	F[7]	Bit	N/A	Equal to Zero
O	EQZM	F[6]	Bit	N/A	Equal to Zero with Mask
O	EQPOM	F[5]	Bit	N/A	Equal to One with Mask
O	EQPAT	F[4]	Bit	N/A	Equal to Pat with Mask
O	EQPATB	F[3]	Bit	N/A	Equal to Bit Inverted Pat with Mask
O	OVER	F[2]	Bit	N/A	Accumulator Overflow
O	UNDER	F[1]	Bit	N/A	Accumulator Underflow
O	OVERUNDER	F[0]	Bit	N/A	Either Over or Under Flow
O	SIGNEDR	SIGNEDR	Bit	N/A	Signed or Unsigned Output of ALU

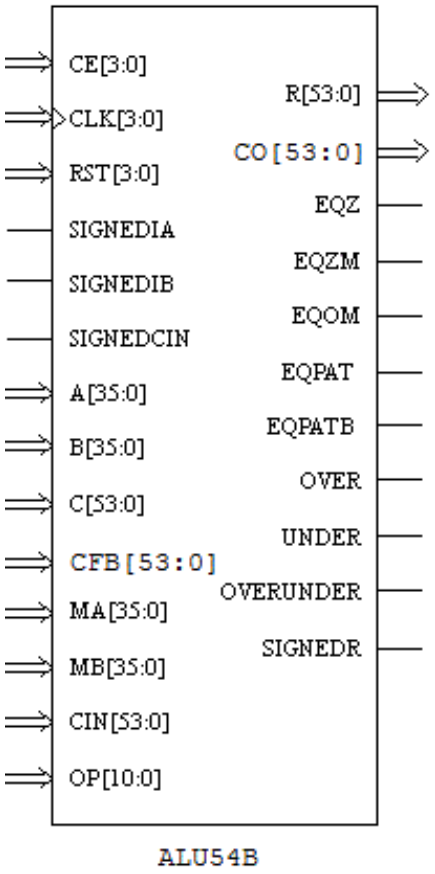
Notes:
1. A and B refer to the first and second multiplier of the slice and not the Ax and Bx inputs to multiplier x.

ALU54B

54-bit Ternary Adder/Subtractor for Highspeed

Architectures Supported:

- ECP5



INPUTS: A35, A34, A33, A32, A31, A30, A29, A28, A27, A26, A25, A24, A23, A22, A21, A20, A19, A18, A17, A16, A15, A14, A13, A12, A11, A10, A9, A8, A7, A6, A5, A4, A3, A2, A1, A0, B35, B34, B33, B32, B31, B30, B29, B28, B27, B26, B25, B24, B23, B22, B21, B20, B19, B18, B17, B16, B15, B14, B13, B12, B11, B10, B9, B8, B7, B6, B5, B4, B3, B2, B1, B0, C53, C52, C51, C50, C49, C48, C47, C46, C45, C44, C43, C42, C41, C40, C39, C38, C37, C36, C35, C34, C33, C32, C31, C30, C29, C28, C27, C26, C25, C24, C23, C22, C21, C20, C19, C18, C17, C16, C15, C14, C13, C12, C11, C10, C9, C8, C7, C6, C5, C4, C3, C2, C1, C0, CFB53, CFB52, CFB51, CFB50, CFB49, CFB48, CFB47, CFB46, CFB45, CFB44, CFB43, CFB42, CFB41, CFB40, CFB39, CFB38, CFB37, CFB36, CFB35, CFB34, CFB33, CFB32, CFB31, CFB30, CFB29, CFB28, CFB27, CFB26, CFB25, CFB24, CFB23, CFB22, CFB21, CFB20, CFB19, CFB18, CFB17, CFB16, CFB15, CFB14, CFB13, CFB12, CFB11, CFB10, CFB9, CFB8, CFB7, CFB6, CFB5, CFB4, CFB3, CFB2, CFB1, CFB0, MA35, MA34, MA33, MA32, MA31, MA30, MA29, MA28, MA27, MA26, MA25, MA24, MA23, MA22, MA21, MA20, MA19, MA18,

MA17, MA16, MA15, MA14, MA13, MA12, MA11, MA10, MA9, MA8, MA7, MA6, MA5, MA4, MA3, MA2, MA1, MA0, MB35, MB34, MB33, MB32, MB31, MB30, MB29, MB28, MB27, MB26, MB25, MB24, MB23, MB22, MB21, MB20, MB19, MB18, MB17, MB16, MB15, MB14, MB13, MB12, MB11, MB10, MB9, MB8, MB7, MB6, MB5, MB4, MB3, MB2, MB1, MB0, CIN53, CIN52, CIN51, CIN50, CIN49, CIN48, CIN47, CIN46, CIN45, CIN44, CIN43, CIN42, CIN41, CIN40, CIN39, CIN38, CIN37, CIN36, CIN35, CIN34, CIN33, CIN32, CIN31, CIN30, CIN29, CIN28, CIN27, CIN26, CIN25, CIN24, CIN23, CIN22, CIN21, CIN20, CIN19, CIN18, CIN17, CIN16, CIN15, CIN14, CIN13, CIN12, CIN11, CIN10, CIN9, CIN8, CIN7, CIN6, CIN5, CIN4, CIN3, CIN2, CIN1, CIN0, CE3, CE2, CE1, CE0, CLK3, CLK2, CLK1, CLK0, RST3, RST2, RST1, RST0, SIGNEDIA, SIGNEDIB, SIGNEDCIN, OP10, OP9, OP8, OP7, OP6, OP5, OP4, OP3, OP2, OP1, OP0

OUTPUTS: R53, R52, R51, R50, R49, R48, R47, R46, R45, R44, R43, R42, R41, R40, R39, R38, R37, R36, R35, R34, R33, R32, R31, R30, R29, R28, R27, R26, R25, R24, R23, R22, R21, R20, R19, R18, R17, R16, R15, R14, R13, R12, R11, R10, R9, R8, R7, R6, R5, R4, R3, R2, R1, R0, CO53, CO52, CO51, CO50, CO49, CO48, CO47, CO46, CO45, CO44, CO43, CO42, CO41, CO40, CO39, CO38, CO37, CO36, CO35, CO34, CO33, CO32, CO31, CO30, CO29, CO28, CO27, CO26, CO25, CO24, CO23, CO22, CO21, CO20, CO19, CO18, CO17, CO16, CO15, CO14, CO13, CO12, CO11, CO10, CO9, CO8, CO7, CO6, CO5, CO4, CO3, CO2, CO1, CO0, EQZ, EQZM, EQOM, EQPAT, EQPATB, OVER, UNDER, OVERUNDER, SIGNEDR

ATTRIBUTES:

REG_OUTPUT1_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_OUTPUT1_RST: "RST0" (default), "RST1", "RST2", "RST3"

REG_FLAG_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_FLAG_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_FLAG_RST: "RST0" (default), "RST1", "RST2", "RST3"

MCPAT_SOURCE: "STATIC" (default), "DYNAMIC"

MASKPAT_SOURCE: "STATIC" (default), "DYNAMIC"

MASK01: any 14-bit hexadecimal value (default: all zeros)

MCPAT: any 14-bit hexadecimal value (default: all zeros)

MASKPAT: any 14-bit hexadecimal value (default: all zeros)

RNDPAT: any 14-bit hexadecimal value (default: all zeros)

REG_INPUTCFB_CLK: "NONE" (default), "CLK0", "CLK1", "CLK2", "CLK3"

REG_INPUTCFB_CE: "CE0" (default), "CE1", "CE2", "CE3"

REG_INPUTCFB_RST: "RST0" (default), "RST1", "RST2", "RST3"

CLK0_DIV: "ENABLED" (default), "DISABLED"

CLK1_DIV: "ENABLED" (default), "DISABLED"

CLK2_DIV: "ENABLED" (default), "DISABLED"

CLK3_DIV: "ENABLED" (default), "DISABLED"

GSR: "ENABLED" (default), "DISABLED"

RESETMODE: "SYNC" (default), "ASYNC"

MULT9_MODE: "DISABLED" (default), "ENABLED"

FORCE_ZERO_BARREL_SHIFT: "DISABLED" (default), "ENABLED"

LEGACY: "DISABLED" (default), "ENABLED"

Notes:

*REG_INPUT_C0 corresponds to the lower 27 bits of the C Input.

*REG_INPUT_C1 corresponds to the upper 27 bits of the C Input.

REG_OUTPUT0 corresponds to [17:0] of R and REG_OUTPUT1_* corresponds to [53:18] of R.

*When REG_INPUTCFB_CLK = NONE, then it means that the CFB ports are not used, and C -> Cr using the C0/C1_CLK attributes.

*When REG_INPUTCFB_CLK != NONE, then the CFB ports are being used and CFB -> CO is using these attributes. C -> Cr is unregistered and a DRC can check to make sure C0/C1_CLK = NONE.

ALU54B Attribute Description

Table 541:

Attribute Name	Values	Default Value	GUI Access
REG_INPUTC0_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y
REG_INPUTC0_CE	CE0, CE1, CE2, CE3	CE0	Y
REG_INPUTC0_RST	RST0, RST1, RST2, RST3	RST0	Y
REG_INPUTC1_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y
REG_INPUTC1_CE	CE0, CE1, CE2, CE3	CE0	Y
REG_INPUTC1_RST	RST0, RST1, RST2, RST3	RST0	Y
REG_OPCODEOP0_0_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y
REG_OPCODEOP0_0_CE	CE0, CE1, CE2, CE3	CE0	Y
REG_OPCODEOP0_0_RST	RST0, RST1, RST2, RST3	RST0	Y
REG_OPCODEOP1_0_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y
REG_OPCODEOP0_1_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y
REG_OPCODEOP0_1_CE	CE0, CE1, CE2, CE3	CE0	Y
REG_OPCODEOP0_1_RST	RST0, RST1, RST2, RST3	RST0	Y
REG_OPCODEOP1_1_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y
REG_OPCODEIN_0_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y
REG_OPCODEIN_0_CE	CE0, CE1, CE2, CE3	CE0	Y
REG_OPCODEIN_0_RST	RST0, RST1, RST2, RST3	RST0	Y
REG_OPCODEIN_1_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y
REG_OPCODEIN_1_CE	CE0, CE1, CE2, CE3	CE0	Y
REG_OPCODEIN_1_RST	RST0, RST1, RST2, RST3	RST0	Y
REG_OUTPUT0_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y

Table 541:

Attribute Name	Values	Default Value	GUI Access
REG_OUTPUT0_CE	CE0, CE1, CE2, CE3	CE0	Y
REG_OUTPUT0_RST	RST0, RST1, RST2, RST3	RST0	Y
REG_OUTPUT1_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y
REG_OUTPUT1_CE	CE0, CE1, CE2, CE3	CE0	Y
REG_OUTPUT1_RST	RST0, RST1, RST2, RST3	RST0	Y
REG_FLAG_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y
REG_FLAG_CE	CE0, CE1, CE2, CE3	CE0	Y
REG_FLAG_RST	RST0, RST1, RST2, RST3	RST0	Y
MCPAT_SOURCE	STATIC, DYNAMIC	STATIC	Y
MASKPAT_SOURCE	STATIC, DYNAMIC	STATIC	Y
MASK01	0x00000000000000 to 0xFFFFFFFFFFFFFF	0x00000000000000	Y
REG_INPUTCFB_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE	Y
REG_INPUTCFB_CE	CE0, CE1, CE2, CE3	CE0	Y
REG_INPUTCFB_RST	RST0, RST1, RST2, RST3	RST0	Y
CLK0_DIV	ENABLED, DISABLED	ENABLED	Y
CLK1_DIV	ENABLED, DISABLED	ENABLED	Y
CLK2_DIV	ENABLED, DISABLED	ENABLED	Y
CLK3_DIV	ENABLED, DISABLED	ENABLED	Y
MCPAT	0x00000000000000 to 0xFFFFFFFFFFFFFF	0x00000000000000	Y
MASKPAT	0x00000000000000 to 0xFFFFFFFFFFFFFF	0x00000000000000	Y
RNDPAT	0x00000000000000 to 0xFFFFFFFFFFFFFF	0x00000000000000	Y
GSR	ENABLED, DISABLED	ENABLED	N
RESETMODE	SYNC, ASYNC	SYNC	Y
MULT9_MODE	ENABLED, DISABLED	DISABLED	N

Table 541:

Attribute Name	Values	Default Value	GUI Access
FORCE_ZERO_BARREL_SHIFT	ENABLED, DISABLED	DISABLED	N
LEGACY	ENABLED, DISABLED	DISABLED	Y

ALU24B Port Description

Table 542:

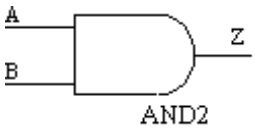
Port Name	I/O	Description
CE[3:0]	I	Clock Enable Inputs
CLK[3:0]	I	Clock Input
RST[3:0]	I	Reset inputs
SIGNEDIA	I	Sign Bit for Input A
SIGNEDIB	I	Sign Bit for Input B
SIGNEDCIN	I	Sign Bit for Carrin In Input
A	I	Input A
B	I	Input B
C	I	Carry In Input/Highspeed Input
CFB[23:0]	I	C Input for Highspeed
MA[17:0]	I	Input A
MB[17:0]	I	Input B
CIN[23:0]	I	Carry In Input
OP[10:0]	I	Opcode
R[53:0]	O	Sum
CO[53:0]	O	Sum – Special Routing output used for Highspeed option
EQZ	O	Equal to Zero Flag
EQZM	O	Equal to Zero with Mask Flag
EQOM	O	Equal to One with Mask Flag
EQPAT	O	Equal to Pattern with Mask Flag
EQPATB	O	Equal to Bit Inverted Pattern with Mask Flag
OVER	O	Accumulator Overflow
UNDER	O	Accumulator Underflow
OVERUNDER	O	Either Over on Underflow
SIGNEDR	O	Sign Bit for Sum Output

AND2

2 Input AND Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B

OUTPUT: Z

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

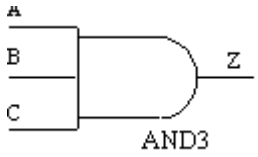
AND3

3 Input AND Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP

- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C

OUTPUT: Z

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

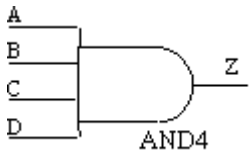
AND4

4 Input AND Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- Platform Manager

- Platform Manager 2



INPUTS: A, B, C, D

OUTPUT: Z

Note

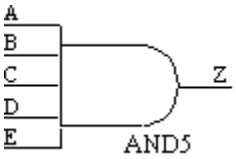
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

AND5

5 Input AND Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C, D, E

OUTPUT: Z

Note

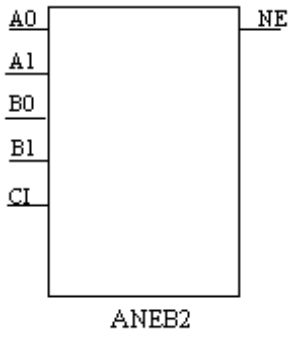
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

ANEB2

"A" Not Equal To "B"

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A0, A1, B0, B1, CI

OUTPUT: NE

Description

ANEB2 is a 2-bit comparator that can be cascaded together to build larger comparators. It has two 2-bit inputs and a carry-in input. The carry-in (CI) on the first stage should be tied LOW. The compare-out (NE) output is LOW if A[1:0] = B[1:0] and HIGH otherwise. To build larger comparators, tie the NE on the lower stage to CI on the upper stage.

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

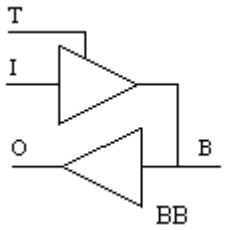
B

BB

CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate – BiDirectional

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: I, T

OUTPUT: O

IOPUT: B

Truth Table

Table 543:

INPUTS		OUTPUTS	BIDIRECTIONAL
I	T	O	B
X	1	U	Z
X	1	1	1
X	1	0	0
0	0	0	0
1	0	1	1

X = Don’t care

U = Unknown

When TSALL=0, O=U, B=Z

For PU/PD buffers, when TSALL=0, O and B will be pulled up or pulled down, respectively.

Note

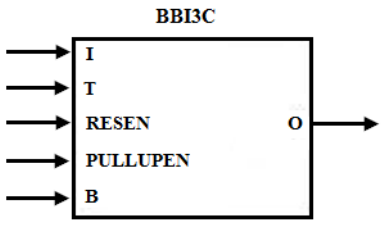
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

BBI3C

IC3 Bidirectional Buffer

Architectures Supported:

- MachXO3D



INPUTS: I, T, RESEN, PULLUPEN

OUTPUT: O

INOUT: B

Description

The following are descriptions of BBI3C port functions.

Table 544:

Port	I/O	Function
I	I	Input port
T	I	Tri-state control port
RESEN	I	Enables I3C strong pull-up (active low)
PULLUPEN	I	Enables I3C weak pull-up (active low)
B	I	Bidirectional port
O	O	Output port

Truth Table

Table 545:

INPUTS		OUTPUTS	BIDIRECTIONAL
I	T	O	B
X	1	U	Z
X	1	1	1
X	1	0	0
0	0	0	0
1	0	1	1

X = Don’t care

U = Unknown

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

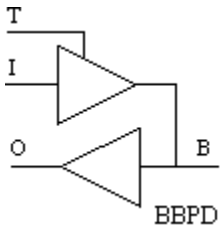
BBPD

CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate and Pull-down – BiDirectional

Architectures Supported:

- ECP5
- LatticeECP/EC

- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: I, T

OUTPUT: O

IOPUT: B

Truth Table

Table 546:

INPUTS		OUTPUTS	BIDIRECTIONAL
I	T	O	B
X	1	U	Pull0
X	1	1	1
X	1	0	0
0	0	0	0
1	0	1	1

X = Don’t care

U = Unknown

When TSALL=0, O=U, B=Z

For PU/PD buffers, when TSALL=0, O and B will be pulled up or pulled down, respectively.

Note

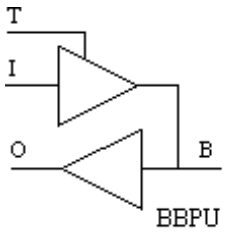
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

BBPU

CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate and Pull-up – BiDirectional

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: I, T

OUTPUT: O

IOPUT: B

Truth Table

Table 547:

INPUTS		OUTPUTS	BIDIRECTIONAL
I	T	O	B
X	1	U	Pull1
X	1	1	1
X	1	0	0
0	0	0	0
1	0	1	1

X = Don’t care

U = Unknown

When TSALL=0, O=U, B=Z

For PU/PD buffers, when TSALL=0, O and B will be pulled up or pulled down, respectively.

Note

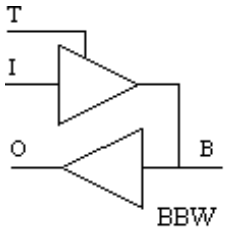
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

BBW

CMOS Input 6mA Sink 3mA Source Sinklim Output Buffer with Tristate – BiDirectional in keepermode

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: I, T

OUTPUT: O

IOPUT: B

Truth Table

Table 548:

INPUTS		OUTPUTS	BIDIRECTIONAL
I	T	O	B
0	1	0	weak 0
1	1	1	weak 1

X = Don’t care

U = Unknown

Note

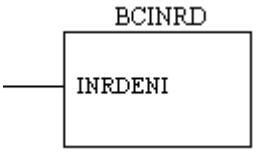
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

BCINRD

Dynamic Bank Controller InRD

Architectures Supported:

- ECP5
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUT: INRDENI

ATTRIBUTES:

BANKID: 0 (default), 1, 2, 3, 4, 5

Description

The dynamic bank controller is used to power down banks InRD (Input Referenced and Differential) and LVDS outputs. The dynamic bank controller is represented with two primitives: BCINRD and BCLVDSO. The INRDENI input is the dynamic signal to enable and disable bank InRD.

For more information, refer to the following technical note on the Lattice web site:

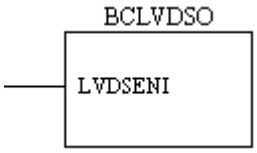
- TN1198 - Power Estimation and Management for MachXO2 Devices

BCLVDSO

Dynamic Bank Controller LVDS

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUT: LVDSENI

Description

The dynamic bank controller is used to power down banks InRD (Input Referenced and Differential) and LVDS outputs. The dynamic bank controller is represented with two primitives: BCLVDSO and BCINRD. The LVDSENI input is the dynamic signal to enable and disable bank InRD.

For more information, refer to the following technical note on the Lattice web site:

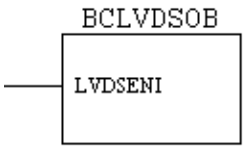
- TN1198 - Power Estimation and Management for MachXO2 Devices

BCLVDSOB

Bank Controller for LVDS Outut Buffers

Architectures Supported:

- ECP5
- LIFMD



INPUT: LVDSENI

ATTRIBUTES:

BANKID:

ECP5: 2 (default), 2, 3, 6, 7

LIFMD: 1, 2

Description

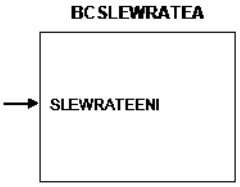
The dynamic bank controller is used to power down banks InRD (Input Referenced and Differential) and LVDS outputs. The LVDSENI input is the dynamic signal to enable and disable LVDS outputs.

BCSLEWRATEA

Bank Controller for Slew Rate

Architectures Supported:

- MachXO3D



INPUT: SLEWRATEENI

Attributes:

Table 549: BCSLEWRATEA Primitives

Primitive Port	Primitive Attribute	Value	Description
SLEWRATEENI			Dynamic signal to enable and disable Bank Slewrate
	BANKID	0 (default), 1, 2, 3, 4, 5	Bank ID to indicate the control of a specific bank

Description

The dynamic bank controller is used to control the power down banks for slew rate slow mode. The SLEWRATEENI input is the dynamic signal to enable and disable the slew rate power saving per bank.

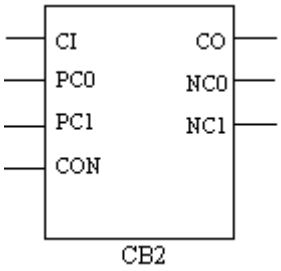
C

CB2

Combinational Logic for 2-Bit Bidirectional Counter

Architectures Supported:

- LatticeECP3
- LatticeXP2
- LatticeSC/M
- LatticeECP2/M
- LatticeECP/EC
- LatticeXP
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: CI, PC0, PC1, CON

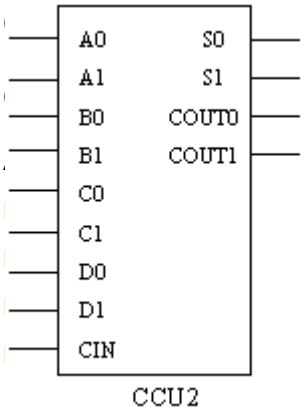
OUTPUTS: CO, NC0, NC1

Description

This primitive realizes the combinational logic needed to implement a 2-bit bidirectional counter by using ripple elements.

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.



INPUT: CIN, A0, B0, C0, D0, A1, B1, C1, D1

OUTPUT: S0, S1, COUT0, COUT1

ATTRIBUTES:

INIT0: hexadecimal value (default: 16'h0000)

INIT1: hexadecimal value (default: 16'h0000)

INJECT1_0: "YES" (default), "NO"

INJECT1_1: "YES" (default), "NO"

Note

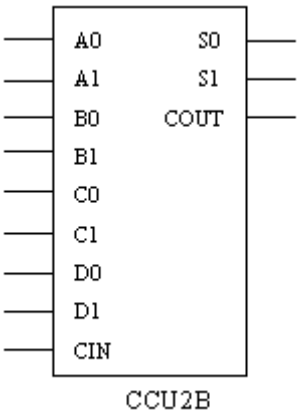
The attributes need to be defined when CCU2 is instantiated.

CCU2B

Carry-Chain

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



INPUTS: A0, B0, C0, D0, A1, B1, C1, D1, CIN

OUTPUTS: S0, S1, COUT

ATTRIBUTES:

INIT0: hexadecimal value (default: 16'h0000)

INIT1: hexadecimal value (default: 16'h0000)

INJECT1_0: "YES" (default), "NO"

INJECT1_1: "YES" (default), "NO"

Note

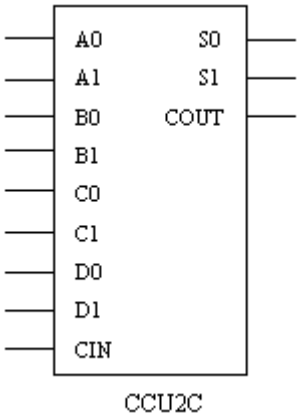
- The attributes need to be defined when CCU2B is instantiated.
- This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

CCU2C

Carry Chain

Architectures Supported:

- ECP5
- LatticeECP3
- LIFMD



INPUTS: CIN, A1, B1, C1, D1, A0, B0, C0, D0

OUTPUTS: S1, S0, COUT

ATTRIBUTES:

INIT0: hexadecimal value (default: 16'h0000)

INIT1: hexadecimal value (default: 16'h0000)

INJECT1_0: "YES" (default), "NO"

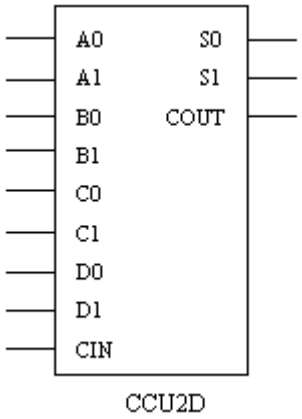
INJECT1_1: "YES" (default), "NO"

CCU2D

Carry Chain

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: CIN, A1, B1, C1, D1, A0, B0, C0, D0

OUTPUTS: S1, S0, COUT

ATTRIBUTES:

INIT0: hexadecimal value (default: 16'h0000)

INIT1: hexadecimal value (default: 16'h0000)

INJECT1_0: "YES" (default), "NO"

INJECT1_1: "YES" (default), "NO"

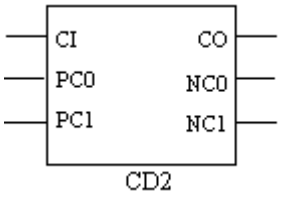
CD2

Combinational Logic for 2-Bit Down-Counter

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager

- Platform Manager 2



INPUTS: CI, PC0, PC1

OUTPUTS: CO, NC0, NC1

Description

This primitive realizes the combinational logic needed to implement a 2-bit down-counter using ripple elements.

Note

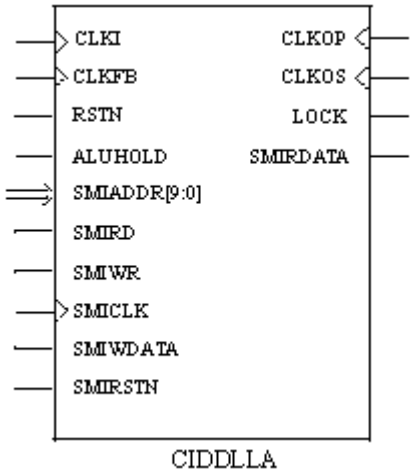
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

CIDDLLA

Clock Injection Delay Removal

Architectures Supported:

- LatticeECP2/M
- LatticeSC/M



INPUTS: CLKI, CLKFB, RSTN, ALUHOLD, SMIADDR9, SMIADDR8, SMIADDR7, SMIADDR6, SMIADDR5, SMIADDR4, SMIADDR3, SMIADDR2, SMIADDR1, SMIADDR0, SMIRD, SMIWR, SMICLK, SMIWDATA, SMIRSTN

OUTPUTS: CLKOP, CLKOS, LOCK, SMIRDATA

ATTRIBUTES:

CLKOP_PHASE: 0 (default), 90, 180, 270, 360

CLKOS_PHASE: 360 + (0, 11, 22, 45) (default: 360)

CLKOS_FPHASE: 0 (default), 11, 22, 45

CLKOP_DUTY50: "DISABLED" (default), "ENABLED"

CLKOS_DUTY50: "DISABLED" (default), "ENABLED"

CLKI_DIV: 1 (default), 2, 4

CLKOS_DIV: 1 (default), 2, 4

GSR: "DISABLED" (default), "ENABLED"

CLKOS_FDEL_ADJ: "DISABLED" (default), "ENABLED"

ALU_LOCK_CNT: integers 3~15 (default: 3)

ALU_UNLOCK_CNT: integers 3~15 (default: 3)

GLITCH_TOLERANCE: integers 0~7 (default: 2 for LatticeECP2/M; 0 for LatticeSC/M)

ALU_INIT_CNTVAL: 0 (default), 4, 8, 12, 16, 32, 48, 64, 72

LOCK_DELAY: integers 0~1000 (in ns) (default: 100)

(*LatticeSC/M only*) SMI_OFFSET: 0x400~0x7FF (default: 12'h410)

(*LatticeSC/M only*) MODULE_TYPE: "CIDDLLA"

(*LatticeSC/M only*) IP_TYPE: "CIDDLLA"

Description

CIDLLA removes the clock tree delay, aligning the external feedback clock to the reference clock. It has a single output coming from the fourth delay block. It features include clock tree insertion removal, N*Tcyc=4*Tdel + Tinj, lock achieved starting from minimum delay, and when it goes through all delay stages, the minimum frequency is 1/(4*Tdel). Its requirements include external feedback only, that you must use all delay cells, a maximum frequency of 700MHz, and a minimum frequency of 100MHz.

For more information, refer to the following technical notes on the Lattice web site:

- TN1098 - LatticeSC sysCLOCK and PLL/DLL User's Guide

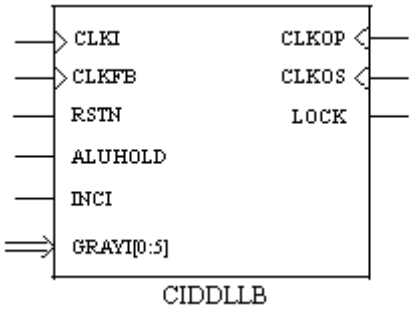
CIDDLLB

Clock Injection Delay Removal

Architectures Supported:

- LatticeECP3



INPUTS: CLKI, CLKFB, RSTN, ALUHOLD, INCI, GRAYI5, GRAYI4, GRAYI3, GRAYI2, GRAYI1, GRAYI0

OUTPUTS: CLKOP, CLKOS, LOCK

ATTRIBUTES:

CLKOP_PHASE: 0 (default), 90, 180, 270, 360

CLKOS_PHASE: 0 (default), 90, 180, 270, 360

CLKOS_FPHASE: 0 (default), 11, 22, 33, 45, 56, 67, 78, 90, 101, 112, 123, 135, 146, 157, 169, 191, 202, 214, 225, 236, 247, 259, 281, 292, 304, 315, 326, 337, 349

CLKI_DIV: 1 (default), 2, 4

CLKOS_DIV: 1 (default), 2, 4

GSR: "DISABLED" (default), "ENABLED"

ALU_LOCK_CNT: integers 3~15 (default: 3)

ALU_UNLOCK_CNT: integers 3~15 (default: 3)

GLITCH_TOLERANCE: integers 0~7 (default: 2)

ALU_INIT_CNTVAL: integers 0~31 (default: 0)

LOCK_DELAY: integers 0~1000 (in ns) (default: 100)

CLKOP_DUTY50: "DISABLED" (default), "ENABLED"

CLKOS_DUTY50: "DISABLED" (default), "ENABLED"

DEL0_GRAY: "DISABLED" (default), "ENABLED"

DEL1_GRAY: "DISABLED" (default), "ENABLED"

DEL2_GRAY: "DISABLED" (default), "ENABLED"

DEL3_GRAY: "DISABLED" (default), "ENABLED"

DEL4_GRAY: "DISABLED" (default), "ENABLED"

Description

CIDDLLB specifies the Clock Injection Delay Removal operation mode for the general purpose DLL (GDLL). In this mode, the feedback connection is supported and the CLKFB is captured on the CIDDLLB primitive.

Port Description

Table 550:

Port Name	Optional	Logical Capture Port Name
ALUHOLD	YES	HOLD
GRAYI[5:0]	YES	GRAY_IN[5:0]
INCI	YES	INC_IN
RSTN	YES	RSTN
CLKFB	NO	CLKFB
CLKI	NO	CLKI
CLK90	YES	CLK90
CLKOP	NO	CLKOP
CLKOS	YES	CLKOS
LOCK	NO	LOCK

For more information, refer to the following technical note on the Lattice web site:

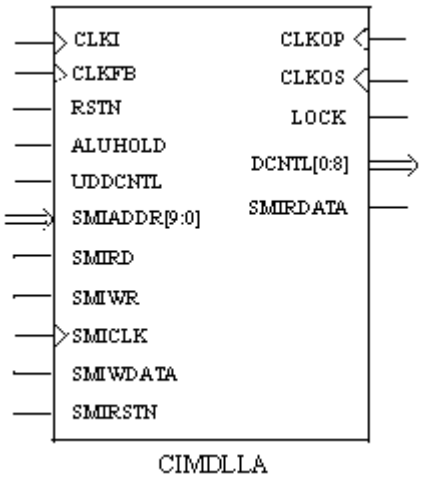
- TN1178 - LatticeECP3 sysCLOCK PLL/DLL Design and Usage Guide

CIMDLLA

Clock Injection Match

Architectures Supported:

- LatticeSC/M



INPUTS: CLKI, CLKFB, RSTN, ALUHOLD, UDDCNTL, SMIADDR9, SMIADDR8, SMIADDR7, SMIADDR6, SMIADDR5, SMIADDR4, SMIADDR3, SMIADDR2, SMIADDR1, SMIADDR0, SMIRD, SMIWR, SMICLK, SMIWDATA, SMIRSTN

OUTPUTS: CLKOP, CLKOS, LOCK, DCNTL0, DCNTL1, DCNTL2, DCNTL3, DCNTL4, DCNTL5, DCNTL6, DCNTL7, DCNTL8, SMIRDATA

ATTRIBUTES:

CLKOS_FPHASE: 0 (default), 11, 22, 45

CLKOS_DIV: 1 (default), 2, 4

GSR: "DISABLED" (default), "ENABLED"

ALU_LOCK_CNT: integers 3~15 (default: 3)

ALU_UNLOCK_CNT: integers 3~15 (default: 3)

GLITCH_TOLERANCE: integers 0~7 (default: 0)

DCNTL_ADJVAL: integers -127~127 (default: 0)

SMI_OFFSET: 0x400~0x7FF (default: 12'h410)

LOCK_DELAY: integers 0~1000 (in ns) (default: 100)

CLKOS_FDEL_ADJ: "DISABLED" (default), "ENABLED"

MODULE_TYPE: "CIMDLLA"

IP_TYPE: "CIMDLLA"

Description

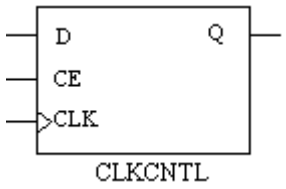
CIMDLLA matches the clock injection to one delay cell. This allows other inputs to take the registered ALU outputs and negate the clock injection delay. Its features include single clock output, lock achieved starting from minimum delay, output control bits, and allowance for +/- delay on these output control bits. Its requirements include external feedback (CLKOP) only, a maximum frequency of 700MHz, a minimum frequency of100MHz, and a maximum delay compensation of 3.9ns.

CLKCNTL

Clock Controller

Architectures Supported:

- LatticeSC/M



INPUTS: D, CE, CLK

OUTPUT: Q

ATTRIBUTES:

CLKMODE: "ECLK" (default), "SCLK"

Description

The CLKCNTL is the post-amble detect circuit required for the DQS input. The DQS generation will use the DELAY, TRDLLA and the CLKCNTL primitives.

The CLKCNTL primitive's instantiation rules allow the CLK input to be fed via secondary (local) routing paths, rather than constraining the routing to be via the Edge Clock tree. The Edge Clock tree is optimized for minimum skew rather than minimum delay. Although the Edge Clock delay is not a problem at the DDR/DDR2 clock frequencies originally targeted (300 MHz), the

CLKCNTL is capable of operating at much higher frequencies (beyond 1 GHz). If the CLK input path utilizes the faster local routing resources, it is capable of properly gating an 800 MHz clock, as is required for testing of DDR3 memory devices. This requires changes to the mapper.

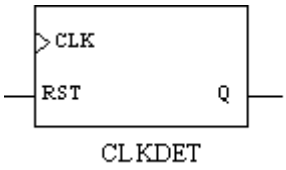
The CLKMODE attribute is supported for the CLKCNTL primitive. The legal values are ECLK (default) and SCLK.

CLKDET

Clock Detect

Architectures Supported:

- LatticeSC/M



INPUTS: CLK, RST

OUTPUT: Q

Truth Table

Table 551:

INPUTS		OUTPUTS
CK	RST	Q
X	1	0
↑	0	1

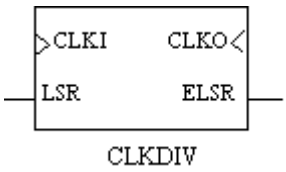
X = Don’t care

CLKDIV

Clock Divider

Architectures Supported:

- LatticeSC/M



INPUTS: CLKI, LSR

OUTPUTS: CLKO, ELSR

ATTRIBUTES:

DIV: 1 (default), 2, 4

GSR: "DISABLED" (default), "ENABLED"

Description

Clock divider. Refer to the following technical note on the Lattice web site for more details.

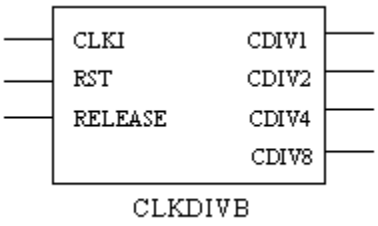
- TN1098 - LatticeSC sysCLOCK and PLL/DLL User's Guide

CLKDIVB

Clock Divider

Architectures Supported:

- LatticeECP2/M
- LatticeECP3
- LatticeXP2



INPUTS: CLKI, RST, RELEASE

OUTPUTS: CDIV1, CDIV2, CDIV4, CDIV8

ATTRIBUTES:

GSR: "DISABLED" (default), "ENABLED"

Description

Clock divider. See the following table for port description.

Table 552:

Port Name	I/O	Definition
RELEASE	I	Asserting the RELEASE signal releases the divided outputs, synchronous to selected input source.
RST	I	Asserting the RST signal forces CDIV1 low synchronously, and forces CDIV2, CDIV4 and CDIV8 low asynchronously. De-asserting RST synchronously allows all outputs to toggle.
CLKI	I	Input clock.
CDIV1	O	Divide by 1 output port.
CDIV2	O	Divide by 2 output port.
CDIV4	O	Divide by 4 output port.
CDIV8	O	Divide by 8 output port.

Refer to the following technical notes on the Lattice web site for more details.

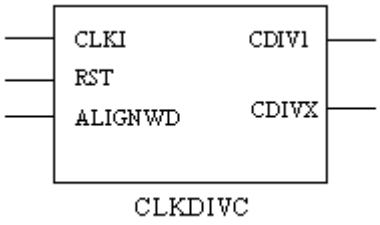
- TN1178 - LatticeECP3 sysCLOCK PLL/DLL Design and Usage Guide
- TN1126 - LatticeXP2 sysCLOCK PLL Design and Usage Guide
- TN1103 - LatticeECP2/M sysCLOCK PLL/DLL Design and Usage Guide

CLKDIVC

Clock Divider

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: CLKI, RST, ALIGNWD

OUTPUTS: CDIV1, CDIVX

ATTRIBUTES:

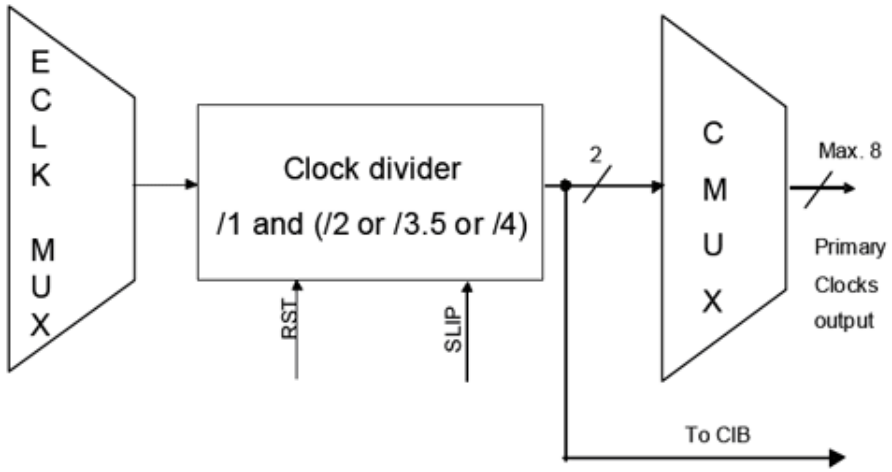
GSR: "DISABLED" (default), "ENABLED"

DIV: 2.0 (default), 3.5, 4.0

Description

A MachXO2/Platform Manager 2 device contains four CLKDIV with 1200 LUTs or more. The CLKDIV, or “clock divider” block, generates clock outputs one half, divided by three and a half or one quarter of the frequency of the input clock. It also generates an output clock of the same frequency as the input clock. All the outputs match input to output delay.

CLKDIV takes its inputs from the outputs of ECLK muxes. The divided outputs of the CLKDIV drive the primary clock center muxes directly and are also available on CIB ports for distribution to routing or secondary high fan out nets. The figure below represents the block diagram of CLKDIV:



The table below shows CLKDIVC IO description.

Table 553:

Port Name	I/O	Unused Nets	Description
RST	I	Tie low	Asserting the RST signal asynchronously forces all outputs low. De-asserting RST synchronously allows all outputs to toggle.
CLKI	I	Tie low	Input clock.
ALIGNWD	I	Tie low	This signal is used for word alignment.
CDIV1	O	Dangle	Divide by 1 output port.
CDIVX	O	Dangle	Divide by 2.0, 3.5, or 4.0 output port.

Refer to the following technical note on the Lattice web site for more details.

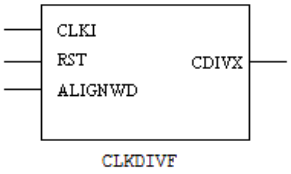
- TN1199 - MachXO2 sysCLOCK PLL Design and Usage Guide

CLKDIVF

Clock Divider

Architectures Supported:

- ECP5



INPUTS: CLKI, RST, ALIGNWD

OUTPUTS: CDIVX

ATTRIBUTES:

GSR: "DISABLED" (default), "ENABLED"

DIV: 2.0 (default)

Description

Clock divider. See the following table for port description.

Table 554:

Port Name	I/O	Unused Nets	Description
RST	I	Tie low	Asynchronous, Active High Reset
CLKI	I	Tie low	Input clock.
ALIGNWD	I	Tie low	This signal is used for word alignment.
CDIVX	O	Dangle	Divide by output port.

CLKDIVG

Clock Divider

Architectures Supported:

- LIFMD

INPUTS: CLKI, RST, ALIGNWD

OUTPUTS: CDIVX

ATTRIBUTES:

GSR: "DISABLED" (default), "ENABLED"

DIV: 2.0 (default)

Description

Clock divider. See the following table for port description.

Table 555:

Port Name	I/O	Unused Nets	Description
RST	I	Tie low	Asynchronous, Active High Reset
CLKI	I	Tie low	Input clock.

Table 555:

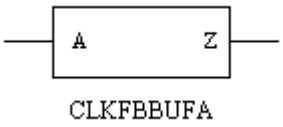
Port Name	I/O	Unused Nets	Description
ALIGNWD	I	Tie low	This signal is used for word alignment.
CDIVX	O	Dangle	Divide by output port.

CLKFBBUFA

Dummy Feedback Delay Between PLL clk Output and PLL fb Port

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUT: A

OUTPUT: Z

Description

The CLKFBBUFA is the dummy feedback path from the PLL clk output to the PLL feedback port to cancel out clock path variation over PVT.

The table below shows the IO description.

Table 556:

Port Name	I/O	Description
A	I	Clock input coming from the PLL CLKOP output
Z	O	Delayed output to the PLL fb port

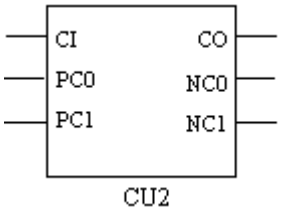
CU2

Combinational Logic for 2-Bit Up-Counter

Architectures Supported:

- LatticeECP/EC

- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: CI, PC0, PC1

OUTPUTS: CO, NC0, NC1

Description

This primitive realizes the combinational logic needed to implement a 2-bit up-counter using ripple elements.

When CI=0, NC[0:1]=PC[0:1] and CO=0

When CI=1, NC[0:1]=PC[0:1]+1, and CO=1 if PC[0:1]=11

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

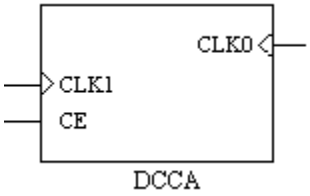
D

DCCA

Dynamic Quadrant Clock Enable/Disable

Architectures Supported:

- ECP5
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: CLKI, CE

OUTPUT: CLKO

Description

DCCA is the dynamic quadrant clock enable/disable primitive. In each quadrant, the dynamic quadrant clock enable/disable is available on the output of the center mux for the primary clocks CLK[5:0]. The dynamic quadrant clock enable/disable feature lets the internal logic control the quadrant primary clock network. When a clock network is disabled, all the logic fed by the clock network does not toggle, reducing the overall power consumption of the device. You need to instantiate a primitive (DCCA) in order to control the enable/disable function.

The DCCA IO description is shown below.

Table 557:

Port Name	I/O	Unused Nets	Description
CLKI	I	Tie low	Input clock
CE	I	Tie high	Clock enable
CLKO	O	Dangle	Output clock

DCCA Usage with VHDL

Library Instantiation

```
library lattice;
use lattice.components.all;
```

Component Declaration

```
component DCCA
   port (CLKI : in std_logic;
         CE   : in std_logic;
         CLKO : out std_logic);
end component;
```

DCCA Instantiation

```
I1: DCCA
   port map (CLKI => CLKI;
             CE   => CE;
             CLKO => CLKO);
end component;
```

DCCA Usage with Verilog HDL

Component Declaration

```
module DCCA (CLKI,
             CE,
             CLKO);
input CLKI;
input CE;
output CLKO;
endmodule
```

DCCA Instantiation

```
DCCA I1 (.CLKI (CLKI),
         .CE   (CE),
         .CLKO (CLKO));
```

- TN1199 - MachXO2 sysCLOCK PLL Design and Usage Guide

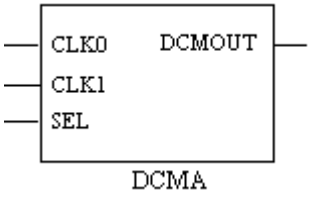
DCMA

Dynamic Clock Mux

Architectures Supported:

- MachXO2

- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: CLK0, CLK1, SEL

OUTPUT: DCMOUT

Description

DCMA is a clock buffer incorporating a multiplexer function, whose output switches between the two clock inputs. It is not recommended that you route the PLL feedback signals through the multiplexer, because the PLL will loose lock.

DCMA IO description is shown in the below table.

Table 558:

Port Name	I/O	Unused Nets	Description
CLK0	I	Tie low	Input clock
CLKI	I	Tie low	Input clock
SEL	I	Tie low	Clock select from CIB
DCMOUT	O	Dangle	Output from the primary clock mux

DCMA Usage with VHDL

Library Instantiation

```
library lattice;
use lattice.components.all;
```

Component Declaration

```
component DCMA
   port (CLK0   : in std_logic;
         CLK1   : in std_logic;
         SEL    : in std_logic;
         DCMOUT :out std_logic);
end component;
```

DCMA Instantiation

```
I1: DCMA
   port map (CLK0 => CLK0,
             CLK1 => CLK1,
             SEL => SEL,
             DCMOUT => DCMOUT);
end component;
```

DCMA Usage with Verilog HDL

Component Declaration

```
module DCMA (CLK0, CLK1, SEL, DCMOUT);
input CLK0;
input CLK1;
input SEL;
output DCMOUT;
endmodule
```

DCMA Instantiation

```
DCMA I1 (.CLK0 (CLK0);
         .CLK1 (CLK1);
         .SEL (SEL);
         .DCMOUT (DCMOUT));
```

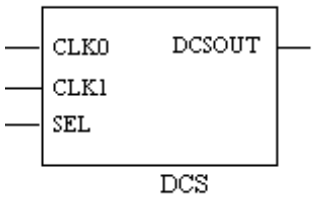
- TN1199 - MachXO2 sysCLOCK PLL Design and Usage Guide

DCS

Dynamic Clock Selection

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2



INPUTS: CLK0 CLK1 SEL

OUTPUT: DCSOUT

ATTRIBUTES:

DCSMODE: "NEG" (default), "POS", "HIGH_LOW", "HIGH_HIGH", "LOW_LOW", "LOW_HIGH","CLK0", "CLK1"

Note

For LatticeECP/EC, LatticeECP2/M, LatticeXP, and LatticeXP2 devices, the DCSMODE default has been changed from POS to NEG since ispLEVER 7.0 SP2. If your pre-7.0SP2 design included the DCS macro and you didn't specify the DCSMODE value, the design may behave differently in Diamond. To avoid the issue, you can manually set DCSMODE to POS in your old design.

Description

DCS is a global clock buffer incorporating a smart multiplexer function that takes two independent input clock sources and avoids glitches or runt pulses on the output clock, regardless of where the enable signal is toggled. Located in pairs at the center of each edge, there are eight DCS primitives per device.

Table 559:

Function	Pins
Input Clock Select	SEL
Primary Clock Input 0	CLK0
Primary Clock Input 1	CLK1
To Primary Clock Mid-Mux	DCSOUT

For each DCS:

- Inputs are from primary clocks at PLC routing block (one branch per DCS)
- Selects are from a routing block's LUT port (A0, B0, etc.)
- Outputs are connected to the DCS output sources of the feedline muxes

The outputs of the DCS then reach primary clock distribution via the feedlines. The connections from CIB to DCS are shown in the table below. The selected CIB interfaces to a PIC and is located at the center of each bank and next to

the mid-muxes. Note that the CIB to DCS connections are merged with the existing PIC-CIB connections at that CIB. It is up to the hardware designer to select the most convenient CIB.

CIB to DCS Connections

Table 560:

CIB	DCS
C7	SEL
CLK0(jclk0)	CLK0
CLK1(jclk2)	CLK1

DCSMODE Values

Table 561:

Attribute Name	Description	Output		Value	DCS Fuse Settings				
		SEL=0	SEL=1		0	1	2	3	4
DCS MODE	Rising edge triggered, latched state is high	CLK0	CLK1	POS	1	0	0	0	0
	Falling edge triggered, latched state is low	CLK0	CLK1	NEG	0	0	0	0	0
	Sel is active high, Disabled output is low	0	CLK1	HIGH_LOW	0	1	0	0	0
	Sel is active high, Disabled output is high	1	CLK1	HIGH_HIGH	1	1	0	0	0
	Sel is active low, Disabled output is low	CLK0	0	LOW_LOW	0	0	1	0	0
	Sel is active low, Disabled output is high	CLK0	1	LOW_HIGH	1	0	1	0	0
	Buffer for CLK0	CLK0	CLK0	CLK0	0	0	1	0	1
	Buffer for CLK1	CLK1	CLK1	CLK1	0	1	0	1	0

For additional information, see Lattice technical notes on the web site:

- TN1103 - LatticeECP2 sysCLOCK PLL/DLL Design and Usage Guide
- TN1126 - LatticeXP2 sysCLOCK PLL Design and Usage Guide

- TN1049 - LatticeECP/EC and LatticeXP sysCLOCK PLL Design and Usage Guide

Note

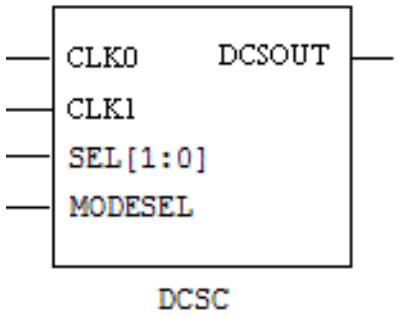
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

DCSC

Dynamic Clock Selection

Architectures Supported:

- ECP5
- LIFMD



INPUTS: CLK0 CLK1, SEL1, SEL0, MODESEL

OUTPUT: DCSOUT

ATTRIBUTES:

DCSMODE: "NEG" (default), "POS", "HIGH_LOW", "HIGH_HIGH", "LOW_LOW", "LOW_HIGH","CLK0", "CLK1"

Description

DCS is a 2-to-1 clock mux. Two modes exist. The glitchless mode switches between two clock sources (CLK0 and CLK1). The other mode added allows switching between the two clock sources asynchronously, based on the Sel signals. The second mode can produce a glitch on the output clock (DCSOUT), since the Sel signals could be changed at the same time the input clocks switching.

In the first mode (glitchless mode), there is a limitation on the circuit. If one of the clock sourcse is at a static H or L, the DCS will not make the switch. This

is because the DCS has to look at the two sources to synchronize the switch in order to not produce a glitch.

If the select inputs change from selecting one source (i.e. [01] to select CLK0), to selecting another source (i.e. [10] to select CLK1), where CLK1 is connected to GND, the user can cycle the select input from [10] -> [00] (a few cycles) -> [01] to allow the switch from active clock (CLK0) to GND without glitching the output.

Alternatively, the user can select non-glitchless mode (MODESEL = 1), and make the switch on the inputs. This could also make the output DCSOUT to switch from active clock (CLK0) to GND, but it could create a glitch when it makes the switch.

Table 562:

Function	Pins
Input Clock Select 0	SEL0
Input Clock Select 1	SEL1
Primary Clock Input 0	CLK0
Primary Clock Input 1	CLK1
Selects glitchless ("0") or non-glitchless ("1") behavior	MODESEL
To Primary Clock Mid-Mux	DCSOUT

DCSMODE Values When MODESEL = 0

Attribute Name	Operation	Default Value	Affected Fuses
DCSMODE	See table below. These options are only available when operating in glitchless mode (CIB pin MODESEL='0').	"POS"	Mode

DCSMODE Attribute Table When CIB MODESEL='0'

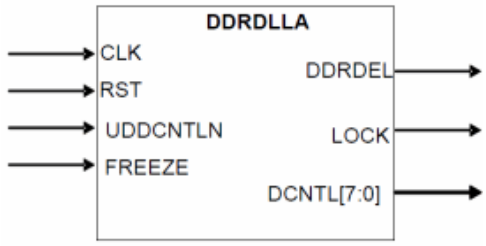
DDRDLLA

90 degree delay for the DQS Input during a memory interface or the clock input for a generic DDR interface

Architectures Supported:

- ECP5
- LIFMD



INPUTS: CLK, RST, UDDCNTLN, FREEZE

OUTPUT: DDRDEL, LOCK, DCNTL7, DCNTL6, DCNTL5, DCNTL4, DCNTL3, DCNTL2, DCNTL1, DCNTL0

ATTRIBUTES:

FORCE_MAX_DELAY: "NO" (default), "YES"

LOCK_CYC: (For simulation only)

Description

The DDRDLL is used to generate a 90 degree delay for the DQS Input during a memory interface or the clock input for a generic DDR interface.

There are two DDRDLL modules per half the device. The DDRDLL outputs delay codes that are used in the DQSBUF elements to delay the DQS input or in the DLLDEL module to delay the input clock. DDRDLL by default will generate 90-degrees, but the user may choose to generate 77, 88, 101 or 112 degrees as well.

DDRDLLA Port Definition

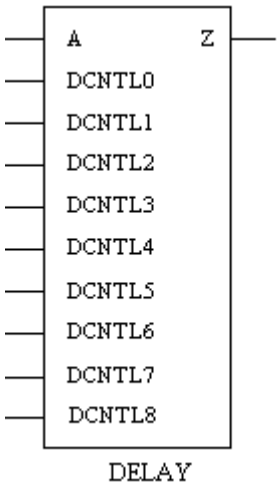
Table 563:

Port Name	I/O	Definition
CLK	I	Reference clock input to the DDRDLL. Should run at the same frequency as the clock to the delayed.
RST	I	Reset Input to the DDRDLL
UDDCNTLN	I	Update Control to update the delay code. When low the delay code out the DDRDLL is updated. Should not be active during a read or a write cycle.
FREEZE	I	When FREEZE goes high, it glitchlessly turns off the DLL internal clock and ring oscillator output clock. When FREEZE goes low, turns it back on.
DDRDEL	O	The delay codes from the DDRDLL to be used in DQSBUF or DLLDEL
LOCK	O	Lock output to indicate the DDRDLL has valid delay output
DCNTL[7:0]	O	The delay codes from the DDRDLL available for the user IP.

DELAY

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP



INPUTS: A, DCNTL0, DCNTL1, DCNTL2, DCNTL3, DCNTL4, DCNTL5, DCNTL6, DCNTL7, DCNTL8

OUTPUT: Z

Description

Sets the input delay for an input. You can choose either dynamic delay or the static delay. For more usage, see related technical notes or contact technical support.

Truth Table

Table 564:

INPUTS	OUTPUTS
A	Z
0	0
1	1

Note

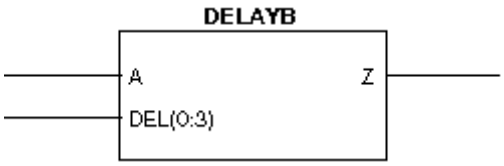
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

DELAYB

Dynamic Delay in PIO

Architectures Supported:

- LatticeECP2/M
- LatticeECP3
- LatticeXP2



INPUTS: A, DEL0, DEL1, DEL2, DEL3

OUTPUT: Z

Description

Data going to the DDR registers can be optionally delayed using the delay block. The DELAYB block receives a 4-bit delay value from the DLL. The user can also choose to implement a fixed delay value instead of using the delay generated by the DLL. The various fixed delay choices can be made in the IPexpress software tool.

The DELAYB block can also be used to delay non-DDR inputs that use the input PIO register.

DELAYB Port Definition

Table 565:

Port Name	I/O	Definition
A	I	DDR input from sysIO buffer.
DEL [0:3]	I	Delay inputs.
Z	O	Output with delay.

Refer to the following technical notes for more details:

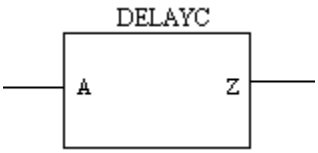
- TN1180 - LatticeECP3 High-Speed I/O Interface
- TN1105 - LatticeECP2/M High-Speed I/O Interface
- TN1138 - LatticeXP2 High-Speed I/O Interface

DELAYC

Fixed Delay in PIO

Architectures Supported:

- LatticeECP3



INPUT: A

OUTPUT: Z

DELAYC Port Definition

Table 566:

Port Name	I/O	Definition
A	I	DDR input from sysIO buffer.
Z	O	Output with delay.

Refer to the following technical note for more details:

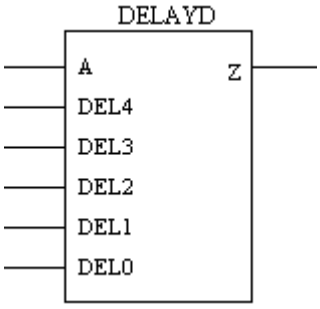
- TN1180 - LatticeECP3 High-Speed I/O Interface

DELAYD

Dynamic Delay for Bottom Bank

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUT: A, DEL4, DEL3, DEL2, DEL1, DEL0

OUTPUT: Z

Description

DELAYD is the dynamic delay for VPIC_RX, IOLA and IOLC cells in bottom side only. It can be used for x2, x4 and 7:1 applications. See the below table for its port description.

Table 567:

Port Name	I/O	Definition
A	I	Data input from IO buffer
DEL4, DEL3, DEL2, DEL1, DEL0	I	Dynamic delay inputs from CIB
Z	O	Output with delay

Refer to the following technical note for more details:

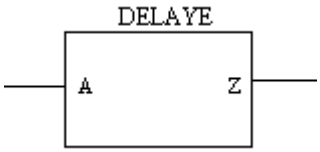
- TN1203 - Implementing High-Speed Interfaces with MachXO2 Devices

DELAYE

Fixed Delay in PIO

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUT: A

OUTPUT: Z

ATTRIBUTES:

DEL_MODE: "SCLK_ZEROHOLD", "ECLK_ALIGNED", "ECLK_CENTERED", "SCLK_ALIGNED", "SCLK_CENTERED", "USER_DEFINED" (default)

DEL_VALUE: "DELAY0" (default), "DELAY1", "DELAY2", ..., "DELAY31"

Description

DELAYE is the fix delay in PIO for all banks and all sides. It can be used for all IO registers and DDR types. See the below table for its IO port description.

Table 568:

Port Name	I/O	Definition
A	I	DDR input from sysIO buffer
Z	O	Output with delay

Refer to the following technical note for more details:

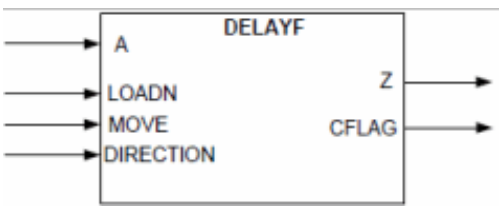
- TN1203 - Implementing High-Speed Interfaces with MachXO2 Devices

DELAYF

Delay

Architectures Supported:

- ECP5
- LIFMD



INPUT: A, LOADIN, MOVE, DIRECTION

OUTPUT: Z, CFLAG

ATTRIBUTES:

DEL_MODE: "ECLK_ALIGNED", "ECLK_CENTERED", "ECLK_CENTERED_MIPI", "ECLK_CENTERED_SLVS", "SCLK_ALIGNED", "SCLK_CENTERED", "SCLK_ZEROHOLD", "USER_DEFINED" (default)

Note

"ECLK_CENTERED_MIPI" and "ECLK_CENTERED_SLVS" apply to LIFMD only.

DEL_VALUE: "DELAY0" (default), "DELAY1", "DELAY2", ..., "DELAY31"

Description

By default DELAYF is configured to factory delay settings based on the clocking structure. The user can overwrite the DELAY setting using the MOVE and DIRECTION control inputs. The LOADN will reset the delay back to the default value.

Table 569:

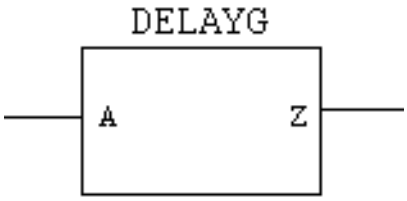
Port Name	I/O	Definition
A	I	Data input from pin or output register block
LOADIN	I	“0” on LOADN will reset to default Delay setting
MOVE	I	“Pulse” on MOVE will change delay setting. DIRECTION will be sampled at “falling edge” of MOVE.
DIRECTION	I	“1” to decrease delay & “0” to increase delay
Z	O	Delayed data to input register block or to pin
CFLAG	O	Flag indicating the delay counter has reached max (when moving up) or min (when moving down) value.

DELAYG

Delay

Architectures Supported:

- ECP5
- LIFMD



INPUT: A

OUTPUT: Z

ATTRIBUTES:

DEL_MODE: "ECLK_ALIGNED", "ECLK_CENTERED", "ECLK_CENTERED_MIPI", "ECLK_CENTERED_SLVS", "SCLK_ALIGNED", "SCLK_CENTERED", "SCLK_ZEROHOLD", "USER_DEFINED" (default)

Note

"ECLK_CENTERED_MIPI" and "ECLK_CENTERED_SLVS" apply to LIFMD only.

DEL_VALUE: "DELAY0" (default), "DELAY1", "DELAY2", ..., "DELAY31"

Description

DELAYG is configured to factory delay settings based on the clocking structure. User cannot change the delay when using this module..

Table 570:

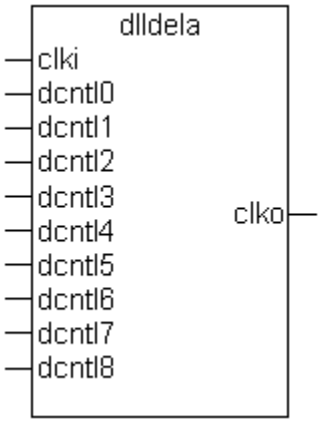
Port Name	I/O	Definition
A	I	Data input from pin or output register block.
Z	O	Delayed data to input register block or to pin.

DLLDELA

Slave Delay

Architectures Supported:

- LatticeECP2/M



INPUTS: CLKI, DCNTL0, DCNTL1, DCNTL2, DCNTL3, DCNTL4, DCNTL5, DCNTL6, DCNTL7, DCNTL8

OUTPUT: CLKO

Description

The Slave Delay Line is designed to generate desired delay in DDR/SPI4 applications. The delay control inputs (DCNTL[8:0]) are fed from the general purpose DLL outputs. The following table shows its port description.

Table 571:

Name	I/O	Description
CLKI	I	Clock input
DCNTL[8:0]	I	Delay control bits
CLKO	O	Clock output

For more details such as application examples, refer to the following technical note on the Lattice web site:

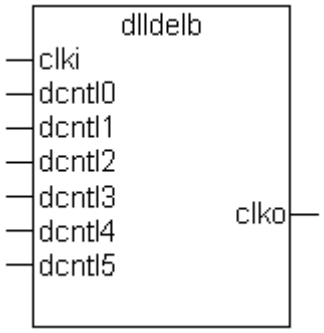
- TN1103 - LatticeECP2 sysCLOCK PLL/DLL Design and Usage Guide

DLLDELB

Slave Delay

Architectures Supported:

- LatticeECP3



INPUTS: CLKI, DCNTL5, DCNTL4, DCNTL3, DCNTL2, DCNTL1, DCNTL0

OUTPUT: CLKO

Description

DLLDELB is the LatticeECP3 slave delay line primitive. The DLLDELB port description is shown in the below table.

Table 572:

Port Name	I/O	Description
CLKI	I	Clock input
DCNTL0	I	Control bit 0 (hard wired to DLL)
DCNTL1	I	Control bit 1 (hard wired to DLL)
DCNTL2	I	Control bit 2 (hard wired to DLL)
DCNTL3	I	Control bit 3 (hard wired to DLL)
DCNTL4	I	Control bit 4 (hard wired to DLL)
DCNTL5	I	Control bit 5 (hard wired to DLL)
CLKO	O	Clock output

DLLDELB Usage with VHDL

```
COMPONENT DLLDELB
   PORT (CLKI   : IN  std_logic;
         DCNTL0 : IN  std_logic;
         DCNTL1 : IN  std_logic;
         DCNTL2 : IN  std_logic;
         DCNTL3 : IN  std_logic;
         DCNTL4 : IN  std_logic;
         DCNTL5 : IN  std_logic;
         CLKO   : OUT std_logic);
END COMPONENT;
```

```
begin
DLLDELAinst0: DLLDELB
   PORT MAP (
             CLKI   =>  clkisig,
             DCNTL0 =>  dcntl0sig,
             DCNTL1 =>  dcntl1sig,
             DCNTL2 =>  dcntl2sig,
             DCNTL3 =>  dcntl3sig,
             DCNTL4 =>  dcntl4sig,
             DCNTL5 =>  dcntl5sig,
             CLKO   =>  clkosig
            );
```

For more details such as application examples, refer to the following technical note on the Lattice web site:

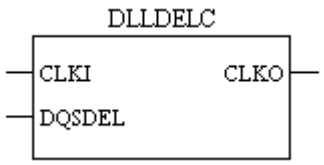
- TN1178 - LatticeECP3 sysCLOCK and PLL/DLL Design and Usage Guide

DLLDELC

Clock Shifting for ECLK or PCLK

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: CLKI, DQSDEL

OUTPUT: CLKO

ATTRIBUTES:

DEL_ADJ: "PLUS" (default), MINUS

DEL_VAL: integers 0~127 (PLUS), 1~128 (MINUS) (default: 0)

Description

DLLDELC is the generic input clock shifting using DQSDEL from DQSDLL. The DLLDELC port description is shown in the below table.

Table 573:

Port Name	I/O	Description
CLKI	I	clk input from I/O buffer
DQSDEL	I	Dynamic delay inputs from DQSDLLC
CLKO	O	Clock output with delay

For more details such as application examples, refer to the following technical note on the Lattice web site:

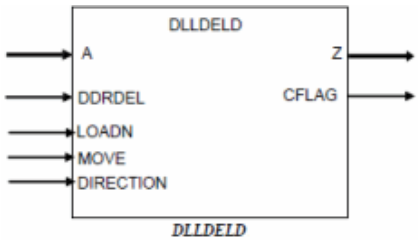
- TN1203 - Implementing High-Speed Interfaces with MachXO2 Devices

DLLDELD

Slave Delay

Architectures Supported:

- ECP5
- LIFMD



INPUTS: A, DDRDEL, LOADN, MOVE, DIRECTION

OUTPUT: Z, CFLAG

Description

DLLDELD is the delay element that receives code from DDRDLL for generic DDR. The DLLDELD port description is shown in the below table.

Table 574:

Port Name	I/O	Description
A	I	Clock Input
DDRDEL	I	Delay inputs from DDRDLL

Table 574:

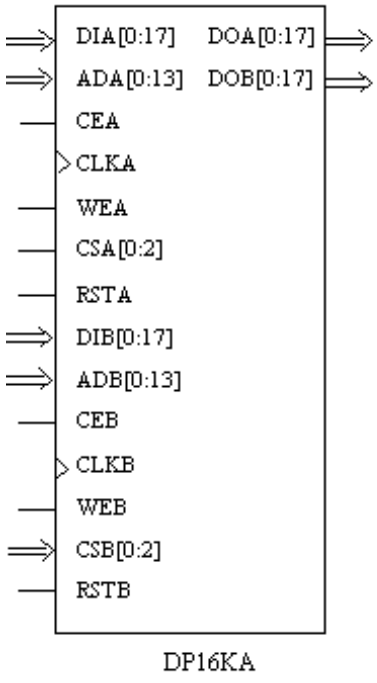
Port Name	I/O	Description
LOADN	I	Used to reset back to 90 degrees delay.
MOVE	I	Pulse is required to change delay settings. The value on Direction will be sampled at the “falling edge” of MOVE.
DIRECTION	I	Indicates delay direction. “1” to decrease delay & “0” to increase delay.
CFLAG	O	Indicates the delay counter has reached max value when moving up or min value when moving down.
Z	O	Delayed Clock output

DP16KA

16K Dual Port Block RAM

Architectures Supported:

- LatticeSC/M



INPUTS: DIA0, DIA1, DIA2, DIA3, DIA4, DIA5, DIA6, DIA7, DIA8, DIA9, DIA10, DIA11, DIA12, DIA13, DIA14, DIA15, DIA16, DIA17, ADA0, ADA1, ADA2, ADA3, ADA4, ADA5, ADA6, ADA7, ADA8, ADA9, ADA10, ADA11,

ADA12, ADA13, CEA, CLKA, WEA, CSA0, CSA1, CSA2, RSTA, DIB0, DIB1, DIB2, DIB3, DIB4, DIB5, DIB6, DIB7, DIB8, DIB9, DIB10, DIB11, DIB12, DIB13, DIB14, DIB15, DIB16, DIB17, ADB0, ADB1, ADB2, ADB3, ADB4, ADB5, ADB6, ADB7, ADB8, ADB9, ADB10, ADB11, ADB12, ADB13, CEB, CLKB, WEB, CSB0, CSB1, CSB2, RSTB

OUTPUTS: DOA0, DOA1, DOA2, DOA3, DOA4, DOA5, DOA6, DOA7, DOA8, DOA9, DOA10, DOA11, DOA12, DOA13, DOA14, DOA15, DOA16, DOA17, DOB0, DOB1, DOB2, DOB3, DOB4, DOB5, DOB6, DOB7, DOB8, DOB9, DOB10, DOB11, DOB12, DOB13, DOB14, DOB15, DOB16, DOB17

ATTRIBUTES:

DATA_WIDTH_A: 1, 2, 4, 9, 18 (default)

DATA_WIDTH_B: 1, 2, 4, 9, 18 (default)

REGMODE_A: "NOREG" (default), "OUTREG"

REGMODE_B: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE_A: any 3-bit binary value (default: 3'b000)

CSDECODE_B: any 3-bit binary value (default: 3'b000)

WRITEMODE_A: "NORMAL" (default), "WRITETHROUGH"

WRITEMODE_B: "NORMAL" (default), "WRITETHROUGH"

GSR: "DISABLED" (default), "ENABLED"

INITVAL_00 to INITVAL_3F: (*Verilog*) 320'hXXX...X (80-bit hexadecimal value)
(*VHDL*) 0xXXX...X (80-bit hexadecimal value)
Default: all zeros

Description

You can refer to the following technical note on the Lattice web site for EBR port definition, attribute definition and usage.

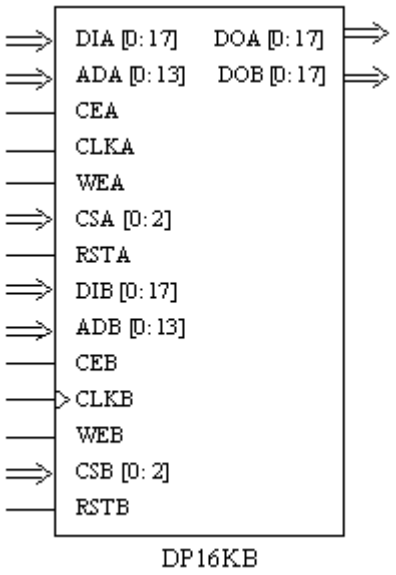
- TN1094 - On-Chip Memory Usage Guide for LatticeSC Devices

DP16KB

True Dual Port Block RAM

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



INPUTS: DIA0, DIA1, DIA2, DIA3, DIA4, DIA5, DIA6, DIA7, DIA8, DIA9, DIA10, DIA11, DIA12, DIA13, DIA14, DIA15, DIA16, DIA17, ADA0, ADA1, ADA2, ADA3, ADA4, ADA5, ADA6, ADA7, ADA8, ADA9, ADA10, ADA11, ADA12, ADA13, CEA, CLKA, WEA, CSA0, CSA1, CSA2, RSTA, DIB0, DIB1, DIB2, DIB3, DIB4, DIB5, DIB6, DIB7, DIB8, DIB9, DIB10, DIB11, DIB12, DIB13, DIB14, DIB15, DIB16, DIB17, ADB0, ADB1, ADB2, ADB3, ADB4, ADB5, ADB6, ADB7, ADB8, ADB9, ADB10, ADB11, ADB12, ADB13, CEB, CLKB, WEB, CSB0, CSB1, CSB2, RSTB

OUTPUTS: DOA0, DOA1, DOA2, DOA3, DOA4, DOA5, DOA6, DOA7, DOA8, DOA9, DOA10, DOA11, DOA12, DOA13, DOA14, DOA15, DOA16, DOA17, DOB0, DOB1, DOB2, DOB3, DOB4, DOB5, DOB6, DOB7, DOB8, DOB9, DOB10, DOB11, DOB12, DOB13, DOB14, DOB15, DOB16, DOB17

ATTRIBUTES:

DATA_WIDTH_A: 1, 2, 4, 9, 18 (default)

DATA_WIDTH_B: 1, 2, 4, 9, 18 (default)

REGMODE_A: "NOREG" (default), "OUTREG"

REGMODE_B: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE_A: any 3-bit binary value (default: 0b000)

CSDECODE_B: any 3-bit binary value (default: 0b000)

WRITEMODE_A: "NORMAL" (default), "WRITETHROUGH"

WRITEMODE_B: "NORMAL" (default), "WRITETHROUGH"

GSR: "DISABLED" (default), "ENABLED"

INITVAL_00 to INITVAL_3F: 80-bit hexadecimal string (default: all zeros)

Description

You can refer to the following technical note on the Lattice web site for EBR port definition, attribute definition and usage.

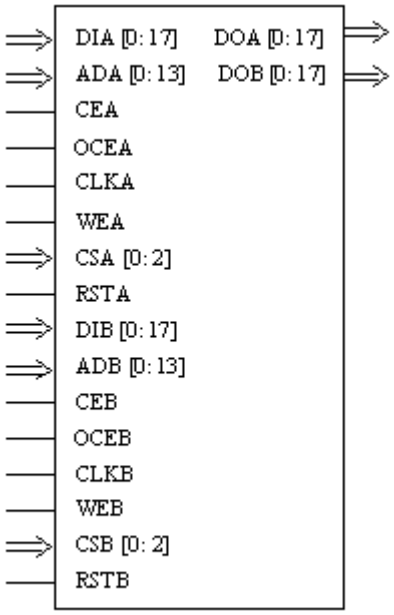
- TN1104 - LatticeECP2/M Memory Usage Guide

DP16KC

True Dual Port Block RAM

Architectures Supported:

- LatticeECP3



DP16KC

INPUTS: DIA17, DIA16, DIA15, DIA14, DIA13, DIA12, DIA11, DIA10, DIA9, DIA8, DIA7, DIA6, DIA5, DIA4, DIA3, DIA2, DIA1, DIA0, ADA13, ADA12, ADA11, ADA10, ADA9, ADA8, ADA7, ADA6, ADA5, ADA4, ADA3, ADA2, ADA1, ADA0, CEA, OCEA, CLKA, WEA, CSA2, CSA1, CSA0, RSTA, DIB17, DIB16, DIB15, DIB14, DIB13, DIB12, DIB11, DIB10, DIB9, DIB8, DIB7, DIB6, DIB5, DIB4, DIB3, DIB2, DIB1, DIB0, ADB13, ADB12, ADB11, ADB10, ADB9, ADB8, ADB7, ADB6, ADB5, ADB4, ADB3, ADB2, ADB1, ADB0, CEB, OCEB, CLKB, WEB, CSB2, CSB1, CSB0, RSTB

OUTPUTS: DOA17, DOA16, DOA15, DOA14, DOA13, DOA12, DOA11, DOA10, DOA9, DOA8, DOA7, DOA6, DOA5, DOA4, DOA3, DOA2, DOA1, DOA0, DOB17, DOB16, DOB15, DOB14, DOB13, DOB12, DOB11, DOB10, DOB9, DOB8, DOB7, DOB6, DOB5, DOB4, DOB3, DOB2, DOB1, DOB0

ATTRIBUTES:

DATA_WIDTH_A: 1, 2, 4, 9, 18 (default)

DATA_WIDTH_B: 1, 2, 4, 9, 18 (default)

REGMODE_A: "NOREG" (default), "OUTREG"

REGMODE_B: "NOREG" (default), "OUTREG"

CSDECODE_A: any 3-bit binary value (default: all zeros)

CSDECODE_B: any 3-bit binary value (default: all zeros)

WRITEMODE_A: "NORMAL" (default), "WRITETHROUGH"

WRITEMODE_B: "NORMAL" (default), "WRITETHROUGH"

GSR: "DISABLED" (default), "ENABLED"

INITVAL_00 to INITVAL_3F: "0xXXX....X" (80-bit hex string) (default: all zeros)

Description

You can refer to the following technical note on the Lattice web site for EBR port definition, attribute definition and usage.

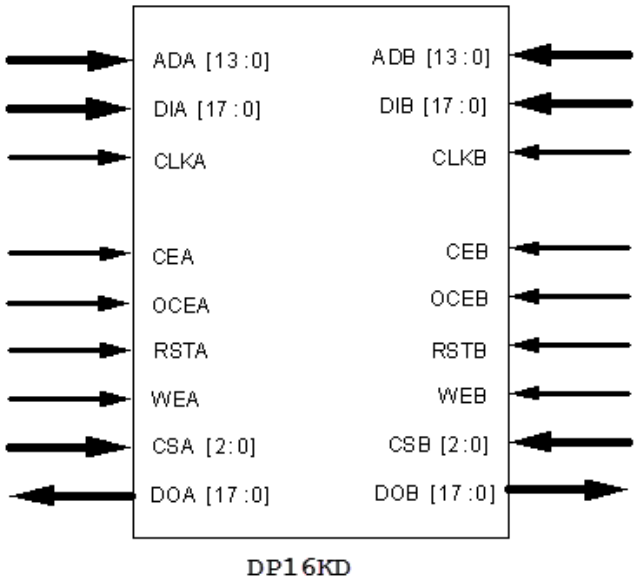
- TN1179 - LatticeECP3 Memory Usage Guide

DP16KD

True Dual Port Block RAM

Architectures Supported:

- ECP5



INPUTS: ADA13, ADA12, ADA11, ADA10, ADA9, ADA8, ADA7, ADA6, ADA5, ADA4, ADA3, ADA2, ADA1, ADA0, DIA17, DIA16, DIA15, DIA14, DIA13, DIA12, DIA11, DIA10, DIA9, DIA8, DIA7, DIA6, DIA5, DIA4, DIA3, DIA2, DIA1, DIA0, CLKA, CEA, OCEA, RSTA, WEA, CSA2, CSA1, CSA0, ADB13, ADB12, ADB11, ADB10, ADB9, ADB8, ADB7, ADB6, ADB5, ADB4, ADB3, ADB2, ADB1, ADB0, DIB17, DIB16, DIB15, DIB14, DIB13, DIB12, DIB11, DIB10, DIB9, DIB8, DIB7, DIB6, DIB5, DIB4, DIB3, DIB2, DIB1, DIB0, CLKB, CEB, OCEB, RSTB. WEB, CSB2, CSB1, CSB0

OUTPUTS: DOA17, DOA16, DOA15, DOA14, DOA13, DOA12, DOA11, DOA10, DOA9, DOA8, DOA7, DOA6, DOA5, DOA4, DOA3, DOA2, DOA1, DOA0, DOB17, DOB16, DOB15, DOB14, DOB13, DOB12, DOB11, DOB10, DOB9, DOB8, DOB7, DOB6, DOB5, DOB4, DOB3, DOB2, DOB1, DOB0

ATTRIBUTES:

DATA_WIDTH_A: 1, 2, 4, 9 (default)

DATA_WIDTH_B: 1, 2, 4, 9 (default)

REGMODE_A: "NOREG" (default), "OUTREG"

REGMODE_B: "NOREG" (default), "OUTREG"

CSDECODE_A: any 3-bit binary value (default: 3’b000)

CSDECODE_B: any 3-bit binary value (default: 3’b000)

WRITEMODE_A: "NORMAL" (default), "WRITETHROUGH", "READBEFORE"

WRITEMODE_B: "NORMAL" (default), "WRITETHROUGH", "READBEFORE"

GSR: "ENABLED" (default), "DISABLED"

RESETMODE: "SYNC" (default), "ASYNC"

ASYNC_RESET_RELEASE: "SYNC" (default), "ASYNC"

INIT_DATA: "STATIC" (default), "DYNAMIC"

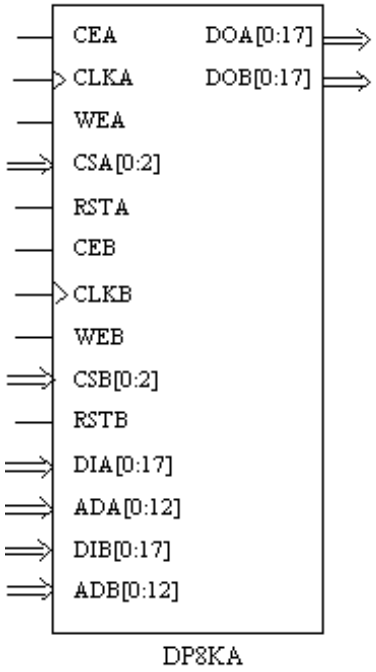
INITVAL_00 to INITVAL_1F: (*Verilog*) 320'hXXX...X (80-bit hex value)
(*VHDL*) 0xXXX...X (80-bit hex value)
Default: all zeros

DP8KA

8K Dual Port Block RAM

Architectures Supported:

- LatticeECP/EC
- LatticeXP



INPUTS: CEA, CLKA, WEA, CSA0, CSA1, CSA2, RSTA, CEB, CLKB, WEB, CSB0, CSB1, CSB2, RSTB, DIA0, DIA1, DIA2, DIA3, DIA4, DIA5, DIA6, DIA7, DIA8, DIA9, DIA10, DIA11, DIA12, DIA13, DIA14, DIA15, DIA16, DIA17, ADA0, ADA1, ADA2, ADA3, ADA4, ADA5, ADA6, ADA7, ADA8, ADA9, ADA10, ADA11, ADA12, DIB0, DIB1, DIB2, DIB3, DIB4, DIB5, DIB6, DIB7, DIB8, DIB9, DIB10, DIB11, DIB12, DIB13, DIB14, DIB15, DIB16, DIB17, ADB0, ADB1, ADB2, ADB3, ADB4, ADB5, ADB6, ADB7, ADB8, ADB9, ADB10, ADB11, ADB12

OUTPUTS: DOA0, DOA1, DOA2, DOA3, DOA4, DOA5, DOA6, DOA7, DOA8, DOA9, DOA10, DOA11, DOA12, DOA13, DOA14, DOA15, DOA16, DOA17, DOB0, DOB1, DOB2, DOB3, DOB4, DOB5, DOB6, DOB7, DOB8, DOB9, DOB10, DOB11, DOB12, DOB13, DOB14, DOB15, DOB16, DOB17

ATTRIBUTES:

DATA_WIDTH_A: 1, 2, 4, 9, 18 (default)

DATA_WIDTH_B: 1, 2, 4, 9, 18 (default)

REGMODE_A: "NOREG" (default), "OUTREG"

REGMODE_B: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE_A: any 3-bit binary value (default: 111)

CSDECODE_B: any 3-bit binary value (default: 111)

WRITEMODE_A: "NORMAL" (default), "WRITETHROUGH"

WRITEMODE_B: "NORMAL" (default), "WRITETHROUGH"

INITVAL_00 to INITVAL_1F: (*Verilog*) 320'hXXX...X (80-bit hexadecimal value)
(*VHDL*) 0xXXX...X (80-bit hexadecimal value)
Default: all zeros

Description

You can refer to the following technical note on the Lattice web site for EBR port definition, attribute definition and usage.

- TN1051 - Memory Usage Guide for LatticeECP/EC and LatticeXP Devices

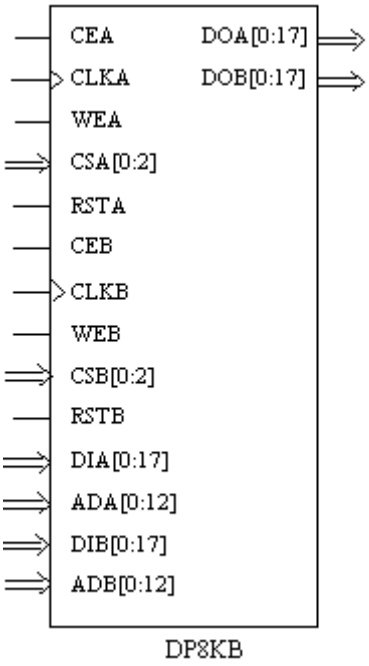
DP8KB

8K Dual Port Block RAM

Architectures Supported:

- MachXO

- Platform Manager



INPUTS: CEA, CLKA, WEA, CSA0, CSA1, CSA2, RSTA, CEB, CLKB, WEB, CSB0, CSB1, CSB2, RSTB, DIA0, DIA1, DIA2, DIA3, DIA4, DIA5, DIA6, DIA7, DIA8, DIA9, DIA10, DIA11, DIA12, DIA13, DIA14, DIA15, DIA16, DIA17, ADA0, ADA1, ADA2, ADA3, ADA4, ADA5, ADA6, ADA7, ADA8, ADA9, ADA10, ADA11, ADA12, DIB0, DIB1, DIB2, DIB3, DIB4, DIB5, DIB6, DIB7, DIB8, DIB9, DIB10, DIB11, DIB12, DIB13, DIB14, DIB15, DIB16, DIB17, ADB0, ADB1, ADB2, ADB3, ADB4, ADB5, ADB6, ADB7, ADB8, ADB9, ADB10, ADB11, ADB12

OUTPUTS: DOA0, DOA1, DOA2, DOA3, DOA4, DOA5, DOA6, DOA7, DOA8, DOA9, DOA10, DOA11, DOA12, DOA13, DOA14, DOA15, DOA16, DOA17, DOB0, DOB1, DOB2, DOB3, DOB4, DOB5, DOB6, DOB7, DOB8, DOB9, DOB10, DOB11, DOB12, DOB13, DOB14, DOB15, DOB16, DOB17

ATTRIBUTES:

DATA_WIDTH_A: 1, 2, 4, 9, 18 (default)

DATA_WIDTH_B: 1, 2, 4, 9, 18 (default)

REGMODE_A: "NOREG" (default), "OUTREG"

REGMODE_B: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE_A: any 3-bit binary value (default: all zeros)

CSDECODE_B: any 3-bit binary value (default: all zeros)

WRITEMODE_A: "NORMAL" (default), "WRITETHROUGH"

WRITEMODE_B: "NORMAL" (default), "WRITETHROUGH"

GSR: "DISABLED" (default), "ENABLED"

INITVAL_00 to INITVAL_1F: (*Verilog*) 320'hXXX...X (80-bit hex value)
(*VHDL*) 0xXXX...X (80-bit hex value)
Default: all zeros

Description

You can refer to the following technical note on the Lattice web site for EBR port definition, attribute definition and usage.

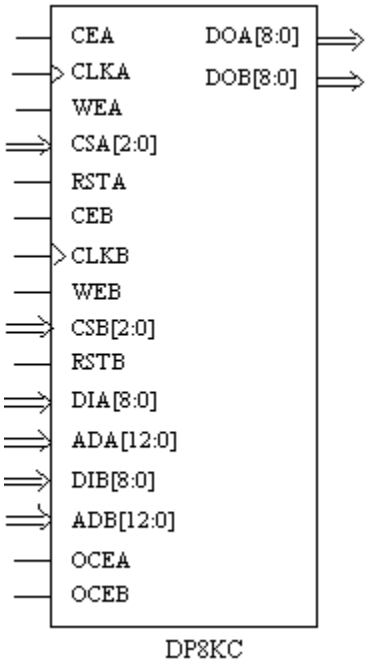
- TN1092 - MachXO Memory Usage Guide

DP8KC

8K True Dual Port Block RAM

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: CEA, CLKA, WEA, CSA2, CSA1, CSA0, RSTA, CEB, CLKB, WEB, CSB2, CSB1, CSB0, RSTB, DIA8, DIA7, DIA6, DIA5, DIA4, DIA3, DIA2, DIA1, DIA0, ADA12, ADA11, ADA10, ADA9, ADA8, ADA7, ADA6, ADA5, ADA4, ADA3, ADA2, ADA1, ADA0, DIB8, DIB7, DIB6, DIB5, DIB4, DIB3, DIB2, DIB1, DIB0, ADB12, ADB11, ADB10, ADB9, ADB8, ADB7, ADB6, ADB5, ADB4, ADB3, ADB2, ADB1, ADB0, OCEA, OCEB

OUTPUTS: DOA8, DOA7, DOA6, DOA5, DOA4, DOA3, DOA2, DOA1, DOA0, DOB8, DOB7, DOB6, DOB5, DOB4, DOB3, DOB2, DOB1, DOB0

ATTRIBUTES:

DATA_WIDTH_A: 1, 2, 4, 9 (default)

DATA_WIDTH_B: 1, 2, 4, 9 (default)

REGMODE_A: "NOREG" (default), "OUTREG"

REGMODE_B: "NOREG" (default), "OUTREG"

CSDECODE_A: any 3-bit binary value (default: 3’b000)

CSDECODE_B: any 3-bit binary value (default: 3’b000)

WRITEMODE_A: "NORMAL" (default), "WRITETHROUGH", "READBEFORE"

WRITEMODE_B: "NORMAL" (default), "WRITETHROUGH", "READBEFORE"

GSR: "ENABLED" (default), "DISABLED"

RESETMODE: "SYNC" (default), "ASYNC"

ASYNC_RESET_RELEASE: "SYNC" (default), "ASYNC"

INIT_DATA: "STATIC" (default), "DYNAMIC"

INITVAL_00 to INITVAL_1F: (*Verilog*) 320'hXXX...X (80-bit hex value)
(*VHDL*) 0xXXX...X (80-bit hex value)
Default: all zeros

Description

The following table describes the I/O ports of the DP8KC primitive.

Table 575:

Port Name	I/O	Definition
CEA, CEB	I	Clock enable for port CLKA and CLKB
OCEA, OCEB	I	Output clock enable for port A and B
CLKA, CLKB	I	Clock for port A and B
RSTA, RSTB	I	Reset for port A and B
WEA, WEB	I	Write enable for port A and B
CSA[2:0], CSB[2:0]	I	Chip select for port A and B
DIA[8:0], DIB[8:0]	I	Input data port A and B (up to 9)
ADA[12:0], ADB[12:0]	I	Address bus port A and B (up to 13)
DOA[8:0], DOB[8:0]	O	Output data port A and B (up to 9)

You can refer to the following technical note on the Lattice web site for EBR port definition, attribute definition and usage.

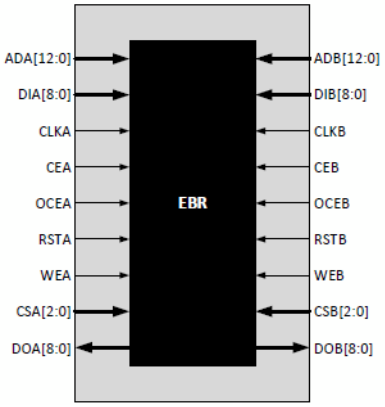
- TN1201 - Memory Usage Guide for MachXO2 Devices

DP8KE

True Dual Port EBR RAM

Architectures Supported:

- LIFMD



INPUTS: DIA8, DIA7, DIA6, DIA5, DIA4, DIA3, DIA2, DIA1, DIA0, ADA12, ADA11, ADA10, ADA9, ADA8, ADA7, ADA6, ADA5, ADA4, ADA3, ADA2, ADA1, ADA0, CEA, OCEA, CLKA, WEA, CSA2, CSA1, CSA0, RSTA, DIB8, DIB7, DIB6, DIB5, DIB4, DIB3, DIB2, DIB1, DIB0, ADB12, ADB11, ADB10, ADB9, ADB8, ADB7, ADB6, ADB5, ADB4, ADB3, ADB2, ADB1, ADB0, CEB, OCEB, CLKB, WEB, CSB2, CSB1, CSB0, RSTB OUTPUTS: DOA8, DOA7, DOA6, DOA5, DOA4, DOA3, DOA2, DOA1, DOA0, DOB8, DOB7, DOB6, DOB5, DOB4, DOB3, DOB2, DOB1, DOB0

OUTPUTS: DOA8, DOA7, DOA6, DOA5, DOA4, DOA3, DOA2, DOA1, DOA0, DOB8, DOB7, DOB6, DOB5, DOB4, DOB3, DOB2, DOB1, DOB0

ATTRIBUTES:

DATA_WIDTH_A: 1, 2, 4, 9 (default)

DATA_WIDTH_B: 1, 2, 4, 9 (default)

REGMODE_A: "NOREG" (default), "OUTREG"

REGMODE_B: "NOREG" (default), "OUTREG"

CSDECODE_A: any 3-bit binary value (default: 3’b000)

CSDECODE_B: any 3-bit binary value (default: 3’b000)

WRITEMODE_A: "NORMAL" (default), "WRITETHROUGH", "READBEFORE"

WRITEMODE_B: "NORMAL" (default), "WRITETHROUGH", "READBEFORE"

GSR: "ENABLED" (default), "DISABLED"

RESETMODE: "SYNC" (default), "ASYNC"

ASYNC_RESET_RELEASE: "SYNC" (default), "ASYNC"

INIT_DATA: "STATIC" (default), "DYNAMIC"

INITVAL_00 to INITVAL_1F: (*Verilog*) 320'hXXX...X (80-bit hex value)
(*VHDL*) 0xXXX...X (80-bit hex value)
Default: all zeros

Description

The following table describes the I/O ports of the DP8KE primitive.

Table 576:

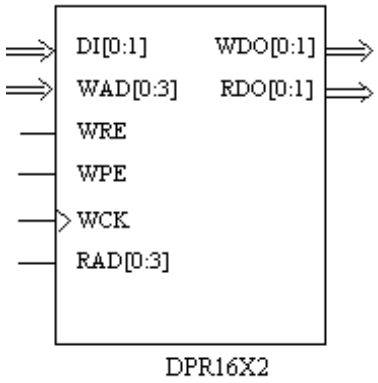
Port Name	Description
CEA, CEB	Clock Enables for Port CLKA and CLKB
OCEA, OCEB	Output Clock Enables for Port A and B
CLKA, CLKB	Clock for port A and port B
RSTA, RSTB	Reset for port A and port B
WEA, WEB	Write enable for port A and port B
CSA[2:0], CSB[2:0]	Chip Selects for port A and port B
DIA[8:0], DIB[8:0]	Input Data port A and port B
ADA[12:0], ADB[12:0]	Address Bus port A and port B
DOA [8:0], DOB[8:0]	Output Data Port A and port B
ADW[8:0]	Write Address
ADR[12:0]	Read Address

DPR16X2

Distributed Dual Port RAM

Architectures Supported:

- LatticeSC/M



INPUTS: DI0, DI1, WAD0, WAD1, WAD2, WAD3, WRE, WPE, WCK, RAD0, RAD1, RAD2, RAD3

OUTPUTS: WDO0, WDO1, RDO0, RDO1

ATTRIBUTES:

INITVAL: (*Verilog*) 64'hXXXXXXXX (16-bit hexadecimal value)
(*VHDL*) 0xXXXXXXXX (16-bit hexadecimal value)
Default: all zeros

GSR: "ENABLED" (default), "DISABLED"

Description

The DPR16X2 symbol represents a 16-word by 2-bit distributed dual port RAM. You can refer to the following technical note on the Lattice web site for port definition, attribute definition and usage.

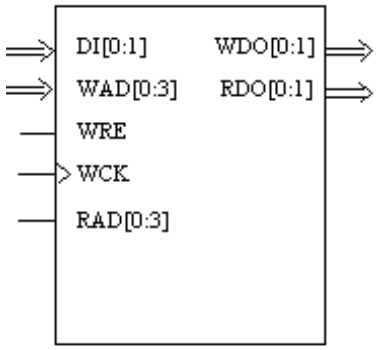
- TN1094 - On-Chip Memory Usage Guide for LatticeSC Devices

DPR16X2B

Distributed Dual Port RAM

Architectures Supported:

- LatticeECP/EC
- LatticeXP
- MachXO
- Platform Manager



DPR16X2B

INPUTS: DI0, DI1, WAD0, WAD1, WAD2, WAD3, WRE, WCK, RAD0, RAD1, RAD2, RAD3

OUTPUTS: WDO0, WDO1, RDO0, RDO1

Description

You can refer to the following technical notes on the Lattice web site for port definition, attribute definition and usage.

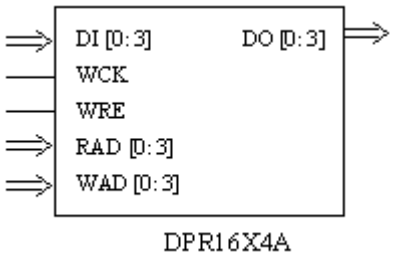
- TN1051 - Memory Usage Guide for LatticeECP/EC and LatticeXP Devices
- TN1092 - MachXO Memory Usage Guide

DPR16X4A

Distributed Pseudo Dual Port RAM

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



DPR16X4A

INPUTS: DI0, DI1, DI2, DI3, WCK, WRE, RAD0, RAD1, RAD2, RAD3, WAD0, WAD1, WAD2, WAD3

OUTPUTS: DO0, DO1, DO2, DO3

Description

PFU-based distributed Pseudo Dual-port RAM primitive. See Memory Primitives Overview for individual port description.

You can also refer to the following technical notes on the Lattice web site for port definition, attributes and usage.

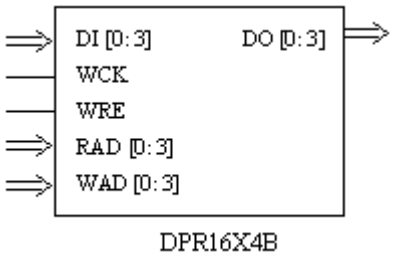
- TN1104 - LatticeECP2/M Memory Usage Guide
- TN1137 - LatticeXP2 Memory Usage Guide

DPR16X4B

Distributed Pseudo Dual Port RAM

Architectures Supported:

- LatticeXP2



INPUTS: WAD0, WAD1, WAD2, WAD3, DI0, DI1, DI2, DI3, WCK, WRE, RAD0, RAD1, RAD2, RAD3

OUTPUTS: DO0, DO1, DO2, DO3

ATTRIBUTES:

INITVAL: (*Verilog*) "64'hXXXXXXXXXXXXXXXX" (16-bit hex string)
(*VHDL*) "0xXXXXXXXXXXXXXXXX" (16-bit hex string)
Default: all zeros

Description

PFU-based distributed Pseudo Dual-port RAM primitive. See Memory Primitives Overview for individual port description.

You can also refer to the following technical note on the Lattice web site for port definition, attributes and usage.

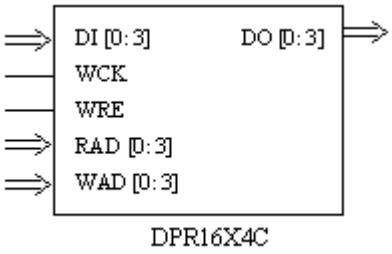
- TN1137 - LatticeXP2 Memory Usage Guide

DPR16X4C

Distributed Pseudo Dual Port RAM

Architectures Supported:

- ECP5
- LatticeECP3
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: DI3, DI2, DI1, DI0, WAD3,WAD2,WAD1,WAD0, WCK, WRE, RAD3,RAD2,RAD1,RAD0

OUTPUTS: DO3, DO2, DO1, DO0

ATTRIBUTES:

INITVAL: "0xXXXXXXXXXXXXXXXX" (16-bit hex string) (default: all zeros)

Description

PFU-based distributed Pseudo Dual-port RAM primitive. See Memory Primitives Overview for individual port description.

You can also refer to the following technical notes on the Lattice web site for port definition, attributes and usage.

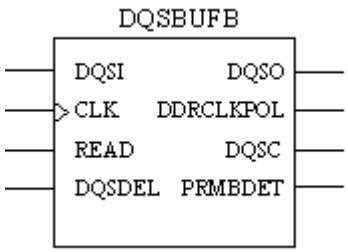
- TN1201 - Memory Usage Guide for MachXO2 Devices
- TN1179 - LatticeECP3 Memory Usage Guide

DQSBUFB

DDR DQS Buffer Used as DDR memory DQS generator

Architectures Supported:

- LatticeECP/EC
- LatticeXP



INPUTS: DQSI, CLK, READ, DQSDEL

OUTPUTS: DQSO, DDRCLKPOL, DQSC, PRMBDET

Description

This cell is used to indicate how many DDR I/Os need to be tied together, aligning the placement of the DDR cell. The input goes to the clock and the output goes to the clock on the DDR cell. For more usage, see related technical notes or contact technical support.

Refer to the following technical note on the Lattice web site for more details:

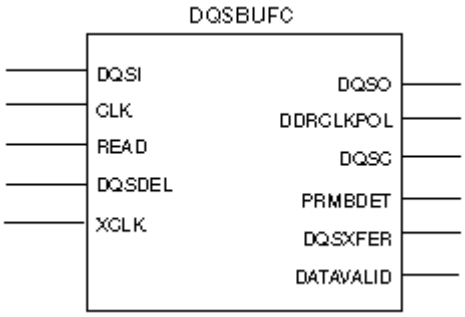
- TN1050 - LatticeECP/EC and LatticeXP DDR Usage Guide

DQSBUFC

DQS Delay Function and Clock Polarity Selection Logic

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



INPUTS: DQSI, CLK, XCLK, READ, DQSDEL

OUTPUTS: DQSO, DDRCLKPOL, DQSC, PRMBDET, DQSXFER, DATAVALID

ATTRIBUTES:

DQS_LI_DEL_VAL: integers 0~63 (PLUS), 1~64 (MINUS) (default: 4)

DQS_LI_DEL_ADJ: "MINUS" (default), "PLUS"

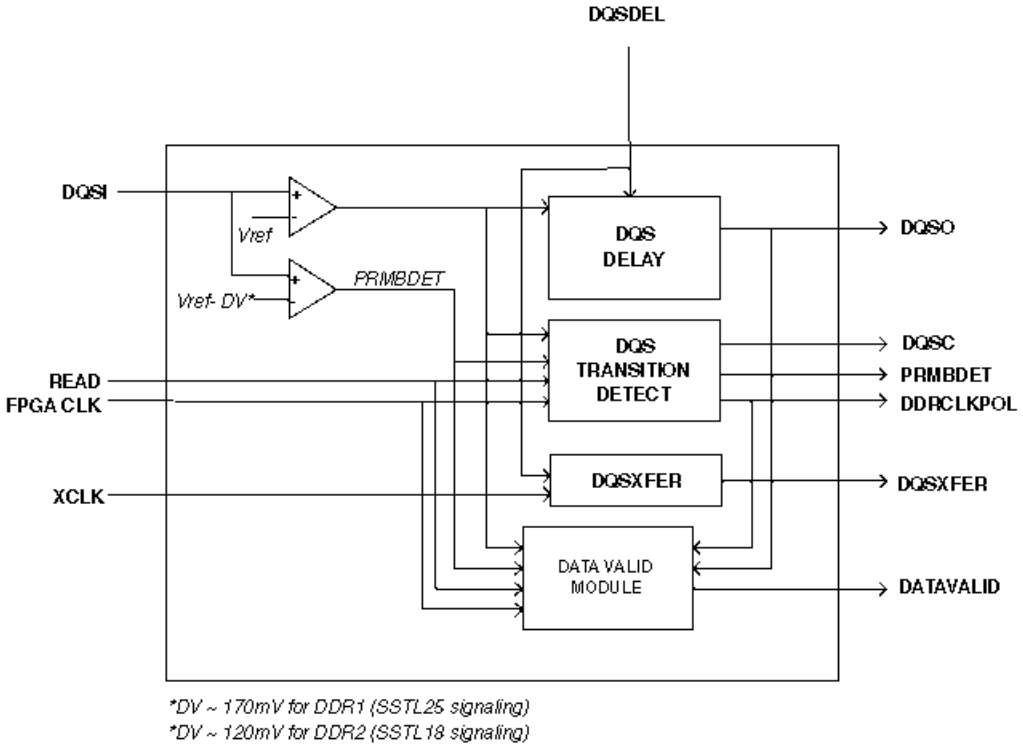
DQS_LO_DEL_VAL: integers 0~63 (PLUS), 1~64 (MINUS) (default: 0)

DQS_LO_DEL_ADJ: "PLUS" (default), "MINUS"

Description

DQSBUFC implements the DQS delay and the DQS transition detector logic. The primitive is composed of the DQS Delay, the DQS Transition Detect and the DQSXFER block as shown in the following figure. This block inputs the DQS and delays it by 90 degrees. It also generates the DDR Clock Polarity and the DQSXFER signal. The preamble detect (PRMBDET) signal is generated from the DQSI input using a voltage divider circuit.

DQSBUFC Function



DQS Delay Block: The DQS Delay block receives the digital control delay line (DQSDEL) coming from one of the two DQSDLL blocks. These control signals are used to delay the DQSI by 90 degrees. DQSO is the delayed DQS and is connected to the clock input of the first set of DDR registers.

DQS Transition Detect: The DQS Transition Detect block generates the DDR Clock Polarity signal based on the phase of the FPGA clock at the first DQS transition. The DDR READ control signal and FPGA CLK inputs to this coming and should be coming from the FPGA core.

DQSXFER: This block generates the 90-degree phase shifted clock to for the DDR Write interface. The input to this block is the XCLK. The user can choose to connect this either to the edge clock or the FPGA clocks. The DQSXFER is routed using the DQSXFER tree to all the I/Os spanned by that DQS.

Data Valid Module: The data valid module generates a DATAVALID signal. This signal indicates to the FPGA that valid data is transmitted out of the input DDR registers to the FPGA core.

The following table describes DQSBUFC I/O ports.

Table 577:

Port Name	I/O	Definition
DQSI	I	DQS strobe signal from memory.
CLK	I	System CLK.
READ	I	Read generated from the FPGA core.
DQSDEL	I	DQS delay from the DQSDLL primitive.
XCLK	I	Edge clock or system CLK.
DQSO	O	Delayed DQS strobe signal, to the input capture register block.
DQSC	O	DQS strobe signal before delay, going to the FPGA core logic.
DDRCLKPOL	O	DDR clock polarity signal.
PRMBDET	O	Preamble detect signal, going to the FPGA core logic.
DQSXFER	O	90 degree shifted clock going to the output DDR register block.
DTATVALID	O	Signal indicating transmission of valid data to the FPGA core.

READ Pulse Generation

The READ signal to the DQSBUFC block is internally generated in the FPGA core. The READ signal goes high when the READ command to control the DDR-SDRAM is initially asserted. This precedes the DQS preamble by one cycle, yet may overlap the trailing bits of a prior read cycle. The DQS Detect circuitry of the LatticeECP2 device requires the falling edge of the READ signal to be placed within the preamble stage.

The preamble state of the DQS can be detected using the CAS latency and the round trip delay for the signals between the FPGA and the memory device. Note that the internal FPGA core generates the READ pulse. The rise of the READ pulse should coincide with the initial READ command of the Read Burst and need to go low before the Preamble goes high.

Refer to the following technical notes on the Lattice web site for more details:

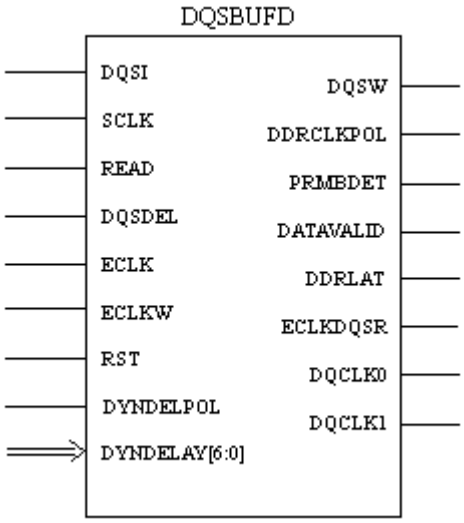
- TN1105 - LatticeECP2/M High-Speed I/O Interface
- TN1138 - LatticeXP2 High-Speed I/O Interface

DQSBUFD

DDR DQS Buffer Used for DDR3_MEM and DDR3_MEMGEN

Architectures Supported:

- LatticeECP3



INPUTS: DQSI, SCLK, READ, DQSDEL, ECLK, ECLKW, RST, DYNDELPOL, DYNDELAY6, DYNDELAY5, DYNDELAY4, DYNDELAY3, DYNDELAY2, DYNDELAY1, DYNDELAY0

OUTPUTS: DQSW, DDRCLKPOL, PRMBDET, DATAVALID, DDRLAT, ECLKDQSR, DQCLK0, DQCLK1

ATTRIBUTES:

DYNDEL_TYPE: "NORMAL" (default), "SHIFTED"

DYNDEL_VAL: integers 0~63 (PLUS), 1~64 (MINUS) (default: 0)

DYNDEL_CNTL: "DYNAMIC" (default), "STATIC"

(*EA only*) NRZMODE: "DISABLED" (default), "ENABLED"

Description

DQSBUFD is the DDR DQS buffer used for DDR3_MEM (DDR3 memory mode) and DDR3_MEMGEN.

- E and EA: DDR3_MEM and DDR3_MEMGEN (left/right)
- EA: DDR3_MEMGEN (top) – only input side

The table below describes the I/O ports.

Table 578:

Signal	I/O	Description
DQSI	I	DQS input coming from the pad.
SCLK	I	System clock.
READ	I	READ signal generated from the FPGA core.
RST	I	Reset input.
DQSDEL	I	Delay input from DQSDLL.
ECLK	I	Edge clock.
ECLKW	I	Edge clock used for the DDR write side.
DYNDELAY[6:0]	I	From user logic to DLL ADW & write clock generation.
DYNDELPOL	I	From user logic to DLL ADW & write clock generation. Will change the polarity of the clock depending on the clock frequency.
DQSW	O	DQS write clock.
DDRCLKPOL	O	DDR clock polarity signal.
PRMBDET	O	The preamble detect signal generated from the DQS signal going to the CIB. DQSI biased to go high when DQSI is tri-state.
DATAVALID	O	Signal indicating the transmission of valid data to the FPGA core.
DDRLAT	O	DDR latch control to input logic. Used to guarantee IDDRX2 gearing by selectively enabling a D flip-flop in the data path.
ECLKDQSR	O	Delay DQS used to capture the data.
DQCLK0	O	One clock edge, at half the frequency of ECLK, used in output gearing, 90 degree out of phase from DQCLK1.
DQCLK1	O	One clock edge, at the frequency of SCLK, used in output gearing.

Refer to the following technical note on the Lattice web site for more details:

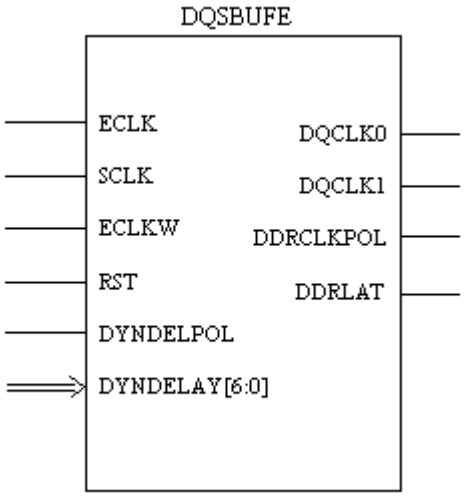
- TN1180 - LatticeECP3 High-Speed I/O Interface

DQSBUFE

DDR DQS Buffer Used for DDR_GENX2

Architectures Supported:

- LatticeECP3



INPUTS: ECLK, SCLK, ECLKW, RST, DYNDELPOL, DYNDELAY6, DYNDELAY5, DYNDELAY4, DYNDELAY3, DYNDELAY2, DYNDELAY1, DYNDELAY0

OUTPUTS: DQCLK0, DQCLK1, DDRCLKPOL, DDRLAT

ATTRIBUTES:

DYNDEL_TYPE: "NORMAL" (default), "SHIFTED"

DYNDEL_VAL: integers 0~63 (PLUS), 1~64 (MINUS) (default: 0)

DYNDEL_CNTL: "DYNAMIC" (default), "STATIC"

Description

DQSBUFE is the DDR DQS buffer used for DDR_GENX2 (DDR generic mode in X2 gearing).

- E: DDR_GENX2 (left/right/top)

The table below describes the I/O ports.

Table 579:

Signal	I/O	Description
SCLK	I	System clock.
ECLK	I	Edge clock.
ECLKW	I	Edge clock used for the DDR write side.
RST	I	Reset input.
DYNDELAY[6:0]	I	From user logic to DLL ADW & write clock generation.

Table 579:

Signal	I/O	Description
DYNDELPOL	I	From user logic to DLL ADW & write clock generation. Will change the polarity of the clock depending on the clock frequency.
DDRCLKPOL	O	DDR clock polarity signal.
DDRLAT	O	DDR latch control to input logic. Used to guarantee IDDRX2 gearing by selectively enabling a D flip-flop in the data path.
DQCLK0	O	One clock edge, at half the frequency of ECLK, used in output gearing, 90 degree out of phase from DQCLK1.
DQCLK1	O	One clock edge, at half the frequency of SCLK, used in output gearing.

Refer to the following technical note on the Lattice web site for more details:

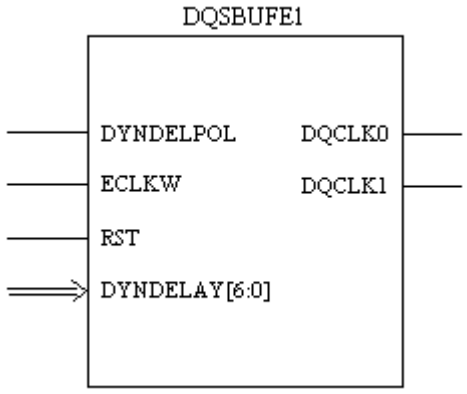
- TN1180 - LatticeECP3 High-Speed I/O Interface

DQSBUFE1

DDR DQS Buffer Used for DDR_GENX2

Architectures Supported:

- LatticeECP3



INPUTS: ECLKW, RST, DYNDELPOL, DYNDELAY6, DYNDELAY5, DYNDELAY4, DYNDELAY3, DYNDELAY2, DYNDELAY1, DYNDELAY0

OUTPUTS: DQCLK0, DQCLK1

ATTRIBUTES:

DYNDEL_TYPE: "NORMAL" (default), "SHIFTED"

DYNDEL_VAL: integers 0~63 (PLUS), 1~64 (MINUS) (default: 0)

DYNDEL_CNTL: "DYNAMIC" (default), "STATIC"

Description

DQSBUFE1 is the DDR DQS buffer used for DDR_GENX2 (DDR generic mode in X2 gearing).

- EA: DDR_GENX2 (left/right)
- EA: DDR_GENX2 (top)

The table below describes the I/O ports.

Table 580:

Signal	I/O	Description
ECLKW	I	Edge clock used for the DDR write side.
RST	I	Reset input.
DYNDELAY[6:0]	I	From user logic to DLL ADW & write clock generation.
DYNDELPOL	I	From user logic to DLL ADW & write clock generation. Will change the polarity of the clock depending on the clock frequency.
DQCLK0	O	One clock edge, at half the frequency of ECLK, used in output gearing, 90 degree out of phase from DQCLK1.
DQCLK1	O	One clock edge, at half the frequency of SCLK, used in output gearing.

Refer to the following technical note on the Lattice web site for more details:

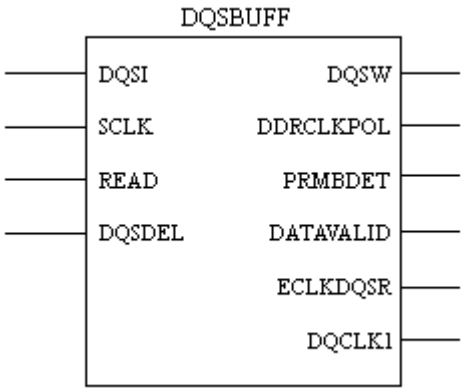
- TN1180 - LatticeECP3 High-Speed I/O Interface

DQSBUFF

DDR DQS Buffer Used for DDR_MEM, DDR2_MEM, and DDR2_MEMGEN

Architectures Supported:

- LatticeECP3



INPUTS: DQSI, SCLK, READ, DQSDEL

OUTPUTS: DQSW, DDRCLKPOL, PRMBDET, DATAVALID, ECLKDQSR, DQCLK1

Description

DQSBUFF is the DDR DQS buffer used for DDR_MEM (DDR memory mode), DDR2_MEM (DDR2 memory mode), and DDR2_MEMGEN.

- E and EA: DDR_MEM, DDR2_MEM, and DDR2_MEMGEN (left/right/top)

The table below describes the I/O ports.

Table 581:

Signal	I/O	Description
DQSI	I	DQS input coming from the pad.
SCLK	I	System clock.
READ	I	READ signal generated from the FPGA core.
DQSDEL	I	Delay input from DQSDLL.
DQSW	O	DQS write clock.
DDRCLKPOL	O	DDR clock polarity signal.
PRMBDET	O	The preamble detect signal generated from the DQS signal going to the CIB. DQSI biased to go high when DQSI is tri-state.
DATAVALID	O	Signal indicating the transmission of valid data to the FPGA core.
ECLKDQSR	O	Delay DQS used to capture the data.
DQCLK1	O	One clock edge, at the frequency of SCLK, used in output gearing.

Refer to the following technical note on the Lattice web site for more details:

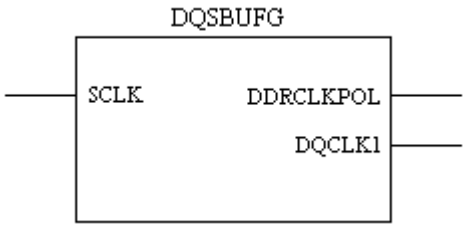
- TN1180 - LatticeECP3 High-Speed I/O Interface

DQSBUFG

DDR DQS Buffer Used for DDR_GENX1

Architectures Supported:

- LatticeECP3



INPUTS: SCLK

OUTPUT: DDRCLKPOL, DQCLK1

Description

DQSBUFG is the DDR DQS buffer used for DDR_GENX1 (DDR generic mode in X1 gearing).

- E: DDR_GENX1 (left/right/top)
- EA: Not allowed because it is not required

The table below describes the I/O ports.

Table 582:

Signal	I/O	Description
SCLK	I	System clock.
DDRCLKPOL	O	DDR clock polarity signal.
DQCLK1	O	One clock edge, at half the frequency of SCLK, used in output gearing.

Refer to the following technical note on the Lattice web site for more details:

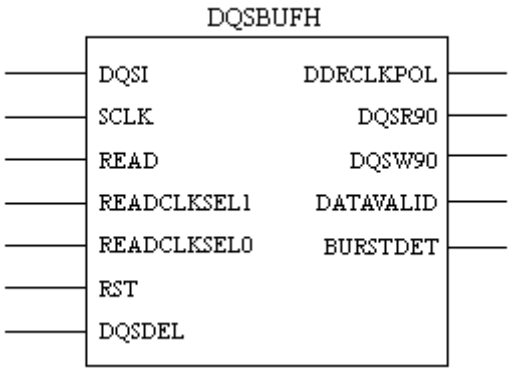
- TN1180 - LatticeECP3 High-Speed I/O Interface

DQSBUFH

DQS Circuit for DDR Memory

Architectures Supported:

- MachXO2
- Platform Manager 2



INPUTS: DQSI, SCLK, READ, READCLKSEL1, READCLKSEL0, RST, DQSDEL

OUTPUTS: DDRCLKPOL, DQSR90, DQSW90, DATAVALID, BURSTDET

ATTRIBUTES:

DQS_LI_DEL_ADJ: "PLUS" (default), "MINUS"

DQS_LI_DEL_VAL: integers 0~63 (PLUS), 1~64 (MINUS) (default: 0)

DQS_LO_DEL_ADJ: "PLUS" (default), "MINUS"

DQS_LO_DEL_VAL: integers 0~63 (PLUS), 1~64 (MINUS) (default: 0)

LPDDR: "DISABLED" (default), "ENABLED"

GSR: "ENABLED" (default), "DISABLED"

Description

DQSBUFH is the DQS circuit for DDR memory. It generates the 90 degree shift for DQS, and the DDRCLKPOL signal. It is used for right side only. The table below describes the I/O ports.

Table 583:

Signal	I/O	Description
DQSI	I	DQS signal from PIO.
READ	I	Signal for DDR read mode, coming from soft IP.
READCLKSEL1, READCLKSEL0	I	Select read clock source and polarity control for READ pulse position control in T/4 precision. The four positions are the rising/falling edges of SCLK or DQSW90. The signals come from soft IP.
SCLK	I	Clock from CIB.
RST	I	RESET for this block.
DQSDEL	I	DQS slave delay control from DQSDLLC.
DDRCLKPOL	O	SCLK polarity control.
DQSR90	O	DQS phase shifted by 90 degree output.
DQSW90	O	SCLK phase shifted by 90 degree output.
DATAVALID	O	Data valid signal for READ mode.
BURSTDET	O	Burst detection signal, moved from soft IP to hardware implementation.

Refer to the following technical note on the Lattice web site for more details:

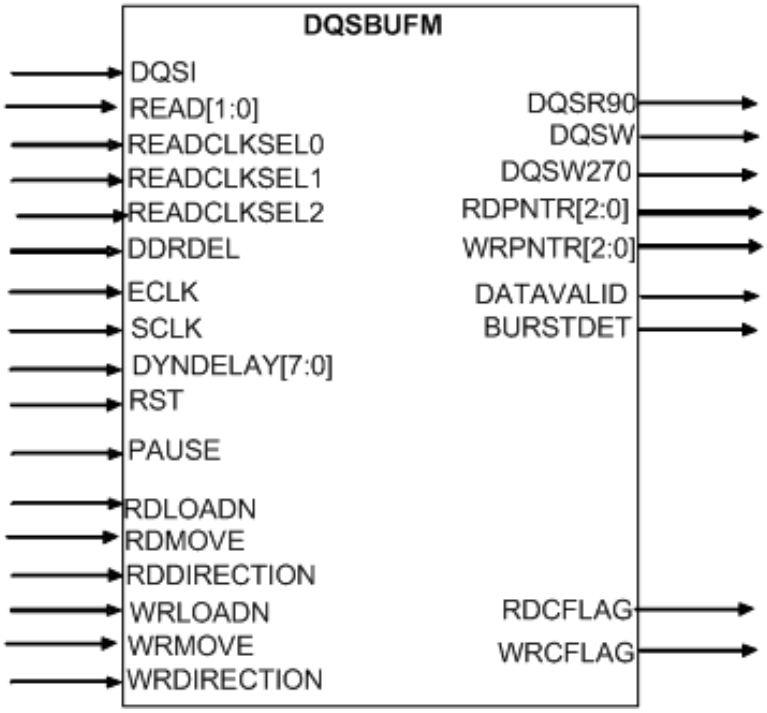
- TN1203 - Implementing High-Speed Interfaces with MachXO2 Devices

DQSBUFM

DQS Circuit for DDR Memory

Architectures Supported:

- ECP5



INPUTS: DQSI, SCLK, READ0, READ1, READCLKSEL0, READCLKSEL1, READCLKSEL2, DDRDEL, ECLK, SCLK, DYNDELAY0, DYNDELAY1, DYNDELAY2, DYNDELAY3, DYNDELAY4, DYNDELAY5, DYNDELAY6, DYNDELAY7, RST, PAUSE, RDLOADN, RDMOVE, RDDIRECTION, WRLOADN, WRMOVE, WRDIRECTION

OUTPUTS: DWSR90, DQSW, DQSW270, RDPNTR0, RDPNTR1, RDPNTR2, WRPNTR0, WRPNTR1, WRPNTR2, DATAVALID, BURSTDET, RDCFLAG, WRCFLAG

ATTRIBUTES:

DQS_LI_DEL_ADJ: "PLUS" (default), "MINUS"

DQS_LI_DEL_VAL: integers 0~63 (PLUS), 1~64 (MINUS) (default: 0)

DQS_LO_DEL_ADJ: "PLUS" (default), "MINUS"

DQS_LO_DEL_VAL: integers 0~63 (PLUS), 1~64 (MINUS) (default: 0)

WRITE_LEVELING: Values: 0T, 1T (default: 0T)

Description

DQSBUFM element is used for DDR3 and DDR2 in X2 mode.

Port Name	I/O	Description
DQSI	I	DQS input from the DQS pin
DDRDEL	I	Delay code from DDRDLL
ECLK	I	Edge Clock
SCLK	I	System Clock
RST	I	Reset Input
READ[1:0]	I	Read input width for DQSBUFM
READCLKSEL0, READCLKSEL1, READCLKSEL2	I	Read clock pulse selection
DYNDELAY[7:0]	I	Dynamic Write leveling delay (only for DDR3)
PAUSE	I	Pause input to stop the DQSW/DQSW270 during write leveling or DDRDLL delay code change.
RDLOADN	I	Used to reset back to 90 degrees delay for Read Side DQS
RDMOVE	I	Pulse is required to change delay settings. The value on Direction will be sampled at “falling edge” of MOVE. Used to change delay on the Read side DQS.
RDDIRECTION	I	Indicates delay direction. “1” decrease delay count, “0” increase delay count. Used to change delay on the Read side DQS.
RDCFLAG	O	Indicates the delay counter has reached max value for the Read side DQS delay.
WRLOADN	I	Used to reset back to 90 degrees delay for Write Side DQS
WRMOVE	I	Pulse is required to change delay settings. The value on Direction will be sampled at “falling edge” of MOVE. Used to change delay on the Write side DQS.
WRDIRECTION	I	Indicates delay direction. “1” decrease delay count, “0” increase delay count. Used to change delay on the Write side DQS.
WRCFLAG	O	Indicates the delay counter has reached max value for the Write side DQS delay.
DQSR90	O	90 delay DQS used for Read
DQSW270	O	90 delay clock used for DQ Write

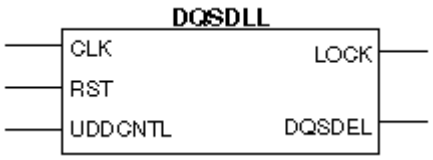
DQSW	O	Clock used for DQS Write
RDPNTR[2:0]	O	Read Pointer for IFIFO module
WRPNTR[2:0]	O	Write Pointer for IFIFO module
DATAVALID	O	Signal indicating start of valid data
BURSTDET	O	Burst Detect indicator

DQSDLL

DLL used as DDR memory DQS DLL

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeXP
- LatticeXP2



INPUTS: CLK, RST, UDDCNTL

OUTPUTS: LOCK, DQSDEL

ATTRIBUTES:

LOCK_SENSITIVITY: "LOW" (default), "HIGH"

Description

DQS delay calibration DLL. The primitive generates a 90-degree phase shift required for the DQS signal and implements the on-chip DQSDLL. Only one DQSDLL should be instantiated for all the DDR implementations on one half of the device. The clock input to this DLL should be at the same frequency as the DDR interface. DLL generates the delay based on this clock frequency and the update control input to this block. The DLL updates the dynamic delay

control to the DQS delay block when this update control (UDDCNTL) input is asserted. The active low signal on UDDCNTL updates the DQS phase alignment and should be initiated at the beginning of READ cycles.

Table 584:

Port Name	I/O	Definition
CLK	I	System CLK should be at the frequency of the DDR interface from the FPGA core.
RST	I	Resets the DQSDLL
UDDCNTL	I	This is an active low port. It provides an update signal to the DLL that will update the dynamic delay. When held low, this signal will update the DQSDEL.
LOCK	O	Indicates when the DLL is in phase.
DQSDEL	O	The digital delay generated by the DLL, should be connected to the DQSBUF primitive.

DQSDLL Configuration: By default, this DLL generates a 90-degree phase shift for the DQS strobe based on the frequency of the input reference clock to the DLL. The user can control the sensitivity to jitter by using the LOCK_SENSITIVITY attribute. This configuration bit can be programmed to be either “HIGH” or “LOW”. The DLL Lock Detect circuit has two modes of operation controlled by the LOCK_SENSITIVITY bit, which selects more or less sensitivity to jitter. If this DLL is operated at or above 150 MHz, it is recommended that the LOCK_SENSITIVITY bit be programmed “HIGH” (more sensitive). When running at or below 100 MHz, it is recommended that the bit be programmed “LOW” (more tolerant). For 133 MHz, the LOCK_SENSITIVITY bit can go either way.

Refer to the following technical notes on the Lattice web site for more details

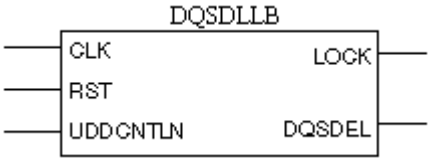
- TN1050 - LatticeECP/EC and LatticeXP DDR Usage Guide
- TN1105 - LatticeECP2/M High-Speed I/O Interface
- TN1138 - LatticeXP2 High-Speed I/O Interface

DQSDLLB

DQS DLL for DDR_MEM, DDR2_MEM, and DDR3_MEM

Architectures Supported:

- LatticeECP3



INPUTS: CLK, RST, UDDCNTLN

OUTPUTS: LOCK, DQSDEL

ATTRIBUTES:

LOCK_SENSITIVITY: "LOW" (default), "HIGH"

Description

DQSDLLB is the DLL used as DDR memory DQS DLL.

- E and EA: DDR_MEM, DDR2_MEM, and DDR3_MEM (left/right)

The table below describes the I/O ports.

Table 585:

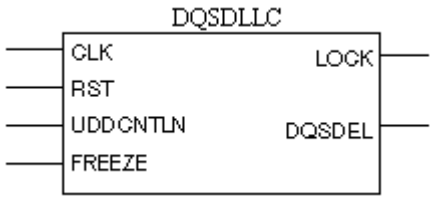
Signal	I/O	Description
CLK	I	Clock from the CIB, coming from a PLL. The clock should run at the DDR memory frequency.
RST	I	RESET input to the master DLL.
UDDCNTLN	I	Update control generated from the core.
DQSDEL	O	DQS delay generated by DQSDLL.
LOCK	O	Lock output of the DQSDLL to the CIB.

DQSDLLC

Master DLL for Generating Required Delay

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: CLK, RST, UDDCNTLN, FREEZE

OUTPUTS: LOCK, DQSDEL

ATTRIBUTES:

DEL_ADJ: "PLUS" (default), MINUS

DEL_VAL: integers 0~127 (PLUS), 1~128 (MINUS) (default: 0)

LOCK_SENSITIVITY: "LOW" (default), "HIGH"

FIN: value range supported by DLL (default: "100.0")

FORCE_MAX_DELAY: "NO" (default), "YES"

GSR: "ENABLED" (default), "DISABLED"

Description

DQSDLLC is the master DLL to generate required delay. See the table below for I/O port descriptions.

Table 586:

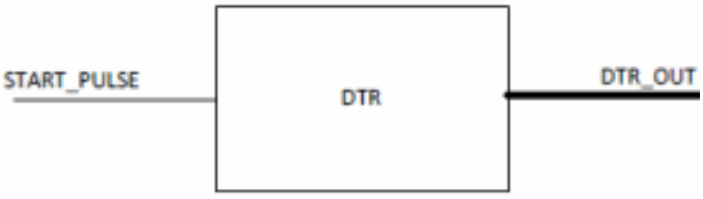
Signal	I/O	Description
CLK	I	Clock from the CIB.
RST	I	DLL reset control.
UDDCNTLN	I	Hold/update control to delay code before adjustment.
FREEZE	I	Signal used to freeze or release DLL input CLK.
DQSDEL	O	DLL delay control code to slave delay cells, connected to DQSDEL of the DQSBUFH element.
LOCK	O	DLL lock signal.

DTR

Digital Temperature Readout

Architectures Supported:

- ECP5



INPUTS: START_PULSE

OUTPUTS: DTR_OUT

Description

Digital Temperature Readout (or DTR) is an on board temperature sensing circuit that provides the junction temperature of the die while running.

See the table below for I/O port descriptions.

Table 587:

Signal	I/O	Description
START_PULSE	I	Pulse to instruct DTR to start capturing temperature.
DTR_OUT	O	8 bit DTR output

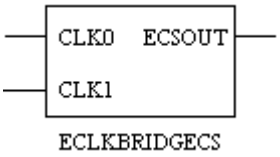
E

ECLKBRIDGECS

ECLK Bridge Block Clock Select

Architectures Supported:

- ECP5
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: CLK0, CLKI, SEL

OUTPUT: ECSOUT

Description

ECLK high speed bridge eases the design of high speed video or DDRX4 mode applications. It takes the high speed edge clocks sources from both sides (top and bottom). The bridge enhances the communication of ECLKs across the die. The bridge is supported for devices equal to or above 1200 LUTs.

The table below describes the I/O ports of the ECLKBRIDGECS primitive.

Table 588:

Port	I/O	Unused Port	Function
CLK0	I	Tie low	Input clock to the edge bridge clock select.
CLK1	I	Tie low	Input clock to the edge bridge clock select.
SEL	I	Tie low	From CIB, edge bridge clock select.
ECSOUT	O	Dangle	Output from edge bridge clock select.

ECLKBRIDGECS Usage with VHDL

Library Instantiation

```
library lattice;
use lattice.components.all;
```

Component Declaration

```
component ECLKBRIDGECS
   port (CLK0   : in std_logic;
         CLK1   : in std_logic;
         SEL    : in std_logic;
         ECSOUT : out std_logic);
end component;
```

ECLKBRIDGECS Instantiation

```
I1: ECLKBRIDGECS
   port map (CLK0   => CLK0;
             CLK1   => CLK1;
             SEL    => SEL;
             ECSOUT => ECSOUT);
end component;
```

ECLKBRIDGECS Usage with Verilog HDL

Component Declaration

```
module ECLKBRIDGECS (CLK0,
                     CLK1,
                     SEL,
                     ECSOUT);
input CLK0;
input CLK1;
input SEL;
output ECSOUT;
endmodule
```

ECLKBRIDGECS Instantiation

```
ECLKBRIDGECS I1 (.CLK0 (CLK0),
                 .CLK1 (CLK1),
                 .SEL   (SEL),
                 .ECSOUT (ECSOUT));
```

For more information and usage, refer to the following technical note on the Lattice web site.

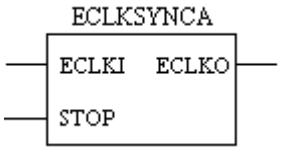
- TN1199 - MachXO2 sysCLOCK PLL Design and Usage Guide

ECLKSYNCA

ECLK Stop Block

Architectures Supported:

- LatticeECP3
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: ECLKI, STOP

OUTPUT: ECLKO

Description

ECLKSYNCA is the optional ECLK synchronization for DDR_MEM (DDR memory mode), DDR2_MEM (DDR2 memory mode), and DDR3_MEM (DDR3 memory mode).

- E and EA: DDR_MEM, DDR2_MEM, and DDR3_MEM (left/right/top)

The table below describes the I/O ports of the ECLKSYNCA primitive.

Table 589:

Port	I/O	Unused Port	Function
ECLKI	I	Tie low	Edge clock input to the stop clock
STOP	I	Tie low	Control signal to stop the edge clock to synchronize the signals derived from ECLK
ECLKO	O	Dangle	Edge clock output from the stop clock

ECLKSYNCA Usage with VHDL

Library Instantiation

```
library lattice;
use lattice.components.all;
```

Component Declaration

```
component ECLKSYNCA
   port (ECLKI : in std_logic;
         STOP  : in std_logic;
         ECLKO : out std_logic);
end component;
```

ECLKSYNCA Instantiation

```
I1: ECLKSYNCA
   port map (ECLKI => ECLKI,
             STOP => STOP,
             ECLKO => ECLKO);
end component;
```

ECLKSYNCA Usage with Verilog HDL

Component Declaration

```
module ECLKSYNCA (ECLKI,  STOP, ECLKO);
input ECLKI;
input STOP;
output ECLKO;
endmodule
```

ECLKSYNCA Instantiation

```
ECLKSYNCA I1 (.ECLKI (ECLKI);
              .STOP (STOP);
              .ECLKO (ECLKO));
```

For more information and usage, refer to the following technical notes on the Lattice web site.

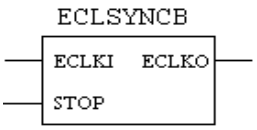
- TN1199 - MachXO2 sysCLOCK PLL Design and Usage Guide
- TN1177 - LatticeECP3 sysIO Usage Guide

ECLKSYNCB

ECLK Stop Block

Architectures Supported:

- ECP5
- LIFMD



INPUTS: ECLKI, STOP

OUTPUT: ECLKO

Description

ECLKSYNCB is the optional ECLK synchronization for DDR_MEM (DDR memory mode), DDR2_MEM (DDR2 memory mode), and DDR3_MEM (DDR3 memory mode). The ECP5 ECLKSYNC is similar to MachXO2 and LaticeECP3 (ECLKSYNA), however it has some added latency.

Asserting the STOP control signal (from CIB) will stop the edge clock and synchronize the signals from ECLK used in high speed DDR mode applications such as DDR memory, generic DDR and 7:1 LVDS. The STOP signal is synchronized with ECLK when asserted. When the STOP signal is released, every clock toggling from the second rising edge clock & after will be output.

The table below describes the I/O ports of the ECLKSYNCB primitive.

Table 590:

Port	I/O	Unused Port	Function
ECLKI	I	Tie low	Edge clock input to the stop block
STOP	I	Tie low	Control signal to stop the edge clock
ECLKO	O	Dangle	Edge clock output from the stop block

ECLKSYNCB Usage with VHDL

Component Declaration

```
component ECLKSYNCB port (
ECLKI : in std_logic;
STOP : in std_logic;
ECLKO : out std_logic);
end component;
```

ECLKSYNCB Instantiation

```
I1: ECLKSYNCB port map (
ECLKI => ECLKI,
STOP => STOP,
ECLKO => ECLKO);
end component;
```

ECLKSYNCB Usage with Verilog HDL

Component Declaration

```
module ECLKSYNCB (ECLKI, STOP, ECLKO)
input ECLKI;
input STOP;
output ECLKO;
endmodule
```

ECLKSYNCB Instantiation

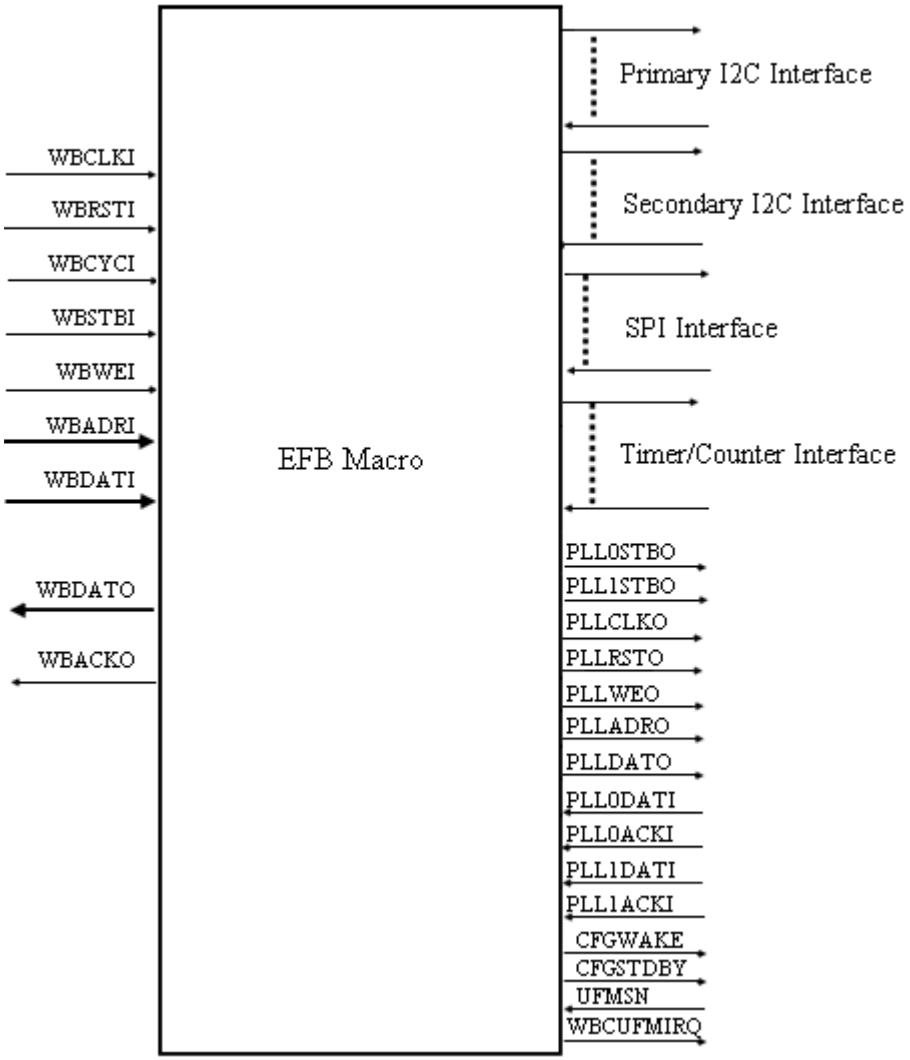
```
ECLKSYNCB I1 (.ECLKI (ECLKI), .STOP (STOP), .ECLKO (ECLKO));
```

EFB

Embedded Function Block

Architectures Supported:

- MachXO2
- MachXO3L
- Platform Manager 2



INPUTS: WBCLKI, WBRSTI, WBCYCI, WBSTBI, WBWEI, WBADRI7, WBADRI6, WBADRI5, WBADRI4, WBADRI3, WBADRI2, WBADRI1, WBADRI0, WBDATI7, WBDATI6, WBDATI5, WBDATI4, WBDATI3, WBDATI2, WBDATI1, WBDATI0, PLL0DATI7, PLL0DATI6, PLL0DATI5, PLL0DATI4, PLL0DATI3, PLL0DATI2, PLL0DATI1, PLL0DATI0, PLL0ACKI, PLL1DATI7, PLL1DATI6, PLL1DATI5, PLL1DATI4, PLL1DATI3, PLL1DATI2, PLL1DATI1, PLL1DATI0, PLL1ACKI, I2C1SCLI, I2C1SDAI, I2C2SCLI, I2C2SDAI, SPISCKI, SPIMISOI, SPIMOSII, SPISCSN, TCCLKI, TCRSTN, TCIC, UFMSN

OUTPUTS: WBDATO7, WBDATO6, WBDATO5, WBDATO4, WBDATO3, WBDATO2, WBDATO1, WBDATO0, WBACKO, PLLCLKO, PLLRSTO, PLL0STBO, PLL1STBO, PLLWEO, PLLADRO4, PLLADRO3, PLLADRO2, PLLADRO1, PLLADRO0, PLLDATO7, PLLDATO6, PLLDATO5, PLLDATO4, PLLDATO3, PLLDATO2, PLLDATO1, PLLDATO0, I2C1SCLO, I2C1SCLOEN, I2C1SDAO, I2C1SDAOEN, I2C2SCLO, I2C2SCLOEN, I2C2SDAO, I2C2SDAOEN, I2C1IRQO, I2C2IRQO, SPISCKO, SPISCKEN, SPIMISOO, SPIMISOEN, SPIMOSIO, SPIMOSIEN, SPIMCSN0, SPIMCSN1, SPIMCSN2, SPIMCSN3, SPIMCSN4, SPIMCSN5, SPIMCSN6, SPIMCSN7, SPICSNEN, SPIIRQO, TCINT, TCOC, WBCUFMIRQ, CFGWAKE, CFGSTDBY

Description

The EFB primitive has seven explicit interfaces: WISHBONE, SPI, I2C (Primary), I2C (Secondary), Timer/Counter, and two PLLs.

DEV_DENSITY:

MachXO2: "256L", "640L", "1200L", "2000L", "4000L", "7000L", "10000L", "640U", "1200U", "2000U", "4000U"

MachXO3LF: "640L_121P", "1300L", "2100L", "4300L", "1300L_256P", "2100L_324P", "4300L_400P", "6900L"

For detailed information regarding the GUI, interface, and usage regarding each EFB interface, refer to the following technical note on the Lattice web site:

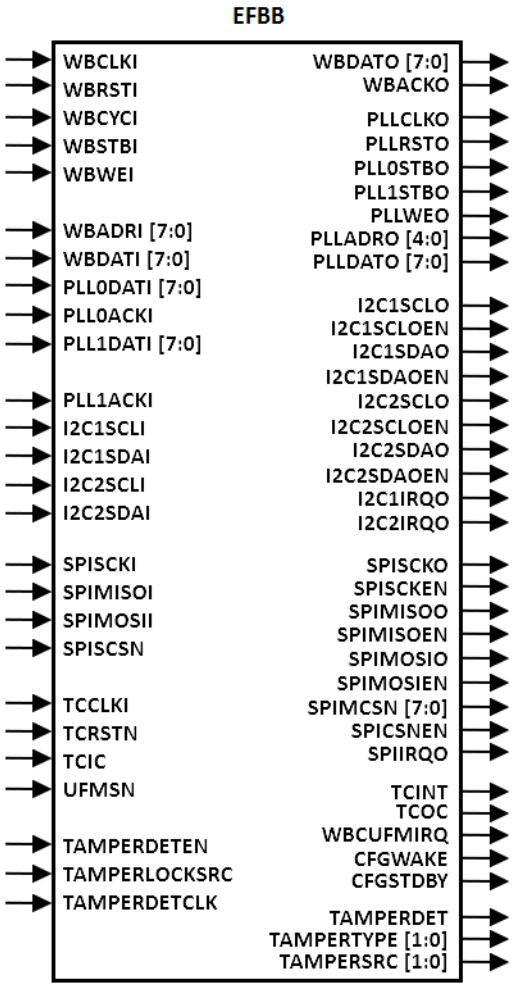
- TN1205 - Using User Flash Memory and Hardened Control Functions in MachXO2 Devices

EFBB

Embedded Function Block for MachXO3D

Architectures Supported:

- MachXO3D



INPUTS: WBCLKI, WBRSTI, WBCYCI, WBSTBI, WBWEI, WBADRI7, WBADRI6, WBADRI5, WBADRI4, WBADRI3, WBADRI2, WBADRI1, WBADRI0, WBDATI7, WBDATI6, WBDATI5, WBDATI4, WBDATI3, WBDATI2, WBDATI1, WBDATI0, PLL0DATI7, PLL0DATI6, PLL0DATI5, PLL0DATI4, PLL0DATI3, PLL0DATI2, PLL0DATI1, PLL0DATI0, PLL0ACKI, PLL1DATI7, PLL1DATI6, PLL1DATI5, PLL1DATI4, PLL1DATI3, PLL1DATI2, PLL1DATI1, PLL1DATI0, PLL1ACKI, I2C1SCLI, I2C1SDAI, I2C2SCLI, I2C2SDAI, SPISCKI, SPIMISOI, SPIMOSII, SPISCSN, TCCLKI, TCRSTN, TCIC, UFMSN,

OUTPUTS: WBDATO7, WBDATO6, WBDATO5, WBDATO4, WBDATO3, WBDATO2, WBDATO1, WBDATO0, WBACKO, PLLCLKO, PLLRSTO, PLL0STBO, PLL1STBO, PLLWEO, PLLADRO4, PLLADRO3, PLLADRO2, PLLADRO1, PLLADRO0, PLLDATO7, PLLDATO6, PLLDATO5, PLLDATO4, PLLDATO3, PLLDATO2, PLLDATO1, PLLDATO0, I2C1SCLO, I2C1SCLOEN, I2C1SDAO, I2C1SDAOEN, I2C2SCLO, I2C2SCLOEN, I2C2SDAO, I2C2SDAOEN, I2C1IRQO, I2C2IRQO,SPISCKO, SPISCKEN, SPIMISOO, SPIMISOEN, SPIMOSIO, SPIMOSIEN,SPIMCSN0, SPIMCSN1, SPIMCSN2, SPIMCSN3, SPIMCSN4, SPIMCSN5, SPIMCSN6, SPIMCSN7, SPICSNEN, SPIIRQO, TCINT, TCOC, WBCUFMIRQ, CFGWAKE, CFGSTDBY;

Description:

The EFBB primitive is based on EFB primitive with addition of parameters related to UFM.

Description:

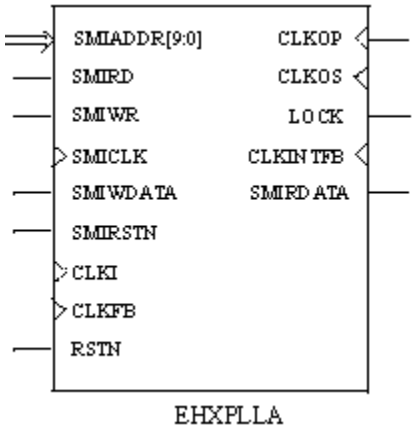
Embedded Function Block (EFB) (formerly known as the CFG block). The EFB includes a SPI, two I2C’s, and a timer/counter peripheral.

EHXPLLA

Enhanced High Performance with Dynamic Input Delay Control PLL

Architectures Supported:

- LatticeSC/M



INPUTS: SMIADDR9, SMIADDR8, SMIADDR7, SMIADDR6, SMIADDR5, SMIADDR4, SMIADDR3, SMIADDR2, SMIADDR1, SMIADDR0, SMIRD, SMIWR, SMICLK, SMIWDATA, SMIRSTN, CLKI, CLKFB, RSTN

OUTPUTS: CLKOP, CLKOS, LOCK, CLKINTFB, SMIRDATA

ATTRIBUTES:

CLKI_DIV: integers 1~64 (default: 1)

CLKFB_DIV: integers 1~64 (default: 1)

CLKOP_DIV: integers 1~64 (default: 1)

CLKOS_DIV: integers 1~64 (default: 1)

CLKI_FDEL: 0 (default), 100, 200, ..., 700

CLKFB_FDEL: 0 (default), 100, 200, ..., 700

CLKOS_FDEL: 0 (default), 100, 200, ..., 700

CLKOP_MODE: "BYPASS" (default), "FDEL0", "VCO", "DIV"

CLKOS_MODE: "BYPASS" (default), "FDEL", "VCO", "DIV"

PHASEADJ: 0 (default), 45, 90, 135, 190, 225, 270, 315

GSR: "ENABLED" (default), "DISABLED"

SMI_OFFSET: 0x400~0x7FF (default: 12'h410)

LOCK_DELAY: integers 0~1000 (in ns) (default: 100)

CLKOS_VCODEL: integers 0~31 (default: 0)

MODULE_TYPE: "EHXPLLA"

IP_TYPE: "EHXPLLA"

Description

The Enhanced Extended Performance PLL (EHXPLLA) includes all features available in the PLL. This primitive includes SMI access so that you may configure the PLL as you require. The EHXPLLA primitive can be created through IPexpress. Note that Some combination of legal values are not allowed, due to other system limitations, such as the frequency of operation.

The following are descriptions of EHXPLLA port functions.

Table 591:

Port	I/O	Function
CLKI	I	CLKI[1:3]: from CIBs CLKI[0]: dedicated clock input pin Frequency: 2~1000 MHz
CLKFB	I	CLKFB[2,3]: from CIBs CLKFB[1]: dedicated external feedback pin CLKFB[0]: internal feedback from VCO output (CLKINTFB) Frequency: 2~1000 MHz
CLKOP	O	PLL output clock – main clock output Frequency: 1.5625~1000 MHz
CLKOS	O	PLL output clock – supplemental clock output Frequency: 1.5625~1000 MHz
LOCK	O	PLL locked to CLK1
CLKINTFB	O	CLKFB internal feedback source from VCO output
RSTN	I	Active low reset
SMIADDR[9:0]	I	SMI address bus
SMICLK	I	SMI clock signal
SMIRSTN	I	SMI reset signal
SMIRD	I	SMI read signal
SMIWDATA	I	SMI write data input
SMIWR	I	SMI write signal
SMIRDATA	O	SMI read data output

You can refer to the following technical note on the Lattice web site for more detailed description and usage.

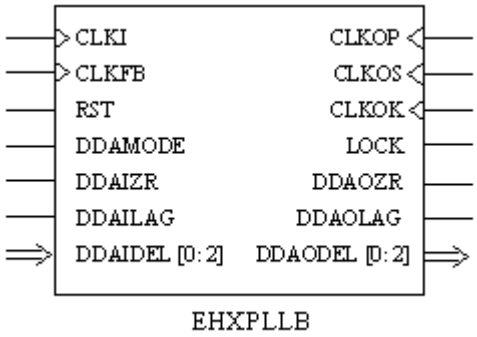
- TN1098 - LatticeSC sysCLOCK PLL/DLL User's Guide

EHXPLLB

Enhanced High Performance with Dynamic Input Delay Control PLL

Architectures Supported:

- LatticeECP/EC
- LatticeXP



EHXPLLB

INPUTS: CLKI, CLKFB, RST, DDAMODE, DDAIZR, DDAILAG, DDAIDEL0, DDAIDEL1, DDAIDEL2

OUTPUTS: CLKOP, CLKOS, CLKOK, LOCK, DDAOZR, DDAOLAG, DDAODEL0, DDAODEL1, DDAODEL2

ATTRIBUTES:

FIN: 20.0000~420.0000 (in MHz) (default: "100.0000")

CLKI_DIV: (*LatticeECP/EC*) integers 1~16 (default: 1);
(*LatticeXP*) integers 1~15 (default: 1)

CLKFB_DIV: (*LatticeECP/EC*) integers 1~16 (default: 1);
(*LatticeXP*) integers 1~15 (default: 1)

CLKOP_DIV: (*LatticeECP/EC*) even integers 2~32 if CLKOS is not used; 2, 4, 8, 16, 32 is CLKOS is used. (Default: 8)
(*LatticeXP*) even integers 2~30 if CLKOS is not used (default: 6); 2, 4, 8, 16 if CLKOS is used (default: 4).

CLKOK_DIV: 2 (default), 4, 6, 8, ..., 126, 128

FDEL: integers -8~8 (default: 0)

PHASEADJ: 0 (default), 45, 90, 135, 190, 225, 270, 315

DUTY: integers 1~7 (default: 4)

DELAY_CNTL: "STATIC" (default), "DYNAMIC"

Description

The following are descriptions of EHXPLLB port functions.

Table 592:

Port	I/O	Function
CLKI	I	Global clock input; frequency: 20~420 MHz.
CLKFB	I	External feedback, internal feedback from CLKOP divider; frequency: 20~420 MHz.
RST	I	"1" to reset M-divider.
DDAMODE	I	DDA mode. "1": pin control (dynamic); "0": fuse control (static).
DDAIZR	I	DDA delay zero. "1": delay = 0; "0": delay = on.
DDAILAG	I	DDA lag/lead. "1": lag; "0": lead.
DDAIDEL[0:2]	I	DDA delay.
CLKOP	O	PLL output clock to clock tree (no phase shift); frequency: 20~420 MHz.
CLKOS	O	PLL output clock to clock tree (phase shifted/duty cycle changed); frequency: 20~420 MHz.
CLKOK	O	PLL output to clock tree (K divider, low speed, output); frequency: 0.156~210 MHz.
LOCK	O	"1" indicates PLL LOCK to CLK_IN.
DDAOZR	O	DDA delay zero output.
DDAOLAG	O	DDA lag/lead output.
DDAODEL[0:2]	O	DDA delay output.

Dynamic Delay Adjustment

The Dynamic Delay Adjustment is controlled by DDAMODE input. This feature is available in EHXPLLB primitive only. When the DDAMODE input is set to “1,” the delay control is done through the inputs, DDAIZR, DDAILAG and DDAIDEL(2:0). For this mode, the attribute “DELAY_CNTL” must be set to “DYNAMIC.”

Equations for Generating Input and Output Frequency Ranges

These values of fIN, fOUT, fVCO are the absolute frequency ranges for the PLL. The values of fINMIN, fINMAX, fOUTMIN, and fOUTMAX, are the calculated frequency ranges based on the divider settings. These calculated frequency ranges become the limits for the specific divider settings used in the design.

fOUT = fIN * (N/M)

fVCO = fOUT * V = fIN * (N/M) * V

fIN = (fVCO /(V*N))*M

Where M = CLKI DIV

N = CLKFB DIV

V = CLKOP DIV

K = CLKOK DIV

fINMIN = ((fVCOMIN /(V*N))*M, if below 33 * M round up to 33 * M

fINMAX = (fVCOMAX/(V*N))*M, if above 420 round down to 420

fOUTMIN = fINMIN*(N/M), if below 33 * N round up to 33 * N

fOUTMAX = fINMAX*(N/M), if above 420 round down to 420

fOUTKMIN = fOUTMIN /K

fOUTKMAX = fOUTMAX /K

You can refer to the following technical note on the Lattice web site for more detailed description and usage.

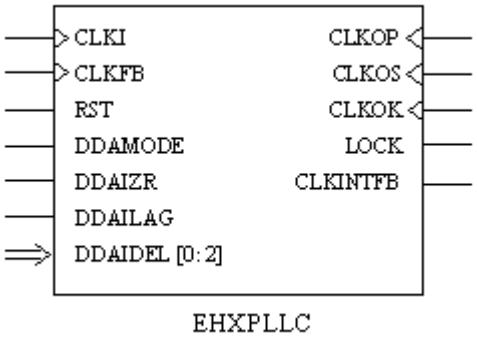
- TN1049 - LatticeECP/EC and LatticeXP sysCLOCK PLL Design and Usage Guide

EHXPLLC

Enhanced Extended Performance PLL

Architectures Supported:

- MachXO
- Platform Manager



EHXPLLC

INPUTS: CLKI, CLKFB, RST, DDAMODE, DDAIZR, DDAILAG, DDAIDEL0, DDAIDEL1, DDAIDEL2

OUTPUTS: CLKOP, CLKOS, CLKOK, LOCK, CLKINTFB

ATTRIBUTES:

FIN: 20.0000~420.0000 (in MHz) (default: "100.0000")

CLKFB_DIV: integers 1~16 (default: 1)

CLKI_DIV: integers 1~16 (default: 1)

CLKOP_DIV: even integers 2~32 if CLKOS is not used; 2, 4, 8, 16, 32 if CLKOS is used. (Default: 8)

CLKOK_DIV: 2 (default), 4, 6, 8, ..., 126, 128

DELAY_CNTL: "STATIC" (default), "DYNAMIC"

FDEL: integers -8~8 (default: 0)

PHASEADJ: 0 (default), 45, 90, 135, 190, 225, 270, 315

DUTY: integers 1~7 (default: 4)

Description

The EHXPLLC primitive is used for MachXO and Platform Manager PLL implementation. The definitions of the PLL I/O ports are shown in the following table. The EHXPLLC includes all features available in the MachXO or Platform Manager PLL.

Table 593:

Port	I/O	Function
CLKI	I	General routing or dedicated global clock input pad.
CLKFB	I	From general routing, clock tree, internal feedback from CLKOP or dedicated external feedback CLKFB Ipad.
RST	I	"1" to reset PLL counters.
CLKOP	O	PLL output clock to clock tree (no phase shift).
CLKOS	O	PLL output clock to clock tree (phase shifted/duty cycle changed).
CLKOK	O	PLL output to clock tree (CLKOK divider, low speed, output).
LOCK	O	"1" indicates PLL LOCK to CLKI; asynchronous signal.
CLKINTFB	O	Internal feedback source. CLKOP divider output before CLOCK TREE.
DDAMODE	I	DDA mode. "1": pin control (dynamic); "0": fuse control (static).
DDAIZR	I	DDA delay zero. "1": delay = 0; "0": delay = on.

Table 593:

Port	I/O	Function
DDAILAG	I	DDA lag/lead. "1": lead; "0": lag.
DDAIDEL[0:2]	I	DDA delay.

You can refer to the following technical note on the Lattice web site for more detailed description and usage.

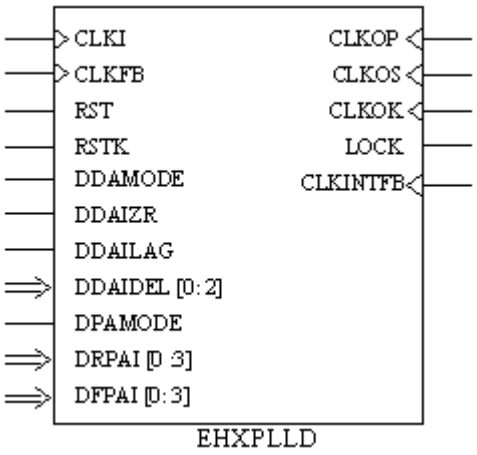
- TN1089 - MachXO sysCLOCK Design and Usage Guide

EHXPLLD

Complex PLL

Architectures Supported:

- LatticeECP2/M



INPUTS: CLKI, CLKFB, RST, RSTK, DDAMODE, DDAIZR, DDAILAG, DDAIDEL0, DDAIDEL1, DDAIDEL2, DPAMODE, DRPAI3, DRPAI2, DRPAI1, DRPAI0, DFPAI3, DFPAI2, DFPAI1, DFPAI0

OUTPUTS: CLKOP, CLKOK, CLKOS, LOCK, CLKINTFB

ATTRIBUTES:

FIN: 20.0000~420.0000 (in MHz) (default: "100.0000")

CLKI_DIV: integers 1~64 (default: 1)

CLKFB_DIV: integers 1~16 (default: 1)

CLKOP_DIV: 2, 4, 8 (default), 16, 32, 48, 64, 80, 96, 112, 128

CLKOK_DIV: 2 (default), 4, 6, 8, ..., 126, 128

FDEL: integers -8~8 (default: 0)

PHASEADJ: 0 (default), 22.5, 45, 67.5, 90, ..., 315, 337.5

DUTY: integers 2~14 (default: 8)

PHASE_CNTL: "STATIC" (default), "DYNAMIC"

DELAY_CNTL: "STATIC" (default), "DYNAMIC"

PLLCAP: "DISABLED" (default), "ENABLED", "AUTO"

CLKOP_BYPASS: "DISABLED" (default), "ENABLED"

CLKOS_BYPASS: "DISABLED" (default), "ENABLED"

CLKOK_BYPASS: "DISABLED" (default), "ENABLED"

Description

The ECP2 devices provide two type of PLLS: SPLL and GPLL. The SPLL is a baseline PLL. The GPLL includes all features of SPLL plus Dynamic Delay Adjustment. The primitive for the SPLL is EPLLD. The primitive for the GPLL are EPLLD and EHXPLLD. See the following table for GPLL and SPLL IO port description.

Table 594:

Port	I/O	Function
CLKI	I	Input clock.
CLKFB	I	Feedback clock.
RST	I	PLL reset (connect to CNTRST port). High active reset.
RSTK	I	Reset for K divider (connect to RESETK port). High active reset.
CLKOP	O	PLL output clock (no phase shift).
CLKOS	O	PLL output clock (phase shifted/duty cycle changed).
CLKOK	O	PLL output to clock tree (no phase shift, low speed).
LOCK	O	PLL LOCK to CLKI, asynchronous signal. Active high indicates PLL lock.
CLKINTFB	O	Internal feedback source. CLKOP divider output before CLOCK TREE.
DDAMODE	I	DDA mode. Active high indicates pin control (DYNAMIC) and active low indicates fuse control (STATIC).
DDAIZR	I	DDA delay zero. Active high indicates “delay = 0” and active low indicates “delay= on.”

Table 594:

Port	I/O	Function
DDAILAG	I	DDA lag/lead. Active high indicates “lead” and active low indicates “lag.”
DDAIDEL[2:0]	I	DDA delay.
DPAMODE	I	Dynamic phase adjust mode. Active high indicates pin control (DYNAMIC) and active low indicates fuse control (STATIC).
DRPAI[3:0]	I	Dynamic coarse phase shift, rising edge setting.
DFPAI[3:0]	I	Dynamic coarse phase shift, falling edge setting.

You can refer to the following technical note on the Lattice web site for more detailed description and usage.

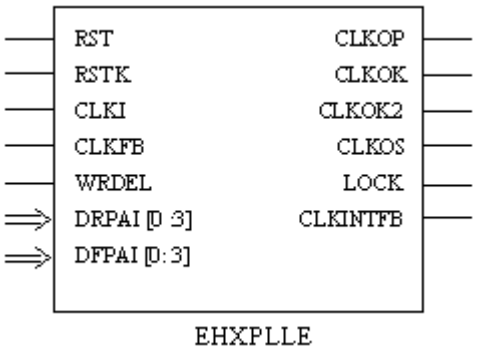
- TN1103 - LatticeECP2/M sysCLOCK PLL/DLL Design and Usage Guide

EHXPLLE

Complex PLL

Architectures Supported:

- LatticeXP2



INPUTS: CLKI, CLKFB, RST, RSTK, WRDEL, DRPAI3, DRPAI2, DRPAI1, DRPAI0, DFPAI3, DFPAI2, DFPAI1, DFPAI0

OUTPUTS: CLKOP, CLKOK, CLKOK2, CLKOS, LOCK, CLKINTFB

ATTRIBUTES:

FIN: 20.0000~420.0000 (in MHz) (default: "100.0000")

CLKFB_DIV: integers 1~64 (default: 1)

CLKI_DIV: integers 1~64 (default: 1)

CLKOP_DIV: 2, 4, 8 (default), 16, 32, 48, 64, 80, 96, 112, 128

CLKOK_DIV: 2 (default), 4, 6, ..., 126, 128

PHASE_CNTL: "STATIC" (default), "DYNAMIC"

PHASEADJ: 0 (default), 22.5, 45, 67.5, 90, ..., 315, 337.5

DUTY: integers 2~14 (default: 8)

CLKOP_BYPASS: "DISABLED" (default), "ENABLED"

CLKOS_BYPASS: "DISABLED" (default), "ENABLED"

CLKOK_BYPASS: "DISABLED" (default), "ENABLED"

CLKOP_TRIM_POL: "FALLING" (default), "RISING"

CLKOP_TRIM_DELAY: integers 0~7 (default: 0)

CLKOS_TRIM_POL: "RISING" (default), "FALLING"

CLKOS_TRIM_DELAY: integers 0~3 (default: 0)

Description

EHXPLLE and EPLLD are the two primitives defined for XP2 GPLL. The EPLLD is used for both ECP2, and XP2 to support design migration. See EPLLD for details on migration. It is recommended to use EPLLD for all PLL configurations except for configurations involving Duty Trim Options, CLKOK2 and the CLKOS Fine Delay Port (WRDEL). Those features are only supported by the EHXPLLE primitive.

See the following table for port description.

Table 595:

Port	I/O	Function
CLKI	I	Input clock.
CLKFB	I	Feedback clock.
RST	I	PLL reset (connect to CNTRST port). High active reset.
RSTK	I	Reset for K divider (connect to RESETK port). High active reset.
CLKOP	O	PLL output clock (no phase shift).
CLKOS	O	PLL output clock (phase shifted/duty cycle changed).
CLKOK	O	PLL output to clock tree (no phase shift, low speed).
CLKOK2	O	PLL output clock (no phase shift, CLKOP/3).

Table 595:

Port	I/O	Function
LOCK	O	PLL LOCK to CLKI, asynchronous signal. Active high indicates PLL lock.
CLKINTFB	O	Internal feedback source. CLKOP divider output before CLOCK TREE.
WRDEL	I	Fine delay adjust (0 = no delay; 1 = ~70ps).
DRPAI[3:0]	I	Dynamic coarse phase shift, rising edge setting.
DFPAI[3:0]	I	Dynamic coarse phase shift, falling edge setting.
DDAMODE	I	DDA mode. Active high indicates pin control (DYNAMIC) and active low indicates fuse control (STATIC).

You can refer to the following technical note on the Lattice web site for more detailed description and usage.

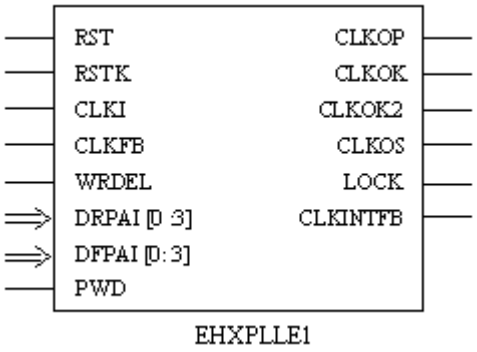
- TN1126 - LatticeXP2 sysCLOCK PLL Design and Usage Guide

EHXPLLE1

Complex PLL

Architectures Supported:

- LatticeXP2



INPUTS: CLKI, CLKFB, RST, RSTK, WRDEL, DRPAI3, DRPAI2, DRPAI1, DRPAI0, DFPAI3, DFPAI2, DFPAI1, DFPAI0, PWD

OUTPUTS: CLKOP, CLKOK, CLKOK2, CLKOS, LOCK, CLKINTFB

ATTRIBUTES:

FIN: 20.0000~420.0000 (in MHz) (default: "100.0000")

CLKFB_DIV: integers 1~64 (default: 1)

CLKI_DIV: integers 1~64 (default: 1)

CLKOP_DIV: 2, 4, 8 (default), 16, 32, 48, 64, 80, 96, 112, 128

CLKOK_DIV: 2 (default), 4, 6, ..., 126, 128

PHASE_CNTL: "STATIC" (default), "DYNAMIC"

PHASEADJ: 0 (default), 22.5, 45, 67.5, 90, ..., 315, 337.5

DUTY: integers 2~14 (default: 8)

CLKOP_BYPASS: "DISABLED" (default), "ENABLED"

CLKOS_BYPASS: "DISABLED" (default), "ENABLED"

CLKOK_BYPASS: "DISABLED" (default), "ENABLED"

CLKOP_TRIM_POL: "FALLING" (default), "RISING"

CLKOP_TRIM_DELAY: integers 0~7 (default: 0)

CLKOS_TRIM_POL: "RISING" (default), "FALLING"

CLKOS_TRIM_DELAY: integers 0~3 (default: 0)

Description

The following are descriptions of EHXPLLE1 port functions.

Table 596:

Port	I/O	Function
CLKI	I	Input clock.
CLKFB	I	Feedback clock.
RST	I	PLL reset (connect to CNTRST port). High active reset.
RSTK	I	Reset for K divider (connect to RESETK port). High active reset.
WRDEL	I	Fine delay adjust (0 = no delay; 1 = ~70ps).
DRPAI[3:0]	I	Dynamic coarse phase shift, rising edge setting.
DFPAI[3:0]	I	Dynamic coarse phase shift, falling edge setting.
DDAMODE	I	DDA mode. Active high indicates pin control (DYNAMIC) and active low indicates fuse control (STATIC).
PWD	I	Dynamic power down signal.
CLKOP	O	PLL output clock (no phase shift).
CLKOS	O	PLL output clock (phase shifted/duty cycle changed).

Table 596:

Port	I/O	Function
CLKOK	O	PLL output to clock tree (no phase shift, low speed).
CLKOK2	O	PLL output clock (no phase shift, CLKOP/3).
LOCK	O	PLL LOCK to CLKI, asynchronous signal. Active high indicates PLL lock.
CLKINTFB	O	Internal feedback source. CLKOP divider output before CLOCK TREE.

You can refer to the following technical note on the Lattice web site for more detailed description and usage.

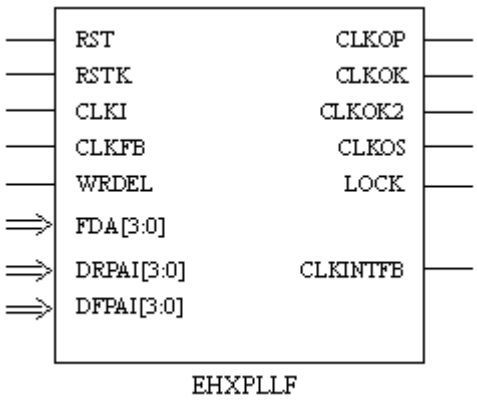
- TN1126 - LatticeXP2 sysCLOCK PLL Design and Usage Guide

EHXPLLF

Complex PLL

Architectures Supported:

- LatticeECP3



INPUTS: CLKI, CLKFB, RST, RSTK, DRPAI3, DRPAI2, DRPAI1, DRPAI0, DFPAI3, DFPAI2, DFPAI1, DFPAI0, FDA3, FDA2, FDA1, FDA0, WRDEL

OUTPUTS: CLKOP, CLKOS, CLKOK, CLKOK2, LOCK, CLKINTFB

ATTRIBUTES:

FIN: 20.0000~420.0000 (in MHz) (default: "100.0000")

CLKI_DIV: integers 1~64 (default: 1)

CLKFB_DIV: integers 1~64 (default: 1)

CLKOP_DIV: 2, 4, 8 (default), 16, 32, 48, 64, 80, 96,112, 128

CLKOK_DIV: 2 (default), 4, 6, 8, ...,126,128

PHASEADJ: 0 (default), 22.5, 45, 67.5, 90, ..., 315, 337.5

DUTY: integers 2~14 (default: 8)

PHASE_DELAY_CNTL: "STATIC" (default), "DYNAMIC"

CLKOP_BYPASS: "DISABLED" (default), "ENABLED"

CLKOS_BYPASS: "DISABLED" (default), "ENABLED"

CLKOK_BYPASS: "DISABLED" (default), "ENABLED"

CLKOP_TRIM_POL: "RISING" (default), "FALLING"

CLKOP_TRIM_DELAY: integers 0~7 (default: 0)

CLKOS_TRIM_POL: "RISING" (default), "FALLING"

CLKOS_TRIM_DELAY: integers 0~3 (default: 0)

DELAY_VAL: integers 0~15 (default: 0)

DELAY_PWD: "DISABLED" (default), "ENABLED"

CLKOK_INPUT: "CLKOP" (default), "CLKOS"

Description

EHXPLLF and EPLLD are the two primitives defined for the LatticeECP3 GPLL. The EPLLD primitive is used for both ECP3, and XP2 for design migration. For the ECP3 new configurations, only EHXPLLF will be supported.

The following table describes EHXPLLF IO port functions.

Table 597:

Port	I/O	Function
CLKI	I	Input clock.
CLKFB	I	Feedback clock.
RST	I	PLL reset (connect to CNTRST port). High active reset.
RSTK	I	Reset for K divider (connect to RESETK port). High active reset.
CLKOP	O	PLL output clock (no phase shift).
CLKOS	O	PLL output clock (phase shifted/duty cycle changed).

Table 597:

Port	I/O	Function
CLKOK	O	PLL output clock (no phase shift, low speed).
CLKOK2	O	PLL output clock (no phase shift, CLKOP/3).
LOCK	O	PLL LOCK to CLKI, asynchronous signal. Active high indicates PLL lock.
CLKINTFB	O	Internal feedback source. CLKOP divider output before CLOCK TREE.
WRDEL	I	Dynamic CLKOS single step fine delay adjust (0 = no delay; 1 = ~70ps).
FDA[3:0]	I	Dynamic CLKOS 16 step fine delay adjustment on CLKOS (each increment is ~125ps).
DRPAI[3:0]	I	Dynamic coarse phase shift, rising edge setting.
DFPAI[3:0]	I	Dynamic duty cycle, falling edge setting.

You can refer to the following technical note on the Lattice web site for EHXPLLF port definition, attribute definition, and usage.

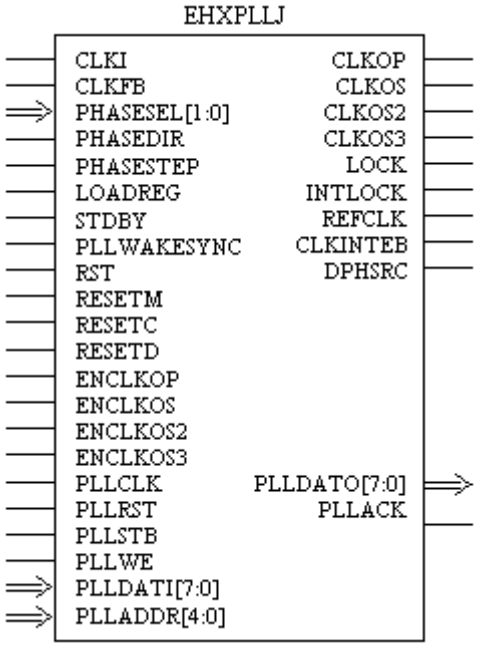
- TN1178 - LatticeECP3 sysCLOCK PLL/DLL Design and Usage Guide

EHXPLLJ

GPLL for MachXO2 and Platform Manager 2

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: CLKI, CLKFB, PHASESEL1, PHASESEL0, PHASEDIR, PHASESTEP, LOADREG, STDBY, PLLWAKESYNC, RST, RESETM, RESETC, RESETD, ENCLKOP, ENCLKOS, ENCLKOS2, ENCLKOS3, PLLCLK, PLLRST, PLLSTB, PLLWE, PLLDATI7, PLLDATI6, PLLDATI5, PLLDATI4, PLLDATI3, PLLDATI2, PLLDATI1, PLLDATI0, PLLADDR4, PLLADDR3, PLLADDR2, PLLADDR1, PLLADDR0

OUTPUTS: CLKOP, CLKOS, CLKOS2, CLKOS3, LOCK, INTLOCK, REFCLK, CLKINTFB, DPHSRC, PLLDATO7, PLLDATO6, PLLDATO5, PLLDATO4, PLLDATO3, PLLDATO2, PLLDATO1, PLLDATO0, PLLACK

ATTRIBUTES:

The EHXPLLJ primitive utilizes many attributes that allow the configuration of the PLL through source constraints. The following table details these attributes:

Table 598:

Attribute	Type	Allowed Values	Default	Description
FREQ_PIN_CLKI	String	10 to 400	100	CLKI frequency (MHz)
FREQ_PIN_CLKOP	String	3.125 to 400	100	CLKOP frequency (MHz)
CLKOP_FTOL	String	0.0, 0.1, 0.2, 0.5, 1.0, 2.0, 5.0, 10.0	0.0	CLKOP frequency tolerance
CLKOP_AFREQ	String		-	CLKOP actual frequency (MHz)
FREQ_PIN_CLKOS	String	0.024 to 400	100	CLKOS frequency (MHz)

Table 598:

Attribute	Type	Allowed Values	Default	Description
CLKOS_FTOL	String	0.0, 0.1, 0.2, 0.5, 1.0, 2.0, 5.0, 10.0	0.0	CLKOS frequency tolerance
CLKOS_AFREQ	String		-	CLKOS actual frequency (MHz)
FREQUENCY_PIN_CLKOS2	String	0.024 to 400	100	CLKOS2 frequency (MHz)
CLKOS2_FTOL	String	0.0, 0.1, 0.2, 0.5, 1.0, 2.0, 5.0, 10.0	0.0	CLKOS2 frequency tolerance
CLKOS2_AFREQ	String		-	CLKOS2 actual frequency (MHz)
FREQUENCY_PIN_CLKOS3	String	0.024 to 400	100	CLKOS3 frequency (MHz)
CLKOS3_FTOL	String	0.0, 0.1, 0.2, 0.5, 1.0, 2.0, 5.0, 10.0	0.0	CLKOS3 frequency tolerance
CLKOS3_AFREQ	String		-	CLKOS3 actual frequency (MHz)
CLKI_DIV	Integer	1 to 128	1	CLKI divider setting
CLKFB_DIV	Integer	1 to 128	1	CLKFB divider setting
CLKOP_DIV	Integer	1 to 128	8	CLKOP divider setting
CLKOS_DIV	Integer	1 to 128	8	CLKOS divider setting
CLKOS2_ DIV	Integer	1 to 128	8	CLKOS2 divider setting
CLKOS3_ DIV	Integer	1 to 128	8	CLKOS3 divider setting
CLOCK_ENABLE_PORTS	Boolean	ENABLED, DISABLED	DISABLED	Clock enable ports
CLKOP_ENABLE	Boolean	ENABLED, DISABLED	ENABLED	CLKOP enable
CLKOS_ENABLE	Boolean	ENABLED, DISABLED	ENABLED	CLKOS enable
CLKOS2_ENABLE	Boolean	ENABLED, DISABLED	ENABLED	CLKOS2 enable
CLKOS3_ENABLE	Boolean	ENABLED, DISABLED	ENABLED	CLKOS3 enable
VCO_BYPASS_A0	Boolean	ENABLE, DISABLED	DISABLED	VCO bypass A0
VCO_BYPASS_B0	Boolean	ENABLE, DISABLED	DISABLED	VCO bypass B0
VCO_BYPASS_C0	Boolean	ENABLE, DISABLED	DISABLED	VCO bypass C0
VCO_BYPASS_D0	Boolean	ENABLE, DISABLED	DISABLED	VCO bypass D0

Table 598:

Attribute	Type	Allowed Values	Default	Description
CLKOP _PHASEADJ	String	0, 45, 90, 135, 180, 225, 270, 315	0	CLKOP desired phase shift selection (O) in static mode
CLKOS_PHASEADJ	String	0, 45, 90, 135, 180, 225, 270, 315	0	CLKOS desired phase shift selection (O) in static mode
CLKOS2_PHASEADJ	String	0, 45, 90, 135, 180, 225, 270, 315	0	CLKOS2 desired phase shift selection (O) in static mode
CLKOS3_PHASEADJ	String	0, 45, 90, 135, 180, 225, 270, 315	0	CLKOS3 desired phase shift selection (O) in static mode
CLKOP_CPHASE	Integer	0 to 127	N/A	CLKOP coarse phase adjust
CLKOS_CPHASE	Integer	0 to 127	N/A	CLKOS coarse phase adjust
CLKOS2_CPHASE	Integer	0 to 127	N/A	CLKOS2 coarse phase adjust
CLKOS3_CPHASE	Integer	0 to 127	N/A	CLKOS3 coarse phase adjust
CLKOP_FPHASE	Integer	0 to 7	N/A	CLKOP fine phase adjust
CLKOS_FPHASE	Integer	0 to 7	N/A	CLKOS fine phase adjust
CLKOS2_FPHASE	Integer	0 to 7	N/A	CLKOS2 fine phase adjust
CLKOS3_FPHASE	Integer	0 to 7	N/A	CLKOS3 fine phase adjust
FEEDBK_PATH	String	CLKOP, CLKOS, CLKOS2, CLKOS3, INT_DIVA, INT_DIVB, INT_DIVC, INT_DIVD, USERCLOCK	CLKOP	Feedback mode
KVCO	Integer	0 to 7	0	VCO gain - Kvco
LPF_CAPACITOR	Integer	0 to 3	0	LPF capacitor
LPF_RESISTOR	Integer	0 to 127	0	LPF resistor
ICP_CURRENT	Integer	0 to 31	0	ICP current
FRACN_ENABLE	Boolean	ENABLE, DISABLED	DISABLED	Fractional-N divider enable
FRACN_DIV	Integer	0 to 65535	0	Fractional-N divider
FRACN_ORDER	Integer	0 to 3	0	Fractional-N noise shaping order
CLKOP_TRIM_POL	String	RISING, FALLING	RISING	CLKOP duty trim polarity
CLKOP_TRIM_DELAY	Integer	0, 1, 2, 4	0	CLKOP duty trim polarity delay
CLKOS_TRIM_POL	String	RISING, FALLING	RISING	CLKOS duty trim polarity
CLKOS_TRIM_DELAY	Integer	0, 1, 2, 4	0	CLKOS duty trim polarity delay

Table 598:

Attribute	Type	Allowed Values	Default	Description
PLL_EXPERT	Boolean	ENABLE, DISABLED	DISABLED	
PLL_USE_WB	Boolean	ENABLE, DISABLED	DISABLED	
PREDIVIDER_MUXA1	Integer	0 to 3	0	
PREDIVIDER_MUXB1	Integer	0 to 3	0	
PREDIVIDER_MUXC1	Integer	0 to 3	0	
PREDIVIDER_MUXD1	Integer	0 to 3	0	
OUTDIVIDER_MUXA2	String	DIVA, REFCLK	DIVA	
OUTDIVIDER_MUXB2	String	DIVB, REFCLK	DIVB	
OUTDIVIDER_MUXC2	String	DIVC, REFCLK	DIVC	
OUTDIVIDER_MUXD2	String	DIVD, REFCLK	DIVD	
FREQ_LOCK_ACCURACY	Integer	0 to 3	0	
PLL_LOCK_MODE	Integer	0 to 7	0	
PLL_LOCK_DELAY	Integer	1600, 800, 400, 200 (in ns)	200	
GMC_GAIN	Integer	0 to 7	0	GM/C gain
GMC_TEST	Integer	0 to 15	14	GM/C test mode
MFG1_TEST	Integer	0 to 7	0	
MFG2_TEST	Integer	0 to 7	0	
MFG_FORCE_VFILTER	Integer	0, 1	0	
MFG_ICP_TEST	Integer	0, 1	0	
MFG_ EN_UP	Integer	0, 1	0	
MFG_ FLOAT_ICP	Integer	0, 1	0	
MFG_GMC_PRESET	Integer	0, 1	0	
MFG_LF_PRESET	Integer	0, 1	0	
MFG_GMC_RESET	Integer	0, 1	0	
MFG_LF_RESET	Integer	0, 1	0	
MFG_LF_RESGRND	Integer	0, 1	0	
MFG_ GMCREF_SEL	Integer	0 to 3	2	
MFG_EN_FILTEROPAMP	Integer	0, 1	1	
STDBY_ENABLE	Boolean	ENABLED, DISABLED	DISABLED	

Table 598:

Attribute	Type	Allowed Values	Default	Description
REFIN_RESET	Boolean	ENABLED, DISABLED	DISABLED	
SYNC_ENABLE	Boolean	ENABLED, DISABLED	DISABLED	
INT_LOCK_STICKY	Boolean	ENABLED, DISABLED	DISABLED	
DPHASE_SOURCE	Boolean	ENABLED, DISABLED	DISABLED	
INTFB_WAKE	Boolean	ENABLED, DISABLED	DISABLED	
PLLRST_ENA	Boolean	ENABLED, DISABLED	DISABLED	
MRST_ENA	Boolean	ENABLED, DISABLED	DISABLED	
DCRST_ENA	Boolean	ENABLED, DISABLED	DISABLED	
DDRST_ENA	Boolean	ENABLED, DISABLED	DISABLED	

Description

EHXPLLJ is the GPLL primitive for MachXO2 and Platform Manager 2. A wrapper will be used around the primitive for configurations without the dynamic control or other ports. The EHXPLLJ primitive uses a single reference clock input.

For detailed information, refer to the following technical note on the Lattice web site.

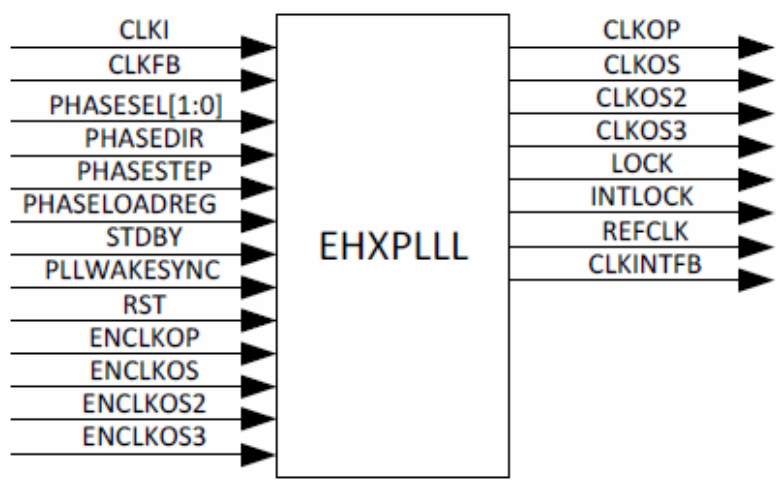
- TN1199 - MachXO2 sysCLOCK PLL Design and Usage Guide

EHXPLLL

GPLL for ECP5

Architectures Supported:

- ECP5



INPUTS: CLKI, CLKFB, PHASESEL1, PHASESEL0, PHASEDIR, PHASESTEP, PHASELOADREG, STDBY, PLLWAKESYNC, RST, ENCLKOP, ENCLKOS, ENCLKOS2, ENCLKOS3

OUTPUTS: CLKOP, CLKOS, CLKOS2, CLKOS3, LOCK, INTLOCK, REFCLK, CLKINTFB

ATTRIBUTES:

The following table details EHXPLLL attributes.

Table 599:

Attribute Name	Type	Range	Default Value	Description
FREQUENCY_PIN_CLKI	NC		100	CLKI Frequency (MHz)
FREQUENCY_PIN_CLKOP				CLKOP Actual Frequency (MHz)
FREQUENCY_PIN_CLKOS				CLKOS Actual Frequency (MHz)
FREQUENCY_PIN_CLKOS2				CLKOS2 Actual Frequency (MHz)
FREQUENCY_PIN_CLKOS3				CLKOS3 Actual Frequency (MHz)
CLKI_DIV	C, S	1 – 128	1	CLKI Divider Setting
CLKFB_DIV	C, S	1 – 80	1	CLKFB Divider Setting
CLKOP_DIV	C, S	1 – 128	8	CLKOP Divider Setting
CLKOS_DIV	C, S	1 – 128	8	CLKOS Divider Setting
CLKOS2_ DIV	C, S	1 – 128	8	CLKOS2 Divider Setting
CLKOS3_ DIV	C, S	1 – 128	8	CLKOS3 Divider Setting
CLKOP_ENABLE	C, S	ENABLED, DISABLED	ENABLED	CLKOP Enable
CLKOS_ENABLE	C, S	ENABLED, DISABLED	DISABLED	CLKOS Enable

Table 599:

Attribute Name	Type	Range	Default Value	Description
CLKOS2_ENABLE	C, S	ENABLED, DISABLED	DISABLED	CLKOS2 Enable
CLKOS3_ENABLE	C, S	ENABLED, DISABLED	DISABLED	CLKOS3 Enable
CLKOP_CPHASE	C, S	0 – 127	N/A	CLKOP Coarse Phase adj
CLKOS_CPHASE	C, S	0 – 127	N/A	CLKOS Coarse Phase adj.
CLKOS2_CPHASE	C, S	0 – 127	N/A	CLKOS2 Coarse Phase adj.
CLKOS3_CPHASE	C, S	0 – 127	N/A	CLKOS3 Coarse Phase adj.
CLKOP_FPHASE	C, S	0 – 7	N/A	CLKOP Fine Phase adj.
CLKOS_FPHASE	C, S	0 – 7	N/A	CLKOS Fine Phase adj.
CLKOS2_FPHASE	C, S	0 – 7	N/A	CLKOS2 Fine Phase adj.
CLKOS3_FPHASE	C, S	0 – 7	N/A	CLKOS3 Fine Phase adj.
FEEDBK_PATH	C, S	CLKOP, CLKOS, CLKOS2, CLKOS3, INT_OP, INT_OS, INT_OS2, INT_OS3, USERCLOCK	CLKOP	Feedback Mode
KVCO	C	0 – 7	0	VCO Gain - Kvco
LPF_CAPACITOR	C	0 – 3	0	LPF Capacitor
LPF_RESISTOR	C	0 – 127	0	LPF Resistor
ICP_CURRENT	C	0 – 31	0	ICP Current
CLKOP_TRIM_POL	C	RISING, FALLING	RISING	CLKOP Duty Trim Polarity
CLKOP_TRIM_DELAY	C	0, 1, 2, 4	0	CLKOP Duty Trim Polarity Multiplier
CLKOS_TRIM_POL	C	RISING, FALLING	RISING	CLKOS Duty Trim Polarity
CLKOS_TRIM_DELAY	C	0, 1, 2, 4	0	CLKOS Duty Trim Polarity Multiplier
OUTDIVIDER_MUXA	C, S	DIVA, REFCLK	DIVA	OUTDIVIDER_MUXA
OUTDIVIDER_MUXB	C, S	DIVB, REFCLK	DIVB	OUTDIVIDER_MUXB
OUTDIVIDER_MUXC	C, S	DIVC, REFCLK	DIVC	OUTDIVIDER_MUXC
OUTDIVIDER_MUXD	C, S	DIVD, REFCLK	DIVD	OUTDIVIDER_MUXD
FREQ_LOCK_ACCURACY	C	0 – 3	0	FREQ_LOCK_ACCURACY
PLL_LOCK_MODE	C, S	0 – 7	0	PLL_LOCK_MODE
PLL_LOCK_DELAY	S	1600, 800, 400, 200 ns	200	PLL_LOCK_DELAY
MFG_GMC_GAIN	C	0 – 7	0	GM/C Gain
MFG_GMC_TEST	C	0 – 15	14	GM/C Test Mode
MFG1_TEST	C	0 – 7	0	MFG1_TEST
MFG2_TEST	C	0 – 7	0	MFG2_TEST

Table 599:

Attribute Name	Type	Range	Default Value	Description
MFG_FORCE_VFILTER	C	0 – 1	0	MFG_FORCE_VFILTER
MFG_ICP_TEST	C	0 – 1	0	MFG_ICP_TEST
MFG_ EN_UP	C	0 – 1	0	MFG_EN_UP
MFG_ FLOAT_ICP	C	0 – 1	0	MFG_FLOAT_ICP
MFG_GMC_PRESET	C	0 – 1	0	MFG_GMC_PRESET
MFG_LF_PRESET	C	0 – 1	0	MFG_LF_PRESET
MFG_GMC_RESET	C	0 – 1	0	MFG_GMC_RESET
MFG_LF_RESET	C	0 – 1	0	MFG_LF_RESET
MFG_LF_RESGRND	C	0 – 1	0	MFG_LF_RESGRND
MFG_ GMCREF_SEL	C	0 – 3	2	MFG_ GMCREF_SEL
MFG_EN_FILTEROPAMP	C	0 – 1	1	MFG_EN_FILTEROPAMP
STDBY_ENABLE	C	ENABLED, DISABLED	DISABLED	STDBY_ENABLE
REFIN_RESET	S	ENABLED, DISABLED	DISABLED	REFIN_RESET
SYNC_ENABLE	S	ENABLED, DISABLED	DISABLED	SYNC_ENABLE
INT_LOCK_STICKY	S	ENABLED, DISABLED	ENABLED	INT_LOCK_STICKY
DPHASE_SOURCE	C, S	ENABLED, DISABLED	DISABLED	DPHASE_SOURCE
PLLRST_ENA	C, S	ENABLED, DISABLED	DISABLED	Enable PLL Reset
INTFB_WAKE	C	ENABLED, DISABLED	DISABLED	Internal Feedback on Wakeup
MFG_VCO_NORESET	C	0 – 1	0	Disable VCO reset in STDBY mode
MFG_STDBY_ANALOGON	C	0 – 1	0	Enable analog bias in STDBY mode
MFG_NO_PLLRESET	C	0 – 1	0	Disable pll_rst_n in STDBY mode

Description

EHXPLLL is the GPLL primitive for ECP5. The following are descriptions of EHXPLLL port functions.

Table 600:

Port	I/O	Function
CLKI	I	Input Clock to PLL.
CLKI2	I	Muxed Input Clock to PLL.
SEL	I	Select Clock
CLKFB	I	Feedback Clock.
PHASESEL[1:0]	I	Select the output affected by Dynamic Phase adjustment.
PHASEDIR	I	Dynamic Phase adjustment direction.

Table 600:

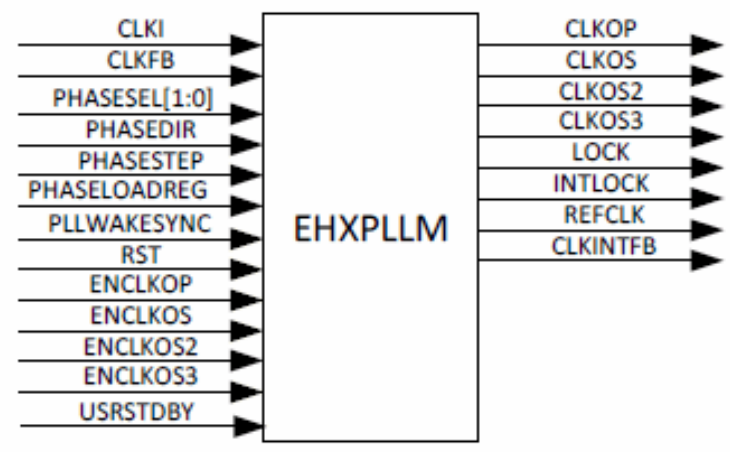
Port	I/O	Function
PHASESTEP	I	Dynamic Phase adjustment step.
PHASELOADREG	I	Load dynamic phase adjustment values into PLL.
CLKOP	O	PLL main output clock.
CLKOS	O	PLL output clock.
CLKOS2	O	PLL output clock.
CLKOS3	O	PLL output clock.
LOCK	O	PLL LOCK to CLKI, Asynchronous signal. Active high indicates PLL lock.
STDBY	I	Standby signal to power down the PLL.
RST	I	Resets the whole PLL.
ENCLKOP	I	Enable PLL output CLKOP
ENCLKOS	I	Enable PLL output CLKOS
ENCLKOS2	I	Enable PLL output CLKOS2
ENCLKOS3	I	Enable PLL output CLKOS3

EHXPLLM

GPLL

Architectures Supported:

- LIFMD



INPUTS: CLKI, CLKFB, PHASESEL1, PHASESEL0, PHASEDIR, PHASESTEP, PHASELOADREG, STDBY, PLLWAKESYNC, RST, ENCLKOP, ENCLKOS, ENCLKOS2, ENCLKOS3, USRSTDBY

OUTPUTS: CLKOP, CLKOS, CLKOS2, CLKOS3, LOCK, INTLOCK, REFCLK, CLKINTFB

EHXPLLM is the GPLL primitive for LIFMD. The following are descriptions of EHXPLLM port functions

Table 601:

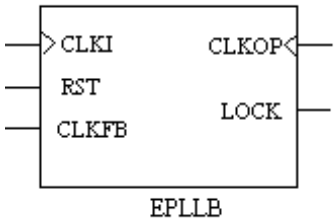
Port	IO	Description
CLKI	I	Input Clock to PLL.
CLKI2	I	Muxed Input Clock to PLL. Note 1.
SEL	I	Select Clock. Note 1.
CLKFB	I	Feedback Clock.
PHASESEL[1:0]	I	Select the output affected by Dynamic Phase adjustment.
PHASEDIR	I	Dynamic Phase adjustment direction.
PHASESTEP	I	Dynamic Phase adjustment step.
PHASELOADREG	I	Load dynamic phase adjustment values into PLL.
CLKOP	O	PLL main output clock.
CLKOS	O	PLL output clock.
CLKOS2	O	PLL output clock.
CLKOS3	O	PLL output clock.
LOCK	O	PLL LOCK to CLKI, Asynchronous signal. Active high indicates PLL lock.
RST	I	Resets the whole PLL.
ENCLKOP	I	Enable PLL output CLKOP
ENCLKOS	I	Enable PLL output CLKOS
ENCLKOS2	I	Enable PLL output CLKOS2
ENCLKOS3	I	Enable PLL output CLKOS3
USRSTDBY	I	User port to put the PLL in sleep mode

EPLLB

Enhanced PLL

Architectures Supported:

- LatticeECP/EC
- LatticeXP



INPUTS: CLKI, RST, CLKFB

OUTPUTS: CLKOP, LOCK

ATTRIBUTES:

FIN: 20.0000~420.0000 (in MHz) (default: "100.0000")

CLKI_DIV: (*LatticeECP/EC*) integers 1~16 (default: 1);
(*LatticeXP*) integers 1~15 (default: 1)

CLKFB_DIV: (*LatticeECP/EC*) integers 1~16 (default: 1);
(*LatticeXP*) integers 1~15 (default: 1)

CLKOP_DIV: (*LatticeECP/EC*) even integers 2~32 if CLKOS is not used; 2, 4, 8, 16, 32 is CLKOS is used. (Default: 8)
(*LatticeXP*) even integers 2~30 if CLKOS is not used (default: 6); 2, 4, 8, 16 if CLKOS is used (default: 4).

FDEL: integers -8~8 (default: 0)

WAKE_ON_LOCK: "OFF" (default), "ON"

FB_MODE: "CLOCKTREE" (default), "INTERNAL", "EXTERNAL"

LOCK_CYC: integer (default: 2)

Description

The following are descriptions of EPLLB port functions.

Table 602:

Port	I/O	Function
CLKI	I	Global clock input; frequency: 20~420 MHz.
RST	I	PLL reset.
CLKFB	I	External feedback, internal feedback from CLKOP divider; frequency: 20~420 MHz.

Table 602:

Port	I/O	Function
CLKOP	O	PLL output clock to clock tree (no phase shift); frequency: 20~420 MHz.
LOCK	O	"1" indicates PLL LOCK to CLK_IN.

You can refer to the following technical note on the Lattice web site for more detailed description and usage.

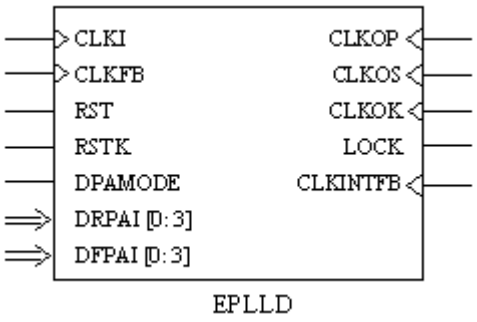
- TN1049 - LatticeECP/EC and LatticeXP sysCLOCK PLL Design and Usage Guide

EPLLD

Enhanced PLL

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



INPUTS: CLKI, CLKFB, RST, RSTK, DPAMODE, DRPAI3, DRPAI2, DRPAI1, DRPAI0, DFPAI3, DFPAI2, DFPAI1, DFPAI0

OUTPUTS: CLKOP, CLKOS, CLKOK, LOCK, CLKINTFB

ATTRIBUTES:

FIN: 20.0000~420.0000 (in MHz) (default: "100.0000")

CLKI_DIV: integers 1~64 (default: 1)

CLKFB_DIV: integers 1~64 (default: 1)

CLKOP_DIV: 2, 4, 8 (default), 16, 32, 48, 64, 80, 96,112, 128

CLKOK_DIV: 2 (default), 4, 6, 8, ..., 126, 128

PHASEADJ: 0 (default), 22.5, 45, 67.5, 90, ..., 315, 337.5

DUTY: integers 2~14 (default: 8)

PHASE_CNTL: "STATIC" (default), "DYNAMIC"

PLLCAP: "DISABLED" (default), "ENABLED", "AUTO"

CLKOP_BYPASS: "DISABLED" (default), "ENABLED"

CLKOS_BYPASS: "DISABLED" (default), "ENABLED"

CLKOK_BYPASS: "DISABLED" (default), "ENABLED"

PLLTYPE: "AUTO" (default), "SPLL", "GPLL"

Description

The following are descriptions of EPLLD port functions.

Table 603:

Port	I/O	Function
CLKI	I	Input clock.
CLKFB	I	Feedback clock.
RST	I	PLL reset (connected to the CNTRST port). High active reset.
RSTK	I	Reset for K divider (connected to the RESETK port). High active reset.
DPAMODE	I	Dynamic phase adjust mode. Active high indicates pin control (DYNAMIC) and active low indicates fuse control (STATIC).
DRPAI[3:0]	I	Dynamic coarse phase shift; rise edge setting.
DFPAI[3:0]	I	Dynamic coarse phase shift; falling edge setting.
CLKOP	O	PLL output clock (no phase shift).
CLKOS	O	PLL output clock (phase shifted/duty cycle changed).
CLKOK	O	PLL output to clock tree (no phase shift, low speed).
LOCK	O	PLL LOCK to CLKI, asynchronous signal. Active high indicates PLL lock.
CLKINTFB	O	Internal feedback source. CLKOP divider output before CLOCK TREE.

The EPLLD primitive can be used for design migration between LatticeECP2. and LatticeXP2, which can be divided into four situations:

Design Migration From LatticeECP2 to LatticeXP2 (EPLLD Configurations):

- EPLLD Configurations without Dynamic Phase & Duty Options: The LatticeECP2 PLL configuration migrates to LatticeXP2 without any changes.
- EPLLD Configurations with Dynamic Phase & Duty Options: The LatticeECP2 PLL configuration has DPAMODE port in the top-level port list. To migrate this configuration to LatticeXP2, the user has to tie the DPAMODE port to GND.

Design Migration From LatticeECP2 to LatticeXP2 (EHXPLLD Configurations): This configuration cannot be migrated to LatticeXP2 because LatticeXP2 does not support Delay Adjust.

Design Migration From LatticeXP2 to LatticeECP2 (EPLLD Configurations):

- EPLLD Configurations without Dynamic Phase & Duty Options: The LatticeXP2 PLL configuration migrates to LatticeECP2 without any changes.
- EPLLD Configurations with Dynamic Phase & Duty Options (No Duty Trim): The LatticeXP2 PLL configuration has no DPAMODE port in the top-level port list. Two options for migration:
  a. Regenerate the PLL configuration for LatticeECP2.
  b. Modify the LatticeXP2 PLL configuration to bring the DPAMODE to top-level port list.

Design Migration From LatticeXP2 to LatticeECP2 (EHXPLLE Configurations): This configuration cannot be migrated to LatticeECP2 because LatticeECP2 does not support Duty Trim Options, CLKOK2 and the CLKOS Fine Delay Port (WRDEL).

You can refer to the following technical notes on the Lattice web site for more detailed description and usage.

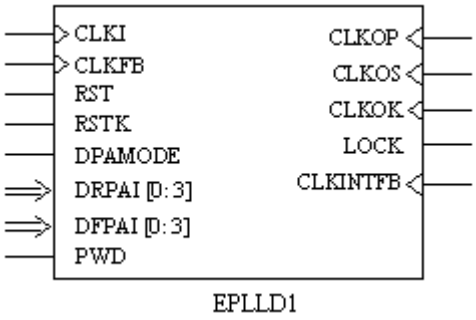
- TN1103 - LatticeECP2 sysCLOCK PLL/DLL Design and Usage Guide
- TN1126 - LatticeXP2 sysCLOCK PLL Design and Usage Guide

EPLLD1

Enhanced PLL

Architectures Supported:

- LatticeXP2



INPUTS: CLKI, CLKFB, RST, RSTK, DPAMODE, DRPAI3, DRPAI2, DRPAI1, DRPAI0, DFPAI3, DFPAI2, DFPAI1, DFPAI0, PWD

OUTPUTS: CLKOP, CLKOS, CLKOK, LOCK, CLKINTFB

ATTRIBUTES:

FIN: 20.0000~420.0000 (in MHz) (default: "100.0000")

CLKI_DIV: integers 1~64 (default: 1)

CLKFB_DIV: integers 1~64 (default: 1)

CLKOP_DIV: 2, 4, 8 (default), 16, 32, 48, 64, 80, 96,112, 128

CLKOK_DIV: 2 (default), 4, 6, 8, ..., 126, 128

PHASEADJ: 0 (default), 22.5, 45, 67.5, 90, ..., 315, 337.5

DUTY: integers 2~14 (default: 8)

PHASE_CNTL: "STATIC" (default), "DYNAMIC"

PLLCAP: "DISABLED" (default), "ENABLED", "AUTO"

CLKOP_BYPASS: "DISABLED" (default), "ENABLED"

CLKOS_BYPASS: "DISABLED" (default), "ENABLED"

CLKOK_BYPASS: "DISABLED" (default), "ENABLED"

PLLTYPE: "AUTO" (default), "SPLL", "GPLL"

Description

The following are descriptions of EPLLD1 port functions.

Table 604:

Port	I/O	Function
CLKI	I	Input clock.
CLKFB	I	Feedback clock.
RST	I	PLL reset (connected to the CNTRST port). High active reset.
RSTK	I	Reset for K divider (connected to the RESETK port). High active reset.
DPAMODE	I	Dynamic phase adjust mode. Active high indicates pin control (DYNAMIC) and active low indicates fuse control (STATIC).
DRPAI[3:0]	I	Dynamic coarse phase shift; rise edge setting.
DFPAI[3:0]	I	Dynamic coarse phase shift; falling edge setting.
PWD	I	Dynamic power down signal.
CLKOP	O	PLL output clock (no phase shift).
CLKOS	O	PLL output clock (phase shifted/duty cycle changed).
CLKOK	O	PLL output to clock tree (no phase shift, low speed).
LOCK	O	PLL LOCK to CLKI, asynchronous signal. Active high indicates PLL lock.
CLKINTFB	O	Internal feedback source. CLKOP divider output before CLOCK TREE.

You can refer to the following technical note on the Lattice web site for more detailed description and usage.

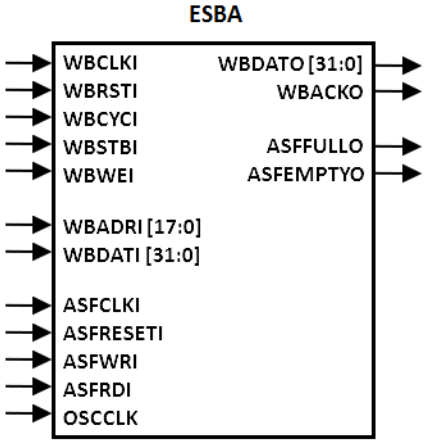
- TN1126 - LatticeXP2 sysCLOCK PLL Design and Usage Guide

ESBA

Embedded Security Block including a WishBone Interface.

Architectures Supported:

- MachXO3D



INPUTS: WBDATI31, WBDATI30, WBDATI29, WBDATI28, WBDATI27, WBDATI26, WBDATI25, WBDATI24, WBDATI23, WBDATI22, WBDATI21, WBDATI20, WBDATI19, WBDATI18, WBDATI17, WBDATI16, WBDATI15, WBDATI14, WBDATI13, WBDATI12, WBDATI11, WBDATI10, WBDATI9, WBDATI8, WBDATI7, WBDATI6, WBDATI5, WBDATI4, WBDATI3, WBDATI2, WBDATI1, WBDATI0, WBSTBI, WBCLKI, ASFCLKI, WBRSTI, ASFRESETI, WBADRI17, WBADRI16, WBADRI15, WBADRI14, WBADRI13, WBADRI12, WBADRI11, WBADRI10, WBADRI9, WBADRI8, WBADRI7, WBADRI6, WBADRI5, WBADRI4, WBADRI3, WBADRI2, WBADRI1, WBADRI0, WBCYCI, WBWEI, ASFWRI, ASFRDI, OSCCLK

OUTPUTS: WBDATO31, WBDATO30, WBDATO29, WBDATO28, WBDATO27, WBDATO26, WBDATO25, WBDATO24, WBDATO23, WBDATO22, WBDATO21, WBDATO20, WBDATO19, WBDATO18, WBDATO17, WBDATO16, WBDATO15, WBDATO14, WBDATO13, WBDATO12, WBDATO11, WBDATO10, WBDATO9, WBDATO8, WBDATO7, WBDATO6, WBDATO5, WBDATO4, WBDATO3, WBDATO2, WBDATO0, WBACKO, ASFFULLO, ASFEMPTYO

ATTRIBUTES:

UDS_TRN: 0 (default)

UDS_TRN_FORMAT: ASCII (default)

Table 605:

Port	I/O	Description
WBDATI[31:0]	I	Write Data Input. Split transactions are not supported requiring the master to stay active on the bus until a valid response is received.
WBDATO[31:0]	O	Read Data Output
WBSTBI	I	Strobe input indicating the WB slave is the target for the current transaction on the WB bus.

Table 605:

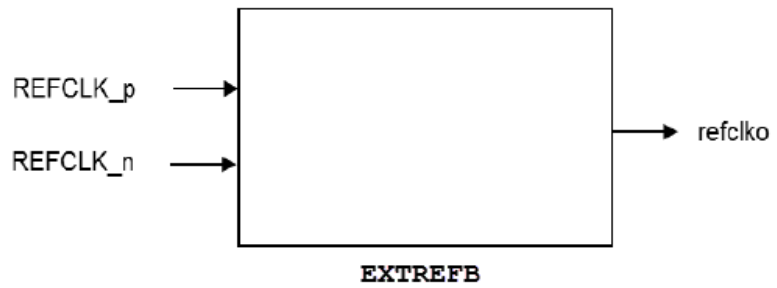
Port	I/O	Description
WBACKO	O	Transfer Acknowledge asserted by the WB slave to the master, indicating the requested transfer has been completed. This signal is qualified by WBSTBI.
WBCLKI	I	Positive edge clock used by all WB interface logic blocks.
ASFFULLO	O	Indicates FIFO is full.
ASFCLKI	I	Clock for ASF.
ASFEMPTYO	O	Indicates FIFO is empty.
WBRSTI	I	Resets the WB logic.
ASFRESETI	I	Resets the ASF logic.
WBADRI[17:0]	I	Address
WBCYCI	I	Cycle input indicates the WB slave a valid bus cycle is present on the bus. In multiple-master configuration, this signal serves as a bus request.
WBWEI	I	Write/Read indicator. 0 : Read transaction; 1 : Write transaction
ASFWRI	I	Write strobe
ASFRDI	I	Read strobe
OSCCLK	I	Input clock used for ESB

EXTREFB

Reference clock input buffer primitive for the dedicated external clock inputs to the Serdes TxPLL

Architectures Supported:

- ECP5



INPUTS: REFCLK_p, REFCLK_n

OUTPUTS: REFCLKO

The table below describes the I/O ports of the EXTREFA primitive.

Table 606:

Port	I/O	Function
REFCLKP	I	External reference clock positive input port.
REFCLKN	I	External reference clock negative input port
REFCLKO	O	Single-ended clock signal to be connected to PCS PLL inputs.

Description

The EXTREFB module takes the differential external reference clock pins (refclkp/n) and sends out a single-ended clock signal to the SerDes TxPLL. The EXTREFB can only connect to SerDes TxPLL in the same DCUA, or to SerDes TxPLL in the complementary sharing DCUA.

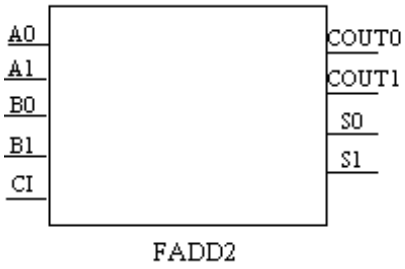
F

FADD2

2 Bit Fast Adder

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP
- MachXO
- Platform Manager



INPUTS: A1, A0, B1, B0, CI

OUTPUTS: COUT1, COUT0, S1, S0

Description

FADD2 is a 2-bit adder. It has a carry-in input (CI) and two 2-bit input (A0, A1 and B0, B1). The FADD2 produces a 2-bit sum output (S0, S1) along with a 2-bit carry-out output (COUT1, COUT).

Example pin functions:

Table 607:

Function	Pins
input	A1, A0, B1, B0
output	S1, S0
carry-in input	CI

Table 607:

Function	Pins
carry-out output (Bit-0)	COUT0
carry-out output (Bit-1)	COUT1

Truth Table

Table 608:

INPUTS					OUTPUTS			
A0	A1	B0	B1	CI	S0	COUT0	S1	COUT1
0	0	0	0	0	0	0	0	0
1	1	0	0	0	1	0	1	0
0	0	1	1	0	1	0	1	0
1	1	1	1	0	0	1	1	1
0	0	0	0	1	1	0	0	0
1	1	0	0	1	0	1	0	1
0	0	1	1	1	0	1	0	1
1	1	1	1	1	1	1	1	1

Note

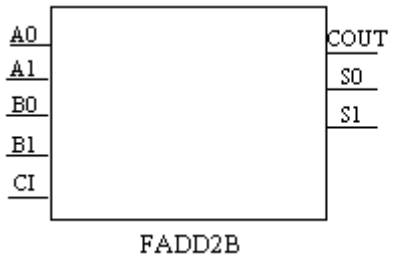
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FADD2B

Fast 2 Bit Adder

Architectures Supported:

- LatticeECP2/M
- LatticeECP3
- LatticeXP2
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: A0, A1, B0, B1, CI

OUTPUTS: COUT, S0, S1

Note

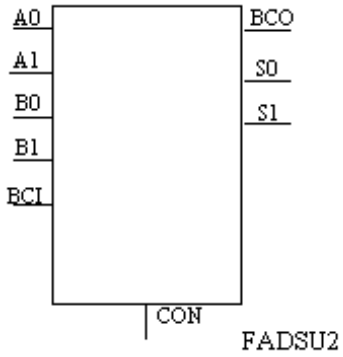
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FADSU2

2 Bit Fast Adder/Subtractor (two's complement)

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A0, A1, B0, B1, BCI, CON

OUTPUTS: BCO, S0, S1

Description

FADSU2 is a 2 bit adder/subtractor. When the control signal (CON) is high FADSU2 functions as a 2 bit adder with a carry-in input (BCI) and two 2 bit inputs (A0:A1 and B0:B1), producing a 2 bit SUM output (S0:S1) along with a carry-out output (BCO).

When the control signal (CON) is low, FADSU2 functions as a 2 bit two's complement subtractor with a borrow-in input (BCI) and two 2 bit inputs (A0:A1 and B0:B1), producing a 2 bit two's complement output of A minus B (S0:S1) along with a borrow-out output (BCO).

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

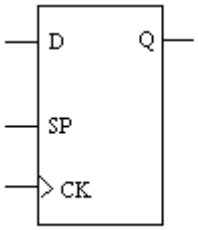
FD1P3AX

Positive Edge Triggered D Flip-Flop with Positive Level Enable, GSR Used for Clear

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2

- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



FD1P3AX

INPUTS: D, SP, CK

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 609:

INPUTS			OUTPUTS
D	SP	CK	Q
X	0	X	Q
0	1	↑	0
1	1	↑	1

X = Don’t care

When GSR=0, Q=0 (D=SP=CK=X)

Note

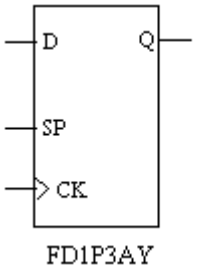
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FD1P3AY

Positive Edge Triggered D Flip-Flop with Positive Level Enable, GSR Used for Preset

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D, SP, CK

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 610:

INPUTS			OUTPUTS
D	SP	CK	Q
X	0	X	Q
0	1	↑	0
1	1	↑	1

X = Don’t care

When GSR=0, Q=1 (D=SP=CK=X)

Note

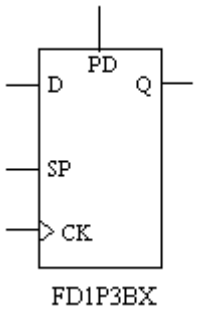
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FD1P3BX

Positive Edge Triggered D Flip-Flop with Positive Level Enable and Positive Level Asynchronous Preset

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D, SP, CK, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 611:

INPUTS				OUTPUTS
D	SP	CK	PD	Q
X	0	X	0	Q
X	X	X	1	1
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

When GSR=0, Q=1 (D=SP=CK=PD=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

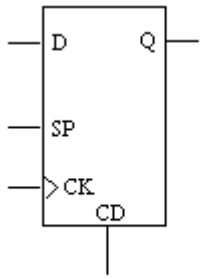
FD1P3DX

Positive Edge Triggered D Flip-Flop with Positive Level Enable and Positive Level Asynchronous Clear

Architectures Supported:

- ECP5

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



FD1P3DX

INPUTS: D, SP, CK, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 612:

INPUTS				OUTPUTS
D	SP	CK	CD	Q
X	0	X	0	Q
X	X	X	1	0
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

When GSR=0, Q=0 (D=SP=CK=CD=X)

Note

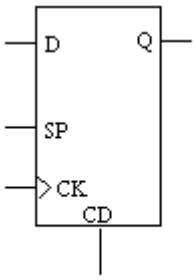
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FD1P3IX

Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear and Positive Level Enable (Clear overrides Enable)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



FD1P3IX

INPUTS: D, SP, CK, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 613:

INPUTS				OUTPUTS
D	SP	CK	CD	Q
X	0	X	0	Q
X	X	↑	1	0
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

When GSR=0, Q=0 (D=SP=CK=CD=X)

Note

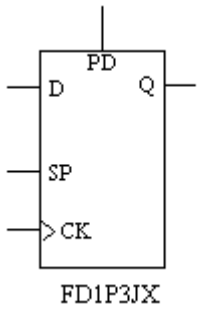
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FD1P3JX

Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset and Positive Level Enable (Preset overrides Enable)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D, SP, CK, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 614:

INPUTS				OUTPUTS
D	SP	CK	PD	Q
X	0	X	0	Q
X	X	↑	1	1
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

When GSR=0, Q=1 (D=SP=CK=PD=X)

Note

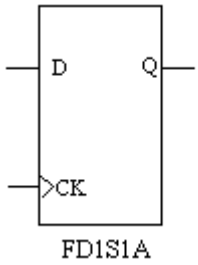
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FD1S1A

Positive Level Data Latch with GSR Used for Clear

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D, CK

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 615:

INPUTS		OUTPUTS
D	CK	Q
X	0	Q
0	1	0
1	1	1

X = Don’t care

When GSR=0, Q=0 (D=CK=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

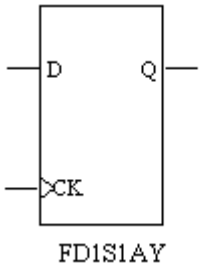
FD1S1AY

Positive Level Data Latch with GSR Used for Preset

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP

- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D, CK

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 616:

INPUTS		OUTPUTS
D	CK	Q
X	0	Q
0	1	0
1	1	1

X = Don’t care

When GSR=0, Q=1 (D=CK=X)

Note

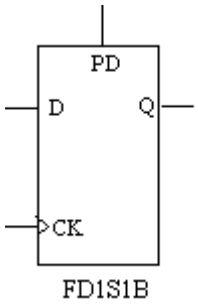
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FD1S1B

Positive Level Data Latch with Positive Level Asynchronous Preset

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D, CK, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 617:

INPUTS			OUTPUTS
D	CK	PD	Q
X	0	0	Q
X	X	1	1
0	1	0	0
1	1	0	1

X= Don’t care

When GSR=0, Q=1 (D=CK=PD=X)

Note

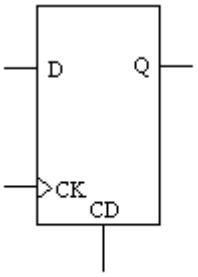
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FD1S1D

Positive Level Data Latch with Positive Level Asynchronous Clear

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



FD1S1D

INPUTS: D, CK, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 618:

INPUTS			OUTPUTS
D	CK	CD	Q
X	0	0	Q
X	X	1	0
0	1	0	0
1	1	0	1

X = Don’t care

When GSR=0, Q=0 (D=CK=CD=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

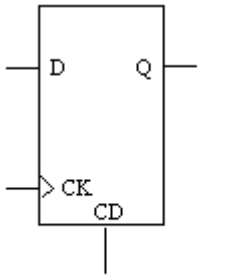
FD1S1I

Positive Level Data Latch with Positive Level Synchronous Clear

Architectures Supported:

- LatticeECP/EC

- LatticeSC/M
- LatticeXP
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



FD1S1I

INPUTS: D, CK, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 619:

INPUTS			OUTPUTS
D	CK	CD	Q
X	0	0	Q
X	1	1	0
0	1	0	0
1	1	0	1

X = Don’t care

When GSR=0, Q=0 (D=CK=CD=X)

Note

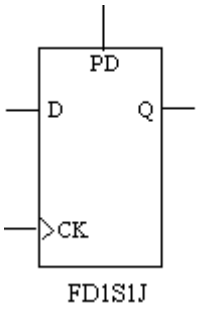
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FD1S1J

Positive Level Data Latch with Positive Level Synchronous Preset

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D, CK, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 620:

INPUTS			OUTPUTS
D	CK	PD	Q
X	0	0	Q
X	1	1	1
0	1	0	0
1	1	0	1

X = Don’t care

When GSR=0, Q=1 (D=CK=PD=X)

Note

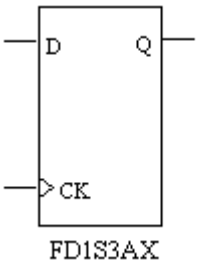
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FD1S3AX

Positive Edge Triggered D Flip-Flop, GSR Used for Clear

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D, CK

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 621:

INPUTS		OUTPUTS
D	CK	Q
0	↑	0
1	↑	1

X = Don’t care

When GSR=0, Q=0 (D=CK=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FD1S3AY

Positive Edge Triggered D Flip-Flop, GSR Used for Preset

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3

- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L

INPUTS: D, CK

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 622:

INPUTS		OUTPUTS
D	CK	Q
0	↑	0
1	↑	1

X = Don’t care

When GSR=0, Q=1 (D=CK=X)

Note

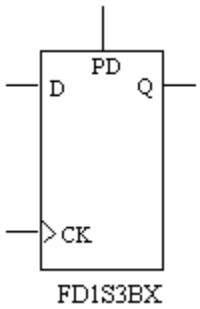
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FD1S3BX

Positive Edge Triggered D Flip-Flop with Positive Level Asynchronous Preset

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D, CK, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 623:

INPUTS			OUTPUTS
D	CK	PD	Q
X	X	1	1
0	↑	0	0
1	↑	X	1

X = Don’t care

When GSR=0, Q=1 (D=CK=PD=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

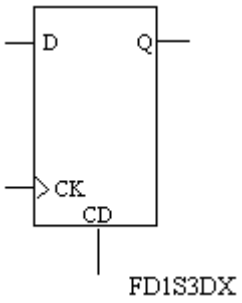
FD1S3DX

Positive Edge Triggered D Flip-Flop with Positive Level Asynchronous Clear

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager

- Platform Manager 2



INPUTS: D, CK, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 624:

INPUTS			OUTPUTS
D	CK	CD	Q
X	X	1	0
0	↑	0	0
1	↑	0	1

X = Don’t care

When GSR=0, Q=0 (D=CK=CD=X)

Note

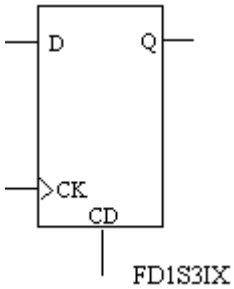
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FD1S3IX

Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D, CK, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 625:

INPUTS			OUTPUTS
D	CK	CD	Q
X	↑	1	0
0	↑	0	0
1	↑	0	1

X = Don’t care

When GSR=0, Q=0 (D=CK=CD=X)

Note

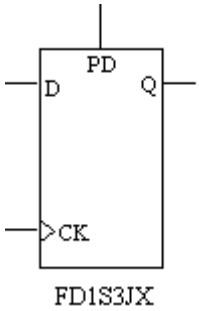
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FD1S3JX

Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



FD1S3JX

INPUTS: D, CK, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 626:

INPUTS			OUTPUTS
D	CK	PD	Q
X	↑	1	1
0	↑	0	0
1	↑	X	1

X = Don’t care

When GSR=0, Q=1 (D=CK=PD=X)

Note

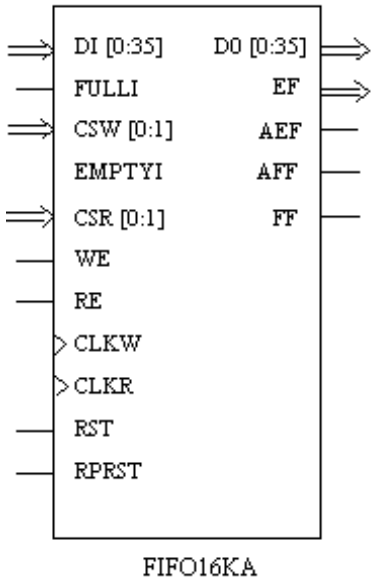
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FIFO16KA

16K FIFO

Architectures Supported:

- LatticeSC/M



INPUTS: DI0, DI1, DI2, DI3, DI4, DI5, DI6, DI7, DI8, DI9, DI10, DI11, DI12, DI13, DI14, DI15, DI16, DI17, DI18, DI19, DI20, DI21, DI22, DI23, DI24, DI25, DI26, DI27, DI28, DI29, DI30, DI31, DI32, DI33, DI34, DI35, FULLI, CSW0, CSW1, EMPTYI, CSR0, CSR1, WE, RE, CLKW, CLKR, RST, RPRST

OUTPUTS: DO0, DO1, DO2, DO3, DO4, DO5, DO6, DO7, DO8, DO9, DO10, DO11, DO12, DO13, DO14, DO15, DO16, DO17, DO18, DO19, DO20, DO21, DO22, DO23, DO24, DO25, DO26, DO27, DO28, DO29, DO30, DO31, DO32, DO33, DO34, DO35, EF, AEF, AFF, FF

ATTRIBUTES:

DATA_WIDTH_W: 1, 2, 4, 9, 18 (default), 36

DATA_WIDTH_R: 1, 2, 4, 9, 18 (default), 36

REGMODE: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE_W: any 2-bit binary value (default: 2'b00)

CSDECODE_R: any 2-bit binary value (default: 2'b00)

GSR: "DISABLED" (default), "ENABLED"

AEPOINTER: any 15-bit binary value (default: all zeros)

AEPOINTER1: any 15-bit binary value (default: all zeros)

AFPOINTER: any 15-bit binary value (default: all zeros)

AFPOINTER1: any 15-bit binary value (default: all zeros)

FULLPOINTER: any 15-bit binary value (default: all zeros)

FULLPOINTER1: any 15-bit binary value (default: all zeros)

Description

You can refer to the following technical note on the Lattice web site on details of EBR port definition, attribute definition and usage.

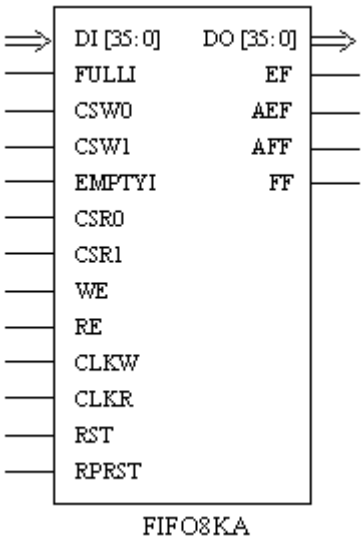
- TN1094 - On-Chip Memory Usage Guide for LatticeSC Devices

FIFO8KA

8K FIFO

Architectures Supported:

- MachXO
- Platform Manager



INPUTS: DI0, DI1, DI2, DI3, DI4, DI5, DI6, DI7, DI8, DI9, DI10, DI11, DI12, DI13, DI14, DI15, DI16, DI17, DI18, DI19, DI20, DI21, DI22, DI23, DI24, DI25, DI26, DI27, DI28, DI29, DI30, DI31, DI32, DI33, DI34, DI35, FULLI, CSW0, CSW1, EMPTYI, CSR0, CSR1, WE, RE, CLKW, CLKR, RST, RPRST

OUTPUTS: DO0, DO1, DO2, DO3, DO4, DO5, DO6, DO7, DO8, DO9, DO10, DO11, DO12, DO13, DO14, DO15, DO16, DO17, DO18, DO19, DO20, DO21,

DO22, DO23, DO24, DO25, DO26, DO27, DO28, DO29, DO30, DO31, DO32, DO33, DO34, DO35, EF, AEF, AFF, FF

ATTRIBUTES:

DATA_WIDTH_W: 1, 2, 4, 9, 18 (default), 36

DATA_WIDTH_R: 1, 2, 4, 9, 18 (default), 36

REGMODE: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE_W: any 2-bit binary value (default: 2'b00)

CSDECODE_R: any 2-bit binary value (default: 2'b00)

AEPOINTER: any 14-bit binary value (default: all zeros)

AEPOINTER1: any 14-bit binary value (default: all zeros)

AFPOINTER: any 14-bit binary value (default: all zeros)

AFPOINTER1: any 14-bit binary value (default: all zeros)

FULLPOINTER: any 14-bit binary value (default: all zeros)

FULLPOINTER1: any 14-bit binary value (default: all zeros)

GSR: "DISABLED" (default), "ENABLED"

Description

You can refer to the following technical note on the Lattice web site on detailed information and usage.

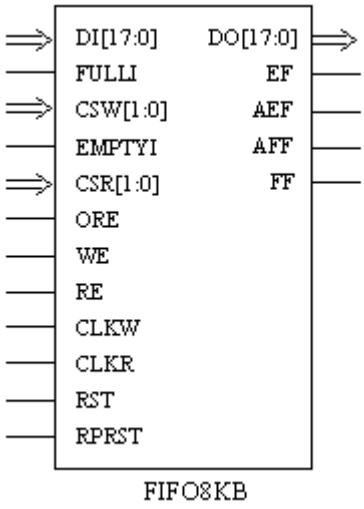
- TN1092 - MachXO Memory Usage Guide

FIFO8KB

8K FIFO Block RAM

Architecture Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: DI17, DI16, DI15, DI14, DI13, DI12, DI11, DI10, DI9, DI8, DI7, DI6, DI5, DI4, DI3, DI2, DI1, DI0, FULLI, CSW1, CSW0, EMPTYI, CSR1, CSR0, ORE, WE, RE, CLKW, CLKR, RST, RPRST

OUTPUTS: DO17, DO16, DO15, DO14, DO13, DO12, DO11, DO10, DO9, DO8, DO7, DO6, DO5, DO4, DO3, DO2, DO1, DO0, EF, AEF, AFF, FF

ATTRIBUTES:

DATA_WIDTH_W: 1, 2, 4, 9, 18 (default)

DATA_WIDTH_R: 1, 2, 4, 9, 18 (default)

REGMODE: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE_W: any 2-bit binary value (default: zeros)

CSDECODE_R: any 2-bit binary value (default: zeros)

GSR: "DISABLED" (default), "ENABLED"

RESETMODE: "ASYNC" (default), "SYNC"

ASYNC_RESET_RELEASE: "SYNC" (default), "ASYNC"

AEPOINTER: any 14-bit binary value (default: all zeros)

AEPOINTER1: any 14-bit binary value (default: all zeros)

AFPOINTER: any 14-bit binary value (default: all zeros)

AFPOINTER1: any 14-bit binary value (default: all zeros)

FULLPOINTER: any 14-bit binary value (default: all zeros)

FULLPOINTER1: any 14-bit binary value (default: all zeros)

Description

The following table describes the I/O ports of the FIFO8KB primitive.

Table 627:

Port Name	I/O	Definition
DI[17:0]	I	Write data (up to 18)
CLKW	I	Write clock
WE	I	Write clock enable
RST	I	Reset write pointers
FULLI	I	Chip select write
CSW[1:0]	I	Chip select write
CLKR	I	Read clock
RE	I	Read clock enable
ORE	I	Read output clock enable
EMPTYI	I	Chip select read
CSR[1:0]	I	Chip select read
RPRST	I	Reset read pointers
DO[17:0]	O	Read data (up to 18)
AFF	O	Almost full flag
FF	O	Full flag
AEF	O	Almost empty flag
EF	O	Empty flag

You can refer to the following technical note on the Lattice web site on detailed information and usage.

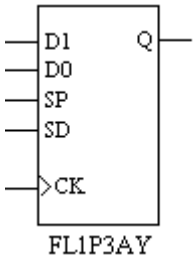
- TN1201 - Memory Usage Guide for MachXO2 Devices

FL1P3AY

Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, and Positive Level Enable, GSR Used for Preset

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, SP, CK, SD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 628:

INPUTS					OUTPUTS
D0	D1	SP	SD	CK	Q
X	X	0	X	X	Q
0	X	1	0	↑	0
1	X	1	0	↑	1
X	0	1	1	↑	0
X	1	1	1	↑	1

X = Don’t care

When GSR=0, Q=1 (D0=D1=SP=SD=CK=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

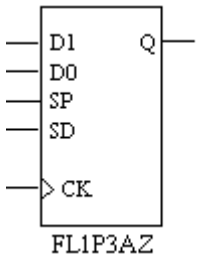
FL1P3AZ

Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, and Positive Level Enable, GSR Used for Clear

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager

- Platform Manager 2



INPUTS: D0, D1, SP, CK, SD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 629:

INPUTS					OUTPUTS
D0	D1	SP	SD	CK	Q
X	X	0	X	X	Q
0	X	1	0	↑	0
1	X	1	0	↑	1
X	0	1	1	↑	0
X	1	1	1	↑	1

X = Don’t care

When GSR=0, Q=0 (D0=D1=SP=SD=CK=X)

Note

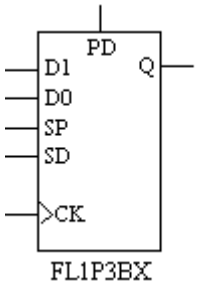
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FL1P3BX

Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Asynchronous Preset, and Positive Level Enable

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, SP, CK, SD, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 630:

INPUTS						OUTPUTS
D0	D1	SP	SD	CK	PD	Q
X	X	0	X	X	0	Q
X	X	X	X	X	1	1
0	X	1	0	↑	0	0
1	X	1	0	↑	X	1
X	0	1	1	↑	0	0
X	1	1	1	↑	X	1

X = Don’t care

When GSR=0, Q=1 (D0=D1=SP=SD=CK=PD=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

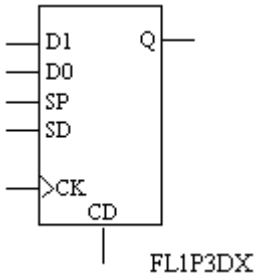
FL1P3DX

Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Asynchronous Clear, and Positive Level Enable

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D

- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, SP, CK, SD, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 631:

INPUTS						OUTPUTS
D0	D1	SP	SD	CK	CD	Q
X	X	0	X	X	0	Q
X	X	X	X	X	1	0
0	X	1	0	↑	X	0
1	X	1	0	↑	0	1
X	0	1	1	↑	X	0
X	1	1	1	↑	0	1

X = Don’t care

When GSR=0, Q=0 (D0=D1=SP=SD=CK=CD=X)

Note

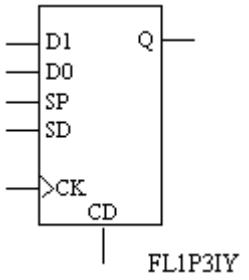
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FL1P3IY

Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Synchronous Clear, and Positive Level Enable (Clear overrides Enable)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, SP, SD, CK, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 632:

INPUTS						OUTPUTS
D0	D1	SP	SD	CK	CD	Q
X	X	0	X	X	0	Q
X	X	X	X	↑	1	0
0	X	1	0	↑	X	0
1	X	1	0	↑	0	1
X	0	1	1	↑	X	0
X	1	1	1	↑	0	1

X = Don’t care

When GSR=0, Q=1 (D0=D1=SP=SD=CK=CD=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

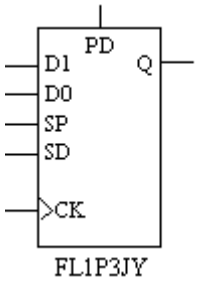
FL1P3JY

Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, Positive Level Data Select, Positive Level Synchronous Preset, and Positive Level Enable (Preset overrides Enable)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D

- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, SP, CK, SD, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 633:

INPUTS						OUTPUTS
D0	D1	SP	SD	CK	PD	Q
X	X	0	X	X	0	Q
X	X	X	X	↑	1	1
0	X	1	0	↑	0	0
1	X	1	0	↑	X	1
X	0	1	1	↑	0	0
X	1	1	1	↑	X	1

X = Don’t care

When GSR=0, Q=1 (D0=D1=SP=SD=CK=PD=X)

Note

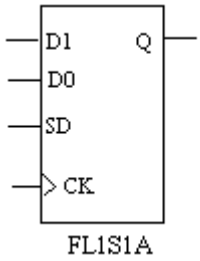
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FL1S1A

Positive Level Loadable Latch with Positive Select, GSR Used for Clear

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, CK, SD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 634:

INPUTS				OUTPUTS
D0	D1	SD	CK	Q
0	X	0	1	0
1	X	0	1	1
X	0	1	1	0
X	1	1	1	1

X = Don’t care

When GSR=0, Q=0 (D0=D1=SD=CK=X)

Note

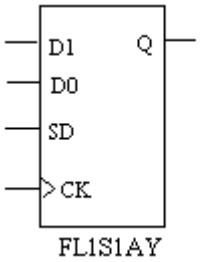
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FL1S1AY

Positive Level Loadable Latch with Positive Select, GSR Used for Preset

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, CK, SD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 635:

INPUTS				OUTPUTS
D0	D1	SD	CK	Q
0	X	0	1	0
1	X	0	1	1
X	0	1	1	0
X	1	1	1	1

X = Don’t care

When GSR=0, Q=1 (D0=D1=SD=CK=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

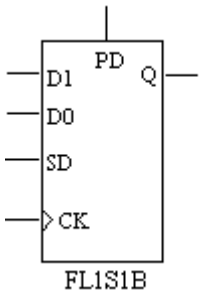
FL1S1B

Positive Level Loadable Latch with Positive Level Data Select and Positive Level Asynchronous Preset

Architectures Supported:

- LatticeECP/EC

- LatticeSC/M
- LatticeXP
- MachXO
- MachXO2
- MachXO3D
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, CK, SD, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 636:

INPUTS					OUTPUTS
D0	D1	SD	CK	PD	Q
X	X	X	0	0	Q
X	X	X	X	1	1
0	X	0	1	0	0
1	X	0	1	X	1
X	0	1	1	0	0
X	1	1	1	X	1

X= Don’t care

When GSR=0, Q=1 (D0=D1=SD=CK=PD=X)

Note

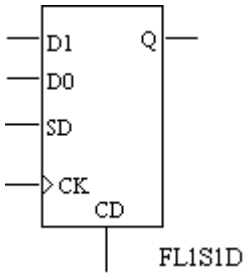
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FL1S1D

Positive Level Loadable Latch with Positive Level Data Select and Positive Level Asynchronous Clear

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP
- MachXO
- MachXO2
- MachXO3D
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, CK, SD, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 637:

INPUTS					OUTPUTS
D0	D1	SD	CK	CD	Q
X	X	X	0	0	Q
X	X	X	X	1	0
0	X	0	1	X	0
1	X	0	1	0	1
X	0	1	1	X	0
X	1	1	1	0	1

X = Don’t care

When GSR=0, Q=0 (D0=D1=SD=CK=CD=X)

Note

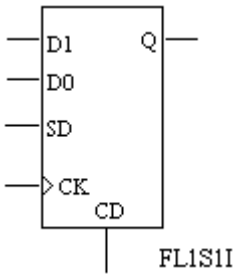
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FL1S1I

Positive Level Loadable Latch with Positive Level Data Select and Positive Level Synchronous Clear

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP
- MachXO
- MachXO2
- MachXO3D
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, CK, SD, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 638:

INPUTS					OUTPUTS
D0	D1	SD	CK	CD	Q
X	X	X	0	0	Q
X	X	X	1	1	0
0	X	0	1	X	0
1	X	0	1	0	1
X	0	1	1	X	0
X	1	1	1	0	1

X = Don’t care

When GSR=0, Q=0 (D0=D1=SD=CK=CD=X)

Note

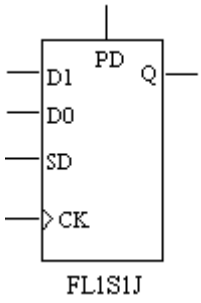
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FL1S1J

Positive Level Loadable Latch with Positive Level Data Select and Positive Level Synchronous Preset

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP
- MachXO
- MachXO2
- MachXO3D
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, CK, SD, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 639:

INPUTS					OUTPUTS
D0	D1	SD	CK	PD	Q
X	X	X	0	0	Q
X	X	X	1	1	1
0	X	0	1	0	0
1	X	0	1	X	1
X	0	1	1	0	0
X	1	1	1	X	1

X = Don’t care

When GSR=0, Q=1 (D0=D1=SD=CK=PD=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

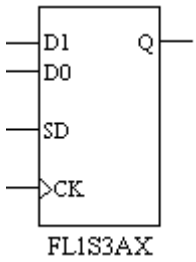
FL1S3AX

Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, GSR Used for Clear

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L

- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, CK, SD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 640:

INPUTS				OUTPUTS
D0	D1	SD	CK	Q
0	X	0	↑	0
1	X	0	↑	1
X	0	1	↑	0
X	1	1	↑	1

X = Don’t care

When GSR=0, Q=0 (D0=D1=SD=CK=X)

Note

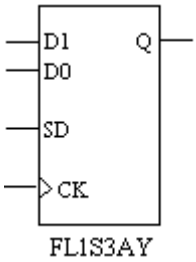
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FL1S3AY

Positive Edge Triggered D Flip-Flop with 2 Input Data Mux, GSR Used for Preset

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, CK, SD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 641:

INPUTS				OUTPUTS
D0	D1	SD	CK	Q
0	X	0	↑	0
1	X	0	↑	1
X	0	1	↑	0
X	1	1	↑	1

X = Don’t care

When GSR=0, Q=1 (D0=D1=SD=CK=X)

Note

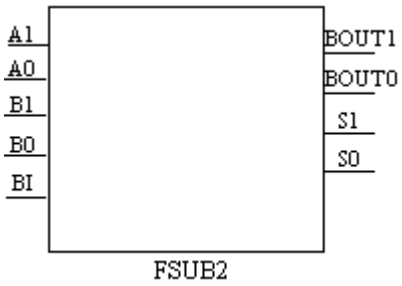
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FSUB2

2 Bit Fast Subtractor (two's complement)

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP
- MachXO
- Platform Manager



INPUTS: A1, A0, B1, B0, BI

OUTPUTS: BOUT1, BOUT0, S1, S0

Description

FSUB2 is a 2-bit two's complement subtractor. It has a borrow-in input (BI) and two 2-bit input (A0, A1 and B0, B1). The FSUB2 produces a 2-bit difference output (S0, S1) along with a 2-bit borrow-out output (BOUT1, BOUT).

Example pin functions:

Table 642:

Function	Pins
input	A1, A0, B1, B0
output	S1, S0
borrow-in input	BI
borrow-out output (Bit-0)	BOUT0
borrow-out output (Bit-1)	BOUT1

Truth Table

Table 643:

INPUTS					OUTPUTS			
A0	A1	B0	B1	BI	S0	BOUT0	S1	BOUT1
0	0	0	0	0	0	0	1	0
1	1	0	0	0	1	1	0	1
0	0	1	1	0	0	0	0	0
1	1	1	1	0	0	0	1	0
0	0	0	0	1	1	1	0	1
1	1	0	0	1	1	1	1	1
0	0	1	1	1	0	0	1	0
1	1	1	1	1	1	1	0	1

Note

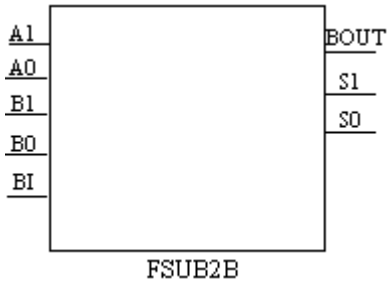
- BI and BO are inverse from standard two's complement behavior.
- This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

FSUB2B

2 Bit Subtractor

Architectures Supported:

- LatticeECP2/M
- LatticeECP3
- LatticeXP2
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: A0, A1, B0, B1, BI

OUTPUTS: BOUT, S0, S1

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

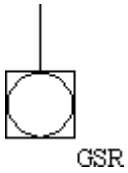
G

GSR

Global Set/Reset Interface

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUT: GSR

Description

GSR is used to reset or set all register elements in your design. The GSR component can be connected to a net from an input buffer or an internally generated net. It is active LOW and when pulsed will set or reset all flip-flops, latches, registers, and counters to the same state as the local set or reset functionality.

It is not necessary to connect signals for GSR to any register elements explicitly. The function will be implicitly connected globally. The functionality of

the GSR for sequential cells without a local set or reset are described in the appropriate library help page.

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

I

IB

Input Buffer

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

IBDDC

Dynamic Delay

Architectures Supported:

- LatticeECP/EC
- LatticeXP

INPUTS: I, DC3, DC2, DC1, DC0

OUTPUT: O

Description

The IBDDC primitive is used to control the input delay dynamically. See the below table for the I/O description.

Table 645:

Port Name	I/O	Definition
I	Input	Input

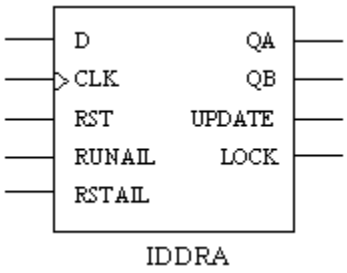
IDDRA

Input DDR

Architectures Supported:

- LatticeSC/M

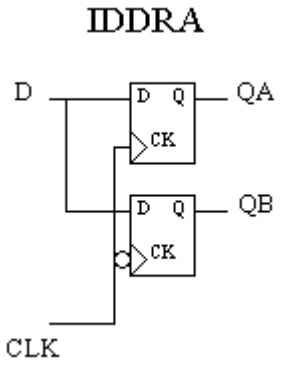


INPUTS: D, CLK, RST, RUNAIL, RSTAIL

OUTPUTS: QA, QB, UPDATE, LOCK

Description

Double Data Rate input logic. The following symbolic diagram shows the flip-flop structure of this primitive.



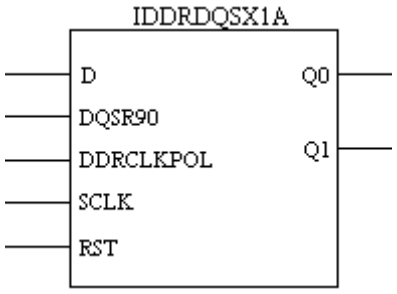
For more usage, see related technical notes or contact technical support.

IDDRDQSX1A

Input for DDR1/2 Memory

Architectures Supported:

- MachXO2
- Platform Manager 2



INPUTS: D, DQSR90, DDRCLKPOL, SCLK, RST

OUTPUTS: Q0, Q1

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

IDDR supports two clock domains (right side only). IDDRDQSX1A is the input for DDR1/2 memory. It is used for right bank only.

See the following table for port description of the IDDRDQSX1A primitive.

Table 654:

Port Name	I/O	Definition
D	I	DDR input from sysIO buffer.
DQSR90	I	Shifted DQS input for read.
DDRCLKPOL	I	DQS clock polarity. This signal is used to connect to the DDRCLKPOL output of DQSBUFH.
SCLK	I	System clock.
RST	I	RESET to this block from CIB.
Q0	O	Data at the positive edge of the clock.
Q1	O	Data at the negative edge of the clock.

For more information and usage, refer to the following technical note on the Lattice web site.

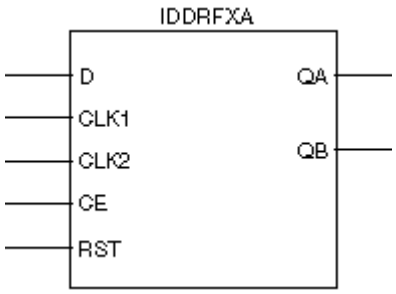
- TN1203 - Implementing High-Speed Interfaces with MachXO2 Devices

IDDRFXA

DDR Generic Input with Full Clock Transfer (x1 Gearbox)

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



INPUTS: D, CLK1, CLK2, RST, CE

OUTPUTS: QA, QB

Description

This primitive inputs DDR data at both edges of clock CLK1 and generates two streams of data aligned to clock CLK2. CLK1 is used to register the DDR registers and the first set of synchronization registers. CLK2 is used by the third stage of registers. Both CLK1 and CLK2 should be clocked by the FPGA clock. The LatticeECP2/M Family Data Sheet explains the input register block in more detail.

Note that LSR is only for second stage register/latch. For supporting DDR modes configured for bidirectional use, software will tie LSR LOW for input registers. The default for LSR is HIGH.

See the following table for port description of the IDDRFXA primitive.

Table 655:

Port Name	I/O	Definition
D	I	DDR data
CLK1	I	Clock connected to the FPGA clock
CLK2	I	Clock connected to the FPGA clock
CE	I	Clock enable signal
RST	I	Signal used to reset the DDR register
QA	O	Data at the positive edge of the CLK
QB	O	Data at the negative edge of the CLK

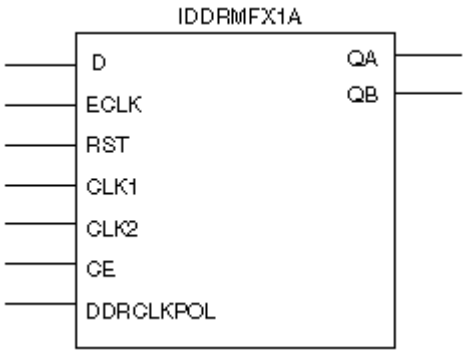
For more usage, see related technical notes or contact technical support.

IDDRMFX1A

DDR Input and DQS to System Clock Transfer Registers with Full Clock Cycle Transfer

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



INPUTS: D, ECLK, CLK1, CLK2, RST, CE, DDRCLKPOL

OUTPUTS: QA, QB

Description

This primitive implements a full clock cycle transfer as compared the to the IDDRMX1A primitive that will only implement a half clock cycle transfer. The DDR registers are designed to use edge clock routing on the I/O side and the primary clock on the FPGA side. The ECLK input is used to connect to the DQS strobe coming from the DQS delay block (DQSBUFC primitive). The CLK1 and CLK2 inputs should be connected to the slow system (FPGA) clock. DDRCLKPOL is an input from the DQS Clock Polarity tree. This signal is generated by the DQS Transition detect circuit in the hardware.

Note that the DDRCLKPOL input to IDDRMFX1A should be connected to the DDRCLKPOL output of DQSBUFC. LSR is only for second stage register/ latch. For supporting DDR modes configured for bidirectional use, software will tie LSR LOW for input registers. The default for LSR is HIGH.

See the following table for port description of the IDDRMFX1A primitive.

Table 656:

Port Name	I/O	Definition
D	I	DDR data.
ECLK	I	The phase shifted DQS should be connected to this input.
RST	I	Reset.
CLK1	I	Slow FPGA CLK.
CLK2	I	Slow FPGA CLK.
CE	I	Clock enable.
DDRCLKPOL	I	DDR clock polarity signal.
QA	O	Data at the positive edge of the CLK.
QB	O	Data at the negative edge of the CLK.

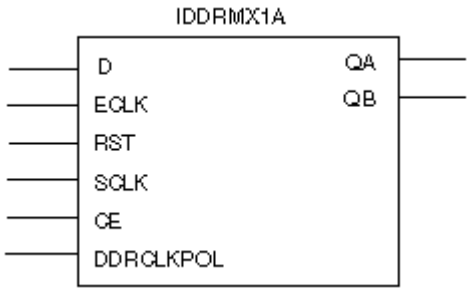
For more usage, see related technical notes or contact technical support.

IDDRMX1A

DDR Input and DQS to System Clock Transfer Registers with Half Clock Cycle Transfer

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



INPUTS: D, ECLK, SCLK, RST, CE, DDRCLKPOL

OUTPUTS: QA, QB

Description

This primitive implements the input register block. The DDR registers are designed to use edge clock routing on the I/O side and the primary clock on the FPGA side. The ECLK input is used to connect to the DQS strobe coming from the DQS delay block (DQSBUFC primitive). The SCLK input should be connected to the system (FPGA) clock. DDRCLKPOL is an input from the DQS Clock Polarity tree. This signal is generated by the DQS Transition detect circuit in the hardware. The DDRCLKPOL signal is used to choose the polarity of the SCLK to the synchronization registers.

Note that the DDRCLKPOL input to IDDRMX1A should be connected to the DDRCLKPOL output of DQSBUFC. LSR is only for second stage register/ latch. For supporting DDR modes configured for bidirectional use, software will tie LSR LOW for input registers. The default for LSR is HIGH.

See the following table for port description of the IDDRMX1A primitive.

Table 657:

Port Name	I/O	Definition
D	I	DDR data.
ECLK	I	The phase shifted DQS should be connected to this input.

Table 657:

Port Name	I/O	Definition
RST	I	Reset.
SCLK	I	System CLK.
CE	I	Clock enable.
DDRCLKPOL	I	DDR clock polarity signal.
QA	O	Data at the positive edge of the CLK.
QB	O	Data at the negative edge of the CLK.

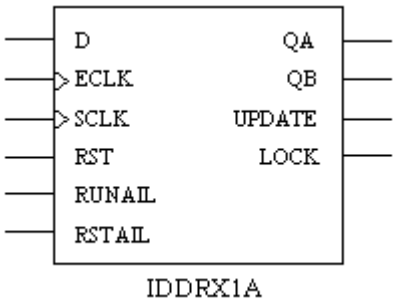
For more usage, see related technical notes or contact technical support.

IDDRX1A

Input DDR

Architectures Supported:

- LatticeSC/M

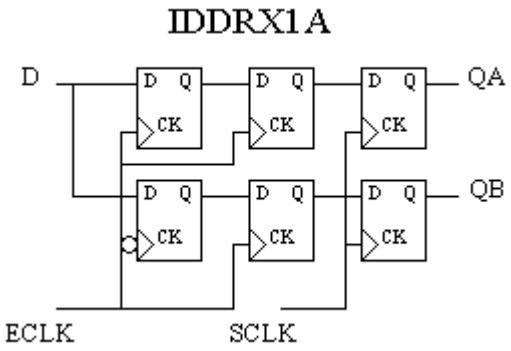


INPUTS: D, ECLK, SCLK, RST, RUNAIL, RSTAIL

OUTPUTS: QA, QB, UPDATE, LOCK

Description

Double Data Rate input logic. The input register block captures DDR input data using edge clock to primary clock domain transfer. It can also be set to perform the same functions as in the shift mode. The following symbolic diagram shows the flip-flop structure of this primitive.



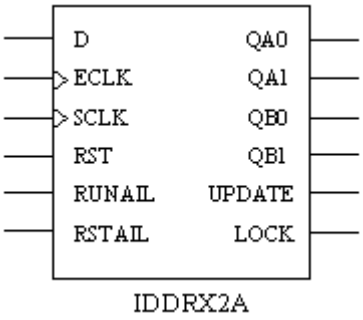
For more usage, see related technical notes or contact technical support.

IDDRX2A

Input DDR

Architectures Supported:

- LatticeSC/M

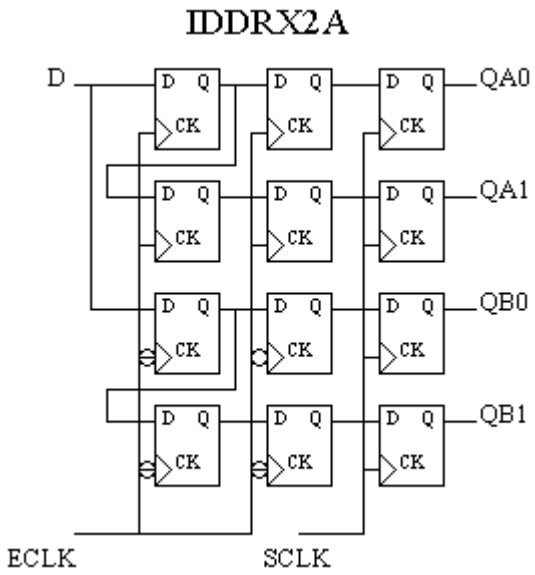


INPUTS: D, ECLK, SCLK, RST, RUNAIL, RSTAIL

OUTPUTS: QA0, QA1, QB0, QB1, UPDATE, LOCK

Description

Double Data Rate input logic. The input register block captures DDR input data using edge clock to primary clock domain transfer. It can also be set to perform the same functions as in the shift mode. The following symbolic diagram shows the flip-flop structure of this primitive.



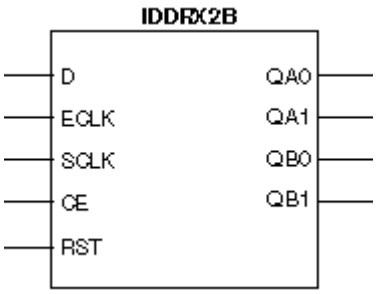
For more usage, see related technical notes or contact technical support.

IDDRX2B

DDR Generic Input with 2x Gearing Ratio

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



INPUTS: D, ECLK, SCLK, CE, RST

OUTPUTS: QA0, QA1, QB0, QB1

Description

This primitive is used when a gearing function is required. This primitive inputs DDR data at both edges of the edge and generates four streams of data. The DDR registers and the first set of synchronization registers are clocked by the ECLK input of the primitive, which should be connected to the fast ECLK. SCLK is used to clock the third stage of registers and should be connected to the FPGA clock. This primitive outputs four streams of data. Two of these data streams are generated using the complementary PIO registers.

Note that LSR is only for second stage register/latch. For supporting DDR modes configured for bidirectional use, software will tie LSR LOW for input registers. The default for LSR is HIGH.

See the following table for port description of the IDDRX2B primitive.

IDDRX2B Ports

Table 658:

Port Name	I/O	Definition
D	I	DDR data
ECLK	I	Clock connected to the fast edge clock
SCLK	I	Clock connected to the FPGA clock
CE	I	Clock enable signal
RST	I	Signal used to reset the DDR register
QA0, QA1	O	Data at the positive edge of the CLK
QB0, QB1	O	Data at the negative edge of the CLK

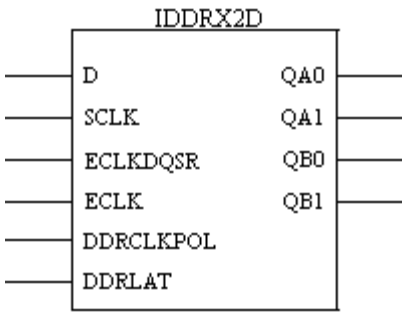
For more usage, see related technical notes or contact technical support.

IDDRX2D

Input DDR for DDR3_MEM, DDR_GENX2, and DDR3_MEMGEN

Architectures Supported:

- LatticeECP3



INPUTS: D, SCLK, ECLKDQSR, ECLK, DDRLAT, DDRCLKPOL

OUTPUTS: QA0, QA1, QB0, QB1

ATTRIBUTES:

(*EA only*) SCLKLATENCY: 1 (default), 2

Description

IDDRX2D is the input DDR for DDR3_MEM, DDR_GENX2 (DDR generic mode in X2 gearing), and DDR3_MEMGEN.

- E: DDR_GENX2 (left/right/top)
- E and EA: DDR3_MEM (left/right)
- E and EA: DDR3_MEMGEN (left/right/top)

See the below table for its port description.

Table 659:

Signal	I/O	Description
D	I	DDR input from sysIO buffer.
ECLK	I	Edge clock. Goes to the second stage of DDR registers.
SCLK	I	System clock. Clock used to transfer from the ECLK to the SCLK domain. SCLK = 1/2 ECLK rate. Goes to the third stage of registers.
ECLKDQSR	I	Phase shifted DQS in case of DDR memory interface. Edge clock for generic DDR interfaces. Connects to DQSBUF. For EA devices, ECLKDQSR should be used only for the DQS strobe.
DDRCLKPOL	I	DDR clock polarity signal.
DDRLAT	I	DDR latch control to input logic. Used to guarantee IDDRX2 gearing by selectively enabling a D flip-flop in the data path.
QA0	O	Data at the positive edge of the clock (IPA).

Table 659:

Signal	I/O	Description
QA1	O	Data at the positive edge of the clock (IPB).
QB0	O	Data at the negative edge of the clock (INA).
QB1	O	Data at the negative edge of the clock (INB).

For more information and usage, refer to the following technical note on the Lattice web site.

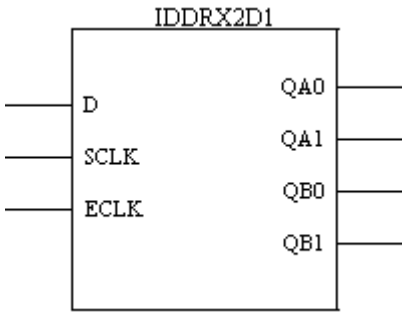
- TN1177 - LatticeECP3 sysIO Usage Guide

IDDRX2D1

Input DDR for DDR_GENX2

Architectures Supported:

- LatticeECP3



INPUTS: D, SCLK, ECLK

OUTPUTS: QA0, QA1, QB0, QB1

ATTRIBUTES:

(*EA only*) DR_CONFIG: "DISABLED" (default), "ENABLED"

Description

IDDRX2D1 is the input DDR for DDR_GENX2 (DDR generic mode in X2 gearing).

- EA: DDR_GENX2 (left/right/top)

See the below table for its port description.

Table 660:

Signal	I/O	Description
D	I	DDR input from sysIO buffer.
ECLK	I	Edge clock. Goes to the first and second stage of DDR registers.
SCLK	I	System clock. Clock used to transfer from the ECLK to the SCLK domain. SCLK = 1/2 ECLK rate. Goes to the third stage of registers.
QA0	O	Data at the positive edge of the clock (IPA).
QA1	O	Data at the positive edge of the clock (IPB).
QB0	O	Data at the negative edge of the clock (INA).
QB1	O	Data at the negative edge of the clock (INB).

For more information and usage, refer to the following technical note on the Lattice web site.

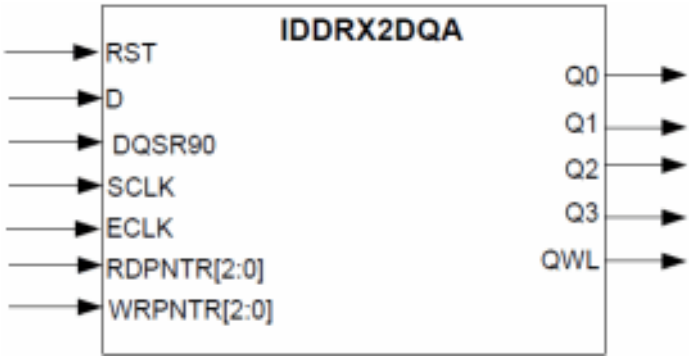
- TN1177 - LatticeECP3 sysIO Usage Guide

IDDRX2DQA

This primitive is used to implement DDR2 memory input interface at higher speeds and DDR3 memory interface.

Architectures Supported:

- ECP5



INPUTS: RST, D, DQSR90, SCLK, ECLK, RDPNTR2, RDPNTR1, RDPNTR0, WRPNTR2, WRPNTR1, WRPNTR0,

OUTPUTS: Q0, Q1, Q3, QWL

See the following table for port description of the IDDRX1DQA primitive.

Table 661:

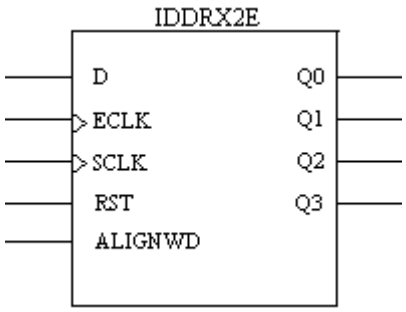
Port Name	I/O	Definition
D	I	DDR Data input
RST	I	Reset to DDR registers
DQSR90	I	DQS clock Input
ECLK	I	Fast edge clock
SCLK	I	Primary clock input (divide by 2 of ECLK)
RDPNTR[2:0]	I	Read Pointer from the DQSBUF module used to transfer data to ECLK
WRPNTR[2:0]	I	Write Pointer from the DQSBUF module used to transfer data to ECLK
Q0, Q2	O	Data at positive edge of DQS
Q1, Q3	O	Data at negative edge of DQS
QWL	O	Data output used for Write Leveling

IDDRX2E

Input for Generic DDR X2 Using 1:4 Gearing

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D, ECLK, SCLK, RST, ALIGNWD

OUTPUTS: Q0, Q1, Q2, Q3

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

IDDRX2E is the input for generic DDR X2 using 1:4 gearing. It uses the VPIC_RX hardware cell. It is used for bottom bank only.

See the below table for port description.

Table 662:

Signal	I/O	Description
D	I	DDR input from sysIO buffer.
ECLK	I	Clock connected to the high speed edge clock tree.
SCLK	I	Clock connected to the system clock.
RST	I	RESET to this block from CIB.
ALIGNWD	I	Data alignment signal used for word alignment. Each operation shifts word alignment by 1 bit.
Q0, Q2	O	Data available at the same edge of the clock.
Q1, Q3	O	Data available at the same edge of the clock.

For more information and usage, refer to the following technical note on the Lattice web site.

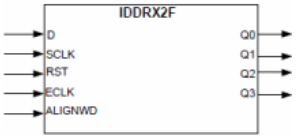
- TN1203 - Implementing High-Speed Interfaces with MachXO2 Devices

IDDRX2F

Generic input DDR Primitive

Architectures Supported:

- ECP5
- LIFMD



INPUTS: D, SCLK, RST, ECLK, ALIGNWD

OUTPUTS: Q0, Q1, Q2, Q3

Description

This primitive is used for Generic X1 IDDR implementation. The following table gives the port description of the IDDRX2F primitive.

Table 663:

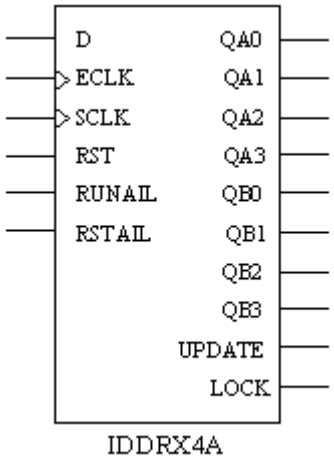
Port Name	I/O	Definition
D	I	DDR Data input.
SCLK	I	Primary clock input (divide by 2 of ECLK).
RST	I	Reset to DDR registers.
ECLK	I	Fast Edge clock.
ALIGNWD	I	This signal is used for Word alignment. It will shift word by one bit.
Q0, Q2	O	Data at positive edge of input ECLK.
Q1, Q3	O	Data at negative edge of input ECLK.

IDDRX4A

Input DDR

Architectures Supported:

- LatticeSC/M

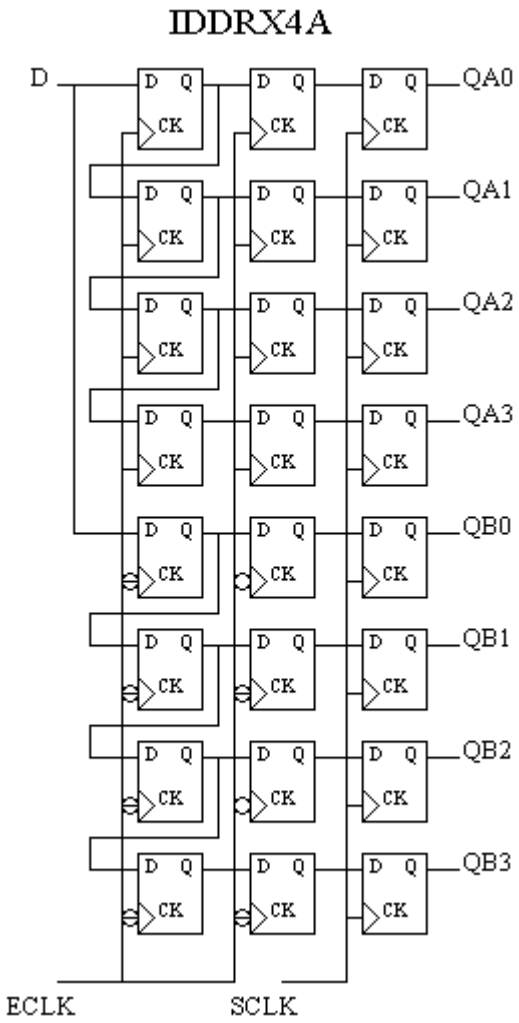


INPUTS: D, ECLK, SCLK, RST, RUNAIL, RSTAIL

OUTPUTS: QA0, QA1, QA2, QA3, QB0, QB1, QB2, QB3, UPDATE, LOCK

Description

Double Data Rate input logic. The input register block captures DDR input data using edge clock to primary clock domain transfer. It can also be set to perform the same functions as in the shift mode. The following symbolic diagram shows the flip-flop structure of this primitive.



For more information, see related technical notes or contact technical support.

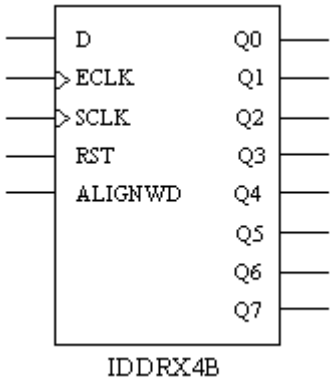
IDDRX4B

Input for Generic DDR X4 Using 1:8 Gearing

Architectures Supported:

- MachXO2
- MachXO3D

- Platform Manager 2



INPUTS: D, ECLK, SCLK, RST, ALIGNWD

OUTPUTS: Q0, Q1, Q2, Q3, Q4, Q5, Q6, Q7

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

IDDRX4B is the input for generic DDR X4 using 1:8 gearing. It uses the VPIC_RX hardware cell. It is used for bottom bank only.

See the below table for IDDRX4B I/O description.

Table 664:

Signal	I/O	Description
D	I	DDR input from sysIO buffer.
ECLK	I	Clock connected to the high speed edge clock tree.
SCLK	I	Clock connected to the system clock.
RST	I	RESET to this block from CIB.
ALIGNWD	I	Data alignment signal used for word alignment. Each operation shifts alignment by 1 bit.
Q0, Q2, Q4, Q6	O	Data available at the same edge of the clock.
Q1, Q3, Q5, Q7	O	Data available at the same edge of the clock.

For more information and usage, refer to the following technical note on the Lattice web site.

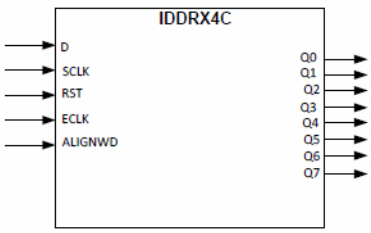
- TN1203 - Implementing High-Speed Interfaces with MachXO2 Devices

IDDRX4C

Input for Generic DDR X4 Using 1:8 Gearing

Architectures Supported:

- LIFMD



Input: D, ECLK, SCLK, RST, ALIGNWD;

Output: Q0, Q1, Q2, Q3, Q4, Q5, Q6, Q7;

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

This primitive is used for 8:1 Input side implementation.

See the below table for IDDRX4C I/O description.

Table 665:

Port	I/O	Description
D	i	DDR Data input
ECLK	I	Edge clock
SCLK	I	Primary clock (Divide by 4 of ECLK)
RST	I	Reset to DDR registers
ALIGNWD	I	This signal is used for Word alignment. It will shift word by 1 bit.
Q0 to Q7	O	8 bits of output data

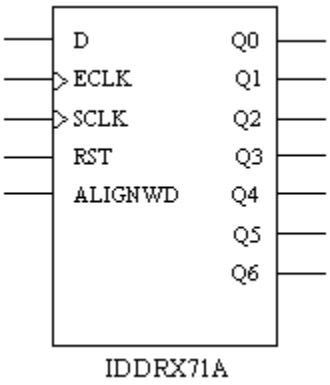
IDDRX71A

7:1 LVDS Input Supporting 1:7 Gearing

Architectures Supported:

- MachXO2

- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D, ECLK, SCLK, RST, ALIGNWD

OUTPUTS: Q0, Q1, Q2, Q3, Q4, Q5, Q6

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

IDDRX71A is the 7:1 LVDS input supporting 1:7 gearing. It is used for bottom bank only. IDDRX71A includes the SLIP circuitry.

See the below table for IDDRX71A I/O description.

Table 666:

Signal	I/O	Description
D	I	DDR input from sysIO buffer.
ECLK	I	Edge clock.
SCLK	I	Clock connected to the system clock.
RST	I	RESET for this block.
ALIGNWD	I	Data alignment signal used for 7:1 LVDS. Each operation shifts alignment by 2 bits.
Q0, Q1, Q2, Q3, Q4, Q5, Q6	O	1:7 LVDS output signals.

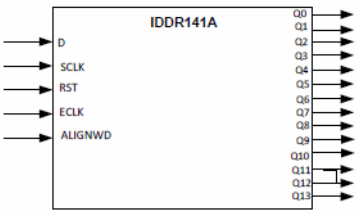
For more information and usage, refer to the following technical note on the Lattice web site.

- TN1203 - Implementing High-Speed Interfaces with MachXO2 Devices

IDDR141A

Architectures Supported:

- LIFMD



Input: D, ECLK, SCLK, RST, ALIGNWD;

Output: Q0, Q1, Q2, Q3, Q4, Q5, Q6, Q7, Q8, Q9, Q10, Q11, Q12, Q13;

Description

This primitive is used for 14:1 Input side implementation. This is an extension of 7:1 for higher speeds.

See the below table for IDDR141A I/O description.

Table 667:

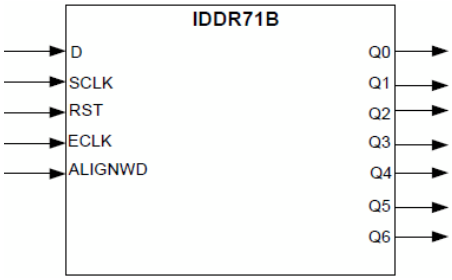
Port	I/O	Description
D	i	DDR Data input
ECLK	I	Edge clock
SCLK	I	Primary clock (Divide by 7 of ECLK)
RST	I	Reset to DDR registers
ALIGNWD	I	This signal is used for Word alignment. It will shift word by 1 bit.
Q0 to Q13	O	14 bits of output data

IDDR71B

7:1 LVDS Input Supporting 1:7 Gearing

Architectures Supported:

- ECP5
- LIFMD



INPUTS: D, ECLK, SCLK, RST, ALIGNWD

OUTPUTS: Q0, Q1, Q2, Q3, Q4, Q5, Q6

Description

This primitive is used for 7:1 LVDS Input side implementation

See the below table for IDDR71B I/O description.

Table 668:

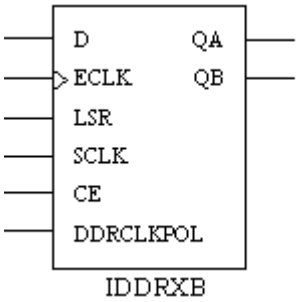
Signal	I/O	Description
D	I	DDR data input
ECLK	I	Edge clock.
SCLK	I	Primary clock. (Divide by 3.5 of ECLK)
RST	I	Reset to DDR registers
ALIGNWD	I	This signal is used for word alignment. It will shift word by 1 bit.
Q0, Q1, Q2, Q3, Q4, Q5, Q6	O	7 bits of output data.

IDDRXB

Input DDR

Architectures Supported:

- LatticeECP/EC
- LatticeXP



INPUTS: D, ECLK, LSR, SCLK, CE, DDRCLKPOL

OUTPUTS: QA, QB

ATTRIBUTES:

REGSET: "RESET" (default), "SET"

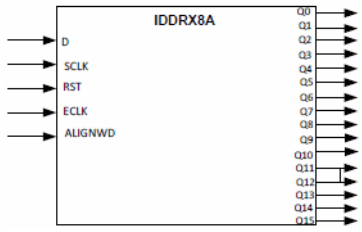
Description

Double Data Rate input logic with half cycle clock domain transfer for the negative edge captured data (both edges of captured data enter core with positive edge flip-flops. For more information, see related technical notes or contact technical support.

IDDRX8A

Architectures Supported:

- LIFMD



Input: D, ECLK, SCLK, RST, ALIGNWD;

Output: Q0, Q1, Q2, Q3, Q4, Q5, Q6, Q7, Q8, Q9, Q10, Q11, Q12, Q13;

Description

This primitive is used for 16:1 Input side implementation.

See the below table for IDDRX8A I/O description.

Table 669:

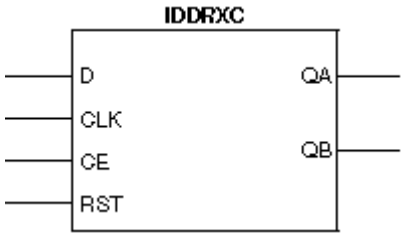
Port	I/O	Description
D	I	DDR Data input
ECLK	I	Edge clock
SCLK	I	Primary clock (Divide by 8 of ECLK)
RST	I	Reset to DDR registers
ALIGNWD	I	This signal is used for Word alignment. It will shift word by 1 bit.
Q0 to Q15	O	16 bits of output data

IDDRXC

DDR Generic Input

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



INPUTS: D, CLK, RST, CE

OUTPUTS: QA, QB

Description

This primitive inputs the DDR data at both edges of the edge and generates two streams of data. CLK of this module can be connected to either the edge clock or the primary FPGA clock.

Note that the DDRCLKPOL input to IDDRXC should be connected to the DDRCLKPOL output of DQSBUFC. LSR is only for second stage register/ latch. To support DDR modes configured for bidirectional use, software will tie LSR LOW for input registers. The default for LSR is HIGH.

See the following table for port description of the IDDRXC primitive.

Table 670:

Port Name	I/O	Definition
D	I	DDR input from sysIO buffer
CLK	I	Clock from the CIB
RST	I	RESET to this block from CIB
CE	I	Clock enable signal
QA	O	Data at the positive edge of the CLK
QB	O	Data at the negative edge of the CLK

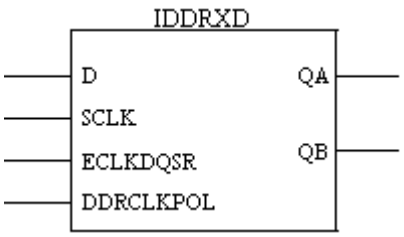
For more usage, see related technical notes or contact technical support.

IDDRXD

Input DDR for DDR_MEM, DDR2_MEM, DDR_GENX1, and DDR2_MEMGEN

Architectures Supported:

- LatticeECP3



INPUTS: D, SCLK, ECLKDQSR, DDRCLKPOL

OUTPUTS: QA, QB

ATTRIBUTES:

(*EA only*) SCLKLATENCY: 1 (default), 2

Description

IDDRXD is the input DDR for DDR_MEM, DDR2_MEM, DDR_GENX1 (DDR generic mode in X1 gearing), and DDR2_MEMGEN.

- E: DDR_MEM, DDR2_MEM, DDR_GENX1, and DDR2_MEMGEN (left/right/top)
- EA: DDR_MEM, DDR2_MEM, and DDR2_MEMGEN (left/right/top)

See the below table for its port description.

Table 671:

Signal	I/O	Description
D	I	DDR input from sysIO buffer.
SCLK	I	System clock.
ECLKDQSR	I	Phase shifted DQS in case of DDR memory interface. Connects to DQSBUF. For EA devices, ECLKDQSR should be used only for the DQS strobe.
DDRCLKPOL	I	DDR clock polarity signal.
QA	O	Data at the positive edge of the clock (mapped to IPB).
QB	O	Data at the negative edge of the clock (mapped to INB).

For more information and usage, refer to the following technical note on the Lattice web site.

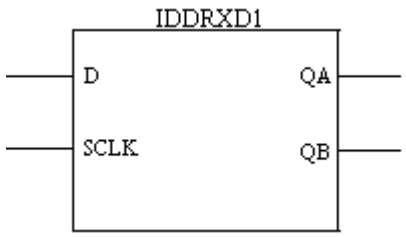
- TN1177 - LatticeECP3 sysIO Usage Guide

IDDRXD1

Input DDR for DDR_GENX1

Architectures Supported:

- LatticeECP3



INPUTS: D, SCLK

OUTPUTS: QA, QB

Description

IDDRXD1 is the input DDR for DDR_GENX1 (DDR generic mode in X1 gearing).

- EA: DDR_GENX1 (left/right/top)

See the below table for its port description.

Table 672:

Signal	I/O	Description
D	I	DDR input from sysIO buffer.
SCLK	I	System clock.
QA	O	Data at the positive edge of the clock (mapped to IPB).
QB	O	Data at the negative edge of the clock (mapped to INB).

For more information and usage, refer to the following technical note on the Lattice web site.

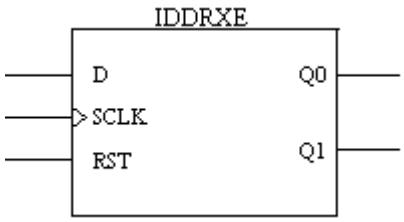
- TN1177 - LatticeECP3 sysIO Usage Guide

IDDRXE

Input for Generic DDR X1 Using 1:2 Gearing

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D, SCLK, RST

OUTPUTS: Q0, Q1

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

IDDRXE is the input for generic DDR X1 using 1:2 gearing. It uses the mPIC (base pic) or PIC (memory pic) hardware cell. It is used for all sides.

See the below table for port description.

Table 673:

Signal	I/O	Description
D	I	DDR input from sysIO buffer
SCLK	I	Clock connected to the system clock
RST	I	RESET for this block
Q0	O	Data at the positive edge of the clock
Q1	O	Data at the negative edge of the clock

For more information and usage, refer to the following technical note on the Lattice web site.

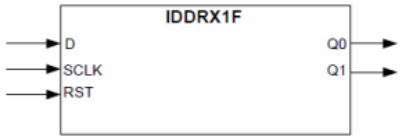
- TN1203 - Implementing High-Speed Interfaces with MachXO2 Devices

IDDRX1F

Generic input DDR Primitive

Architectures Supported:

- ECP5
- LIFMD



INPUTS: D, SCLK, RST

OUTPUTS: Q0, Q1

Description

- This primitive is used for Generic X1 IDDR implementation. The following table gives the port description of the IDDRX1F primitive.

Table 674:

Port Name	I/O	Definition
D	I	DDR Data input.
SCLK	I	Primary clock input.
RST	I	Reset to DDR registers.

Table 674:

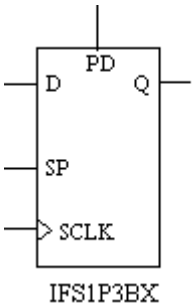
Port Name	I/O	Definition
Q0	O	Data at positive edge of clock.
Q1	O	Data at negative edge of clock.

IFS1P3BX

Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and System Clock (used in input PIC area only)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D, SP, SCLK, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

This primitive must be paired with an input or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 675:

INPUTS				OUTPUTS
D	SP	SCLK	PD	Q
X	0	X	0	Q
X	X	X	1	1
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

When GSR=0, Q=1 (D=SP=SCLK=PD=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

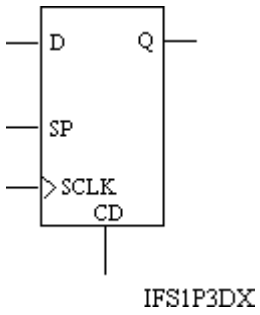
IFS1P3DX

Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and System Clock (used in input PIC area only)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO2

- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D, SP, SCLK, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

This primitive must be paired with an input or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 676:

INPUTS				OUTPUTS
D	SP	SCLK	CD	Q
X	0	X	0	Q
X	X	X	1	0
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

When GSR=0, Q=0 (D=SP=SCLK=CD=X)

Note

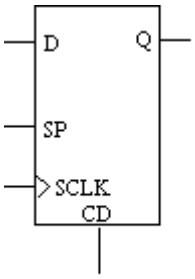
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

IFS1P3IX

Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable, and System Clock (Clear overrides Enable) (used in input PIC area only)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



IFS1P3IX

INPUTS: D, SP, SCLK, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

This primitive must be paired with an input or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 677:

INPUTS				OUTPUTS
D	SP	SCLK	CD	Q
X	0	X	0	Q
X	X	↑	1	0
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

When GSR=0, Q=0 (D=SP=SCLK=CD=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

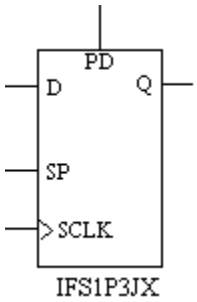
IFS1P3JX

Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable, and System Clock (Preset overrides Enable) (used in input PIC area only)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO2

- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D, SP, SCLK, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

This primitive must be paired with an input or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 678:

INPUTS				OUTPUTS
D	SP	SCLK	PD	Q
X	0	X	0	Q
X	X	↑	1	1
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

When GSR=0, Q=1 (D=SP=SCLK=PD=X)

Note

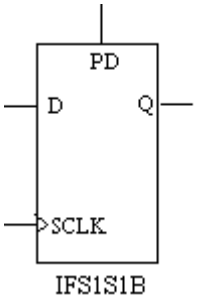
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

IFS1S1B

Positive Level Data Latch with Positive Level Asynchronous Preset and System Clock (used in input PIC area only)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D, SCLK, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

This primitive must be paired with an input or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 679:

INPUTS			OUTPUTS
D	SCLK	PD	Q
X	0	0	Q
X	X	1	1
0	1	0	0
1	1	0	1

X= Don’t care

When GSR=0, Q=1 (D=SCLK=PD=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

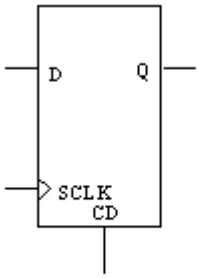
IFS1S1D

Positive Level Data Latch with Positive Level Asynchronous Clear and System Clock (used in input PIC area only)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO2
- MachXO3D

- MachXO3L
- Platform Manager 2



IFS1S1D

INPUTS: D, SCLK, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

This primitive must be paired with an input or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 680:

INPUTS			OUTPUTS
D	SCLK	CD	Q
X	0	0	Q
X	X	1	0
0	1	0	0
1	1	0	1

X = Don’t care

When GSR=0, Q=0 (D=SCLK=CD=X)

Note

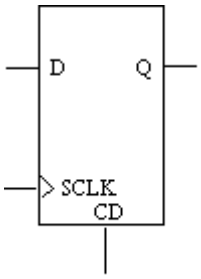
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

IFS1S1I

Positive Level Data Latch with Positive Level Synchronous Clear and System Clock (used in input PIC area only)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



IFS1S1I

INPUTS: D, SCLK, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

This primitive must be paired with an input or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 681:

INPUTS			OUTPUTS
D	SCLK	CD	Q
X	0	0	Q
X	1	1	0
0	1	0	0
1	1	0	1

X = Don’t care

When GSR=0, Q=0 (D=SCLK=CD=X)

Note

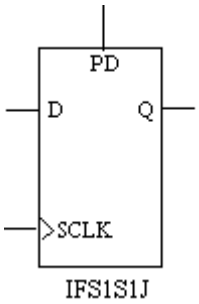
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

IFS1S1J

Positive Level Data Latch with Positive Level Synchronous Preset and System Clock (used in input PIC area only)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D, SCLK, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

This primitive must be paired with an input or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 682:

INPUTS			OUTPUTS
D	SCLK	PD	Q
X	0	0	Q
X	1	1	1
0	1	0	0
1	1	0	1

X = Don’t care

When GSR=0, Q=1 (D=SCLK=PD=X)

Note

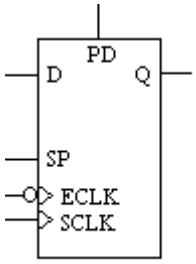
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

ILF2P3BX

Negative Level Edge Clocked (ECLK) Latch, Feeding Positive Edge Triggered System Clocked (SCLK) Flip-Flop, and Positive Level Asynchronous Preset (used in input PIC area only)

Architectures Supported:

- LatticeSC/M



ILF2P3BX

INPUTS: D, SP, ECLK, SCLK, PD

OUTPUT: Q

Description

This primitive must be paired with an input or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 683:

INPUTS					**OUTPUTS**	
D	SP	ECLK	SCLK	PD	LATCH_Q	Q
X	X	X	X	1	LATCH_Q	1
X	0	1	X	0	LATCH_Q	Q
0	X	0	B	0	0	Q
1	X	0	B	0	1	Q
X	1	1	↑	0	0	0
X	1	1	↑	0	1	1
0	1	0	↑	0	0	0
1	1	0	↑	0	1	1

X = Don’t care

LATCH_Q = Output data from latch

B = Not rising edge

When GSR=0, Q=1 (D=SP=ECLK=SCLK=PD=X)

Note

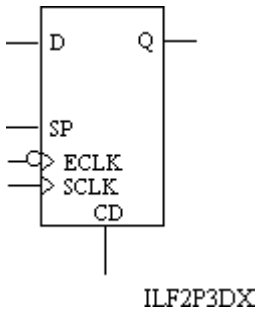
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

ILF2P3DX

Negative Level Edge Clocked (ECLK) Latch, Feeding Positive Edge Triggered System Clocked (SCLK) Flip-Flop, and Positive Level Asynchronous Clear (used in input PIC area only)

Architectures Supported:

- LatticeSC/M



INPUTS: D, SP, ECLK, SCLK, CD

OUTPUT: Q

Description

This primitive must be paired with an input or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 684:

INPUTS					OUTPUTS	
D	SP	ECLK	SCLK	CD	LATCH_Q	Q
X	X	X	X	1	LATCH_Q	0
X	0	1	X	0	LATCH_Q	Q
0	X	0	B	0	0	Q
1	X	0	B	0	1	Q
X	1	1	↑	0	0	0
X	1	1	↑	0	1	1
0	1	0	↑	0	0	0
1	1	0	↑	0	1	1

X = Don’t care

LATCH_Q = Output data from latch

B = Not rising edge

When GSR=0, Q=0 (D=SP=ECLK=SCLK=CD=X)

Note

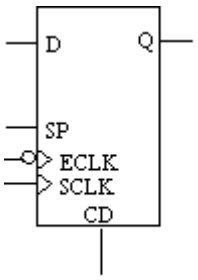
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

ILF2P3IX

Negative Level Edge Clocked (ECLK) Latch, Feeding Positive Edge Triggered System Clocked (SCLK) Flip-Flop, with Positive Level Synchronous Clear and Positive Level Enable (Clear overrides Enable) (used in input PIC area only)

Architectures Supported:

- LatticeSC/M



ILF2P3IX

INPUTS: D, SP, ECLK, SCLK, CD

OUTPUT: Q

Description

This primitive must be paired with an input or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 685:

INPUTS					**OUTPUTS**	
D	SP	ECLK	SCLK	CD	LATCH_Q	Q
X	X	X	↑	1	LATCH_Q	0
X	0	1	X	0	LATCH_Q	Q
0	X	0	B	0	0	Q
1	X	0	B	0	1	Q
X	1	1	↑	0	0	0
X	1	1	↑	0	1	1
0	1	0	↑	0	0	0
1	1	0	↑	0	1	1

X = Don’t care

LATCH_Q = Output data from latch

B = Not rising edge

When GSR = 0, Q = 0 (D = SP = ECLK = SCLK = CD = X)

Note

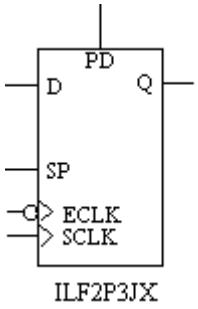
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

ILF2P3JX

Negative Level Edge Clocked (ECLK) Latch, Feeding Positive Edge Triggered System Clocked (SCLK) Flip-Flop, and Positive Level Synchronous Preset (Preset overrides Enable) (used in input PIC area only)

Architectures Supported:

- LatticeSC/M



INPUTS: D, SP, ECLK, SCLK, PD

OUTPUT: Q

Description

This primitive must be paired with an input or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 686:

INPUTS					OUTPUTS	
D	SP	ECLK	SCLK	PD	LATCH_Q	Q
X	X	X	↑	1	LATCH_Q	1
X	0	1	X	0	LATCH_Q	Q
0	X	0	B	0	0	Q
1	X	0	B	0	1	Q
X	1	1	↑	0	0	0
X	1	1	↑	0	1	1
0	1	0	↑	0	0	0
1	1	0	↑	0	1	1

X = Don’t care

LATCH_Q = Output data from latch

B = Not rising edge

When GSR = 0, Q = 1 (D = SP = ECLK = SCLK = PD = X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

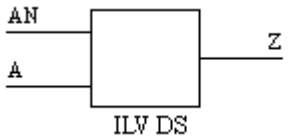
ILVDS

LVDS Input Buffer

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, AN

OUTPUT: Z

Truth Table

Table 687:

INPUTS		OUTPUTS
A	AN	Z
0	1	0
1	0	1

Note

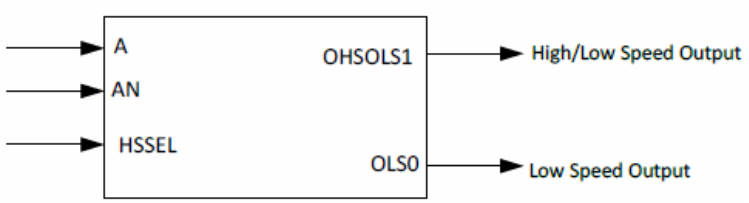
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

IMIPI

Special Primitive for MIPI Input Support

Architectures Supported:

- ECP5



INPUTS:A, AN, HSSEL

OUTPUT: OHSLS, OLS

The IMIPI I/O description is shown below.

Table 688:

Port Name	I/O	Description
A	I	PAD C Input
AN	I	PAD D Input
HSSEL	I	High Speed Select Signal. This is shared with the Tristate input of the buffer. HSSEL=1: High Speed mode, 100 ohm differential termination is on. PADC logic select differential signal to IOL for gearing. HS_SEL=0: Low Speed mode, 100 ohm termination is turned off. OHSLS selected as ratioed lvcmos input buffer from I input (PADC), OLS selected as lvcmos input from IN input (PADD).
OHSLS	O	High Speed or Low Speed Output depending on HSSEL
OLS	O	Low speed output.

Description

Primitive used when implementing MIPI interface.

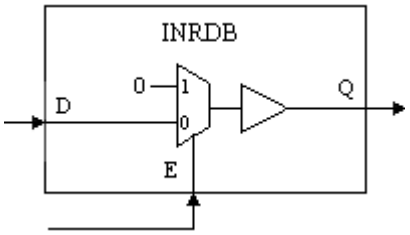
INRDB

Input Reference and Differential Buffer

Architectures Supported:

- ECP5
- LIFMD
- MachXO2
- MachXO3D

- MachXO3L
- Platform Manager 2



INPUTS: D, E

OUTPUT: Q

Description

The INRDB primitive is used to support post-PAR simulation of Dynamic Bank Controller. The Dynamic Bank Controller signals to the IO are hardwired and cannot be changed for the simulation, so the INRDB and LVDSOB primitives are defined to support the simulation.

For more information, refer to the following technical note on the Lattice web site:

- TN1198 - Power Estimation and Management for MachXO2 Device

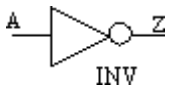
INV

Inverter

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L

- Platform Manager
- Platform Manager 2



INPUT: A

OUTPUT: Z

Note

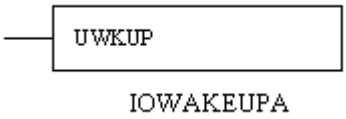
- It is possible that this primitive will be optimized away.
- This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

IOWAKEUPA

XP2 Wake-up Controller

Architectures Supported:

- LatticeXP2



INPUT: UWKUP

Description

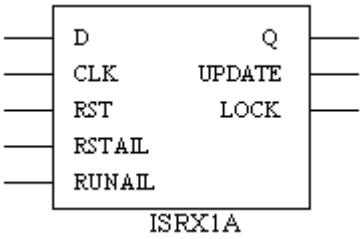
LatticeXP2 Wake-up controller.

ISRX1A

Input 1-Bit Shift Register

Architectures Supported:

- LatticeSC/M

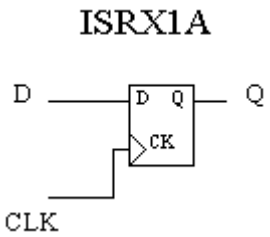


INPUTS: D, CLK, RST, RSTAIL, RUNAIL

OUTPUTS: Q, UPDATE, LOCK

Description

Shift register input logic that uses adaptive FF to capture input data. The following symbolic diagram shows the flip-flop structure of this primitive.

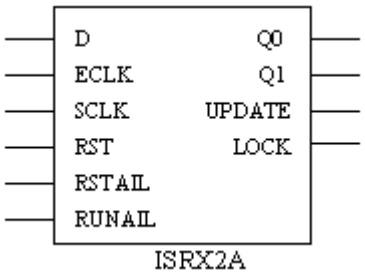


ISRX2A

Input 2-Bit Shift Register

Architectures Supported:

- LatticeSC/M

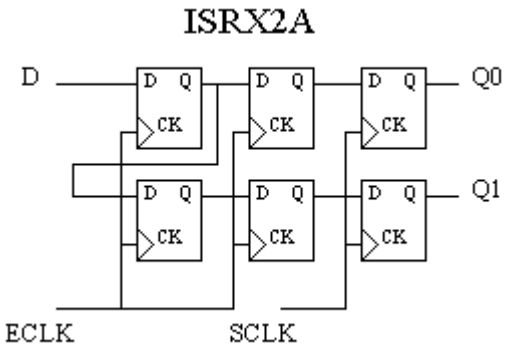


INPUTS: D, ECLK, SCLK, RST, RSTAIL, RUNAIL

OUTPUTS: Q0, Q1, UPDATE, LOCK

Description

Shift register input logic that allows clock domain transfer from edge clock to primary clock and parallel transfer to the core of incoming serial data. The following symbolic diagram shows the flip-flop structure of this primitive.

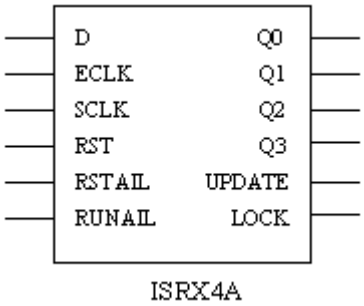


ISRX4A

Input 4-Bit Shift Register

Architectures Supported:

- LatticeSC/M

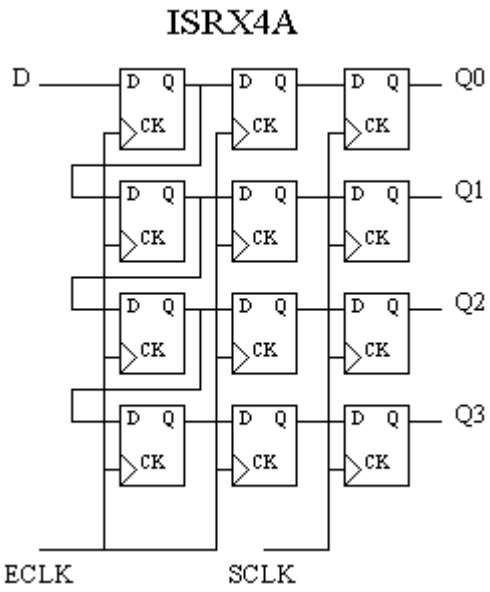


INPUTS: D, ECLK, SCLK, RST, RSTAIL, RUNAIL

OUTPUTS: Q0, Q1, Q2, Q3, UPDATE, LOCK

Description

Shift register input logic that allows clock domain transfer from edge clock to primary clock and parallel transfer to the core of incoming serial data. The following symbolic diagram shows the flip-flop structure of this primitive.



I2CA

Architectures Supported:

- LIFMD

InputL CSI;CLKI;STBI; WEI; ADRI3, ADRI2, ADRI1, ADRI0; DATI9, DATI8, DATI7, DATI6, DATI5, DATI4, DATI3, DATI2, DATI1, DATI0; DATO9, DATO8, DATO7, DATO6, DATO5, DATO4, DATO3, DATO2, DATO1, DATO0; FIFORST; MRDCMPL;SCLI;

Output: ACKO; SRWO; I2CIRQ; I2CWKUP, SRDWR; TXFIFOAE; TXFIFOE; TXFIFOF; RXFIFOE; RXFIFOAF;RXFIFOF; SCLO; SCLOE; SDAI; SDAO; SDAOE;

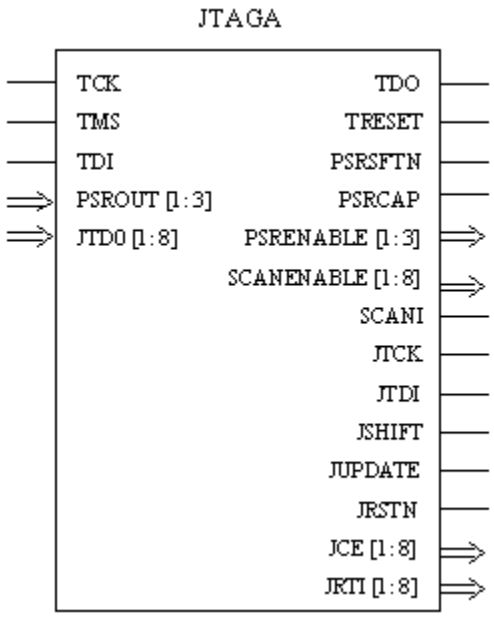
J

JTAGA

JTAG (Joint Test Action Group) Controller

Architectures Supported:

- LatticeSC/M



INPUTS: TCK, TMS, TDI, PSROUT1, PSROUT2, PSROUT3, JTDO1, JTDO2, JTDO3, JTDO4, JTDO5, JTDO6, JTDO7, JTDO8

OUTPUTS: TDO, TRESET, PSRSFTN, PSRCAP, PSRENABLE1, PSRENABLE2, PSRENABLE3, SCANENABLE1, SCANENABLE2, SCANENABLE3, SCANENABLE4, SCANENABLE5, SCANENABLE6, SCANENABLE7, SCANENABLE8, SCANI, JTCK, JTDI, JSHIFT, JUPDATE, JRSTN, JCE1, JCE2, JCE3, JCE4, JCE5, JCE6, JCE7, JCE8, JRTI1, JRTI2, JRTI3, JRTI4, JRTI5, JRTI6, JRTI7, JRTI8

Description

The JTAGA primitive provides the control and interconnect circuit used by the boundary scan function. This function allows the testing of increasingly complex ICs and IC packages. The LatticeSC/M device has enhanced its interface capability to the PLC array with increased scan chain connectivity and tap state machine flags such as shift capture update, reset, run test idle.

Example pin functions:

Table 689:

Pins	I/O	Function	Description
TCK TMS TDI TDO	I I I O	interface pins	Test clock (TCK), Test mode select (TMS), Test data in (TDI) and Test data out (TDO) are four interface pins for this primitive. The TDI, TMS and TCK pins are connected to the dedicated IO pads on the device.
PSROUT[1:3] JTDO[1:8]	I I	user boundary scan-ring outputs	These are the outputs of the last registers of the user scan rings to the boundary scan block. Inputs to the boundary scan macro are based on the instruction loaded.
TRESET	O	reset	Active high output of the boundary scan macro to the routing. The output is high when the boundary scan macro is in test logic reset state.
PSRSFTN	O	shift_not data register	Active low output of the boundary scan macro. The output is low when the boundary scan macro is in the shift data state and the programmable scan ring instructions are loaded.
PSRCAP	O	capture data register	Active high output of the boundary scan macro. The output is high when the boundary scan macro is in the capture data state and the programmable scan ring instructions are loaded.
PSRENABLE[1:3] SCANENABLE[1:8]	O	enable flag	Active high outputs of the boundary scan macro to the routing. The output equals a high upon update of the specific instructions, PLC_SCAN_RING[1:3] and SCAN[1:8], respectively.
SCANI	O	scan in	Private pin used for testing of the system bus that multiplexes the TDI and SCANOUT[11:14].
JTCK	O	test clock	The boundary scan clock which is output from the boundary scan macro to the scan rings.
JTDI	O	test data in	The output of the boundary scan macro from where the test data is output to the scan rings.
JSHIFT	O	shift data register	Active high output of the boundary scan macro. The output is high when the boundary scan macro is in the shift data state and the scan instructions are loaded.
JUPDATE	O	update data register	Active high output of the boundary scan macro. The output is high when the boundary scan macro is in the update data state and when the PLC_SCAN_RING or SCAN instructions are loaded.

Table 689:

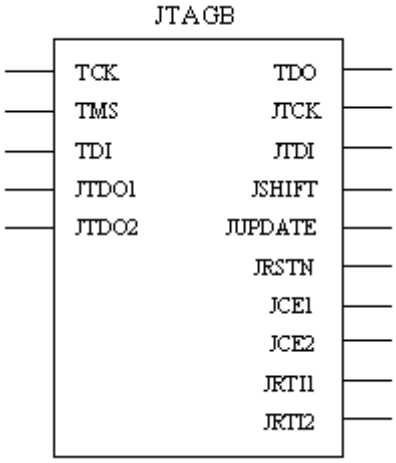
Pins	I/O	Function	Description
JRSTN	O	reset_not	Active low output of the boundary scan macro to the routing. The output is low when the boundary scan macro is in test logic reset state.
JCE[1:8]	O	clock enable	Active high output of the boundary scan macro to the routing. The output is high when the boundary scan macro is in the SHIFT or CAPTURE state during the SCAN[1:8] instructions, respectively.
JRTI[1:8]	O	run test idle	Active high output of the boundary scan macro. The output is high when the boundary scan macro is in the run test idle state and during the SCAN[1:8] instructions.

JTAGB

JTAG (Joint Test Action Group) Controller

Architectures Supported:

- LatticeECP/EC
- LatticeXP



INPUTS: TCK, TMS, TDI, JTDO1, JTDO2

OUTPUTS: TDO, JTCK, JTDI, JSHIFT, JUPDATE, JRSTN, JCE1, JCE2, JRTI1, JRTI2

ATTRIBUTES:

ER1: "ENABLED" (default), "DISABLED"

ER2: "ENABLED" (default), "DISABLED"

Description

Table 690:

Signal	I/O	Description
TCK	I	Test Clock, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly from the pad of device TCK pin. Clocks registers and TAP Controller.
TMS	I	Test Mode Select, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly from the pad of device TMS pin. Controls state machine switching for TAP Controller.
TDI	I	Test Data Input, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly from the pad of device TDI pin.
JTDO[2:1]	I	JTAG Test Data Output one (scans output bus entering JTAG block), for internal logic to control non-disruptive re-configuration through JTAG port, JTAG serial interface to the device. Lattice supports two private JTAG instructions, ER1 (0x32) and ER2 (0x38). If ER1 instruction is shifted into the JTAG instruction register, TDO output will come from JTDO1. If ER2 instruction is shifted into the JTAG instruction register, TDO output will come from JTDO2.
TDO	O	Test Data Output, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly to the pad of device TDO pin
JTCK	O	JTAG Test Clock (connects to TCK), for internal logic to control non-disruptive re-configuration through JTAG port. Signal is coming from TCK input and going into the FPGA fabric.
JTDI	O	JTAG Test Data Input, for internal logic to control non-disruptive re-configuration through JTAG port. Signal is coming from TDI input and going into the FPGA fabric.
JSHIFT	O	JTAG Shift. Signal goes high when TAP Controller State is Shift-DR.
JUPDATE	O	JTAG Update. Signal goes high when TAP controller state is Update-DR.
JRSTN	O	JTAG Reset (active low). Signal goes low when TAP controller state is Test-Logic-Reset.

Table 690:

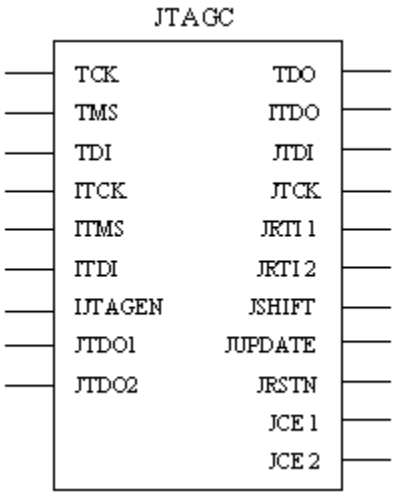
Signal	I/O	Description
JCE[2:1]	O	JTAG Clock Enable one (BS is to boundary scan ring (L2). Lattice supports two private JTAG instructions, ER1 (0x32) and ER2 (0x38). If ER1 instruction is shifted into the JTAG instruction register, JCE1 will go high when TAP controller is in Capture-DR or Shift-DR states. If ER2 instruction is shifted into the JTAG instruction register, JCE2 will go high when TAP controller is in Capture-DR or Shift-DR states.
JRTI[2:1]	O	JTAG Run-Test/Idle. Lattice supports two private JTAG instructions ER1 (0x32) and ER2 (0x38). If ER1 instruction is shifted into the JTAG instruction register, JRTI1 will go high when TAP controller is in Run-Test/Idle state. If ER2 instruction is shifted into the JTAG instruction register, JRTI2 will go high when TAP controller is in Run-Test/Idle state.

JTAGC

JTAG (Joint Test Action Group) Controller

Architectures Supported:

- LatticeECP2/M



INPUTS: TCK, TMS, TDI, ITCK, ITMS, ITDI, IJTAGEN, JTDO1, JTDO2

OUTPUTS: TDO, ITDO, JTDI, JTCK, JRTI1, JRTI2, JSHIFT, JUPDATE, JRSTN, JCE1, JCE2

Note

- The internal JTAG mode is not supported. The ITCK, ITMS, ITDI, and ITDO ports are non-operations and hence do not use them.
- The IJTAGEN port should always be tied to VCC.

ATTRIBUTES:

ER1: "ENABLED" (default), "DISABLED"

ER2: "ENABLED" (default), "DISABLED"

Description

Table 691:

Signal	I/O	Description
TCK	I	Test Clock, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly from the pad of device TCK pin. Clocks registers and TAP Controller.
TMS	I	Test Mode Select, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly from the pad of device TMS pin. Controls state machine switching for TAP Controller.
TDI	I	Test Data Input, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly from the pad of device TDI pin.
ITCK	I	Internal Test Clock for internal logic to control non-disruptive re-configuration through JTAG port, comes from configuration block CIB.
ITMS	I	Internal Test Mode Select, for internal logic to control non-disruptive re-configuration through JTAG port, comes from configuration block CIB.
ITDI	I	Internal Test Data Input, for internal logic to control non-disruptive re-configuration through JTAG port, comes from configuration block CIB.
IJTAGEN	I	Internal JTAG Enable (active low), for internal logic to control non-disruptive re-configuration through JTAG port, comes from configuration block CIB.
JTDO[2:1]	I	JTAG Test Data Output one (scans output bus entering JTAG block), for internal logic to control non-disruptive re-configuration through JTAG port, JTAG serial interface to the device. Lattice supports two private JTAG instructions, ER1 (0x32) and ER2 (0x38). If ER1 instruction is shifted into the JTAG instruction register, TDO output will come from JTDO1. If ER2 instruction is shifted into the JTAG instruction register, TDO output will come from JTDO2.
TDO	O	Test Data Output, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly to the pad of device TDO pin.

Table 691:

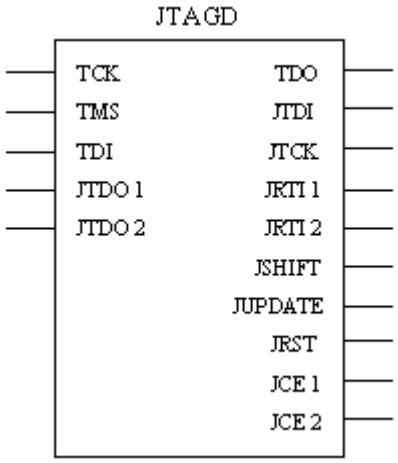
Signal	I/O	Description
ITDO	O	Internal Test Data Output for internal logic to control non-disruptive re-configuration through JTAG port, comes from configuration block CIB.
JTDI	O	JTAG Test Data Input, for internal logic to control non-disruptive re-configuration through JTAG port Signal is coming from TDI input and going into the FPGA fabric.
JTCK	O	JTAG Test Clock (connects to TCK), for internal logic to control non-disruptive re-configuration through JTAG port Signal is coming from TCK input and going into the FPGA fabric.
JRTI[2:1]	O	JTAG Run-Test/Idle. Lattice supports two private JTAG instructions ER1 (0x32) and ER2 (0x38). If ER1 instruction is shifted into the JTAG instruction register, JRTI1 will go high when TAP controller is in Run-Test/Idle state. If ER2 instruction is shifted into the JTAG instruction register, JRTI2 will go high when TAP controller is in Run-Test/Idle state.
JSHIFT	O	JTAG Shift. Signal goes high when TAP Controller State is Shift-DR.
JUPDATE	O	JTAG Update. Signal goes high when TAP controller state is Update-DR.
JRSTN	O	JTAG Reset (active low). Signal goes low when TAP controller state is Test-Logic-Reset.
JCE[2:1]	O	JTAG Clock Enable one (BS is to boundary scan ring (L2). Lattice supports two private JTAG instructions, ER1 (0x32) and ER2 (0x38). If ER1 instruction is shifted into the JTAG instruction register, JCE1 will go high when TAP controller is in Capture-DR or Shift-DR states. If ER2 instruction is shifted into the JTAG instruction register, JCE2 will go high when TAP controller is in Capture-DR or Shift-DR states.

JTAGD

JTAG (Joint Test Action Group) Controller

Architectures Supported:

- MachXO
- Platform Manager



INPUTS: TCK, TMS, TDI, JTDO1, JTDO2

OUTPUTS: TDO, JTDI, JTCK, JRTI1, JRTI2, JSHIFT, JUPDATE, JRST, JCE1, JCE2

ATTRIBUTES:

ER1: "ENABLED" (default), "DISABLED"

ER2: "ENABLED" (default), "DISABLED"

Description

Table 692:

Signal	I/O	Description
TCK	I	Test Clock, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly from the pad of device TCK pin Clocks registers and TAP Controller
TMS	I	Test Mode Select, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly from the pad of device TMS pin Controls state machine switching for TAP Controller
TDI	I	Test Data Input, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly from the pad of device TDI pin
JTDO[2:1]	I	JTAG Test Data Output one (scans output bus entering JTAG block), for internal logic to control non-disruptive re-configuration through JTAG port, JTAG serial interface to the device. Lattice supports two private JTAG instructions, ER1 (0x32) and ER2 (0x38). If ER1 instruction is shifted into the JTAG instruction register, TDO output will come from JTDO1. If ER2 instruction is shifted into the JTAG instruction register, TDO output will come from JTDO2.

Table 692:

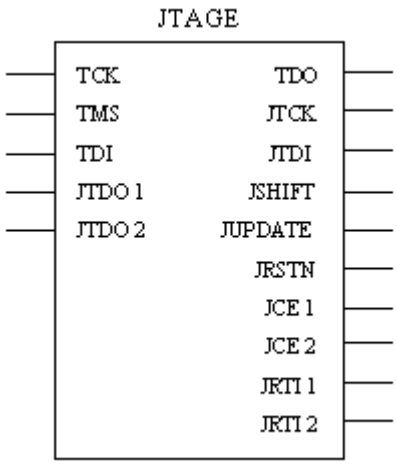
Signal	I/O	Description
TDO	O	Test Data Output, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly to the pad of device TDO pin
JTDI	O	JTAG Test Data Input, for internal logic to control non-disruptive re-configuration through JTAG port Signal is coming from TDI input and going into the FPGA fabric.
JTCK	O	JTAG Test Clock (connects to TCK), for internal logic to control non-disruptive re-configuration through JTAG port Signal is coming from TCK input and going into the FPGA fabric.
JRTI[2:1]	O	JTAG Run-Test/Idle Lattice supports two private JTAG instructions ER1 (0x32) and ER2 (0x38). If ER1 instruction is shifted into the JTAG instruction register, JRTI1 will go high when TAP controller is in Run-Test/Idle state. If ER2 instruction is shifted into the JTAG instruction register, JRTI2 will go high when TAP controller is in Run-Test/Idle state.
JSHIFT	O	JTAG Shift Signal goes high when TAP Controller State is Shift-DR.
JUPDATE	O	JTAG Update Signal goes high when TAP controller state is Update-DR.
JRST	O	JTAG Reset (active high) Signal goes high when TAP controller state is Test-Logic-Reset.
JCE[2:1]	O	JTAG Clock Enable one (BS is to boundary scan ring (L2). Lattice supports two private JTAG instructions, ER1 (0x32) and ER2 (0x38). If ER1 instruction is shifted into the JTAG instruction register, JCE1 will go high when TAP controller is in Capture-DR or Shift-DR states. If ER2 instruction is shifted into the JTAG instruction register, JCE2 will go high when TAP controller is in Capture-DR or Shift-DR states.

JTAGE

JTAG (Joint Test Action Group) Controller

Architectures Supported:

- LatticeECP3
- LatticeXP2



INPUTS: TCK, TMS, TDI, JTDO1, JTDO2

OUTPUTS: TDO, JTCK, JTDI, JSHIFT, JUPDATE, JRSTN, JCE1, JCE2, JRTI1, JRTI2

ATTRIBUTES:

ER1: "ENABLED" (default), "DISABLED"

ER2: "ENABLED" (default), "DISABLED"

Description

Table 693:

Signal	I/O	Description
TCK	I	Test Clock, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly from the pad of device TCK pin. Clocks registers and TAP Controller.
TMS	I	Test Mode Select, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly from the pad of device TMS pin. Controls state machine switching for TAP Controller.
TDI	I	Test Data Input, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly from the pad of device TDI pin.
JTDO[2:1]	I	JTAG Test Data Output one (scans output bus entering JTAG block), for internal logic to control non-disruptive re-configuration through JTAG port, JTAG serial interface to the device. Lattice supports two private JTAG instructions, ER1 (0x32) and ER2 (0x38). If ER1 instruction is shifted into the JTAG instruction register, TDO output will come from JTDO1. If ER2 instruction is shifted into the JTAG instruction register, TDO output will come from JTDO2.

Table 693:

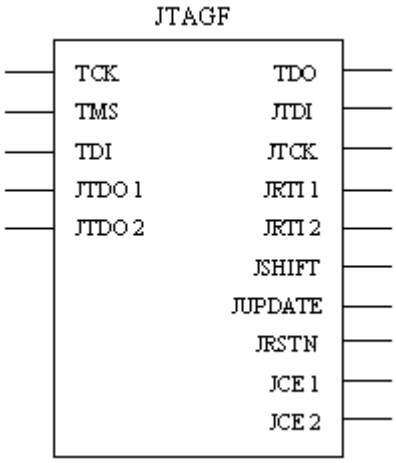
Signal	I/O	Description
TDO	O	Test Data Output, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly to the pad of device TDO pin.
JTDI	O	JTAG Test Data Input, for internal logic to control non-disruptive re-configuration through JTAG port Signal is coming from TDI input and going into the FPGA fabric.
JTCK	O	JTAG Test Clock (connects to TCK), for internal logic to control non-disruptive re-configuration through JTAG port Signal is coming from TCK input and going into the FPGA fabric.
JRTI[2:1]	O	JTAG Run-Test/Idle. Lattice supports two private JTAG instructions ER1 (0x32) and ER2 (0x38). If ER1 instruction is shifted into the JTAG instruction register, JRTI1 will go high when TAP controller is in Run-Test/Idle state. If ER2 instruction is shifted into the JTAG instruction register, JRTI2 will go high when TAP controller is in Run-Test/Idle state.
JSHIFT	O	JTAG Shift. Signal goes high when TAP Controller State is Shift-DR.
JRSTN	O	JTAG Reset (active low) Signal goes low when TAP controller state is Test-Logic-Reset.
JUPDATE	O	JTAG Update. Signal goes high when TAP controller state is Update-DR.
JCE[2:1]	O	JTAG Clock Enable one (BS is to boundary scan ring (L2). Lattice supports two private JTAG instructions, ER1 (0x32) and ER2 (0x38). If ER1 instruction is shifted into the JTAG instruction register, JCE1 will go high when TAP controller is in Capture-DR or Shift-DR states. If ER2 instruction is shifted into the JTAG instruction register, JCE2 will go high when TAP controller is in Capture-DR or Shift-DR states.

JTAGF

JTAG (Joint Test Action Group) Controller

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: TCK, TMS, TDI, JTDO1, JTDO2

OUTPUTS: TDO, JTDI, JTCK, JRTI1, JRTI2, JSHIFT, JUPDATE, JRSTN, JCE1, JCE2

ATTRIBUTES:

ER1: "ENABLED" (default), "DISABLED"

ER2: "ENABLED" (default), "DISABLED"

Description

The JTAGF primitive is used to provide access to internal JTAG signals from within the FPGA fabric. This is used for some cores, such as REVEAL, and other purposes. It is not a component an ordinary user would normally use directly.

Table 694:

Signal	I/O	Description
TCK	I	Test Clock, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly from the pad of device TCK pin. Clocks registers and TAP Controller.
TMS	I	Test Mode Select, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly from the pad of device TMS pin. Controls state machine switching for TAP Controller.
TDI	I	Test Data Input, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly from the pad of device TDI pin.

Table 694:

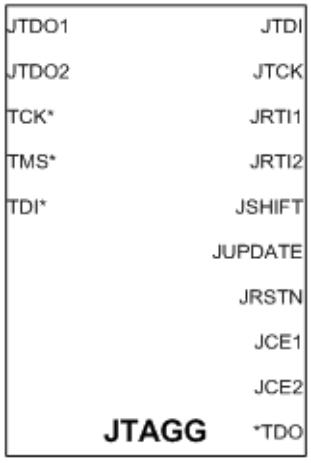
Signal	I/O	Description
JTDO[2:1]	I	JTAG Test Data Output one (scans output bus entering JTAG block), for internal logic to control non-disruptive re-configuration through JTAG port, JTAG serial interface to the device. Lattice supports two private JTAG instructions, ER1 (0x32) and ER2 (0x38). If ER1 instruction is shifted into the JTAG instruction register, TDO output will come from JTDO1. If ER2 instruction is shifted into the JTAG instruction register, TDO output will come from JTDO2.
TDO	O	Test Data Output, one of the pins for the Test Access Port (TAP), JTAG serial interface to the device, connected directly to the pad of device TDO pin.
JTDI	O	JTAG Test Data Input, for internal logic to control non-disruptive re-configuration through JTAG port Signal is coming from TDI input and going into the FPGA fabric.
JTCK	O	JTAG Test Clock (connects to TCK), for internal logic to control non-disruptive re-configuration through JTAG port Signal is coming from TCK input and going into the FPGA fabric.
JRTI[2:1]	O	JTAG Run-Test/Idle. Lattice supports two private JTAG instructions ER1 (0x32) and ER2 (0x38). If ER1 instruction is shifted into the JTAG instruction register, JRTI1 will go high when TAP controller is in Run-Test/Idle state. If ER2 instruction is shifted into the JTAG instruction register, JRTI2 will go high when TAP controller is in Run-Test/Idle state.
JSHIFT	O	JTAG Shift. Signal goes high when TAP Controller State is Shift-DR.
JRSTN	O	JTAG Reset (active low) Signal goes low when TAP controller state is Test-Logic-Reset.
JUPDATE	O	JTAG Update. Signal goes high when TAP controller state is Update-DR.
JCE[2:1]	O	JTAG Clock Enable one (BS is to boundary scan ring (L2). Lattice supports two private JTAG instructions, ER1 (0x32) and ER2 (0x38). If ER1 instruction is shifted into the JTAG instruction register, JCE1 will go high when TAP controller is in Capture-DR or Shift-DR states. If ER2 instruction is shifted into the JTAG instruction register, JCE2 will go high when TAP controller is in Capture-DR or Shift-DR states.

JTAGG

JTAG (Joint Test Action Group) Controller

Architectures Supported:

- ECP5



INPUTS: TCK, TMS, TDI, JTDO2, JTDO1

OUTPUTS: TDO, JTDI, JTCK, JRTI2, JRTI1, JSHIFT, JUPDATE, JRSTN, JCE2, JCE1

Description

The JTAGG element is used to provide access to internal JTAG signals from within the FPGA fabric. This element is used for some cores, such as Reveal Logic Analyzer, and other purposes. Most users would typically not use this component directly.

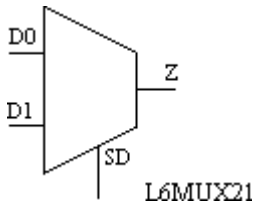
L

L6MUX21

2 to 1 Mux

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, SD

OUTPUT: Z

Truth Table

Table 695:

INPUTS			OUTPUTS
D0	D1	SD	Z
0	X	0	0
1	X	0	1
X	0	1	0
X	1	1	1

Note

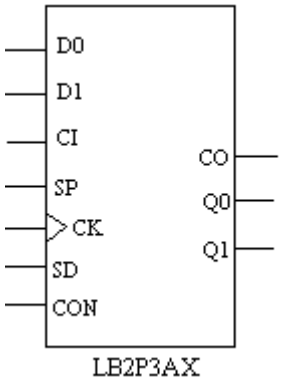
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

LB2P3AX

2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Clear

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, CI, SP, CK, SD, CON

OUTPUTS: CO, Q0, Q1

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Note

When CON = 0, CI and CO are active LOW

Truth Table

Table 696:

INPUTS						OUTPUTS	
D[0:1]	SD	CI	SP	CK	CON	CO	Q[0:1]
D[0:1]	1	0	1	↑	1	0	D[0:1]
D[0:1]	1	1	1	↑	1	*	D[0:1]
X	0	0	X	X	1	0	Q[0:1]
X	X	0	0	X	1	0	Q[0:1]
X	X	1	0	X	1	*	Q[0:1]
X	0	1	1	↑	1	*	count+1
D[0:1]	1	1	1	↑	0	1	D[0:1]
D[0:1]	1	0	1	↑	0	**	D[0:1]
X	0	1	X	X	0	1	Q[0:1]
X	X	1	0	X	0	1	Q[0:1]
X	X	0	0	X	0	**	Q[0:1]
X	0	0	1	↑	0	**	count-1

X = Don’t care

* When Q[0:1] is 11, CO will be 1; otherwise, CO will be 0

** When Q[0:1] is 00, CO will be 0; otherwise, CO will be 1

When GSR=0, CO=!CON•CI, Q[0:1]=0 (D[0:1]=SP=CK=SD=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

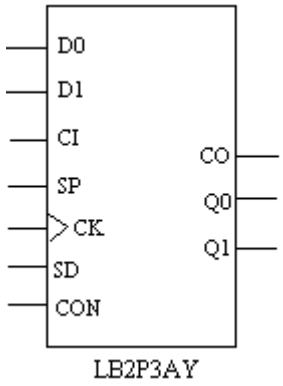
LB2P3AY

2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Preset

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M

- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, CI, SP, CK, SD, CON

OUTPUTS: CO, Q0, Q1

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Note

When CON = 0, CI and CO are active LOW

Truth Table

Table 697:

INPUTS						OUTPUTS	
D[0:1]	SD	CI	SP	CK	CON	CO	Q[0:1]
D[0:1]	1	0	1	↑	1	0	D[0:1]
D[0:1]	1	1	1	↑	1	*	D[0:1]
X	0	0	X	X	1	0	Q[0:1]
X	X	0	0	X	1	0	Q[0:1]
X	X	1	0	X	1	*	Q[0:1]
X	0	1	1	↑	1	*	count+1
D[0:1]	1	1	1	↑	0	1	D[0:1]
D[0:1]	1	0	1	↑	0	**	D[0:1]
X	0	1	X	X	0	1	Q[0:1]
X	X	1	0	X	0	1	Q[0:1]
X	X	0	0	X	0	**	Q[0:1]
X	0	0	1	↑	0	**	count-1

X = Don’t care

* When Q[0:1] is 11, CO will be 1; otherwise, CO will be 0

** When Q[0:1] is 00, CO will be 0; otherwise, CO will be 1

When GSR=0, Q[0:1]=1, CO=!CON+CI (D[0:1]=SP=CK=SD=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

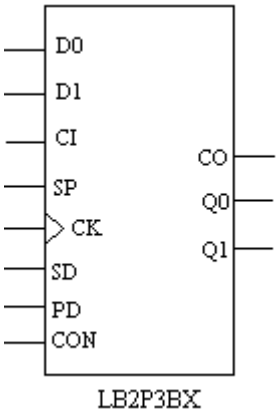
LB2P3BX

2 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable and Positive Level Asynchronous Preset

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M

- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, CI, SP, CK, SD, PD, CON

OUTPUTS: CO, Q0, Q1

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Note

When CON = 0, CI and CO are active LOW

Truth Table

Table 698:

INPUTS							OUTPUTS	
D[0:1]	SD	CI	SP	CK	CON	PD	CO	Q[0:1]
X	X	0	X	X	1	1	0	1
X	X	1	X	X	1	1	1	1

X = Don’t care

* When Q[0:1] is 11, CO will be 1; otherwise, CO will be 0

** When Q[0:1] is 00, CO will be 0; otherwise, CO will be 1

When GSR=0, CO=!CON+CI, Q[0:1]=1 (D[0:1]=SP=CK=SD=PD=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

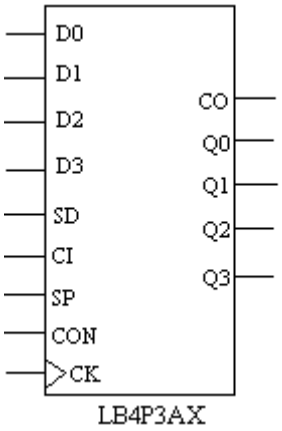
LB4P3AX

4 Bit Positive Edge Triggered Loadable Bidirectional Counter with Positive Clock Enable, GSR Used for Clear

Architectures Supported:

- LatticeECP/EC

- LatticeSC/M
- LatticeXP



INPUTS: D0, D1, D2, D3, CI, SP, CK, SD, CON

OUTPUTS: CO, Q0, Q1, Q2, Q3

Note

When CON = 0, CI and CO are active LOW

Truth Table

Table 702:

INPUTS					OUTPUTS		
D[0:3]	SD	CI	SP	CK	CON	CO	Q[0:3]
D[0:3]	1	0	1	↑	1	0	D[0:3]

When GSR=0, CO=!CON+CI, Q[0:3]=1 (D[0:3]=SP=CK=SD=PD=X)

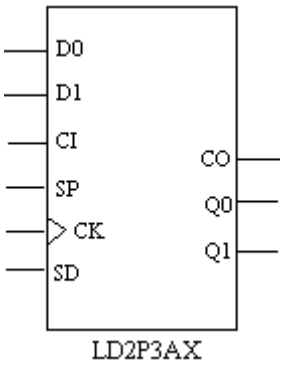
LD2P3AX

2 Bit Positive Edge Triggered Loadable Down-Counter with Positive Clock Enable, GSR Used for Clear

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP

- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, CI, SP, CK, SD

OUTPUTS: CO, Q0, Q1

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Note

CI and CO are active LOW

Truth Table

Table 708:

INPUTS					OUTPUTS	
D[0:1]	SD	CI	SP	CK	CO	Q[0:1]

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP

INPUTS: D0, D1, D2, D3, CI, SP, CK, SD, CD

OUTPUTS: CO, Q0, Q1, Q2, Q3

Note

CI and CO are active LOW

Truth Table

Table 717:

INPUTS						**OUTPUTS**	
D[0:3]	SD	CI	SP	CK	CD	CO	Q[0:3]
X	X	0	X	X	1	0	0
X	X	1	X	X	1	1	0
D[0:3]	1	1	1	↑	0	1	D[0:3]
D[0:3]	1	0	1	↑	0	*	D[0:3]
X	0	1	X	X	0	1	Q[0:3]
X	X	1	0	X	0	1	Q[0:3]
X	X	0	0	X	0	*	Q[0:3]
X	0	0	1	↑	0	*	count-1

X = Don’t care

* When Q[0:3] is 0000, CO will be 0; otherwise, CO will be 1

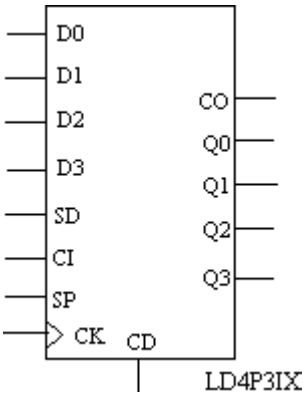
When GSR=0, CO=CI, Q[0:3]=0 (D[0:3]=SP=CK=SD=CD=X)

LD4P3IX

4 Bit Positive Edge Triggered Loadable Down-Counter with Positive Clock Enable and Positive Level Synchronous Clear (Clear overrides Enable)

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP



INPUTS: D0, D1, D2, D3, CI, SP, CK, SD, CD

OUTPUTS: CO, Q0, Q1, Q2, Q3

Note

CI and CO are active LOW

Truth Table

Table 718:

INPUTS						OUTPUTS	
D[0:3]	SD	CI	SP	CK	CD	CO	Q[0:3]
X	X	0	X	↑	1	0	0
X	X	1	X	↑	1	1	0
D[0:3]	1	1	1	↑	0	1	D[0:3]
D[0:3]	1	0	1	↑	0	*	D[0:3]
X	0	1	X	X	0	1	Q[0:3]
X	X	1	0	X	0	1	Q[0:3]
X	X	0	0	X	0	*	Q[0:3]
X	0	0	1	↑	0	*	count-1

X = Don’t care

* When Q[0:3] is 0000, CO will be 0; otherwise, CO will be 1

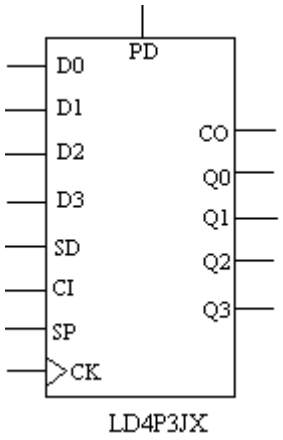
When GSR=0, CO=CI, Q[0:3]=0 (D[0:3]=SP=CK=SD=CD=X)

LD4P3JX

4 Bit Positive Edge Triggered Loadable Down-Counter with Positive Clock Enable and Positive Level Synchronous Preset (Preset overrides Enable)

Architectures Supported:

- LatticeECP/EC
- LatticeSC/M
- LatticeXP



INPUTS: D0, D1, D2, D3, CI, SP, CK, SD, PD

OUTPUTS: CO, Q0, Q1, Q2, Q3

Note

CI and CO are active LOW

Truth Table

Table 719:

INPUTS						**OUTPUTS**	
D[0:3]	SD	CI	SP	CK	PD	CO	Q[0:3]
X	X	X	X	↑	1	1	1
D[0:3]	1	1	1	↑	0	1	D[0:3]
D[0:3]	1	0	1	↑	0	*	D[0:3]
X	0	1	X	X	0	1	Q[0:3]
X	X	1	0	X	0	1	Q[0:3]
X	X	0	0	X	0	*	Q[0:3]
X	0	0	1	↑	0	*	count-1

X = Don’t care

* When Q[0:3] is 0000, CO will be 0; otherwise, CO will be 1

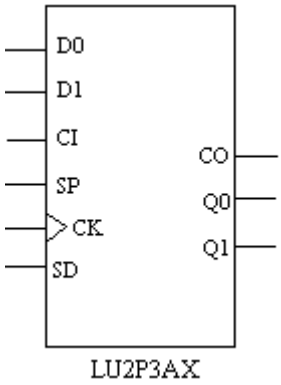
When GSR=0, CO=1, Q[0:3]=1 (D[0:3]=SP=CK=SD=PD=X)

LU2P3AX

2 Bit Positive Edge Triggered Loadable Up-Counter with Positive Clock Enable, GSR Used for Clear

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, CI, SP, CK, SD

OUTPUTS: CO, Q0, Q1

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 720:

INPUTS					OUTPUTS	
D[0:1]	SD	CI	SP	CK	CO	Q[0:1]
D[0:1]	1	0	1	↑	0	D[0:1]
D[0:1]	1	1	1	↑	*	D[0:1]
X	0	0	X	X	0	Q[0:1]
X	X	0	0	X	0	Q[0:1]
X	X	1	0	X	*	Q[0:1]
X	0	1	1	↑	*	count+1

X = Don’t care

* When Q[0:1] is 11, CO will be 1; otherwise, CO will be 0

When GSR=0, CO=0, Q[0:1]=0 (D[0:1]=SP=CK=SD=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

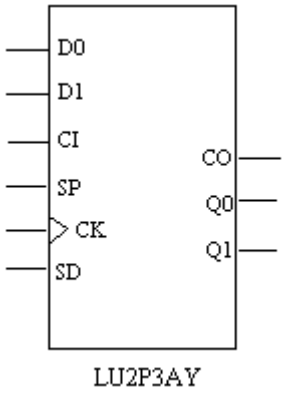
LU2P3AY

2 Bit Positive Edge Triggered Loadable Up-Counter with Positive Clock Enable, GSR Used for Preset

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager

- Platform Manager 2



INPUTS: D0, D1, CI, SP, CK, SD

OUTPUTS: CO, Q0, Q1

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 721:

INPUTS					OUTPUTS	
D[0:1]	SD	CI	SP	CK	CO	Q[0:1]
D[0:1]	1	0	1	↑	0	D[0:1]
D[0:1]	1	1	1	↑	*	D[0:1]
X	0	0	X	X	0	Q[0:1]
X	X	0	0	X	0	Q[0:1]
X	X	1	0	X	*	Q[0:1]
X	0	1	1	↑	*	count+1

X = Don’t care

* When Q[0:1] is 11, CO will be 1; otherwise, CO will be 0

When GSR=0, CO=CI, Q[0:1]=1 (D[0:1]=CI=SP=CK=SD=X)

Note

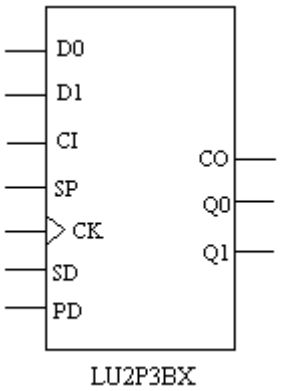
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

LU2P3BX

2 Bit Positive Edge Triggered Loadable Up-Counter with Positive Clock Enable and Positive Level Asynchronous Preset

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, CI, SP, CK, SD, PD

OUTPUTS: CO, Q0, Q1

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 722:

INPUTS						OUTPUTS	
D[0:1]	SD	CI	SP	CK	PD	CO	Q[0:1]
X	X	0	X	X	1	0	1
X	X	1	X	X	1	1	1
D[0:1]	1	0	1	↑	0	0	D[0:1]
D[0:1]	1	1	1	↑	0	*	D[0:1]
X	0	0	X	X	0	0	Q[0:1]
X	X	0	0	X	0	0	Q[0:1]
X	X	1	0	X	0	*	Q[0:1]
X	0	1	1	↑	0	*	count+1

X = Don’t care

* When Q[0:1] is 11, CO will be 1; otherwise, CO will be 0

When GSR=0, CO=CI, Q[0:1]=1 (D[0:1]=SP=CK=SD=PD=X)

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

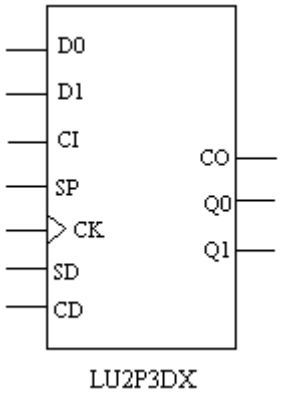
LU2P3DX

2 Bit Positive Edge Triggered Loadable Up-Counter with Positive Clock Enable and Positive Level Asynchronous Clear

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D

- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, CI, SP, CK, SD, CD

OUTPUTS: CO, Q0, Q1

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Truth Table

Table 723:

INPUTS						**OUTPUTS**	
D[0:1]	SD	CI	SP	CK	CD	CO	Q[0:1]
X	X	X	X	X	1	0	0
D[0:1]	1	0	1	↑	0	0	D[0:1]

When GSR=0, CO=CI, Q[0:3]=1 (D[0:3]=SP=CK=SD=PD=X)

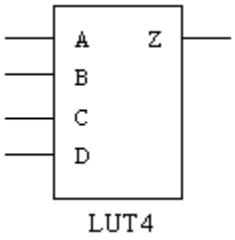
LUT4

4-Input Look Up Table

Architectures Supported:

- ECP5
- LatticeECP3
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: A, B, C, D

OUTPUT: Z

ATTRIBUTES:

INIT: hexadecimal value (default: 16'h0000)

Description

LUT4 defines the programmed state of a LUT4 primitive of a Slice. While this primitive is typically targeted by logic synthesis tools, it can also be instantiated in HDL source for intimate control over LUT4 programming. The contents of the look up table are addressed by the 4 input pins to access 1 of 16 locations.

The programming of the LUT4 (that is, the 0 or 1 value of each memory location within the LUT4) is determined by the value assigned with INIT. The value is expressed in hexadecimal code. Highest memory locations are in the most significant hex digit, the lowest in the least significant digit.

For example, hex value BF80 produces these 16 memory locations and values:

1011 1111 1000 0000

Memory location 0 (D=0, C=0, B=0, A=0) contains a 0, memory location 2 (D=0, C=0, B=1, A=0) contains a 0. Memory location 15 (D=1, C=1, B=1, A=1) contains a 1, etc.

The LUT4 may encode the Boolean logic for any Boolean expression of 4 input variables. For example, if the required expression was:

Z = (D*C) + (B*!A)

then the INIT value can be derived from the truth table resulting from the expression:

```
D C B A : Z
0 0 0 0 : 0
0 0 0 1 : 0
0 0 1 0 : 1
0 0 1 1 : 0

0 1 0 0 : 0
0 1 0 1 : 0
0 1 1 0 : 1
0 1 1 1 : 0

1 0 0 0 : 0
1 0 0 1 : 0
1 0 1 0 : 1
1 0 1 1 : 0

1 1 0 0 : 1
1 1 0 1 : 1
1 1 1 0 : 1
```

```
1 1 1 1 : 1
```

INIT = F444 (16)

LUT4 Usage with Verilog HDL

```
// LUT4 module instantiation
LUT4
   #(.init  (16'hF444))
   I1 ( .A (A), .B (B), .C (C), .D (D), .Z (Q[0]) );
```

LUT4 Usage with VHDL

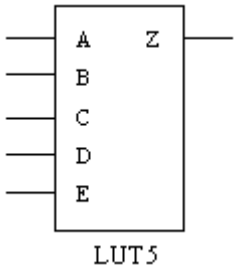
```
-- LUT4 component instantiation
I1 : LUT4
   Generic Map (INIT=>b"1111_0100_0100_0100")
   Port Map ( A=>A, B=>B, C=>C, D=>D, Z=>N_1 );
```

LUT5

5-Input Look Up Table

Architectures Supported:

- ECP5
- LatticeECP3
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: A, B, C, D, E

OUTPUT: Z

ATTRIBUTES:

INIT: hexadecimal value (default: 32'h00000000)

Description

LUT5 defines the programmed state of a LUT5 primitive of a Slice. While this primitive is typically targeted by logic synthesis tools, it can also be instantiated in HDL source for intimate control over LUT5 programming. The contents of the look up table are addressed by the 5 input pins to access 1 of 32 locations.

The programming of the LUT5 (that is, the 0 or 1 value of each memory location within the LUT5) is determined by the value assigned with INIT. The value is expressed in hexadecimal code. Highest memory locations are in the most significant hex digit, the lowest in the least significant digit.

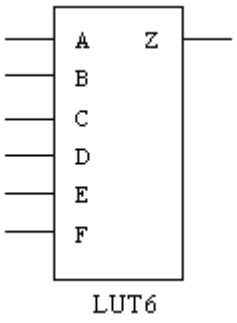
For more information on INIT attribute usage, see the LUT4 topic.

LUT6

6-Input Look Up Table

Architectures Supported:

- ECP5
- LatticeECP3
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: A, B, C, D, E, F

OUTPUT: Z

ATTRIBUTES:

INIT: hexadecimal value (default: 64'h0000000000000000)

Description

LUT6 defines the programmed state of a LUT6 primitive of a Slice. While this primitive is typically targeted by logic synthesis tools, it can also be instantiated in HDL source for intimate control over LUT6 programming. The contents of the look up table are addressed by the 6 input pins to access 1 of 64 locations.

The programming of the LUT6 (that is, the 0 or 1 value of each memory location within the LUT6) is determined by the value assigned with INIT. The value is expressed in hexadecimal code. Highest memory locations are in the most significant hex digit, the lowest in the least significant digit.

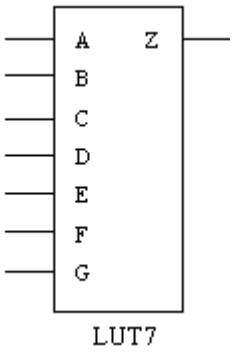
For more information on INIT attribute usage, see the LUT4 topic.

LUT7

7-Input Look Up Table

Architectures Supported:

- ECP5
- LatticeECP3
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: A, B, C, D, E, F, G

OUTPUT: Z

ATTRIBUTES:

INIT: hexadecimal value (default: 128'00000000000000000000000000000000)

Description

LUT7 defines the programmed state of a LUT7 primitive of a Slice. While this primitive is typically targeted by logic synthesis tools, it can also be instantiated in HDL source for intimate control over LUT7 programming. The contents of the look up table are addressed by the 7 input pins to access 1 of 128 locations.

The programming of the LUT7 (that is, the 0 or 1 value of each memory location within the LUT7) is determined by the value assigned with INIT. The value is expressed in hexadecimal code. Highest memory locations are in the most significant hex digit, the lowest in the least significant digit.

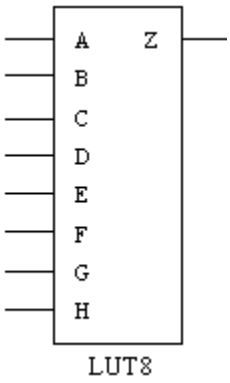
For more information on INIT attribute usage, see the LUT4 topic.

LUT8

8-Input Look Up Table

Architectures Supported:

- ECP5
- LatticeECP3
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: A, B, C, D, E, F, G, H

OUTPUT: Z

ATTRIBUTES:

INIT: hexadecimal value (default: 256'h00000000000000000000000000000000000000000000000000000000000000000000000)

Description

LUT8 defines the programmed state of a LUT8 primitive of a Slice. While this primitive is typically targeted by logic synthesis tools, it can also be instantiated in HDL source for intimate control over LUT8 programming. The contents of the look up table are addressed by the 8 input pins to access 1 of 256 locations.

The programming of the LUT8 (that is, the 0 or 1 value of each memory location within the LUT8) is determined by the value assigned with INIT. The value is expressed in hexadecimal code. Highest memory locations are in the most significant hex digit, the lowest in the least significant digit.

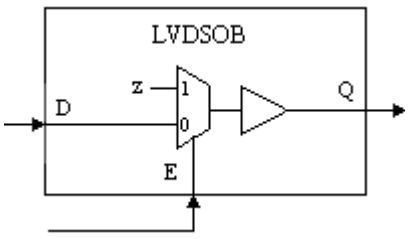
For more information on INIT attribute usage, see the LUT4 topic.

LVDSOB

LVDS Output Buffer

Architectures Supported:

- ECP5
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D, E

OUTPUT: Q

Description

The LVDSOB primitive is used to support post-PAR simulation of Dynamic Bank Controller. The Dynamic Bank Controller signals to the IO are hardwired and cannot be changed for the simulation, so the LVDSOB and INRDB primitives are defined to support the simulation.

For more information, refer to the following technical note on the Lattice web site:

- TN1198 - Power Estimation and Management for MachXO2 Device

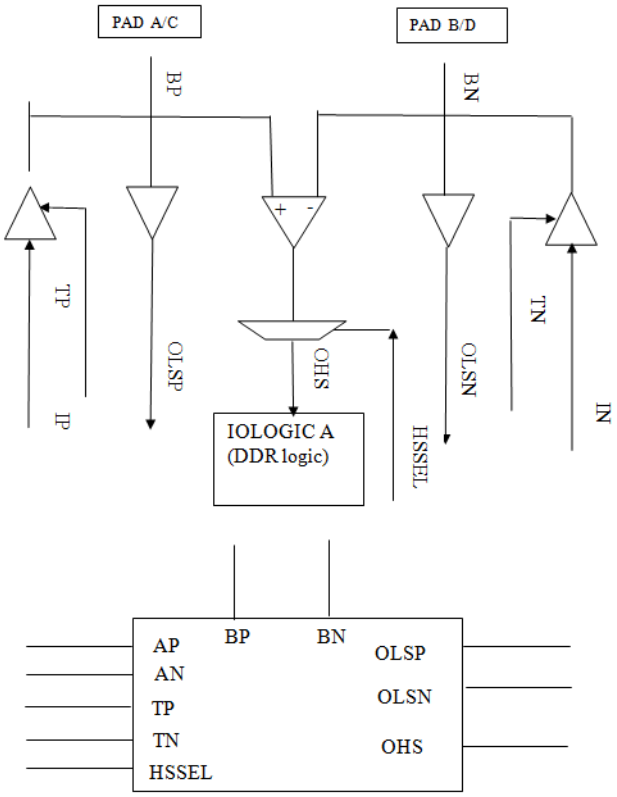
M

MIPI

Special Primitive for MIPI Input Support

Architectures Supported:

- LIFMD



INPUTS/OUTPUTS: BP, BN

INPUTS: AP, AN, HSSEL, TP, TN

OUTPUT: OLSP, OLSN, OHS

Description

This primitive is used when implementing MIPI interface. HS RX, LP RX and LP TX modes are supported.

The following are descriptions of MIPI port functions.

Table 732:

Port	I/O	Description
BP	I/O	PAD A, C
BN	I/O	PAD B, D
AP	I	Input from fabric to PAD A,C
AN	i	Input from fabric to PAD B,D
HSSEL	i	High Speed Select Signal. HSSEL=1: High Speed mode, 100 ohm differential termination is on. HS_SEL=0: Low Speed mode, 100 ohm termination is turned off.
TP	i	Tristate for PAD A,C
TN	I	Tristate for PAD B,D
OLSP	O	Low Speed to IOLOGIC A
OLSN	O	Low Speed to IOLOGIC B
OHS	O	High Speed Differential to IOLOGIC

MIPIDPHYA

Architectures Supported:

- LIFMD

INPUTS/OUTPUTS: CKP; CKN. DPy; DNy

INPUTS: CLKRXHSEN;CLKRXLPEN; CLKCDEN; CLKDTXLPP; CLKTXLPEN; CLKDTXLPN; CLKTXHSEN; CLKTXHSGATE; CLKTXHSPD; DyRXLPEN; DyCDEN; DyDTXLPP; DyTXLPEN; DyDTXLPN; DyRXHSEN; DyHSDESEREN; DyTXHSEN; DyHSTXDATA15; input DyHSTXDATA14, DYHSTXDATA13, DYHSTXDATA12, DYHSTXDATA11, DYHSTXDATA10; DyHSTXDATA9, DYHSTXDATA8, DYHSTXDATA7, DYHSTXDATA6, DYHSTXDATA5; DyHSTXDATA4, DYHSTXDATA3, DYHSTXDATA2, DYHSTXDATA1, DYHSTXDATA0; DyHSSEREN; DyTXHSPD; LBEN; PDDPHY; PDBIAS; PDCKG; CLKREF; PDPLL

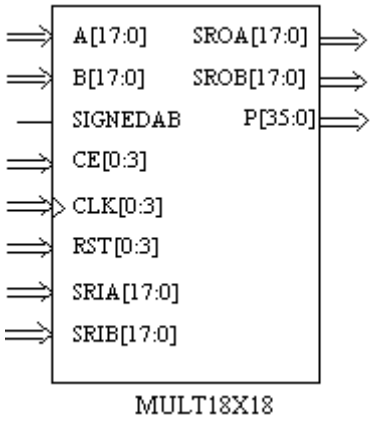
OUTPUTS: CLKHSBYTE; CLKDRXLPP; CLKDRXLPN; CLKDCDN; CLKDRXHS; DyDRXLPP; DyDRXLPN; DyDCDP; DyDCDN; DyHSRXDATA15; DyHSRXDATA14, DYHSRXDATA13, DYHSRXDATA12, DYHSRXDATA11, DYHSRXDATA10; DyHSRXDATA9, DYHSRXDATA8, DYHSRXDATA7, DYHSRXDATA6, DYHSRXDATA5; DyHSRXDATA4, DYHSRXDATA3, DYHSRXDATA2, DYHSRXDATA1, DYHSRXDATA0; HSBYTECLKD; HSBYTECLKS; DySYNC; DyERRSYNC; DyNOSYNC; DyDRXHS; LOCK

MULT18X18

DSP Multiplier

Architectures Supported:

- LatticeECP (DSP Blocks Only)



INPUTS: A17, A16, A15, A14, A13, A12, A11, A10, A9, A8, A7, A6, A5, A4, A3, A2, A1, A0, B17, B16, B15, B14, B13, B12, B11, B10, B9, B8, B7, B6, B5, B4, B3, B2, B1, B0, SIGNEDAB, CE0, CE1, CE2, CE3, CLK0, CLK1, CLK2, CLK3, RST0, RST1, RST2, RST3, SRIA17, SRIA16, SRIA15, SRIA14, SRIA13, SRIA12, SRIA11, SRIA10, SRIA9, SRIA8, SRIA7, SRIA6, SRIA5, SRIA4, SRIA3, SRIA2, SRIA1, SRIA0, SRIB17, SRIB16, SRIB15, SRIB14, SRIB13, SRIB12, SRIB11, SRIB10, SRIB9, SRIB8, SRIB7, SRIB6, SRIB5, SRIB4, SRIB3, SRIB2, SRIB1, SRIB0

OUTPUTS: SROA17, SROA16, SROA15, SROA14, SROA13, SROA12, SROA11, SROA10, SROA9, SROA8, SROA7, SROA6, SROA5, SROA4, SROA3, SROA2, SROA1, SROA0, SROB17, SROB16, SROB15, SROB14, SROB13, SROB12, SROB11, SROB10, SROB9, SROB8, SROB7, SROB6, SROB5, SROB4, SROB3, SROB2, SROB1, SROB0, P35, P34, P33, P32, P31, P30, P29, P28, P27, P26, P25, P24, P23, P22, P21, P20, P19, P18, P17, P16, P15, P14, P13, P12, P11, P10, P9, P8, P7, P6, P5, P4, P3, P2, P1, P0

Description

LatticeECP DSP Block Multiplier. MULT18X18 is a combinational signed 18-bit by 18-bit multiplier used in the DSP block. The value represented in the 18-bit input A is multiplied by the value represented in the 18-bit input B. Output P is the 36-bit product of A and B. MULT18X18 may be represented as either unsigned or two's complement signed. The primitive consists of three types of optional pipeline registers:

- Input registers, located before the multipliers and registering the operands
- Multiplier pipeline registers, located after the multipliers and product registration
- Output registers, located before leaving the block, and registering the mode-specific output.

There are 12 register controls signals that enter the DSP block: CLK[0:3], CE0[0:3], and RST[0:3]. Each incoming signal also has the option of being tied high, tied low, or inverted. These 12 control signals are used to control the

register banks in the DSP block. Dynamic control signals must match the register pipelining of the datapath. To facilitate this, the following bank control for each individual dynamic signal's input register and pipeline register (total 8 signals x 2 registers / signal = 16 registers) is as follows:

- Bypass or no-bypass of the registers.
- Clock is selected from CLK[0:3], one of four sources available to the DSP block.
- Clock enable is selected from CE0[0:3], one of four sources available to the DSP block.
- Reset is selected from RST[0:3], one of four sources available to the DSP block.

You can turn registers off or on via attribute settings. For example, setting REG_INPUTA_CLK= "CLK0" means the input A register is used, and the clock drive A register is coming from CLK0 of the DSP block. Setting REG_INPUTA_CE= "CE1" means input A register CE control is coming from CE1 of the DSP block. Setting REG_INPUTA_RST= "RST3" means input A register reset control is coming from RST3 of the DSP block. If REG_INPUT_A_CLK="NONE", this means the input A register is bypassed, therefore, REG_INPUT_A_RST or REG_INPUT_A_CE becomes irrelevant.

In case you want to use the register but do not care about the clock enable (CE), then this pin needs to be tied to VCC (always enabled). In this case you could set REG_INPUT_A_CE="CE3", then tie CE3 of the to VCC. If you want to use the register but do not care about the reset (RST), then this pin must to be tied to GND (always do not reset). In this case, you you could set REG_INPUT_A_RST="RST2", then tie RST2 of the to GND.

SIGNEDAB is a pin which controls whether the multiplier performs the signed or unsigned operation. It applied to both operand A and B. It can be tied to VCC (signed) or GROUND (unsigned). There are also two delay registers associated with this control pin, in order to match with incoming data. Setting REG_SIGNEDAB_0_CLK= "CLK0 | CLK1 | CLK2 | CLK3"will turn on the pipeline register for SIGNEDAB. Setting REG_SIGNEDAB_0_CLK= "NONE" will turn off the first pipeline register for SIGNEDAB. Setting REG_SIGNEDAB_1_CLK= "NONE" will turn off the second pipeline register for SIGNEDAB.

Input registers receive operand values from a serial shift chain or routing input. There is separate control for A and B operands. When in shift chain mode, multiplier operands may be bypassed using the bank bypass feature. The shift chain supports one chain of two 18-bit operands or two chains of two 9-bit operands. GSR "DISABLED" attribute disables the asynchronous global set reset input when in user mode.

You can refer to the following technical note on the Lattice web site for more details.

Description

LatticeECP Block Adder/Subtractor. MULT18X18ADDSUB can be configured to either add or subtract its inputs, adding or subtracting the inputs from two multiplier products. The add/subtract control is either configured as a static HIGH (Vcc), LOW (GND). In Lattice Diamond, the static settings are implemented by setting Vcc or GND in the CIB ISB.

The primitive consists of three types of optional pipeline registers:

- Input registers, located before the multipliers and registering the operands

- Multiplier pipeline registers, located after the multipliers and product registration
- Output registers, located before leaving the block, and registering the mode-specific output.

See the description of MULT18X18 for more information on control signals for DSP blocks and attributes.

You can also refer to the following technical note on the Lattice web site for more details.

SHIFT_IN_B3: "FALSE" (default), "TRUE"

GSR: "ENABLED" (default), "DISABLED"

Description

LatticeECP DSP Block Adder/Subtractor. MULT18X18ADDSUBSUM can be configured to either add or subtract its inputs, adding or subtracting the inputs from two multiplier products. The add/subtract control is either configured as a static HIGH (Vcc), LOW (GND), or as dynamic control signals ADDNSUB1 and ADDNSUB3. In Lattice Diamond, the static settings are implemented by setting ADDNSUB1 and ADDNSUB3 signal to Vcc or GND in the CIB ISB.

The primitive consists of three types of optional pipeline registers:

- Input registers, located before the multipliers and registering the operands
- Multiplier pipeline registers, located after the multipliers and product registration
- Output registers, located before leaving the block, and registering the mode-specific output.

See the description of MULT18X18 for more information on control signals for DSP blocks and attributes.

Refer to the following technical note on the Lattice web site.

- TN1057 - LatticeECP sysDSP Usage Guide

MULT18X18ADDSUBSUM pin functions:

Table 735:

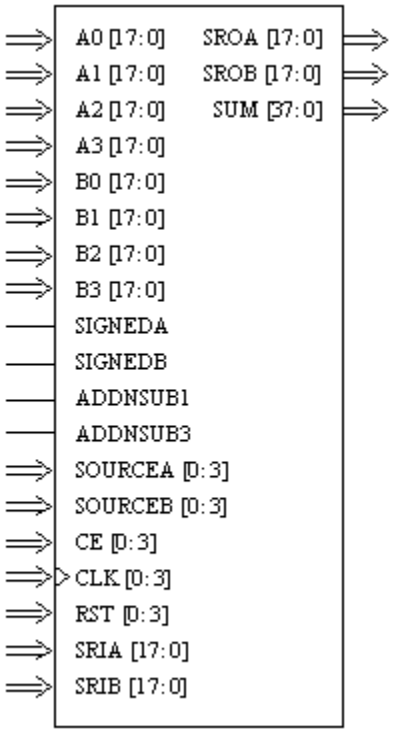
Function	Pins
input data A and B	A0|1|2|3[17:0], B0|1|2|3[17:0]
signed input (0 = unsigned, 1 = signed)	SIGNEDAB
add/subtract (0 = add, 1 = subtract)	ADDNSUB1, ADDNSUB3
clock enable	CE[0:3]
clock input	CLK[0:3]
reset	RST[0:3]
shifted input A and B (from previous stage)	SRIA[17:0], SRIB[17:0]
shifted output A and B (from previous stage)	SROA[17:0], SROB[17:0]
output product sum data	SUM[37:0]

MULT18X18ADDSUBSUMB

DSP Multiplier Add/Subtract/Sum

Architectures Supported:

- LatticeECP2/M
- LatticeECP3 (*for LatticeECP2/M backward compatibility only*)
- LatticeXP2



INPUTS: A017, A016, A015, A014, A013, A012, A011, A010, A09, A08, A07, A06, A05, A04, A03, A02, A01, A00, A117, A116, A115, A114, A113, A112, A111, A110, A19, A18, A17, A16, A15, A14, A13, A12, A11, A10, A217, A216, A215, A214, A213, A212, A211, A210, A29, A28, A27, A26, A25, A24, A23, A22, A21, A20, A317, A316, A315, A314, A313, A312, A311, A310, A39, A38, A37, A36, A35, A34, A33, A32, A31, A30, B017, B016, B015, B014, B013, B012, B011, B010, B09, B08, B07, B06, B05, B04, B03, B02, B01, B00, B117, B116, B115, B114, B113, B112, B111, B110, B19, B18, B17, B16, B15, B14, B13, B12, B11, B10, B217, B216, B215, B214, B213, B212, B211, B210, B29, B28, B27, B26, B25, B24, B23, B22, B21, B20, B317, B316, B315, B314, B313, B312, B311, B310, B39, B38, B37, B36, B35, B34, B33, B32, B31, B30, SIGNEDA, SIGNEDB, ADDNSUB1, ADDNSUB3, SOURCEA0, SOURCEA1, SOURCEA2, SOURCEA3, SOURCEB0, SOURCEB1, SOURCEB2, SOURCEB3, CE0, CE1, CE2, CE3, CLK0, CLK1, CLK2, CLK3, RST0, RST1, RST2, RST3, SRIA17, SRIA16, SRIA15, SRIA14, SRIA13, SRIA12, SRIA11, SRIA10, SRIA9, SRIA8, SRIA7, SRIA6, SRIA5, SRIA4, SRIA3, SRIA2, SRIA1, SRIA0, SRIB17, SRIB16, SRIB15, SRIB14, SRIB13, SRIB12, SRIB11, SRIB10, SRIB9, SRIB8, SRIB7, SRIB6, SRIB5, SRIB4, SRIB3, SRIB2, SRIB1, SRIB0

OUTPUTS: SROA17, SROA16, SROA15, SROA14, SROA13, SROA12, SROA11, SROA10, SROA9, SROA8, SROA7, SROA6, SROA5, SROA4, SROA3, SROA2, SROA1, SROA0, SROB17, SROB16, SROB15, SROB14, SROB13, SROB12, SROB11, SROB10, SROB9, SROB8, SROB7, SROB6, SROB5, SROB4, SROB3, SROB2, SROB1, SROB0, SUM37, SUM36, SUM35, SUM34, SUM33, SUM32, SUM31, SUM30, SUM29, SUM28, SUM27, SUM26, SUM25, SUM24, SUM23, SUM22, SUM21, SUM20,

CAS_MATCH_REG	"FALSE", "TRUE"	"FALSE"	Cascade match register option
MULT_BYPASS	"DISABLED", "ENABLED"	"ENABLED"	Multiplier bypass option
RESETMODE	"SYNC", "ASYNC"	"SYNC"	Global set reset selection
GSR	"ENABLED", "DISABLED"	"ENABLED"	Reset mode selection

Note:
The multipliers linked by SROA/SRIA or SROB/SRIB pin pair can only be implemented in a continuous shift chain with multipliers placed next to each other. However, the length of the shift chain is limited on each DSP row and different depending on the device selected. For example, with the LatticeECP3-35 device, each DSP row has 32 MULT18s. So for the shift chained MULT18, it can support a continuous chain of length 32 for MULT18. If a chain is more than 32 MULT18s, you have to employ SRO/A,B pin pair for connecting the 32nd and 33rd MULT18s for implementing the chain in two DSP rows. But this capability is only limited to port A on SRO side in LatticeECP3. That is to say, only SROA is allowed to connect to A,B input pin of another MULT18, but not SROB. So if a chain is linked by SROB/SRIB pin pair, the length cannot exceed 32 for the LatticeECP3-35 device.

Description

MULT18X18MAC supports operand bit widths for 18X18 multiplication and accumulates the output up to 52 bits. The DSP block includes optional registers for the input and intermediate pipeline stage. Pipeline stages may be set using a pipeline attribute. The output registers are required for the accumulator. Signed and unsigned arithmetic are supported. The OVERFLOW bit is also provided when the accumulated results are in the overflow condition. ACCUMSLOAD determines the mode of operation for either loading the multiplier product or to accumulate.

The primitive consists of three types of optional pipeline registers:

- Input registers, located before the multipliers and registering the operands
- Multiplier pipeline registers, located after the multipliers and product registration
- Output registers, located before leaving the block, and registering the mode-specific output.

See the description of MULT18X18 for more information on control signals for DSP blocks and attributes.

Refer to the following technical note on the Lattice web site.

- TN1057 - LatticeECP sysDSP Usage Guide

MULT18X18MAC pin functions:

Table 740:

Function	Pins
input data A and B	A[17:0], B[17:0]
signed input (0 = unsigned, 1 = signed)	SIGNEDAB

Table 740:

Function	Pins
add/subtract (0 = add, 1 = subtract)	ADDNSUB
Accumulate (HIGH) /Load (LOW) Mode	ACCUMSLOAD
clock enable	CE[0:3]
clock input	CLK[0:3]
clock reset	RST[0:3]
shifted input A and B (from previous stage)	SRIA[17:0], SRIB[17:0]
shifted output A and B (from previous stage)	SROA[17:0], SROB[17:0]
output data	ACCUM[51:0]
overflow	OVERFLOW

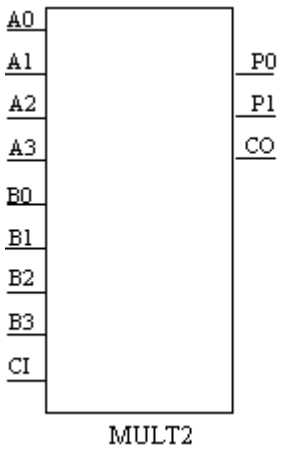
MULT2

2x2 Multiplier

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeXP
- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A0, A1, A2, A3, B0, B1, B2, B3, CI

OUTPUTS: P0, P1, CO

Description

MULT2 is a 2x2 multiplier. This primitive is useful for implementing an array multiplier using a dedicated carry chain. With this unique configuration, the two separate “and” inputs can be added together to perform the add and shift operations within a single slice. MULT2 must be cascaded together when performing the multiply function. Here are descriptions of the MULT2 pins:

Table 741:

Function	Pins
multiplicand	A0, A1, A2, A3
multiplier	B0, B1, B2, B3
carry in	CI
carry out	CO
output	P0, P1

The equations for this primitive are shown in the table below:

Table 742:

Equations
CO_int, P0 = A0*B0 + A1*B1 + CI
CO, P1 = A2*B2 + A3*B3 + CO_int

CO_int and P0 are the carry-out and sum of a full adder with inputs (A0 AND B0), (A1 AND B1), and CI. CO and P1 are the carry-out and sum of a full adder with inputs (A2 AND B2), (A3 AND B3), and CO_int.

Refer to the following technical notes on the Lattice web site.

GSR: "ENABLED" (default), "DISABLED"

Description

LatticeECP Block Multiplier. MULT36X36 is a combinational signed 36-bit by 36-bit multiplier used in the DSP block. The value represented in the 36-bit input A is multiplied by the value represented in the 36-bit input B. Output P is the 72-bit product of A and B. MULT36X36 may be represented as either unsigned or two's complement signed. The primitive consists of three types of optional pipeline registers:

- Input registers, located before the multipliers and registering the operands
- Multiplier pipeline registers, located after the multipliers and product registration
- Output registers, located before leaving the block, and registering the mode-specific output.

See the description of MULT18X18 for more information on control signals for DSP blocks and attributes.

Input registers receive operand values from a serial shift chain or routing input. There is separate control for A and B operands. When in shift chain mode, multiplier operands may be bypassed using the bank bypass feature. The shift chain supports one chain of two 18-bit operands or two chains of two 9-bit operands. GSR "DISABLED" attribute disables the asynchronous global set reset input when in user mode.

Refer to the following technical note on the Lattice web site.

- TN1057 - LatticeECP sysDSP Usage Guide

MULT36X36 pin functions:

Table 743:

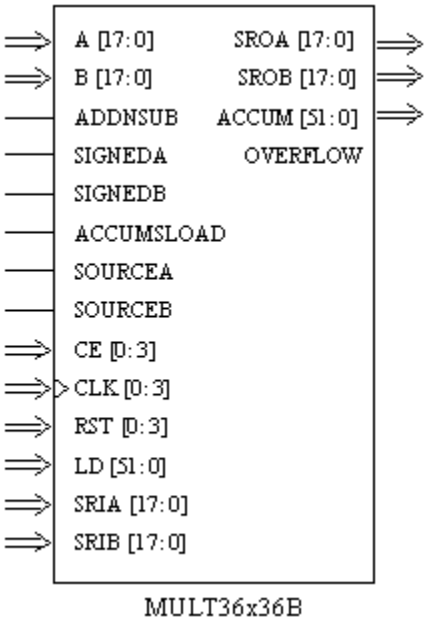
Function	Pins
input data A and B	A[35:0], B[35:0]
signed input (0 = unsigned, 1 = signed)	SIGNEDAB
clock enable	CE[0:3]
clock input	CLK[0:3]
clock reset	RST[0:3]
output data	P[71:0]

MULT36X36B

DSP Multiplier

Architectures Supported:

- LatticeECP2/M
- LatticeECP3 (*for LatticeECP2/M backward compatibility only*)
- LatticeXP2



MULT36x36B

INPUTS: A35, A34, A33, A32, A31, A30, A29, A28, A27, A26, A25, A24, A23, A22, A21, A20, A19, A18, A17, A16, A15, A14, A13, A12, A11, A10, A9, A8, A7, A6, A5, A4, A3, A2, A1, A0, B35, B34, B33, B32, B31, B30, B29, B28,

Description

LatticeECP DSP Block Multiplier. MULT9X9 is a combinational signed 9-bit by 9-bit multiplier used in the DSP block. The value represented in the 9-bit input A is multiplied by the value represented in the 9-bit input B. Output P is the 18-bit product of A and B. MULT9X9 may be represented as either unsigned or two's complement signed. The primitive consists of three types of optional pipeline registers:

- Input registers, located before the multipliers and registering the operands
- Multiplier pipeline registers, located after the multipliers and product registration
- Output registers, located before leaving the block, and registering the mode-specific output.

See the description of MULT18X18 for more information on control signals for DSP blocks and attributes.

Refer to the following technical note on the Lattice web site.

Description

LatticeECP DSP Block Adder/Subtractor. MULT18X18ADDSUB can be configured to either add or subtract its inputs, adding or subtracting the inputs from two multiplier products. The add/subtract control is either configured as a static HIGH (Vcc), LOW (GND), or as dynamic control signals ADDNSUB1 and ADDNSUB3. In Lattice Diamond, the static settings are implemented by setting ADDNSUB1 and ADDNSUB3 signal to Vcc or GND in the CIB ISB.

The primitive consists of three types of optional pipeline registers:

- Input registers, located before the multipliers and registering the operands
- Multiplier pipeline registers, located after the multipliers and product registration
- Output registers, located before leaving the block, and registering the mode-specific output.

See the description of MULT18X18 for more information on control signals for DSP blocks and attributes.

Refer to the following technical note on the Lattice web site.

MULT9X9ADDSUB pin functions:

Table 745:

Function	Pins
input data A and B	A0|1[8:0], B0|1[8:0]
signed input (0 = unsigned, 1 = signed)	SIGNEDAB
add/subtract (0 = add, 1 = subtract)	ADDNSUB
clock enable	CE[0:3]
clock input	CLK[0:3]
reset	RST[0:3]
shifted input A and B (from previous stage)	SRIA[8:0], SRIB[8:0]
shifted output A and B (from previous stage)	SROA[8:0], SROB[8:0]
output product sum data	SUM[18:0]

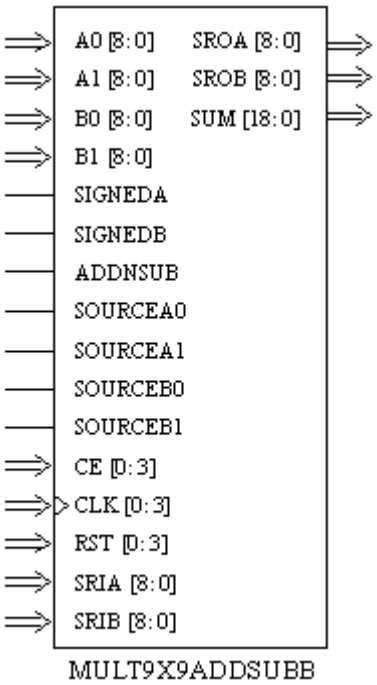
MULT9X9ADDSUBB

DSP Multiplier Add/Subtract

Architectures Supported:

- LatticeECP2/M

- LatticeECP3 (*for LatticeECP2/M backward compatibility only*)
- LatticeXP2



INPUTS: A08, A07, A06, A05, A04, A03, A02, A01, A00, A18, A17, A16, A15, A14, A13, A12, A11, A10, B08, B07, B06, B05, B04, B03, B02, B01, B00, B18, B17, B16, B15, B14, B13, B12, B11, B10, SIGNEDA, SIGNEDB, ADDNSUB, SOURCEA0, SOURCEA1, SOURCEB0, SOURCEB1, CE0, CE1, CE2, CE3, CLK0, CLK1, CLK2, CLK3, RST0, RST1, RST2, RST3, SRIA8, SRIA7, SRIA6, SRIA5, SRIA4, SRIA3, SRIA2, SRIA1, SRIA0, SRIB8, SRIB7, SRIB6, SRIB5, SRIB4, SRIB3, SRIB2, SRIB1, SRIB0

Description

LatticeECP DSP Block Adder/Subtractor. MULT9X9ADDSUBSUM can be configured to either add or subtract its inputs, adding or subtracting the inputs from two multiplier products. The add/subtract control is either configured as a static HIGH (Vcc), LOW (GND), or as dynamic control signals ADDNSUB1 and ADDNSUB3. In Lattice Diamond, the static settings are implemented by setting ADDNSUB1 and ADDNSUB3 signal to Vcc or GND in the CIB ISB.

The primitive consists of three types of optional pipeline registers:

- Input registers, located before the multipliers and registering the operands
- Multiplier pipeline registers, located after the multipliers and product registration
- Output registers, located before leaving the block, and registering the mode-specific output.

See the description of MULT18X18 for more information on control signals for DSP blocks and attributes.

GSR: "ENABLED" (default), "DISABLED"

Description

MULT9X9MAC supports operand bit widths for 9X9 multiplication and accumulates the output up to 34 bits. The DSP block includes optional registers for the input and intermediate pipeline stage. Pipeline stages may be set using a pipeline attribute. The output registers are required for the accumulator. Signed and unsigned arithmetic are supported. The

OVERFLOW bit is also provided when the accumulated results are in the overflow condition. ACCUMSLOAD determines the mode of operation for either loading the multiplier product or to accumulate.

The primitive consists of three types of optional pipeline registers:

- Input registers, located before the multipliers and registering the operands
- Multiplier pipeline registers, located after the multipliers and product registration
- Output registers, located before leaving the block, and registering the mode-specific output.

See the description of MULT18X18 for more information on control signals for DSP blocks.

Refer to the following technical note on the Lattice web site.

- TN1057 - LatticeECP sysDSP Usage Guide

MULT9X9MAC pin functions:

Table 751:

Function	Pins
input data A and B	A[8:0], B[8:0]
signed input (0 = unsigned, 1 = signed)	SIGNEDAB
add/subtract (0 = add, 1 = subtract)	ADDNSUB
Accumulate (HIGH) /Load (LOW) Mode	ACCUMSLOAD
clock enable	CE[0:3]
clock input	CLK[0:3]
reset	RST[0:3]
shifted input A and B (from previous stage)	SRIA[8:0], SRIB[8:0]
shifted output A and B (from previous stage)	SROA[8:0], SROB[8:0]
output data	ACCUM[33:0]
overflow	OVERFLOW

MUX161

16-Input Mux within the PFU (4 Slices)

01110	D14	11110	D30
01111	D15	11111	D31

Note

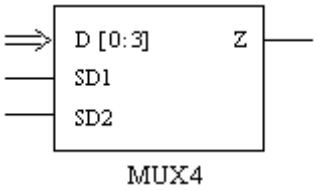
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

MUX4

4-bit Multiplexer

Architectures Supported:

- LatticeECP/EC
- LatticeXP



INPUTS: D0, D1, D2, D3, SD1, SD2

OUTPUT: Z

Description

For more usage, see related technical notes or contact technical support.

Note

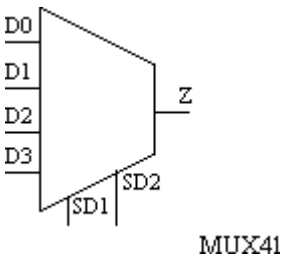
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

MUX41

4 to 1 Mux

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



MUX41

INPUTS: D0, D1, D2, D3, SD1, SD2

OUTPUT: Z

Description

For more usage, see related technical notes or contact technical support.

Truth Table

Table 755:

INPUTS						OUTPUTS
D0	D1	D2	D3	SD1	SD2	Z
0	X	X	X	0	0	0
1	X	X	X	0	0	1
X	0	X	X	1	0	0

X = Don’t care

Note

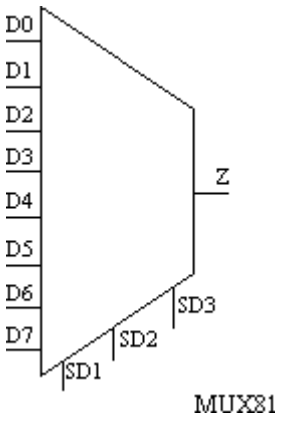
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

MUX81

8 to 1 Mux

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: D0, D1, D2, D3, D4, D5, D6, D7, SD1, SD2, SD3

OUTPUT: Z

Description

For more usage, see related technical notes or contact technical support.

X = Don’t care

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

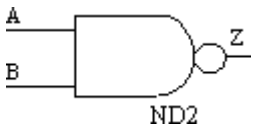
N

ND2

2 Input NAND Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B

OUTPUT: Z

Note

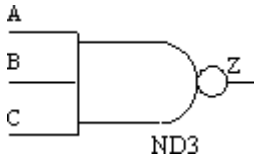
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

ND3

3 Input NAND Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C

OUTPUT: Z

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

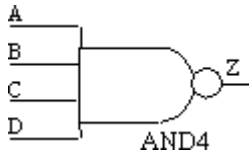
ND4

4 Input NAND Gate

Architectures Supported:

- ECP5
- LatticeECP/EC

- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C, D

OUTPUT: Z

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

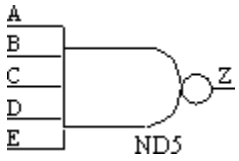
ND5

5 Input NAND Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD

- MachXO
- MachXO2
- MachXO3D
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C, D, E

OUTPUT: Z

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

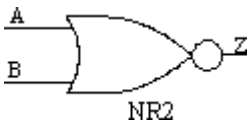
NR2

2 Input NOR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager

- Platform Manager 2



INPUTS: A, B

OUTPUT: Z

Note

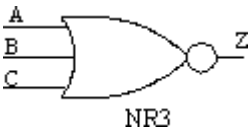
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

NR3

3 Input NOR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C

OUTPUT: Z

Note

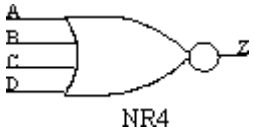
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

NR4

4 Input NOR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C, D

OUTPUT: Z

Note

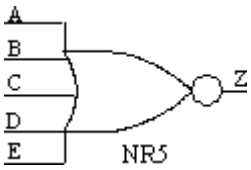
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

NR5

5 Input NOR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C, D, E

OUTPUT: Z

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

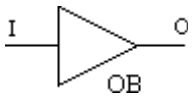
O

OB

Output Buffer

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUT: I

OUTPUT: O

Truth Table

Table 757:

INPUTS	OUTPUTS
I	O
1	1
0	0
Z	U

U = Unknown

Note

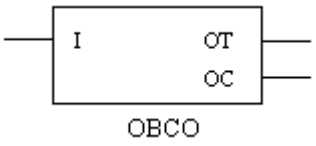
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OBCO

Output Complementary Buffer

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUT: I

OUTPUTS: OT, OC

Note

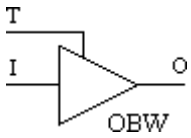
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OBW

Output Buffer with Tristate

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- Platform Manager



INPUTS: I, T

OUTPUT: O

Truth Table

Table 758:

INPUTS		OUTPUTS
I	T	O
0	1	weak 0
1	1	weak 1

Note

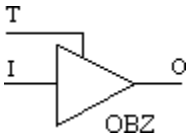
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OBZ

Output Buffer with Tristate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: I, T

OUTPUT: O

Truth Table

Table 759:

INPUTS		OUTPUTS
I	T	O
X	1	Z
0	0	0
1	0	1

X = Don’t care

When TSALL=0, O=Z

Note

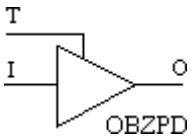
- For PU/PD buffers, when TSALL=0, O will be pulled up or pulled down, respectively. The letters PU (PD) in the buffer name indicate that a pull-up (pull-down) primitive is available. This is used to generate a logic high level (low level) for nodes that may be floating.
- This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OBZPD

Output Buffer with Tristate and Pull-down

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- Platform Manager



INPUTS: I, T

OUTPUT: O

Truth Table

Table 760:

INPUTS		OUTPUTS
I	T	O
X	1	Z
0	0	0
1	0	1

X = Don’t care

When TSALL=0, O=Z

Note

- For PU/PD buffers, when TSALL=0, O will be pulled up or pulled down, respectively. The letters PU (PD) in the buffer name indicate that a pull-up (pull-down) primitive is available. This is used to generate a logic high level (low level) for nodes that may be floating.
- This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

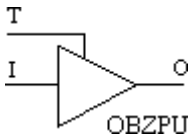
OBZPU

Output Buffer with Tristate and Pull-up

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP

- LatticeXP2
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: I, T

OUTPUT: O

Truth Table

Table 761:

INPUTS		OUTPUTS
I	T	O
X	1	Z
0	0	0
1	0	1

X = Don’t care

When TSALL=0, O=Z

Note

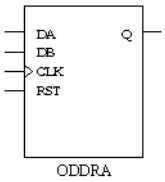
- For PU/PD buffers, when TSALL=0, O will be pulled up or pulled down, respectively. The letters PU (PD) in the buffer name indicate that a pull-up (pull-down) primitive is available. This is used to generate a logic high level (low level) for nodes that may be floating.
- This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

ODDRA

Output DDR

Architectures Supported:

- LatticeSC/M

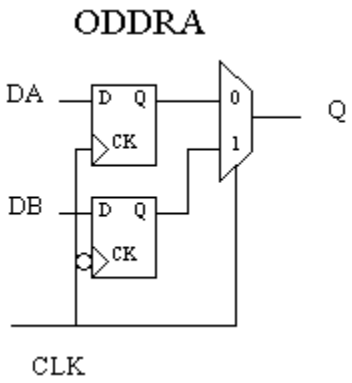


INPUTS: DA, DB, CLK, RST

OUTPUT: Q

Description

Output DDR data (positive edge and negative edge data) to the buffer. The following symbolic diagram shows the flip-flop structure of this primitive.

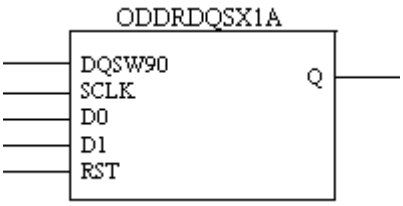


ODDRDQSX1A

Output for DDR1/2 Memory

Architectures Supported:

- MachXO2
- Platform Manager 2



INPUTS: DQSW90, SCLK, D0, D1, RST

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

ODDRDQSX1A is the output for DDR1/2 memory using the PIC hardware cell. It is used for right side only. See the below table for the port description.

Table 762:

Signal	I/O	Description
DQSW90	I	Shifts the DQS signal by 90 degree, from DQSBUFH
SCLK	I	Clock from the CIB
D0	I	Data A primary phase of data (first out)
D1	I	Data B secondary phase of data (second out)
RST	I	RESET to this block from the CIB
Q	O	DDR output data

For more information and usage, refer to the following technical note on the Lattice web site.

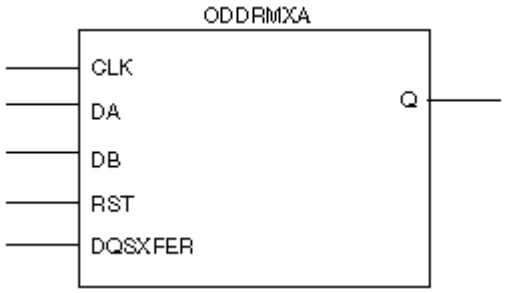
- TN1203 - Implementing High-Speed Interfaces with MachXO2 Devices

ODDRMXA

DDR Output Registers

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



INPUTS: CLK, DA, DB, RST, DQSXFER

OUTPUT: Q

Description

The ODDRMXA primitive implements the output register for both write and tristate functions. This primitive is used to output DDR data and DQS strobe to the memory. All DDR output tristate functions are also implemented using this primitive.

The following table provides description of all I/O ports associated with the ODDRMXA primitive.

Table 763:

Port Name	I/O	Definition
CLK	I	System CLK or ECLK
DA	I	Data at the negative edge of the clock
DB	I	Data at the positive edge of the clock
RST	I	Reset
DQSXFER	I	90-degree phase shifted clock coming from the DQSBUFC block
Q	O	DDR data to the memory

Notes:

- RST should be held low during DDR Write operation. By default the software will implement CE High and RST low.
- DDR output and tristate registers do not have CE support. RST is available for tristate DDRX mode (while reading). LSR will default to set when used in tristate mode.
- When asserting reset during DDR writes, it is important to know that it resets only the flip-flops but not the latches.

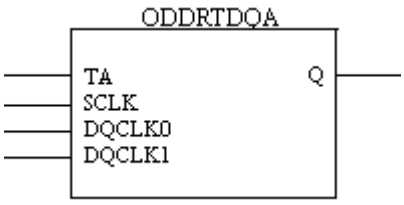
For more usage, see related technical notes or contact technical support.

ODDRTDQA

Tri-State for DQ: DDR3_MEM and DDR_GENX2

Architectures Supported:

- LatticeECP3



INPUTS: TA, SCLK, DQCLK1, DQCLK0

OUTPUT: Q

Description

ODDRTDQA is the tri-state for DQ used for DDR3_MEM (DDR3 memory mode) and DDR_GENX2.

- E and EA: DDR3_MEM and DDR_GENX2 (left/right)

See the below table for the port description.

Table 764:

Signal	I/O	Description
TA	I	Tri-state input.
SCLK	I	System clock.
DQCLK0	I	One clock edge, at the frequency of SCLK, used in output gearing, 90 degree out of phase from DQCLK1.
DQCLK1	I	One clock edge, at the frequency of SCLK, used in output gearing.
Q	O	Tri-state output.

For more information and usage, refer to the following technical note on the Lattice web site.

- TN1177 - LatticeECP3 sysIO Usage Guide

ODDRTDQSA

Tri-State for Single-Ended and Differential DQS: DDR_MEM, DDR2_MEM, and DDR3_MEM

Architectures Supported:

- LatticeECP3

INPUTS: TA, SCLK, DQSTCLK, DQSW, DB

OUTPUT: Q

Description

ODDRTDQSA is the tri-state for single-ended and differential DQS, used in DDR_MEM (DDR memory mode), DDR2_MEM (DDR2 memory mode), and DDR3_MEM (DDR3 memory mode).

- E and EA: DDR_MEM and DDR2_MEM (left/right/top)
- E and EA: DDR3_MEM (left/right)

See the below table for the port description.

Table 765:

Signal	I/O	Description
TA	I	Tri-state input
SCLK	I	System clock
DQSW	I	DQS write clock
DQSTCLK	I	DQS tri-state clock
DB	I	Data input (ONEGB)
Q	O	DQS tri-state output

For more information and usage, refer to the following technical note on the Lattice web site.

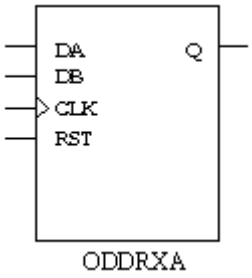
- TN1177 - LatticeECP3 sysIO Usage Guide

ODDRXA

Output DDR

Architectures Supported:

- LatticeSC/M

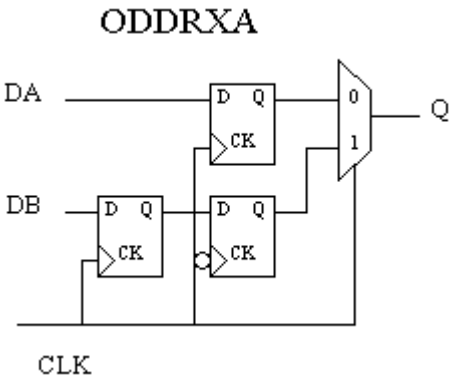


INPUTS: DA, DB, CLK, RST

OUTPUT: Q

Description

Output DDR data with half cycle clock domain transfer. The following symbolic diagram shows the flip-flop structure of this primitive.

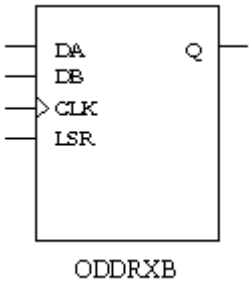


ODDRXB

Output DDR

Architectures Supported:

- LatticeECP/EC
- LatticeXP



INPUTS: DA, DB, CLK, LSR

OUTPUT: Q

ATTRIBUTES:

REGSET: "RESET" (default), "SET"

Description

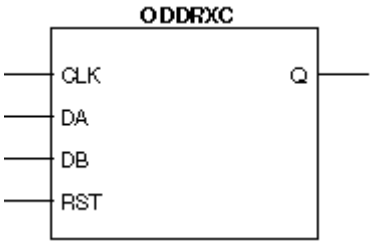
Output DDR data with half cycle clock domain transfer.

ODDRXC

DDR Generic Output

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



INPUTS: DA, DB, CLK, RST

OUTPUT: Q

Description

This DDR output module inputs two data streams and multiplexes them together to generate a single stream of data going to the sysIO™ buffer. CLK to this module can be connected to the edge clock or to the FPGA clock. This primitive is also used when DDR function is required for the tristate signal. See the following table for port description.

Table 766:

Port Name	I/O	Definition
DA	I	Data at the negative edge of the clock
DB	I	Data at the positive edge of the clock
CLK	I	Clock from CIB
RST	I	Reset signal
Q	O	DDR data to the memory

Notes:

- LSR should be held low during DDR Write operation. By default, the software will be implemented with CE High and LSR low.
- DDR output and tristate registers do not have CE support. LSR is available for the tristate DDRX mode (while reading). The LSR will default to set when used in the tristate mode.
- CE and LSR support is available for the regular (non-DDR) output mode.
- When asserting reset during DDR writes, it is important to keep in mind that this would only reset the flip-flops but not the latches.

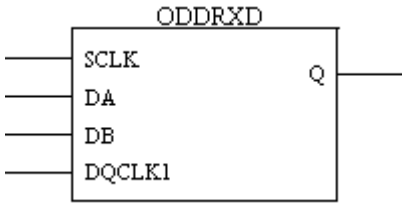
For more usage, see related technical notes or contact technical support.

ODDRXD

Output DDR for DDR_MEM, DDR2_MEM, DDR_GENX1, and DDR2_MEMGEN

Architectures Supported:

- LatticeECP3



INPUTS: SCLK, DA, DB, DQCLK1

OUTPUT: Q

ATTRIBUTES:

(*EA only*) MEMMODE: "DISABLED" (default), "ENABLED"

Description

ODDRXD is the output DDR for DDR_MEM (DDR memory mode), DDR2_MEM (DDR2 memory mode), DDR_GENX1 (DDR generic mode in X1 gearing), and DDR2_MEMGEN.

- E and EA: DDR_MEM, DDR2_MEM, and DDR2_MEMGEN (left/right/top)
- E: DDR_GENX1 (left/right/top)

The port information is described in the below table.

Table 767:

Signal	I/O	Description
SCLK	I	System clock.
DA	I	Data at the positive edge of the clock (OPOSA).
DB	I	Data at the negative edge of the clock (ONEGB).
DQCLK1	I	One clock edge, at the frequency of SCLK, used in output gearing.
Q	O	DDR data output.

For more information and usage, refer to the following technical note on the Lattice web site.

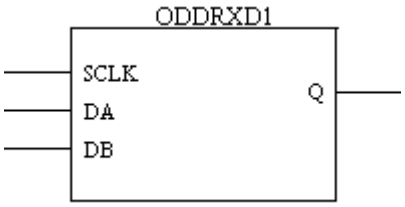
- TN1177 - LatticeECP3 sysIO Usage Guide

ODDRXD1

Output DDR for DDR_GENX1

Architectures Supported:

- LatticeECP3



INPUTS: SCLK, DA, DB

OUTPUT: Q

Description

ODDRXD1 is the output DDR for DDR_GENX1 (DDR generic mode in X1 gearing).

- EA: DDR_GENX1 (left/right/top)

The port information is described in the below table.

Table 768:

Signal	I/O	Description
SCLK	I	System clock
DA	I	Data at the positive edge of the clock (OPOSA)
DB	I	Data at the negative edge of the clock (ONEGB)
Q	O	DDR data output

For more information and usage, refer to the following technical note on the Lattice web site.

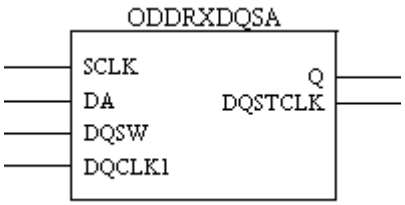
- TN1177 - LatticeECP3 sysIO Usage Guide

ODDRXDQSA

Output for Single-Ended and Differential DQS: DDR_MEM, DDR2_MEM, and DDR2_MEMGEN

Architectures Supported:

- LatticeECP3



INPUTS: SCLK, DA, DQSW, DQCLK1

OUTPUTS: Q, DQSTCLK

ATTRIBUTES:

(*EA only*) MEMMODE: "DISABLED" (default), "ENABLED"

Description

ODDRXDQSA is the output for single-ended and differential DQS, used for DDR_MEM (DDR memory mode), DDR2_MEM (DDR2 memory mode), and DDR2_MEMGEN.

- E and EA: DDR_MEM, DDR2_MEM, and DDR2_MEMGEN (left/right/top)

See the below table for the port description.

Table 769:

Signal	I/O	Description
SCLK	I	System clock.
DA	I	Data input (OPOSA).
DQSW	I	DQS write clock.
DQCLK1	I	One clock edge, at the frequency of SCLK, used in output gearing.
Q	O	DQS data output.
DQSTCLK	O	DQS Tri-state clock.

For more information and usage, refer to the following technical note on the Lattice web site.

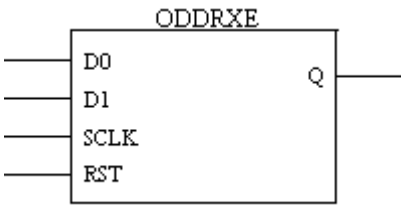
- TN1177 - LatticeECP3 sysIO Usage Guide

ODDRXE

Output for Generic DDR X1 Using 2:1 Gearing

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D0, D1, SCLK, RST

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

ODDRXE is the output for generic DDR X1 using 2:1 gearing. It uses the mPIC or PIC hardware cell. It is used for all sides.

The port information is described in the below table.

Table 770:

Signal	I/O	Description
D0	I	Data A primary phase of data (first out)
D1	I	Data B secondary phase of data (second out)
SCLK	I	Clock from the CIB
RST	I	RESET to this block from the CIB
Q	O	DDR output data

For more information and usage, refer to the following technical note on the Lattice web site.

- TN1203 - Implementing High-Speed Interfaces with MachXO2 Devices

ODDRX1F

Generic X1 ODDR implementation

Architectures Supported:

- ECP5
- LIFMD

INPUTS: D0, D1, SCLK, RST

OUTPUTS: Q

Description

This primitive is used for Generic X1 ODDR implementation.

The following table gives the port description.

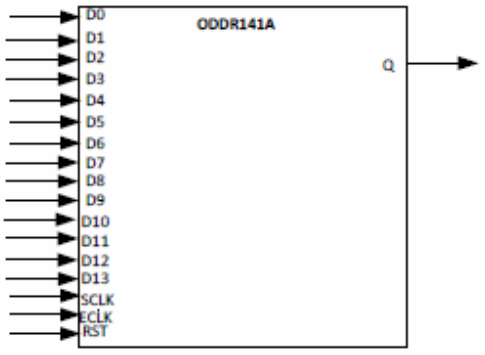
Table 771:

Signal	I/O	Description
D0	I	Data input ODDR (first to be sent out)
D1	I	Data input ODDR (second to be sent out)
SCLK	I	SCLK input
RST	I	Reset input
Q	O	DDR data output on both edges of SCLK

ODDR141A

Architectures Supported:

- LIFMD



INPUT: D0, D1, D2, D3, D4, D5, D6, D7, D8, D9, D10, D11, D12, D13, ECLK , SCLK, RST

OUTPUT: Q

Description

This primitive is used for Generic X1 ODDR implementation.

The following table gives the port description.

Table 772:

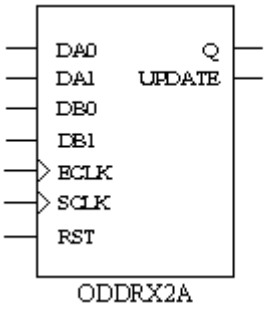
Signal	I/O	Description
D0...D13	I	Data input to the ODDR
ECLK	I	ECLK input (7x speed of SCLK)
SCLK	I	SCLK input
RST	I	Reset Input
Q	O	DDR data output on both edges of ECLK

ODDRX2A

Output DDR

Architectures Supported:

- LatticeSC/M

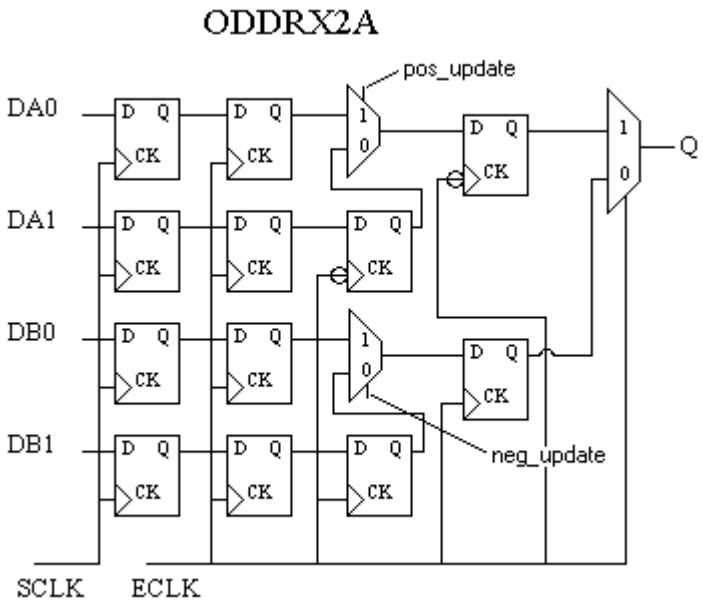


INPUTS: DA0, DA1, DB0, DB1, ECLK, SCLK, RST

OUTPUTS: Q, UPDATE

Description

Outputs DDR data to the buffer through the shift register and clock domain transfer from primary clock to edge clock. The following symbolic diagram shows the flip-flop structure of this primitive.



The pos_update and neg_update pins are select pins of the MUXes' internal

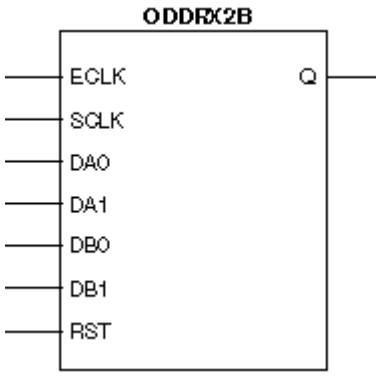
signals which go out as UPDATE signals depending upon the value of the UPDT parameter.

ODDRX2B

DDR Generic Output with 2x Gearing Ratio

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



INPUTS: DA0, DB0, DA1, DB1, ECLK, SCLK, RST

OUTPUT: Q

Description

This DDR output module can be used when a gearbox function is required. This primitive inputs four data streams and multiplexed them together to generate a single stream of data going to the sysIO buffer.

DDR registers of the complementary PIO is used when using this mode. The complementary PIO register can no longer be used to perform the DDR function. There are two clocks going to this primitive. ECLK is connected to the faster edge clock, while SCLK is connected to the slower FPGA clock. The DDR data output of this primitive is aligned to the faster edge clock.

Note that LSR should be held low during DDR Write operation. By default, the software will be implemented CE High and LSR low.

The following table lists port names and descriptions for the ODDRX2B primitive.

Table 773:

Port Name	I/O	Definition
DA0, DB0	I	Data at the negative edge of the clock
DA1, DB1	I	Data at the positive edge of the clock
ECLK	I	Clock connected to the faster edge clock

Table 773:

Port Name	I/O	Definition
SCLK	I	Clock connected to the slower edge clock
RST	I	Reset
Q	O	DDR data output

For more usage, see related technical notes or contact technical support.

ODDRX2D

Output DDR for DDR3_MEM and DDR_GENX2

Architectures Supported:

- LatticeECP3

INPUTS: SCLK, DA1, DB1, DA0, DB0, DQCLK1, DQCLK0

OUTPUT: Q

ATTRIBUTES:

ISI_CAL: "BYPASS" (default), "DEL1", "DEL2", "DEL3", "DEL4", "DEL5", "DEL6", "DEL7"

(*EA only*) MEMMODE: "DISABLED" (default), "ENABLED"

Description

ODDRX2D is the output DDR for DDR3_MEM (DDR3 memory mode) and DDR_GENX2 (DDR generic mode in X2 gearing).

- E and EA: DDR3_MEM and DDR_GENX2 (left/right)

The below table describes the port information.

Table 774:

Signal	I/O	Description
SCLK	I	System clock.
DA0	I	First data at the positive edge of the clock (OPOSA).
DA1	I	First data at the negative edge of the clock (OPOSB).
DB0	I	Second data at the positive edge of the clock (ONEGA).
DB1	I	Second data at the negative edge of the clock (ONEGB).
DQCLK0	I	One clock edge, at half the frequency of ECLK, used in output gearing, 90 degree out of phase from DQCLK1.
DQCLK1	I	One clock edge, at half the frequency of ECLK, used in output gearing.
Q	O	DDR data output.

For more information and usage, refer to the following technical note on the Lattice web site.

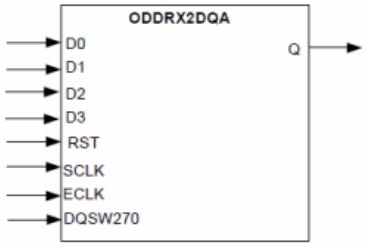
- TN1177 - LatticeECP3 sysIO Usage Guide

ODDRX2DQA

Memory Output DDR Primitive for DQ outputs

Architectures Supported:

- ECP5



INPUTS: D0, D1, D2, D3, RST, SCLK, ECLK, DQSW270

OUTPUTS: Q

Description

The following table gives the port description.

Table 775:

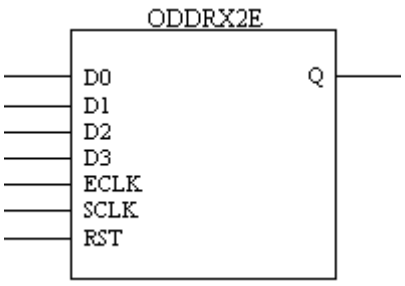
Signal	I/O	Description
D0, D1, D2, D3	I	Data input to the ODDR
RST	I	Reset input
ECLK	I	Fast Edge clock output
DQSW270	I	Clock that is 270 degrees ahead of the clock used to generate the DQS output.
SCLK	I	SCLK input
Q	O	DDR data output on both edges of DQSW270

ODDRX2E

Output for Generic DDR X2 Using 4:1 Gearing

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D0, D1, D2, D3, ECLK, SCLK, RST

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

ODDRX2E is the output for generic DDR X2 using 4:1 gearing. It uses the VPIC_TX hardware cell. It is used for top bank only. See the below table for port information.

Table 776:

Signal	I/O	Description
D0, D2	I	Data at the same edge of the clock
D1, D3	I	Data at the same edge of the clock
ECLK	I	Edge clock
SCLK	I	Clock from the CIB
RST	I	RESET to this block from the CIB
Q	O	DDR output data

For more information and usage, refer to the following technical note on the Lattice web site.

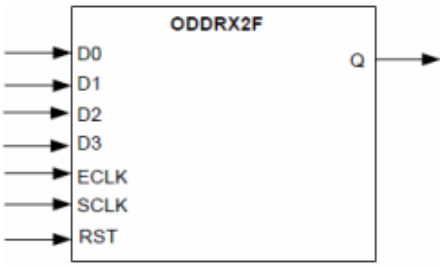
- TN1203 - Implementing High-Speed Interfaces with MachXO2 Devices

ODDRX2F

Generic X2 ODDR implementation

Architectures Supported:

- ECP5
- LIFMD



INPUTS: D0, D1, D2, D3, ECLK, SCLK, RST

OUTPUTS: Q

Description

This primitive is used for Generic X2 ODDR implementation.

The following table gives the port description.

Table 777:

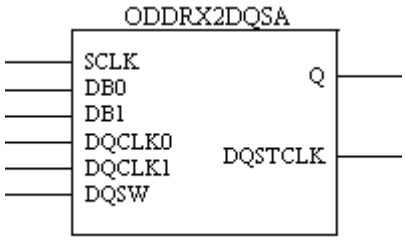
Signal	I/O	Description
D0, D2	I	Data input to the ODDR (sent out on the same edge)
D1, D3	I	Data input to the ODDR (sent out on the same edge)
ECLK	I	ECLK input (2x speed of SCLK)
SCLK	I	SCLK input
RST	I	Reset input
Q	O	DDR data output on both edges of ECLK

ODDRX2DQSA

Output for Differential DQS: DDR3_MEM

Architectures Supported:

- LatticeECP3



INPUTS: SCLK, DB1, DB0, DQCLK1, DQCLK0, DQSW

OUTPUTS: Q, DQSTCLK

ATTRIBUTES:

ISI_CAL: "BYPASS" (default), "DEL1", "DEL2", "DEL3", "DEL4", "DEL5", "DEL6", "DEL7"

(*EA only*) MEMMODE: "DISABLED" (default), "ENABLED"

Description

ODDRX2DQSA is the output for differential DQS used for DDR3_MEM (DDR3 memory mode).

- E and EA: DDR3_MEM (left/right)

See the below table for the port description.

Table 778:

Signal	I/O	Description
SCLK	I	System clock.
DB0	I	Data input (OPOSA).
DB1	I	Data input (OPOSB).
DQSW	I	DQS write clock.
DQCLK0	I	One clock edge, at half the frequency of ECLK, used in output gearing, 90 degree out of phase from DQCLK1.
DQCLK1	I	One clock edge, at half the frequency of SCLK, used in output gearing.
Q	O	DDR data output.
DQSTCLK	O	DQS Tri-state clock.

For more information and usage, refer to the following technical note on the Lattice web site.

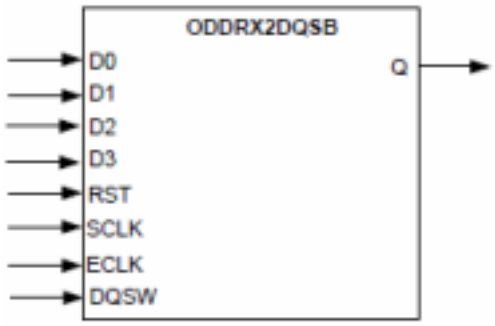
- TN1177 - LatticeECP3 sysIO Usage Guide

ODDRX2DQSB

Memory Output DDR Primitive for DQS Output

Architectures Supported:

- ECP5



INPUTS: D0, D1, D2, D3, RST, SCLK, ECLK, DQSW

OUTPUTS: Q

Description

The following table gives the port description.

Table 779:

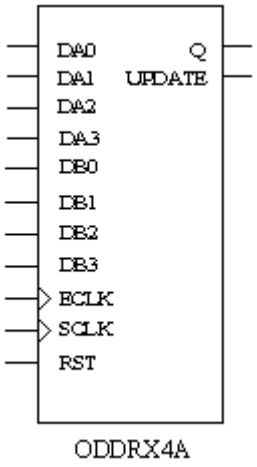
Signal	I/O	Description
D0, D1, D2, D3	I	Data input to the ODDR
RST	I	Reset input
ECLK	I	ECLK input
DQSW	I	DQSW includes write leveling phase shift from ECLK
SCLK	I	SCLK input
Q	O	DDR data output on both edges of DQSW

ODDRX4A

Output DDR

Architectures Supported:

- LatticeSC/M



INPUTS: DA0, DA1, DA2, DA3, DB0, DB1, DB2, DB3, ECLK, SCLK, RST

OUTPUTS: Q, UPDATE

ATTRIBUTES:

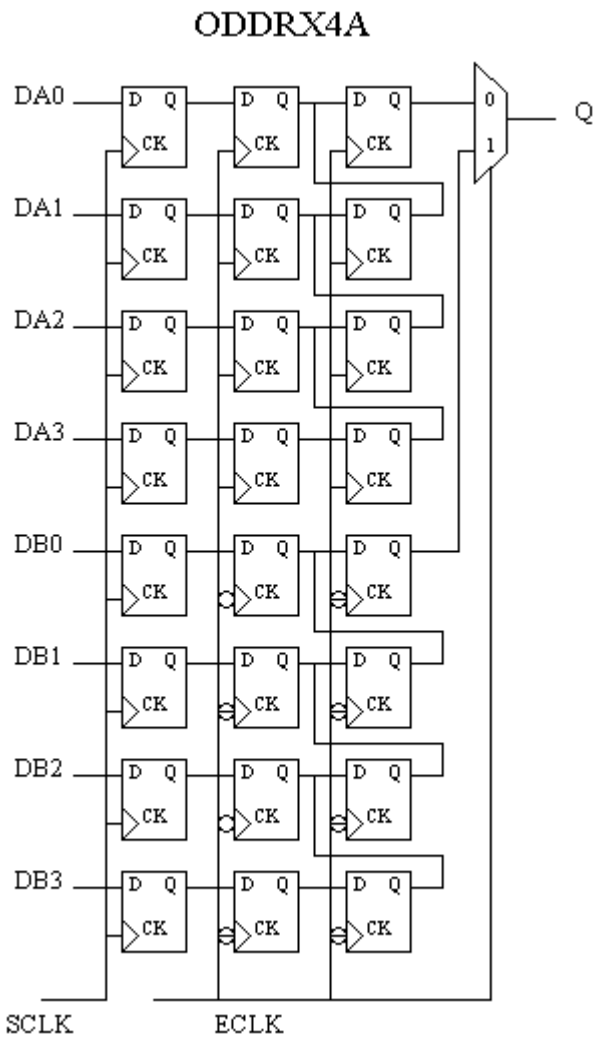
LSRMODE: "LOCAL" (default), "EDGE"

UPDT: "POS" (default), "NEG"

REGSET: "RESET" (default), "SET"

Description

Outputs DDR data to the buffer through the shift register and clock domain transfer from primary clock to edge clock. The following symbolic diagram shows the flip-flop structure of this primitive.



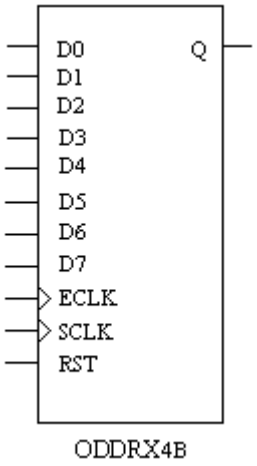
ODDRX4B

Output for Generic DDR X4 Using 8:1 Gearing

Architectures Supported:

- MachXO2

- MachXO3D
- Platform Manager 2



INPUTS: D0, D1, D2, D3, D4, D5, D6, D7, ECLK, SCLK, RST

OUTPUTS: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

ODDRX4B is the output for generic DDR X4 using 8:1 gearing. It uses the VPIC_TX hardware cell. It is used for top bank only. See the below table for the port description.

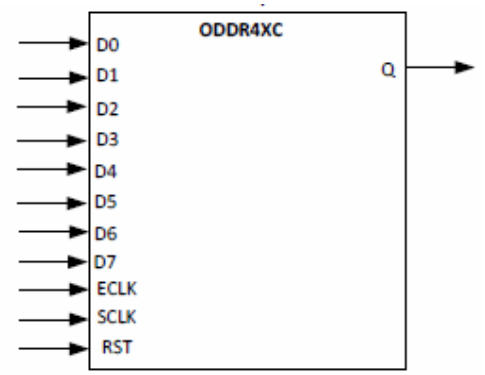
Table 780:

Signal	I/O	Description
D0, D2, D4, D6	I	Data at the same edge of the clock
D1, D3, D5, D7	I	Data at the same edge of the clock
ECLK	I	Edge clock
SCLK	I	Clock from the CIB
RST	I	RESET to this block from the CIB
Q	O	DDR output data

ODDRX4C

Architectures Supported:

- LIFMD



INPUT: D0, D1, D2, D3, D4, D5, D6, D7, ECLK , SCLK, RST

OUTPUT: Q

Description

This primitive is used for 8:1 LVDS ODDR implementation.

See the below table for the port description.

Table 781:

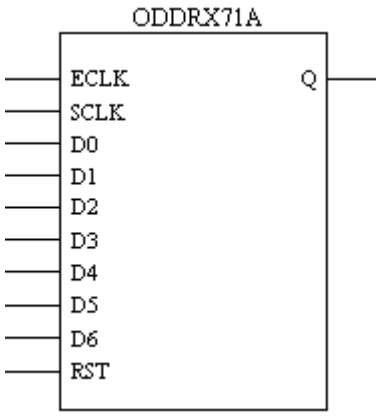
Signal	I/O	Description
D0...D7	I	Data input to the ODDR
ECLK	I	ECLK input (4x speed of SCLK)
SCLK	I	SCLK input
RST	I	Reset Input
Q	O	DDR data output on both edges of ECLK

ODDRX71A

7:1 LVDS Output

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: ECLK, SCLK, D0, D1, D2, D3, D4, D5, D6, RST

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Description

ODDRX71A is the 7:1 LVDS output that supports 7:1 gearing. It is used for top bank only. See the below table for the port description.

Table 782:

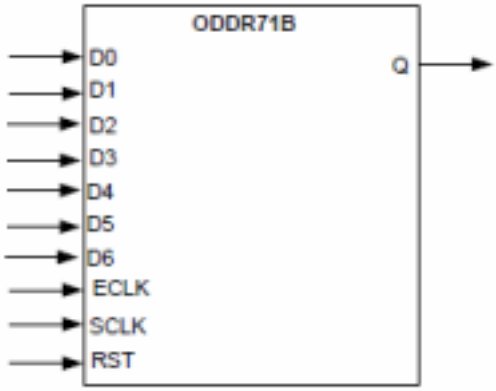
Signal	I/O	Description
ECLK	I	Edge clock
SCLK	I	Clock connected to the system clock
D0, D1, D2, D3, D4, D5, D6	I	Data available for 7:1 muxing
RST	I	RESET for this block
Q	O	7:1 LVDS signal output

ODDR71B

7:1 LVDS ODDR implementation

Architectures Supported:

- ECP5
- LIFMD



INPUTS: D0, D1, D2, D3, D4, D5, D6, ECLK, SCLK, RST

OUTPUT: Q

Description

This primitive is used for 7:1 LVDS ODDR implementation.

Table 783:

Signal	I/O	Description
ECLK	I	ECLK input (3.5x speed of SCLK)
SCLK	I	SCLK input
D0, D1, D2, D3, D4, D5, D6	I	Data input to the ODDR
RST	I	Reset input
Q	O	DDR data output on both edges of ECLK

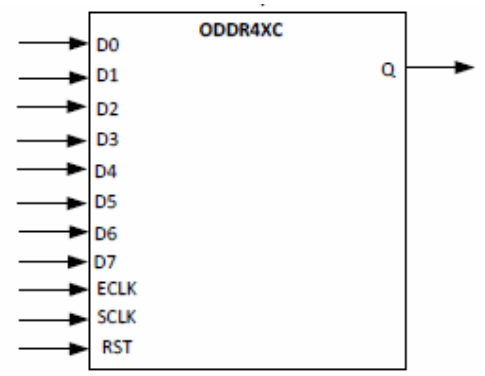
ODDRX8A

Architectures Supported:

- LIFMD

INPUT: D0, D1, D2, D3, D4, D5, D6, D7, D8, D9, D10, D11, D12, D13, D14, D15 ECLK , SCLK, RST

OUTPUT: Q



Description

This primitive is used for 16:1 LVDS ODDR implementation

See the below table for the port description.

Table 784:

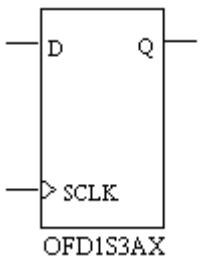
Signal	I/O	Description
D0...D15	I	Data input to the ODDR
ECLK	I	ECLK input (8x speed of SCLK)
SCLK	I	SCLK input
RST	I	Reset Input
Q	O	DDR data output on both edges of ECLK

OFD1S3AX

Positive Edge Triggered D Flip-Flop, GSR Used for Clear. Used to Tri-State DDR/DDR2

Architectures Supported:

- LatticeECP3



INPUTS: D, SCLK

OUTPUT: Q

ATTRIBUTES:

GSR: "DISABLED" (default), "ENABLED"

Description

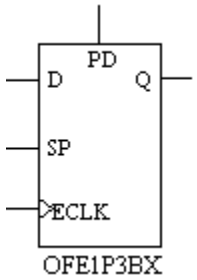
OFD1S3AX is a primitive used to implement DDR and DDR2 DQ tri-state. This primitive is functionally equivalent to the FD1S3AX primitive.

OFE1P3BX

Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and Edge Clock (used in output PIC area only)

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeSC/M
- LatticeXP
- LatticeXP2



INPUTS: D, SP, ECLK, PD

OUTPUT: Q

Note

This primitive must be paired with an output or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 785:

INPUTS				OUTPUTS
D	SP	ECLK	PD	Q
X	0	X	0	Q
X	X	X	1	1
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

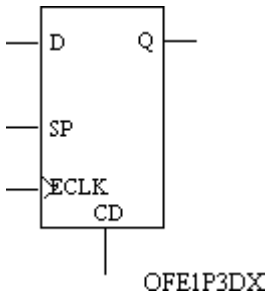
When GSR=0, Q=1 (D=SP=ECLK=PD=X)

OFE1P3DX

Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and Edge Clock (used in output PIC area only)

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeSC/M
- LatticeXP
- LatticeXP2



INPUTS: D, SP, ECLK, CD

OUTPUT: Q

Note

This primitive must be paired with an output or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 786:

INPUTS				OUTPUTS
D	SP	ECLK	CD	Q
X	0	X	0	Q
X	X	X	1	0
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

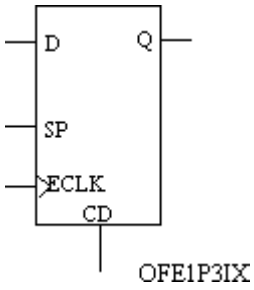
When GSR=0, Q=0 (D=SP=ECLK=CD=X)

OFE1P3IX

Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable (Clear overrides Enable), and Edge Clock (used in output PIC area only)

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeSC/M
- LatticeXP
- LatticeXP2



INPUTS: D, SP, ECLK, CD

OUTPUT: Q

Note:

This primitive must be paired with an output or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 787:

INPUTS				OUTPUTS
D	SP	ECLK	CD	Q
X	0	X	0	Q
X	X	↑	1	0
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

When GSR=0, Q=0 (D=SP=ECLK=CD=X)

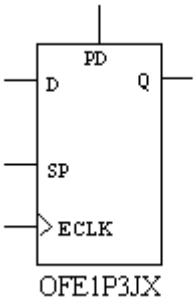
OFE1P3JX

Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable (Preset overrides Enable), and Edge Clock (used in output PIC area only)

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M

- LatticeSC/M
- LatticeXP
- LatticeXP2



INPUTS: D, SP, ECLK, PD

OUTPUT: Q

Note

This primitive must be paired with an output or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 788:

INPUTS				OUTPUTS
D	SP	ECLK	PD	Q
X	0	X	0	Q
X	X	↑	1	1
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

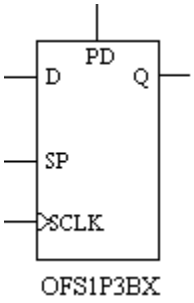
When GSR=0, Q=1 (D=SP=ECLK=PD=X)

OFS1P3BX

Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Preset, and System Clock (used in output PIC area only)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D, SP, SCLK, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Note

This primitive must be paired with an output or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 789:

INPUTS				OUTPUTS
D	SP	SCLK	PD	Q
X	0	X	0	Q
X	X	X	1	1
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

When GSR=0, Q=1 (D=SP=SCLK=PD=X)

Note

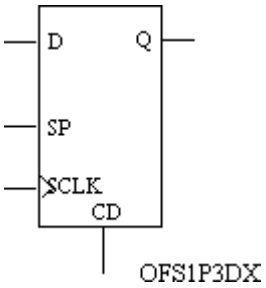
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OFS1P3DX

Positive Edge Triggered D Flip-Flop with Positive Level Enable, Positive Level Asynchronous Clear, and System Clock (used in output PIC area only)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D, SP, SCLK, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Note

This primitive must be paired with an output or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 790:

INPUTS				OUTPUTS
D	SP	SCLK	CD	Q
X	0	X	0	Q
X	X	X	1	0
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

When GSR=0, Q=0 (D=SP=SCLK=CD=X)

Note

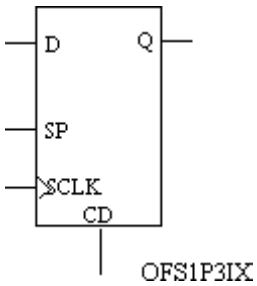
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OFS1P3IX

Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Clear, Positive Level Enable (Clear overrides Enable), and System Clock (used in output PIC area only)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D, SP, SCLK, CD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Note

This primitive must be paired with an output or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 791:

INPUTS				OUTPUTS
D	SP	SCLK	CD	Q
X	0	X	0	Q
X	X	↑	1	0
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

When GSR=0, Q=0 (D=SP=SCLK=CD=X)

Note

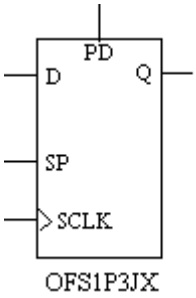
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OFS1P3JX

Positive Edge Triggered D Flip-Flop with Positive Level Synchronous Preset, Positive Level Enable (Preset overrides Enable), and System Clock (used in output PIC area only)

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D, SP, SCLK, PD

OUTPUT: Q

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

Note

This primitive must be paired with an output or bidirectional buffer. The mapper automatically assigns the primitive and its buffer to the same PIC. Use the PIN or LOC properties, or the LOCATE COMP preference, on the buffer per normal use, but not on this primitive.

Truth Table

Table 792:

INPUTS				OUTPUTS
D	SP	SCLK	PD	Q
X	0	X	0	Q
X	X	↑	1	1
0	1	↑	0	0
1	1	↑	0	1

X = Don’t care

When GSR=0, Q=1 (D=SP=SCLK=PD=X)

Note

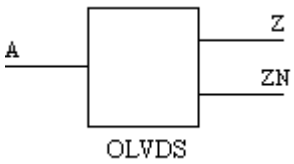
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OLVDS

LVDS Output Buffer

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUT: A

OUTPUTS: Z, ZN

Truth Table

Table 793:

INPUTS	OUPUTS	
A	Z	ZN
0	0	1
1	1	0

Note

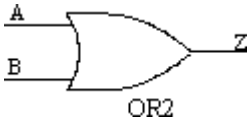
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OR2

2 Input OR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B

OUTPUT: Z

Note

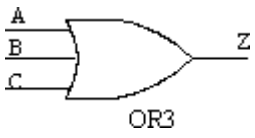
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OR3

3 Input OR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C

OUTPUT: Z

Note

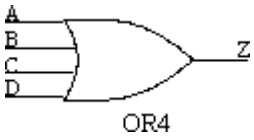
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OR4

4 Input OR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C, D

OUTPUT: Z

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

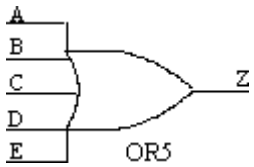
OR5

5 Input OR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC

- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C, D, E

OUTPUT: Z

Note

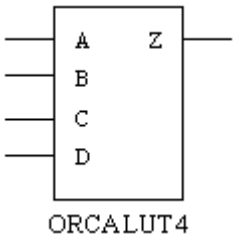
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

ORCALUT4

4-Input Look Up Table

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeXP
- LatticeXP2
- MachXO
- Platform Manager



INPUTS: A, B, C, D

OUTPUT: Z

ATTRIBUTES:

INIT: hexadecimal value (default: 16'h0000)

Description

ORCALUT4 defines the programmed state of a LUT4 primitive of a Slice. While this primitive is typically targeted by logic synthesis tools, it can also be instantiated in HDL source for intimate control over LUT4 programming. The contents of the look up table are addressed by the 4 input pins to access 1 of 16 locations.

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

The programming of the ORCALUT4 (that is, the 0 or 1 value of each memory location within the LUT4) is determined by the value assigned with INIT. The value is expressed in hexadecimal code. Highest memory locations are in the most significant hex digit, the lowest in the least significant digit.

For example, hex value BF80 produces these 16 memory locations and values:

1011 1111 1000 0000

Memory location 0 (D=0, C=0, B=0, A=0) contains a 0, memory location 2 (D=0, C=0, B=1, A=0) contains a 0. Memory location 15 (D=1, C=1, B=1, A=1) contains a 1, etc.

The ORCALUT4 may encode the Boolean logic for any Boolean expression of 4 input variables. For example, if the required expression was:

Z = (D*C) + (B*!A)

then the INIT value can be derived from the truth table resulting from the expression:

```
D C B A : Z
```

```
0 0 0 0 : 0
0 0 0 1 : 0
0 0 1 0 : 1
0 0 1 1 : 0

0 1 0 0 : 0
0 1 0 1 : 0
0 1 1 0 : 1
0 1 1 1 : 0

1 0 0 0 : 0
1 0 0 1 : 0
1 0 1 0 : 1
1 0 1 1 : 0

1 1 0 0 : 1
1 1 0 1 : 1
1 1 1 0 : 1
1 1 1 1 : 1
```

INIT = F444 (16)

Adding INIT to HDL

INIT can be used as an HDL attribute. The following examples demonstrate how to use INIT with the ORCALUT4 primitive in your Verilog or VHDL source. INIT takes binary value in HDL.

Verilog Example

```
// synopsys translate_off
// parameter definition
defparam I1.init = 16'hF444 ;
// synopsys translate_on

// ORCALUT4 module instantiation
ORCALUT4 I1 (.A(A), .B (B), .C(C), .D(D), .Z(Q[0]))
/* synthesis init = "16'hF444" */;
```

VHDL Example

```
-- component definition
component ORCALUT4
   port (
         A,B,C,D: In std_logic;
               Z: Out std_logic
         );
end component;

-- attribute definition
  attribute INIT: string;
  attribute INIT of I1: label is "1000000000000000";--Z=A*B*C*D
...
-- ORCALUT4 component instantiation
I1 : ORCALUT4
```

```
Port Map ( A=>A, B=>B, C=>C, D=>D, Z=>N_1 );
```

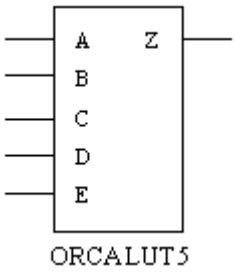
For generic examples of how to use HDL attributes, see “Adding FPGA Attributes to HDL” in online Help.

ORCALUT5

5-Input Look Up Table

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeXP
- LatticeXP2
- MachXO
- Platform Manager



INPUTS: A, B, C, D, E

OUTPUT: Z

ATTRIBUTES:

INIT: hexadecimal value (default: 32'h0000_0000)

Description

ORCALUT5 defines the programmed state of a LUT5 primitive of a Slice. While this primitive is typically targeted by logic synthesis tools, it can also be instantiated in HDL source for intimate control over LUT5 programming. The contents of the look up table are addressed by the 5 input pins to access 1 of 32 locations.

The programming of the ORCALUT5 (that is, the 0 or 1 value of each memory location within the LUT5) is determined by the value assigned with INIT. The

value is expressed in hexadecimal code. Highest memory locations are in the most significant hex digit, the lowest in the least significant digit.

For more information on INIT attribute usage, see the ORCALUT4 topic.

Note

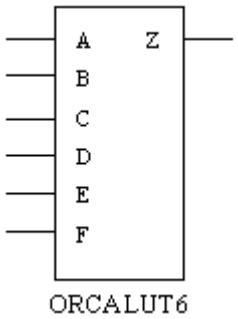
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

ORCALUT6

6-Input Look Up Table

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeXP
- LatticeXP2
- MachXO
- Platform Manager



INPUTS: A, B, C, D, E, F

OUTPUT: Z

ATTRIBUTES:

INIT: hexadecimal value (default: 64'h0000_0000_0000_0000)

Description

ORCALUT6 defines the programmed state of a LUT6 primitive of a Slice. While this primitive is typically targeted by logic synthesis tools, it can also be instantiated in HDL source for intimate control over LUT6 programming. The contents of the look up table are addressed by the 6 input pins to access 1 of 64 locations.

The programming of the ORCALUT6 (that is, the 0 or 1 value of each memory location within the LUT6) is determined by the value assigned with INIT. The value is expressed in hexadecimal code. Highest memory locations are in the most significant hex digit, the lowest in the least significant digit.

For more information on INIT attribute usage, see the ORCALUT4 topic.

Note

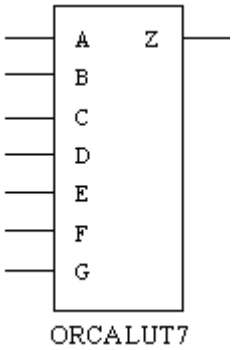
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

ORCALUT7

7-Input Look Up Table

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeXP
- LatticeXP2
- MachXO
- Platform Manager



INPUTS: A, B, C, D, E, F, G

OUTPUT: Z

ATTRIBUTES:

INIT: hexadecimal value (default: 128'h0000_0000_0000_0000_0000_0000_0000_0000)

Description

ORCALUT7 defines the programmed state of a LUT7 primitive of a Slice. While this primitive is typically targeted by logic synthesis tools, it can also be instantiated in HDL source for intimate control over LUT7 programming. The contents of the look up table are addressed by the 7 input pins to access 1 of 128 locations.

The programming of the ORCALUT7 (that is, the 0 or 1 value of each memory location within the LUT7) is determined by the value assigned with INIT. The value is expressed in hexadecimal code. Highest memory locations are in the most significant hex digit, the lowest in the least significant digit.

For more information on INIT attribute usage, see the ORCALUT4 topic.

Note

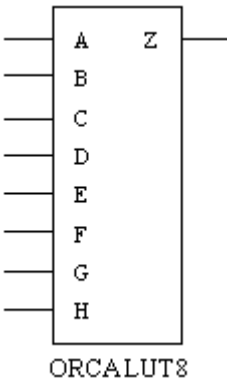
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

ORCALUT8

8-Input Look Up Table

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeXP
- LatticeXP2
- MachXO
- Platform Manager



INPUTS: A, B, C, D, E, F, G, H

OUTPUT: Z

ATTRIBUTES:

INIT: hexadecimal value (default: 256'h0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000_0000)

Description

ORCALUT8 defines the programmed state of a LUT8 primitive of a Slice. While this primitive is typically targeted by logic synthesis tools, it can also be instantiated in HDL source for intimate control over LUT8 programming. The contents of the look up table are addressed by the 8 input pins to access 1 of 256 locations.

The programming of the ORCALUT8 (that is, the 0 or 1 value of each memory location within the LUT8) is determined by the value assigned with INIT. The value is expressed in hexadecimal code. Highest memory locations are in the most significant hex digit, the lowest in the least significant digit.

For more information on INIT attribute usage, see the ORCALUT4 topic.

Note

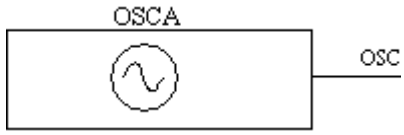
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OSCA

Internal Oscillator

Architectures Supported:

- LatticeSC/M



OUTPUT: OSC

ATTRIBUTES:

DIV: 1 (default), 2, 4, 8, 16, 32, 64, 128

Description

The OSCA is the source of the internal clock for configuration. After configuration this oscillator is disabled by default. If needed, it can be enabled by instantiating the OSCA or the Sysbus (with sys_clk_sel=OSC option). OSCA may be used as a general-purpose clock to drive FPGA logic.

The internal clock frequency can be one of eight values: 1, 1/2, 1/4, 1/8, 1/16, 1/32, 1/64, or 1/128 of the oscillator frequency (about 128 MHz). During start-up, the clock divider is set to 1/128 (about 1 MHz). During initialization, it is set to 1/8 (about 16 MHz). After initialization, if OSCA is enabled, it is set to the user-specified value.

Note

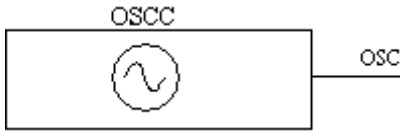
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OSCC

Internal Oscillator

Architectures Supported:

- MachXO
- Platform Manager



OUTPUT: OSC

Description

OSCC is a dedicated oscillator in the MachXO and Platform Manager device and the source of the internal clock for configuration. The oscillator frequency range is 18 to 26 MHz. The output of the oscillator can also be routed as an input clock to the clock tree. The oscillator frequency output can be further divided by internal logic (user logic) for lower frequencies, if desired. The oscillator is powered down when not in use. The example below illustrates proper usage for instantiating the OSCC primitive in VHDL.

```
COMPONENT OSCC
   PORT (OSC:OUT std_logic);
END COMPONENT;

begin

OSCInst0: OSCC
   PORT MAP (
            OSC => osc_int
```

```
);
```

Note

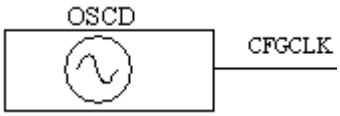
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OSCD

Oscillator for Configuration Clock

Architectures Supported:

- LatticeECP2/M



OUTPUT: CFGCLK

ATTRIBUTES:

NOM_FREQ: 2.5 (default), 4.3, 5.4, 6.9, 8.1, 9.2, 10.0, 13.0, 15.0, 20.0, 26.0, 30.0, 34.0, 41.0, 45.0, 55.0, 60.0, 130.0 (in MHz)

Description

OSCD is the primitive name of the ECP2/M oscillator. The internal oscillator is the source of the internal clock for configuration and is nominally running at 130 MHz. The oscillator is configurable by the user.

During configuration, the internal clock frequency is selected with bits 5-0 in configuration control register 0. The default frequency is 2.5 MHz, where the default values of bits 5-0 are all zeros. IO description and attribute descriptions are shown in the following tables.

OSCD Port Definition

Table 794:

Port Name	I/O	Description
CFGCLK	Output	Oscillator clock output

OSCD Usage with VHDL

```
COMPONENT OSCD
-- synthesis translate_off
   GENERIC(NOM_FREQ: string:= "2.5");
-- synthesis translate_on
   PORT (CFGCLK: OUT std_logic);
```

```
END COMPONENT;

   attribute NOM_FREQ : string;
   attribute NOM_FREQ of OSCins0 : label is "2.5";

begin

OSCInst0: OSCD
-- synthesis translate_off
   GENERIC MAP (NOM_FREQ => "2.5")
-- synthesis translate_on
   PORT MAP ( CFGCLK => osc_int);
```

OSCD Usage with Verilog HDL

```
module OSC_TOP(OSC_CLK);
output OSC_CLK;
OSCD OSCinst0 (.CFGCLK(OSC_CLK));
defparam OSCinst0.NOM_FREQ = "2.5";
endmodule
```

Note

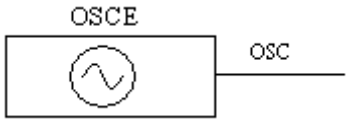
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OSCE

Oscillator for Configuration Clock

Architectures Supported:

- LatticeXP2



OUTPUT: OSC

ATTRIBUTES:

NOM_FREQ: 2.5 (default), 3.1, 4.3, 5.4, 6.9, 8.1, 9.2, 10.0, 13.0, 15.0, 20.0, 26.0, 32.0, 40.0, 54.0, 80.0, 163.0 (in MHz)

Description

OSCE is the primitive name of the XP2 oscillator. The internal oscillator is the source of the internal clock and is configurable by the user.

During configuration, the internal clock frequency is selected with bits 5-0 in configuration control register 0. The default frequency is 2.5 MHz, where the default values of bits 5-0 are all zeros. IO description and attribute descriptions are shown in the following tables.

OSCE Port Definition

Table 795:

Port Name	I/O	Description
OSC	Output	Oscillator clock output

OSCE Usage with VHDL

```
COMPONENT OSCE
-- synthesis translate_off
   GENERIC (NOM_FREQ: string := "2.5");
-- synthesis translate_on
   PORT (OSC :OUT std_logic);
END COMPONENT;

   attribute NOM_FREQ : string;
   attribute NOM_FREQ of OSCinst0 : label is "2.5";

begin

OSCInst0: OSCE
-- synthesis translate_off
   GENERIC MAP (
                NOM_FREQ => "2.5"
               )
-- synthesis translate_on
   PORT MAP (
             OSC => osc_int
             );
```

Note

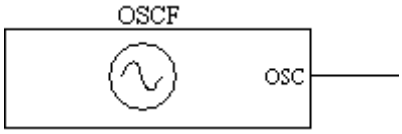
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

OSCF

Oscillator for Configuration Clock

Architectures Supported:

- LatticeECP3



OUTPUT: OSC

ATTRIBUTES:

NOM_FREQ: 2.5 (default), 4.3, 5.4, 6.9, 8.1, 9.2, 10.0, 13.0, 15.0, 20.0, 26.0, 30.0, 34.0, 41.0, 45.0, 55.0, 60.0, 130.0 (in MHz)

Description

OSCF is the primitive name of the LatticeECP3 oscillator. The internal oscillator is the source of the internal clock and is configurable by the user.

During configuration, the internal clock frequency is selected with bits 5-0 in configuration control register 0. The default frequency is 2.5 MHz, where the default values of bits 5-0 are all zeros. IO description and attribute descriptions are shown in the following tables.

OSCF Port Definition

Table 796:

Port Name	I/O	Description
OSC	Output	Oscillator clock output

OSCF Usage with VHDL

```
COMPONENT OSCF
-- synthesis translate_off
   GENERIC  (NOM_FREQ: string :=  "2.5");
-- synthesis translate_on
   PORT (OSC: OUT std_logic);
END COMPONENT;

   attribute NOM_FREQ : string;
   attribute NOM_FREQ of OSCinst0 : label is "2.5";

begin

OSCInst0: OSCF
-- synthesis translate_off
   GENERIC MAP (
                NOM_FREQ => "2.5"
               )
-- synthesis translate_on
```

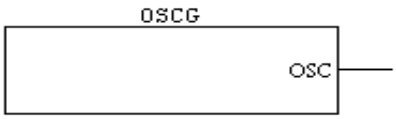
```
PORT MAP (
          OSC => osc_int
         );
```

OSCG

Oscillator for ECP5

Architectures Supported:

- ECP5



OUTPUT: OSC

ATTRIBUTES:

DIV: See table below for OSCG user clock frequency values. The default Divide Ratio value is 128. Base frequency is 310 MHz.

Table 797: User Clock Frequency Values

Divide Ratio	Frequency (Ftyp) (MHz)	Divide Ratio	Frequency (Ftyp) (MHz)	Divide Ratio	Frequency (Ftyp) (MHz)	Divide Ratio	Frequency (Ftyp) (MHz)
2	155.0	18	17.2	36	8.6	72	4.3
3	103.3	19	16.3	38	8.2	76	4.1
4	77.5	20	15.5	40	7.8	80	3.9
5	62.0	21	14.8	42	7.4	84	3.7
6	51.7	22	14.1	44	7.0	88	3.5
7	44.3	23	13.5	46	6.7	92	3.4
8	38.8	24	12.9	48	6.5	96	3.2
9	34.4	25	12.4	50	6.2	100	3.1
10	31.0	26	11.9	52	6.0	104	3.0
11	28.2	27	11.5	54	5.7	108	2.9
12	25.8	28	11.1	56	5.5	112	2.8
13	23.8	29	10.7	58	5.3	116	2.7
14	22.1	30	10.3	60	5.2	120	2.6
15	20.7	31	10.0	62	5.0	124	2.5

Table 797: User Clock Frequency Values (Continued)

Divide Ratio	Frequency (Ftyp) (MHz)	Divide Ratio	Frequency (Ftyp) (MHz)	Divide Ratio	Frequency (Ftyp) (MHz)	Divide Ratio	Frequency (Ftyp) (MHz)
16	19.4	32	9.7	64	4.8	128	2.4
17	18.2	34	9.1	68	4.6		

See the I/O port description in the below table.

Table 798:

Port Name	I/O	Description
OSC	Output	Oscillator clock output

Description

The OSCG element performs multiple functions on the ECP5 device. It is used for configuration, soft error detect (SED), as well as optionally in user mode. In user mode, the OSCG element has the following features:

- It permits a design to be fully self-clocked, as long as the quality of the OSCG element's silicon-based oscillator is adequate, and provides performance superior to a "roll-your-own" user-created implementation.
- If it's unused it can be turned off for power savings.
- It has a direct connection to primary clock routing through the left mid-mux.
- It can be configured for operation at a wide range of frequencies via configuration bits.
- The bandgap controller can't be shut off in ECP5 so there is no need for any caveats for BGOFF.

The one feature available to the user is the user-mode OSCG oscillator frunction.

The OSCG provides an internal clock source to user designs.

OSCG Usage with VHDL

```
COMPONENT OSCG
-- synthesis translate_off
  GENERIC (DIV: integer := 128);
-- synthesis translate_on
PORT (
  OSC      : OUT std_logic);
END COMPONENT;

attribute DIV : integer;
attribute DIV of OSCinst0 : label is 128;

begin
OSCInst0: OSCG
-- synthesis translate_off
```

```
  GENERIC MAP (DIV  => 128)
-- synthesis translate_on
PORT MAP (OSC      => OSC);
```

OSCG Usage with Verilog

```
module OSC_TOP(OSC_CLK);

output OSC_CLK;

OSCG OSCinst0 (.OSC(OSC_CLK));
defparam OSCinst0.DIV = 2;

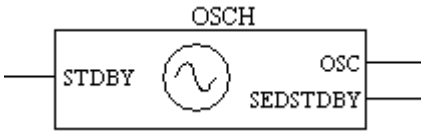
endmodule
```

OSCH

Oscillator for MachXO2/Platform Manager 2

Architectures Supported:

- MachXO2
- MachXO3L
- Platform Manager 2



INPUT: STDBY

OUTPUT: OSC, SEDSTDBY

ATTRIBUTES:

NOM_FREQ: 2.08 (default), 2.15, 2.22, 2.29, 2.38, 2.46, 2.56, 2.66, 2.77, 2.89, 3.02, 3.17, …, 19.0, 20.46, 22.17, 24.18, 26.6, 29.56, 33.25, 38.0, 44.33, 53.2, 66.5, 88.67, 133.0 (in MHz)

Description

OSCH is the primitive name of the MachXO2/Platform Manager 2 oscillator. See the IO port description in the below table.

Table 799:

Port Name	I/O	Description
STDBY	Input	Standby – power down oscillator

Table 799:

Port Name	I/O	Description
OSC	Output	Oscillator clock output
SEDSTDBY	Output	Standby – power down SED clock

By default, the internal oscillator will be enabled even if the user does not have it instantiated in the design. User can disable the internal oscillator by instantiating it in the design and using the STDBY port. This port can be connected to a user signal or an I/O pin. The user must insure that the oscillator is not turned off when it is needed for operations such as WISHBONE bus operations, SPI or I2C configuration, SPI or I2C user mode operation, SPI or I2C background Flash updates or SED.

OSCH Usage with VHDL

```
COMPONENT OSCH
-- synthesis translate_off
   GENERIC  (NOM_FREQ: string :=  "2.56");
-- synthesis translate_on
   PORT (STDBY   : IN  std_logic;
         OSC     : OUT std_logic;
         SEDSTDBY: OUT std_logic);
END COMPONENT;

   attribute NOM_FREQ : string;
   attribute NOM_FREQ of OSCinst0 : label is "2.56";

begin

OSCInst0: OSCH
-- synthesis translate_off
   GENERIC MAP (
                NOM_FREQ => "2.5"
               )
-- synthesis translate_on
   PORT MAP (STDBY => stdby,
             OSC   => osc_int,
             SEDSTDBY => stdby_sed
            );
```

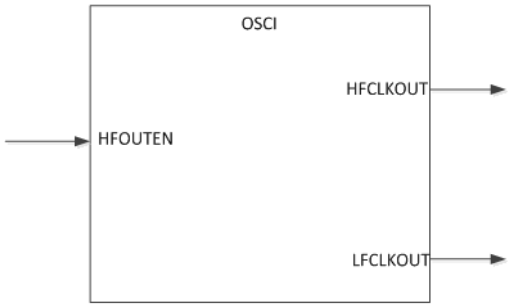
For more information, refer to the following technical note on the Lattice web site:

- TN1199 - MachXO2 sysCLOCK PLL Design and Usage Guide

OSCI

Architectures Supported:

- LIFMD



INPUTS: HFOUTEN

OUTPUTS: HFCLKOUT, LFCLKOUT

See the I/O port description in the below table.

Table 800:

Port Name	I/O	Description
HFOUTEN	Input	High frequency clock output enable.
HFCLKOUT	Output	High frequency clock output.
LFCLKOUT	Output	Low Frequency clock output

Description

OSCI runs at 10 KHz in low frequency mode and at maximum 48 MHz in high frequency mode with output divider by 1, 2, 4 or 8.

OSCI provides internal clock sources to user designs. These clocks can directly route to the global clock network or to local fabric.

OSCI Usage with VHDL

```
Component Instantiation
Library lattice;
use lattice.components.all;

Component and Attribute Declaration
component OSCI
Generic (HFCLKDIV : Integer);
Port (
    HFOUTEN : in STD_LOGIC;
    HFCLKOUT : out STD_LOGIC;
    LFCLKOUT : out STD_LOGIC);
end component;
attribute HFCLKDIV : Integer;
attribute HFCLKDIV of I1 : label is 1; -- 1,2,4,8

OSCI Instantiation
```

```
I1: OSCI
generic map (HFCLKDIV => 1)
port map
    HFOUTEN => HFOUTEN,
    HFCLKOUT => HFCLKOUT,
    LFCLKOUT => LFCLKOUT);
```

OSCI Usage with Verilog

```
Component and Attribute Declaration
module OSCI (HFOUTEN, HFCLKOUT,
LFCLKOUT);
parameter HFCLKDIV = 1;
input HFOUTEN;
input HFCLKOUT;
output LFCLKOUT;
endmodule
OSCI Instantiation
defparam I1.HFCLKDIV = 1; // 1,2,4,8
OSCI I1 (
.HFOUTEN(HFOUTEN),
.HFCLKOUT(HFCLKOUT),
.LFCLKOUT(LFCLKOUT));
```

For more information, refer to the following technical note on the Lattice web site:

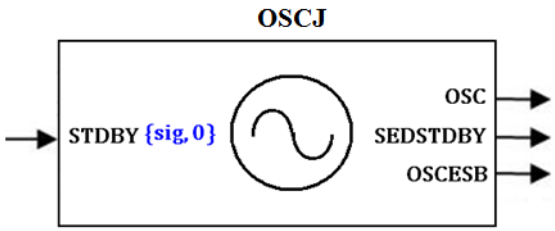
- FPGA-TN- 02015 - CrossLink sysCLOCK PLL/DLL Design and Usage Guide

OSCJ

Oscillator for MachXO3D

Architectures Supported:

- MachXO3D



INPUT: STDBY

OUTPUT: OSC, SEDSTDBY, OSCESB

ATTRIBUTES:

NOM_FREQ = 2.08 (default), 2.15, 2.22, 2.29, 2.38, 2.46, 2.56, 2.66, 2.77,

2.89, 3.02, 3.17, …, 19.0, 20.46, 22.17, 24.18, 26.6, 29.56, 33.25, 38.0,44.33, 53.2, 66.5, 88.67, 133.0 (in MHz)

Description

OSCJ is the primitive name of the MachXO3D oscillator. OSCJ has additional output pin named OSCESB, which is connected to the input clock of ESB.

See the IO port description in the below table.

Table 801:

Port Name	I/O	Description
STDBY	I	Standby – power down oscillator
OSC	O	Oscillator clock output
SEDSTDBY	O	Standby – power down SED clock
OSCESB	O	Oscillator clock output connected to input clock of ESB primitive The frequency is fixed at 66.5MHz

OSHX2A

Memory Output DDR Primitive for Address and Command

Architectures Supported:

- ECP5

INPUT: DO, D1, SCLK, ECLK, RST

OUTPUT: Q

Description

This primitive is used to generate the CS_N output for DDR2, DDR3, DDR3L & LPDDR memory interface.

The I/O port description are given in the following table.

Table 802:

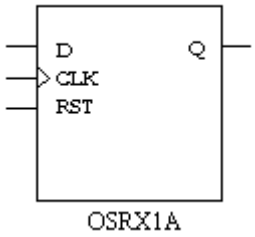
Port Name	I/O	Description
DO, D1	I	Data input
ECLK	I	ECLK input (2x speed of SCLK)
SCLK	I	SCLK input
RST	I	Reset input
Q	O	Address and command input

OSRX1A

Output 1-Bit Shift Register

Architectures Supported:

- LatticeSC/M



INPUTS: D, CLK, RST

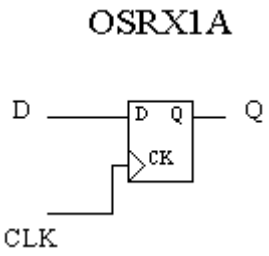
OUTPUT: Q

ATTRIBUTES:

REGSET: "RESET" (default), "SET"

Description

Outputs data through the shift register to the output data. The following symbolic diagram shows the flip-flop structure of this primitive.

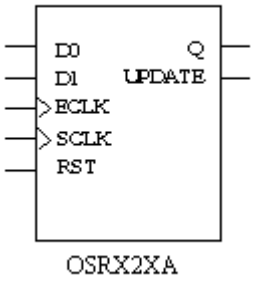


OSRX2A

Output 2-Bit Shift Register

Architectures Supported:

- LatticeSC/M



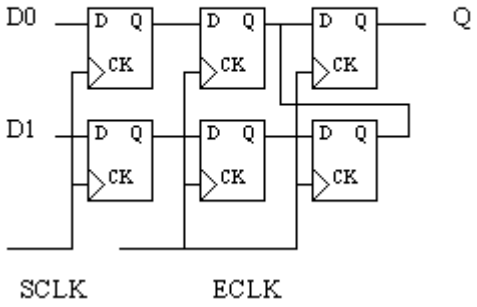
INPUTS: D0, D1, ECLK, SCLK, RST

OUTPUTS: Q, UPDATE

Description

Outputs data through the shift register to the output data. The following symbolic diagram shows the flip-flop structure of this primitive.

OSRX2A

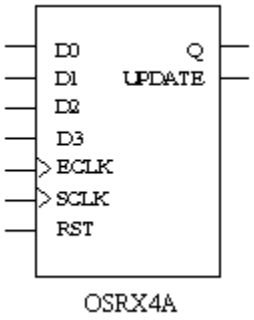


OSRX4A

Output 4-Bit Shift Register

Architectures Supported:

- LatticeSC/M



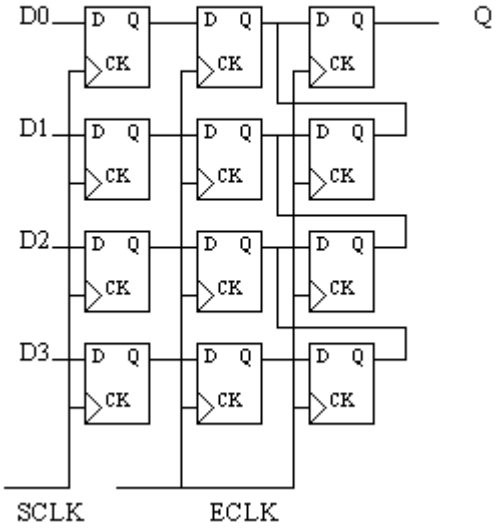
INPUTS: D0, D1, D2, D3, ECLK, SCLK, RST

OUTPUTS: Q, UPDATE

Description

Outputs data through the shift register to the output data. The following symbolic diagram shows the flip-flop structure of this primitive.

OSRX4A



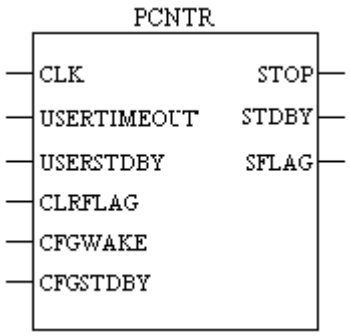
P

PCNTR

Power Controller

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: CLK, USERTIMEOUT, USERSTDBY, CLRFLAG, CFGWAKE, CFGSTDBY

OUTPUTS: STOP, STDBY, SFLAG

ATTRIBUTES:

STDBYOPT: "USER_CFG" (default), "USER", "CFG"

TIMEOUT: "BYPASS" (default), "USER", "COUNTER"

WAKEUP: "USER_CFG" (default), "USER", "CFG"

POROFF: "FALSE" (default), "TRUE"

BGOFF: "FALSE" (default), "TRUE"

Description

PCNTR is the MachXO2/Platform Manager 2 power controller primitive.

For more information, refer to the following technical note on the Lattice web site:

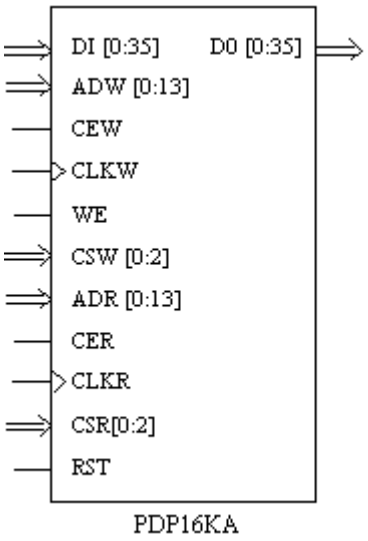
- TN1198 - Power Estimation and Management for MachXO2 Device

PDP16KA

16K Pseudo Dual Port Block RAM

Architectures Supported:

- LatticeSC/M



INPUTS: DI0, DI1, DI2, DI3, DI4, DI5, DI6, DI7, DI8, DI9, DI10, DI11, DI12, DI13, DI14, DI15, DI16, DI17, DI18, DI19, DI20, DI21, DI22, DI23, DI24, DI25, DI26, DI27, DI28, DI29, DI30, DI31, DI32, DI33, DI34, DI35, ADW0, ADW1, ADW2, ADW3, ADW4, ADW5, ADW6, ADW7, ADW8, ADW9, ADW10, ADW11, ADW12, ADW13, CEW, CLKW, WE, CSW0, CSW1, CSW2, ADR0, ADR1, ADR2, ADR3, ADR4, ADR5, ADR6, ADR7, ADR8, ADR9, ADR10, ADR11, ADR12, ADR13, CER, CLKR, CSR0, CSR1, CSR2, RST

OUTPUTS: DO0, DO1, DO2, DO3, DO4, DO5, DO6, DO7, DO8, DO9, DO10, DO11, DO12, DO13, DO14, DO15, DO16, DO17, DO18, DO19, DO20, DO21, DO22, DO23, DO24, DO25, DO26, DO27, DO28, DO29, DO30, DO31, DO32, DO33, DO34, DO35

ATTRIBUTES:

DATA_WIDTH_W: 1, 2, 4, 9, 18 (default), 36

DATA_WIDTH_R: 1, 2, 4, 9, 18 (default), 36

REGMODE: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE_W: any 3-bit binary value (default: 3'b000)

CSDECODE_R: any 3-bit binary value (default: 3'b000)

GSR: "DISABLED" (default), "ENABLED"

INITVAL_00 to INITVAL_3F: (*Verilog*) 320'hXXX...X (80-bit hexadecimal value)
(*VHDL*) 0xXXX...X (80-bit hexadecimal value)
Default: all zeros

Description

You can refer to the following technical note on the Lattice web site on details of EBR port definition, attribute definition and usage.

- TN1094 - On-Chip Memory Usage Guide for LatticeSC Devices

Note

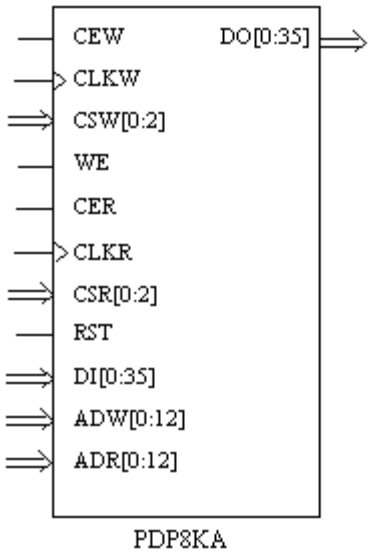
When the write data width (DATA_WIDTH_W) is set to 36, the WE port is invalid, that is, it has no effect on the data output.

PDP8KA

8K Pseudo Dual Port Block RAM

Architectures Supported:

- LatticeECP/EC
- LatticeXP



INPUTS: CEW, CLKW, CSW0, CSW1, CSW2, WE, CER, CLKR, CSR0, CSR1, CSR2, RST, DI0, DI1, DI2, DI3, DI4, DI5, DI6, DI7, DI8, DI9, DI10, DI11, DI12, DI13, DI14, DI15, DI16, DI17, DI18, DI19, DI20, DI21, DI22, DI23, DI24, DI25, DI26, DI27, DI28, DI29, DI30, DI31, DI32, DI33, DI34, DI35, ADW0, ADW1, ADW2, ADW3, ADW4, ADW5, ADW6, ADW7, ADW8, ADW9, ADW10, ADW11, ADW12, ADR0, ADR1, ADR2, ADR3, ADR4, ADR5, ADR6, ADR7, ADR8, ADR9, ADR10, ADR11, ADR12

OUTPUTS: DO0, DO1, DO2, DO3, DO4, DO5, DO6, DO7, DO8, DO9, DO10, DO11, DO12, DO13, DO14, DO15, DO16, DO17, DO18, DO19, DO20, DO21, DO22, DO23, DO24, DO25, DO26, DO27, DO28, DO29, DO30, DO31, DO32, DO33, DO34, DO35

ATTRIBUTES (LatticeXP/EC):

DATA_WIDTH_W: 1, 2, 4, 9, 18, 36 (default)

DATA_WIDTH_R: 1, 2, 4, 9, 18, 36 (default)

REGMODE: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE_W: any 3-bit binary value (default: 111)

CSDECODE_R: any 3-bit binary value (default: 111)

GSR: "DISABLED" (default), "ENABLED"

INITVAL_00 to INITVAL_1F: (*Verilog*) 320'hXXX...X (80-bit hexadecimal value)
(*VHDL*) 0xXXX...X (80-bit hexadecimal value)
Default: all zeros

Description

You can refer to the following technical note on the Lattice web site on details of EBR port definition, attribute definition and usage.

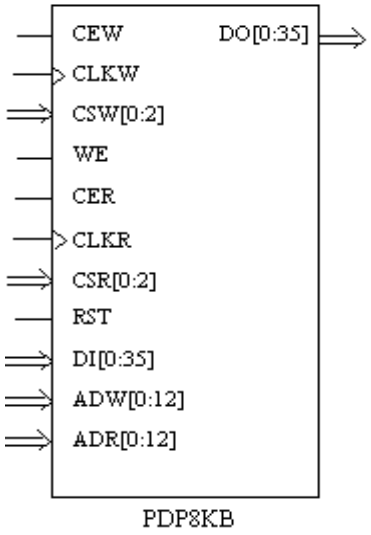
- TN1051 - Memory Usage Guide for LatticeECP/EC and LatticeXP Devices

PDP8KB

8K Pseudo Dual Port Block RAM

Architectures Supported:

- MachXO
- Platform Manager



INPUTS: CEW, CLKW, CSW0, CSW1, CSW2, WE, CER, CLKR, CSR0, CSR1, CSR2, RST, DI0, DI1, DI2, DI3, DI4, DI5, DI6, DI7, DI8, DI9, DI10, DI11, DI12, DI13, DI14, DI15, DI16, DI17, DI18, DI19, DI20, DI21, DI22, DI23, DI24, DI25, DI26, DI27, DI28, DI29, DI30, DI31, DI32, DI33, DI34, DI35, ADW0, ADW1, ADW2, ADW3, ADW4, ADW5, ADW6, ADW7, ADW8, ADW9, ADW10, ADW11, ADW12, ADR0, ADR1, ADR2, ADR3, ADR4, ADR5, ADR6, ADR7, ADR8, ADR9, ADR10, ADR11, ADR12

OUTPUTS: DO0, DO1, DO2, DO3, DO4, DO5, DO6, DO7, DO8, DO9, DO10, DO11, DO12, DO13, DO14, DO15, DO16, DO17, DO18, DO19, DO20, DO21, DO22, DO23, DO24, DO25, DO26, DO27, DO28, DO29, DO30, DO31, DO32, DO33, DO34, DO35

ATTRIBUTES:

DATA_WIDTH_W: 1, 2, 4, 9, 18 (default), 36

DATA_WIDTH_R: 1, 2, 4, 9, 18 (default), 36

REGMODE: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE_W: any 3-bit binary value (default: 3'b000)

CSDECODE_R: any 3-bit binary value (default: 3'b000)

GSR: "DISABLED" (default), "ENABLED"

INITVAL_00 to INITVAL_1F: (*Verilog*) "320'hXXX...X" (80-bit hex string)
(*VHDL*) "0xXXX...X" (80-bit hex string)
Default: all zeros

Description

You can refer to the following technical note on the Lattice web site on details of EBR port definition, attribute definition and usage.

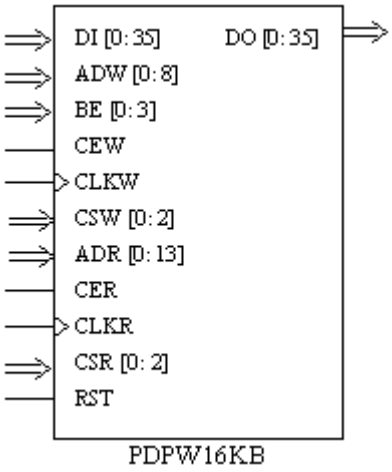
- TN1092 - MachXO Memory Usage Guide

PDPW16KB

Pseudo Dual Port Block RAM

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



INPUTS: DI0, DI1, DI2, DI3, DI4, DI5, DI6, DI7, DI8, DI9, DI10, DI11, DI12, DI13, DI14, DI15, DI16, DI17, DI18, DI19, DI20, DI21, DI22, DI23, DI24, DI25, DI26, DI27, DI28, DI29, DI30, DI31, DI32, DI33, DI34, DI35, ADW0, ADW1, ADW2, ADW3, ADW4, ADW5, ADW6, ADW7, ADW8, BE0, BE1, BE2, BE3, CEW, CLKW, CSW0, CSW1, CSW2, ADR0, ADR1, ADR2, ADR3, ADR4, ADR5, ADR6, ADR7, ADR8, ADR9, ADR10, ADR11, ADR12, ADR13, CER, CLKR, CSR0, CSR1, CSR2, RST

OUTPUTS: DO0, DO1, DO2, DO3, DO4, DO5, DO6, DO7, DO8, DO9, DO10, DO11, DO12, DO13, DO14, DO15, DO16, DO17, DO18, DO19, DO20, DO21, DO22, DO23, DO24, DO25, DO26, DO27, DO28, DO29, DO30, DO31, DO32, DO33, DO34, DO35

ATTRIBUTES:

DATA_WIDTH_W: 1, 2, 4, 9, 18, 36 (default)

DATA_WIDTH_R: 1, 2, 4, 9, 18, 36 (default)

REGMODE: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE_W: any 3-bit binary value (default: 0b000)

CSDECODE_R: any 3-bit binary value (default: 0b000)

GSR: "DISABLED" (default), "ENABLED"

INITVAL_00 to INITVAL_3F: "0xXXX...X" (80-bit hex string) (default: all zeros)

Description

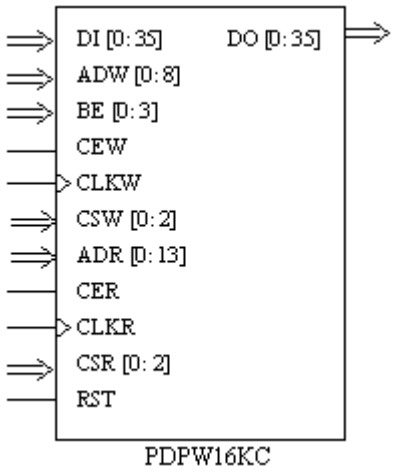
PDPW16KC

Pseudo Dual Port Block RAM

Architectures Supported:

- LatticeECP3



INPUTS: DI35, DI34, DI33, DI32, DI31, DI30, DI29, DI28, DI27, DI26, DI25, DI24, DI23, DI22, DI21, DI20, DI19, DI18, DI17, DI16, DI15, DI14, DI13, DI12, DI11, DI10, DI9, DI8, DI7, DI6, DI5, DI4, DI3, DI2, DI1, DI0, ADW8, ADW7, ADW6, ADW5, ADW4, ADW3, ADW2, ADW1, ADW0, BE3, BE2, BE1, BE0, CEW, CLKW, CSW2, CSW1, CSW0, ADR13, ADR12, ADR11, ADR10,

ADR9, ADR8, ADR7, ADR6, ADR5, ADR4, ADR3, ADR2, ADR1, ADR0, CER, CLKR, CSR2, CSR1, CSR0, RST

OUTPUTS: DO35, DO34, DO33, DO32, DO31, DO30, DO29, DO28, DO27, DO26, DO25, DO24, DO23, DO22, DO21, DO20, DO19, DO18, DO17, DO16, DO15, DO14, DO13, DO12, DO11, DO10, DO9, DO8, DO7, DO6, DO5, DO4, DO3, DO2, DO1, DO0

ATTRIBUTES:

DATA_WIDTH_W: 1, 2, 4, 9, 18, 36 (default)

DATA_WIDTH_R: 1, 2, 4, 9, 18 (default), 36

REGMODE: "NOREG" (default), "OUTREG"

CSDECODE_W: any 3-bit binary value (default: all zeros)

CSDECODE_R: any 3-bit binary value (default: all zeros)

GSR: "DISABLED" (default), "ENABLED"

INITVAL_00 to INITVAL_3F: "0xXXX...X" (80-bit hex string) (default: all zeros)

Description

You can refer to the following technical note on the Lattice web site for EBR port definition, attribute definition and usage.

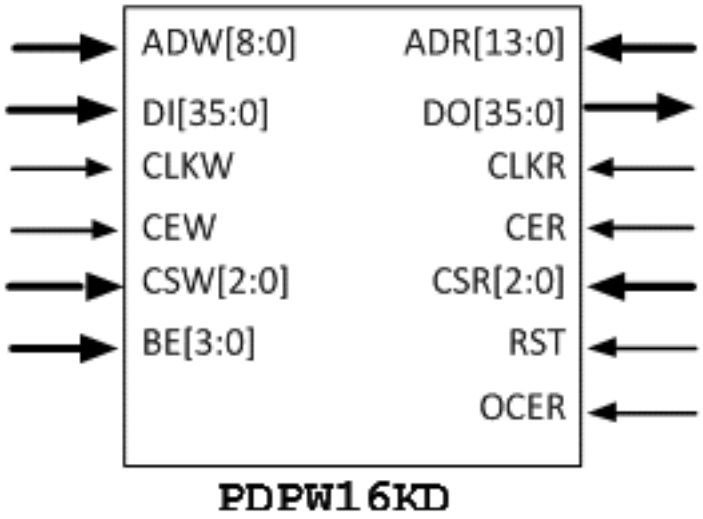
- TN1179 - LatticeECP3 Memory Usage Guide

PDPW16KD

Pseudo Dual Port RAM

Architectures Supported:

- ECP5



INPUTS: DI35, DI34, DI33, DI32, DI31, DI30, DI29, DI28, DI27, DI26, DI25, DI24, DI23, DI22, DI21, DI20, DI19, DI18, DI17, DI16, DI15, DI14, DI13, DI12, DI11, DI10, DI9, DI8, DI7, DI6, DI5, DI4, DI3, DI2, DI1, DI0, ADW8, ADW7, ADW6, ADW5, ADW4, ADW3, ADW2, ADW1, ADW0, ADR8, ADR7, ADR6, ADR5, ADR4, ADR3, ADR2, ADR1, ADR0, BE3, BE2, BE1, BE0, CEW, CLKW, CSW2, CSW1, CSW0, ADR13, ADR12, ADR11, ADR10, ADR9, ADR8, ADR7, ADR6, ADR5, ADR4, ADR3, ADR2, ADR1, ADR0, CER, CLKR, CSR2, CSR1, CSR0, OCER, RST

OUTPUTS: DO35, DO34, DO33, DO32, DO31, DO30, DO29, DO28, DO27, DO26, DO25, DO24, DO23, DO22, DO21, DO20, DO19, DO18, DO17, DO16, DO15, DO14, DO13, DO12, DO11, DO10, DO9, DO8, DO7, DO6, DO5, DO4, DO3, DO2, DO1, DO0

ATTRIBUTES:

The following table lists PDPW16KD Attributes:

Figure 62:

Description	Attribute Name	Attribute Type	Value	Default Value
Read Port Data Width	DATA_WIDTH_R	C	1, 2, 4, 9, 18, 36	36
Write Port Data Width	DATA_WIDTH_W	C	36	36
Enable Output Registers	REGMODE	C	NOREG, OUTREG	NOREG

Figure 62:

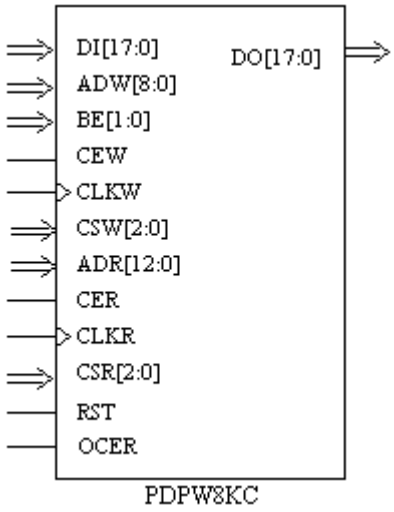
Description	Attribute Name	Attribute Type	Value	Default Value
Enable GSR	GSR	C	ENABLED, DISABLED	ENABLED
Reset Mode	RESETMODE	C	ASYNC, SYNC	SYNC
Reset Release	ASYNC_RESET_RELEASE	C	ASYNC, SYNC	SYNC
Memory File Format		C	BINARY, HEX, ADDRESSEDHEX	
Chip Select Decode for Port A	CSDECODE_W	C		0b000
Chip Select Decode for Port B	CSDECODE_R	C		0b000
Init Value	INITVAL_00… INITVAL_3F	C		
MEM_LPC_FILE	MEM_LPC_FILE	Core Only		
MEM_INIT_FILE	MEM_INIT_FILE	Core Only		
Defines if the memory file can be updated	INIT_DATA	C	STATIC, DYNAMIC	STATIC
Enable Output ClockEn	OCER	C	ENABLE, DISABLE	DISABLE
WID		Core Only		

PDPW8KC

Pseudo Dual Port Block RAM

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: DI17, DI16, DI15, DI14, DI13, DI12, DI11, DI10, DI9, DI8, DI7, DI6, DI5, DI4, DI3, DI2, DI1, DI0, ADW8, ADW7, ADW6, ADW5, ADW4, ADW3, ADW2, ADW1, ADW0, BE1, BE0, CEW, CLKW, CSW2, CSW1, CSW0, ADR12, ADR11, ADR10, ADR9, ADR8, ADR7, ADR6, ADR5, ADR4, ADR3, ADR2, ADR1, ADR0, CER, CLKR, CSR2, CSR1, CSR0, RST, OCER

OUTPUTS: DO17, DO16, DO15, DO14, DO13, DO12, DO11, DO10, DO9, DO8, DO7, DO6 DO5, DO4, DO3, DO2, DO1, DO0

ATTRIBUTES:

DATA_WIDTH_W: 18 (default)

DATA_WIDTH_R: 1, 2, 4, 9, 18 (default: 9)

REGMODE: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE_W: any 3-bit binary value (default: all zeros)

CSDECODE_R: any 3-bit binary value (default: all zeros)

GSR: "ENABLED" (default), "DISABLED"

RESETMODE: "SYNC" (default), "ASYNC"

ASYNC_RESET_RELEASE: "SYNC" (default), "ASYNC"

INIT_DATA: "STATIC" (default), "DYNAMIC"

INITVAL_00 to INITVAL_1F: (*Verilog*) "320'hXXX...X" (80-bit hex string)
(*VHDL*) "0xXXX...X" (80-bit hex string)
Default: all zeros

Description

The following table describes the I/O ports of the PDPW8KC primitive.

Table 803:

Port Name	I/O	Definition
CLKR	I	Read clock
CLKW	I	Write clock
RST	I	Reset
CSW[1:0]	I	Chip select write
CSR[1:0]	I	Chip select read
CER	I	Read clock enable
CEW	I	Write clock enable
OCER	I	Read output clock enable
BE[1:0]	I	Byte enable
DI[17:0]	I	Write data (up to 18)
ADW[8:0]	I	Write address (up to 9)
ADR[12:0]	I	Read address (up to 13)
DO[17:0]	O	Read data (up to 18)

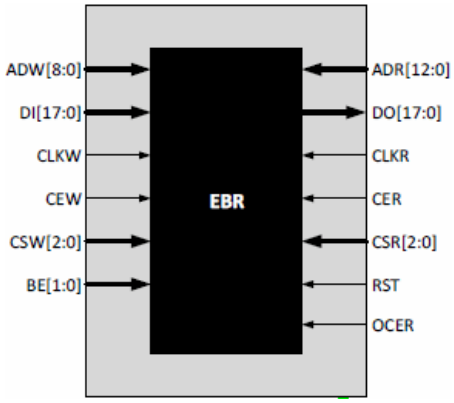
You can refer to the following technical note on the Lattice web site on details of EBR port definition, attribute definition and usage.

- TN1201 - Memory Usage Guide for MachXO2 Devices

PDPW8KE

Architectures Supported:

- LIFMD



INPUTS: DI17, DI16, DI15, DI14, DI13, DI12, DI11, DI10, DI9, DI8, DI7, DI6, DI5, DI4, DI3, DI2, DI1, DI0, BE1, BE0, ADW8, ADW7, ADW6, ADW5, ADW4, ADW3, ADW2, ADW1, ADW0, CEW, CLKW, CSW2, CSW1, CSW0, ADR12, ADR11, ADR10, ADR9, ADR8, ADR7, ADR6, ADR5, ADR4, ADR3, ADR2, ADR1, ADR0, CER, OCER, CLKR, CSR2, CSR1, CSR0, RST

OUTPUTS: DO17, DO16, DO15, DO14, DO13, DO12, DO11, DO10, DO9, DO8, DO7, DO6, DO5, DO4, DO3, DO2, DO1, DO0

.

Table 804:

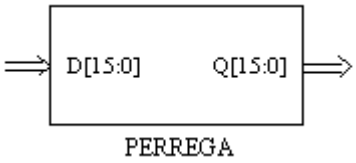
Port Name	Definition
CLKR	Read Clock
CLKW	Write Clock
RST	Reset
CSW[2:0]	Chip Select Write
CSR[2:0]	Chip Select Read
CER	Read Clock Enable
CEW	Write Clock Enable
OCER	Read Output Clock Enable
BE[1:0]	Byte Enable
{DIB[8:0], DIA[8:0]}	Write Data
ADW[8:0]	Write Address
ADW[12:0]	Read Address

PERREGA

Persistent User Register

Architectures Supported:

- LatticeECP3



INPUTS: D15, D14, D13, D12, D11, D10, D9, D8, D7, D6, D5, D4, D3, D2, D1, D0

OUTPUTS: Q15, Q14, Q13, Q12, Q11, Q10, Q9, Q8, Q7, Q6, Q5, Q4, Q3, Q2, Q1, Q0

Description

The PERREGA primitive enables you to use 16-bit registers to store information when the device goes into the configuration mode. The data on these registers will stay intact during the reconfiguration and be available for use after then. For example, you can use these registers to capture the last pattern that causes an error to reboot from the golden source when using SED.

These latches are available through the internal CIB. The below table describes the I/O ports of the PERREGA primitive.

Table 805:

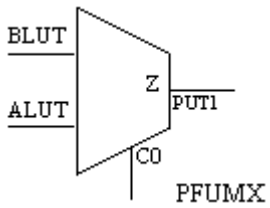
Signal	Type	Description	Function
D[15:0]	CIB Input	Parallel Data In	Provides parallel data from the FPGA fabric for the latch.
Q[15:0]	CIB Output	Parallel Data Out	Provides parallel data to the FPGA fabric for the latch.
PROGRAMN	Control Signal	High to Low Edge on the PROGRAMN pin	Latch in the data from D[15:0].
DONE	Internal Signal	Done signal	Prohibits multiple latching due to transitional glitches on the LE CIB or PROGRAMN pin.

PFUMX

2-Input Mux within the PFU, C0 Used for Selection with Positive Select

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: ALUT, BLUT, C0

OUTPUT: Z

Truth Table

Table 806:

INPUTS			OUTPUTS
BLUT	ALUT	C0	Z
X	1	1	1
X	0	1	0
1	X	0	1
0	X	0	0

X = Don’t care

Note

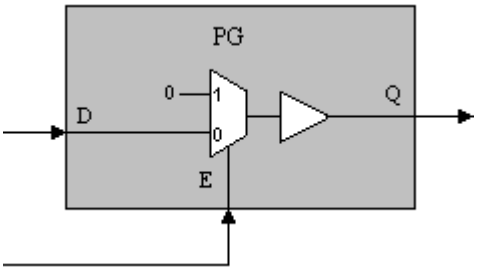
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

PG

Power Guard

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: D, E

OUTPUT: Q

Description

In the power guard mode, the receiver input is disconnected from the pad and held low with a weak pull down. The pad can be toggling and no receiver power will be used. Power guard is enabled on a bank by bank basis. Each bank has a CIB input signal to enable power guard. In addition, each PIO has individually programmable bit control to disable or enable the power guard capability.

PG is the power guard primitive for MachXO2/Platform Manager 2 devices. You can generate a primitive for a group of I/O pins and then connect it in the design. The PG primitive D port must be connected to the IO pin. You are required to connect the enable input of the primitive to the signal that is used to activate the power guard function. Only one enable signal can be used for all I/Os within an individual I/O bank using power guard. An individual I/O pin is only allowed to connect to one PG primitive module but there could be more than one PG module active in a single I/O bank. Once an I/O signal is connected to the power guard primitive, the software sets the individually

programmable bit for that PIO to enable power guard. The default setting for this bit is to disable the power guard function for a PIO.

The following table describes the IO ports of the PG primitive.

Table 807:

Port Name	I/O	Description
D	I	This is the signal coming from an input or I/O pad. This pin cannot have any fanout—only connects between pad and PG.
E	I	This is the “ENABLE” input that is tied to BIE (Block Input Enable). When E=0, Q is connected to D. When E=1, Q is isolated from D.
Q	O	This is the output of the power guard that drives towards the core. When E=0, the output Q is driven by the input D.

For more information, refer to the following technical note on the Lattice web site:

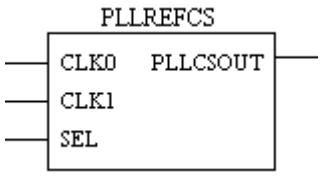
- TN1198 - Power Estimation and Management for MachXO2 Device

PLLREFCS

PLL Dynamic Reference Clock Switching

Architectures Supported:

- ECP5
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: CLK0, CLK1, SEL

OUTPUT: PLLCSOUT

Description

The PLLREFCS primitive is used to support the dynamic reference clock switching using the SEL signal. This primitive does not require a wrapper.

You only need to instantiate the PLLREFCS primitive if you want to select between two different reference clocks in your application. If you only use one reference clock for the PLL, the software will automatically make the correct connections.

The following table describes the I/O ports of the PLLREFCS primitive.

Table 808:

Port Name	I/O	Description
CLK0, CLK1	I	There are two clock input MUXES (8 inputs each) which are labeled as REFCLK1 and REFCLK2. CLK0 is the output of REFCLK1. CLK1 is the output of REFCLK2.
SEL	I	Selects which signal goes to the input clock MUX.
PLLCSOUT	O	

For more information, refer to the following technical note on the Lattice web site:

- TN1199 - MachXO2 sysCLOCK PLL Design and Usage Guide

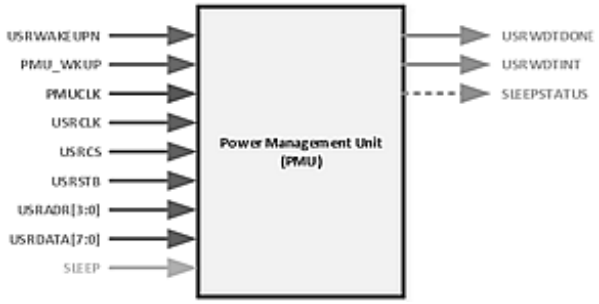
PMUA

Power Management Unit

The PMU user primitive serves as configurable HDL module that can be instantiated in user design to achieve power reduction for Lattice FPGA products. The primitive is treated as a black box in the software.

Architectures Supported:

- LIFMD



INPUTS: USRWAKEUP; I2CWAKEUP; INTCLK; EXTCLK; USRCLK; USRCS; USRSTB; USRADR3, USRADR2, USRADR1, USRADR0;

USRDATA7, USRDATA6, USRDATA5, USRDATA4, USRDATA3, USRDATA2, USRDATA1, USRDATA0; SLEEP

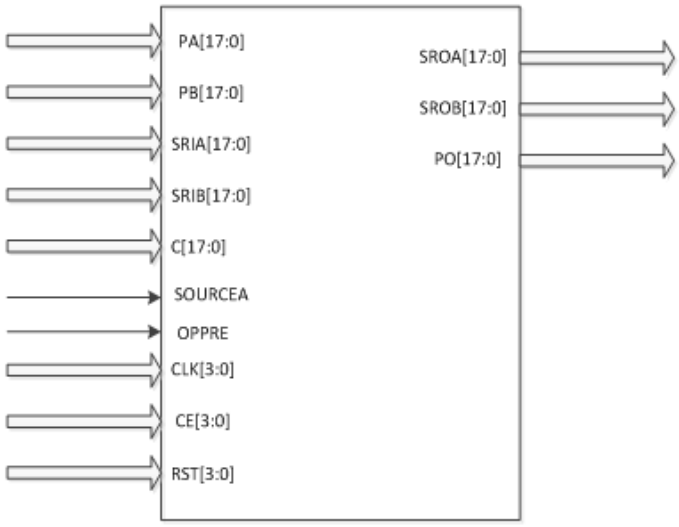
OUTPUT: USRWDTDONE; USRWDTINT; SLEEPSTATUS

PRADD18A

18-bit PreAdder/Shift

Architectures Supported:

- ECP5



PRADD18A

INPUTS: PA17, PA16, PA15, PA14, PA13, PA12, PA11, PA10, PA9, PA8, PA7, PA6, PA5, PA4, PA3, PA2, PA1, PA0, PB17, PB16, PB15, PB14, PB13, PB12, PB11, PB10, PB9, PB8, PB7, PB6, PB5, PB4, PB3, PB2, PB1, PB0, SRIA17, SRIA16, SRIA15, SRIA14, SRIA13, SRIA12, SRIA11, SRIA10, SRIA9, SRIA8, SRIA7, SRIA6, SRIA5, SRIA4, SRIA3, SRIA2, SRIA1, SRIA0, SRIB17, SRIB16, SRIB15, SRIB14, SRIB13, SRIB12, SRIB11, SRIB10, SRIB9, SRIB8, SRIB7, SRIB6, SRIB5, SRIB4, SRIB3, SRIB2, SRIB1, SRIB0, C17, C16, C15, C14, C13, C12, C11, C10, C9, C8, C7, C6, C5, C4, C3, C2, C1, C0, SOURCEA, OPPRE, CLK3, CLK2, CLK1, CLK0, CE3, CE2, CE1, CE0, RST3, RST2, RST1, RST0

OUTPUT: SROA17, SROA16, SROA15, SROA14, SROA13, SROA12, SROA11, SROA10, SROA9, SROA8, SROA7, SROA6, SROA5, SROA4, SROA3, SROA2, SROA1, SROA0, SROB17, SROB16, SROB15, SROB14, SROB13, SROB12, SROB11, SROB10, SROB9, SROB8, SROB7, SROB6, SROB5, SROB4, SROB3, SROB2, SROB1, SROB0, PO17, PO16, PO15, PO14, PO13, PO12, PO11, PO10, PO9, PO8, PO7, PO6, PO5, PO4, PO3, PO2, PO1, PO0

ATTRIBUTES:

The attributes of PRADD18A are identical to the attributes of PRADD9A.

Description

The following table describes the I/O ports of the PRADD18A primitive.

Table 809:

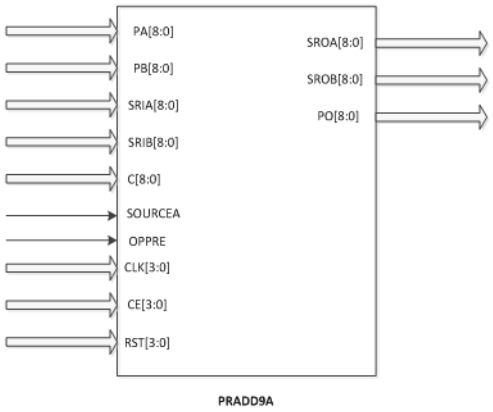
Port Name	I/O	Description
CE[3:0]	I	Clock Enable Inputs
CLK[3:0]	I	Clock Inputs
RST[3:0]	I	Reset Inputs
SOURCEA	I	Source Selector for Pre-adder Input A
PA[17:0]	I	Pre-adder Parallel Input A
PB[17:0]	I	Pre-adder Parallel Input B
SRIA[17:0]	I	Pre-adder Shift Input A
SRIB[17:0]	I	Pre-adder Shift Input A, backward direction
C[17:0]	I	Input used for high-speed option
SROA[17:0]	O	Pre-adder Shift Output A
SROB[17:0]	O	Pre-adder Shift Output B
PO[17:0]	O	Pre-adder Addition Output
OPPRE	I	Opcode for PreAdder

PRADD9A

9-bit PreAdder/Shift

Architectures Supported:

- ECP5



INPUTS: PA8, PA7, PA6, PA5, PA4, PA3, PA2, PA1, PA0, PB8, PB7, PB6, PB5, PB4, PB3, PB2, PB1, PB0, SRIA8, SRIA7, SRIA6, SRIA5, SRIA4, SRIA3, SRIA2, SRIA1, SRIA0, SRIB8, SRIB7, SRIB6, SRIB5, SRIB4, SRIB3, SRIB2, SRIB1, SRIB0, C8, C7, C6, C5, C4, C3, C2, C1, C0, SOURCEA, OPPRE, CLK3, CLK2, CLK1, CLK0, CE3, CE2, CE1, CE0, RST3, RST2, RST1, RST0

OUTPUT: SROA8, SROA7, SROA6, SROA5, SROA4, SROA3, SROA2, SROA1, SROA0, SROB8, SROB7, SROB6, SROB5, SROB4, SROB3, SROB2, SROB1, SROB0, PO8, PO7, PO6, PO5, PO4, PO3, PO2, PO1, PO0

ATTRIBUTES

The following table describes the attributes for PRADD9A primitive.

Table 810:

Attribute Name	Values	Default Value
REG_INPUTA_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE
REG_INPUTA_CE	CE0, CE1, CE2, CE3	CE0
REG_INPUTA_RST	RST0, RST1, RST2, RST3	RST0
REG_INPUTB_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE
REG_INPUTB_CE	CE0, CE1, CE2, CE3	CE0
REG_INPUTB_RST	RST0, RST1, RST2, RST3	RST0
REG_INPUTC_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE
REG_INPUTC_CE	CE0, CE1, CE2, CE3	CE0
REG_INPUTC_RST	RST0, RST1, RST2, RST3	RST0
REG_OPPRE_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE

Table 810:

Attribute Name	Values	Default Value
REG_OPPRE_CE	CE0, CE1, CE2, CE3	CE0
REG_OPPRE_RST	RST0, RST1, RST2, RST3	RST0
CLK0_DIV	ENABLED, DISABLED	ENABLED
CLK1_DIV	ENABLED, DISABLED	ENABLED
CLK2_DIV	ENABLED, DISABLED	ENABLED
CLK3_DIV	ENABLED, DISABLED	ENABLED
HIGHSPEED_CLK	NONE, CLK0, CLK1, CLK2, CLK3	NONE
GSR	ENABLED, DISABLED	ENABLED
CAS_MATCH_REG	TRUE, FALSE	FALSE
SOURCEA_MODE	A_SHIFT, C_SHIFT, A_C_DYNAMIC, HIGHSPEED	A_SHIFT
SOURCEB_MODE	SHIFT, PARALLEL, INTERNAL	SHIFT
FB_MUX	SHIFT, SHIFT_BYPASS, DISABLED	SHIFT
RESETMODE	SYNC, ASYNC	SYNC
PRADD_LOC	0, 1	0
SYMMETRY_MODE	DIRECT, INTERNAL	DIRECT

PRADD_LOC = 0 indicates left location; 1 indicates the right location

*Symmetry_MODE: DIRECT = MUX_PA0 set to 1. INTERNAL = MUX_PA0 set to 0.

*For 1D FIR Filter operation, Symmetry_Mode will be set to INTERNAL. Left leg of PreAdder will get input from Reg 12 output and the right leg will get input from Reg 13 output.

*For 2D FIR Filter operation, Symmetry_Mode will be set to DIRECT. Left leg of PreAdder will get the direct input from MUIA0 and the right leg of the PreAdder will get MUIA0 delayed by 2 clock cycles (Reg 12 and Reg 13). In this mode, external MUIB0 port will not be used. Also, SOURCEB_MODE must also be set to INTERNAL.

Details of SOURCEA_MODE Attribute

Table 811:

IPExpress Operation	SOURCEA_MODE Attribute	SOURCEA Port	Mc1_pa_mux3	Mc1_pa_mux4
Shift	A_SHIFT	1	00	01
A	A_SHIFT	0	00	00
C	C_SHIFT	0	01	00
A/C Dynamic	A_C_DYNAMIC	Live	10	00
HighspeedAC	HIGHSPEED	0	11	00
Dynamic Shift/A	A_SHIFT	Live	00	10
Dynamic Shift/C	C_SHIFT	Live	01	10

Details of SOURCEB_MODE Attribute

Table 812:

SOURCEB_MODE Attribute	Operation (mc1_pa_b0 mux)
SHIFT	SRIB coming from the adjacent PREADDER on the right
PARALLEL	PB
INTERNAL	Output of Reg. 12

Details of FB_MUX Attribute

Table 813:

FB_MUX Attribute	Operation (MUX_FB0)
SHIFT	Output of Reg. 16
SHIFT_BYPASS	Output of Reg. 15
DISABLED	For placer only (PreAdder on the left side)

Description

The following table describes the I/O ports of the PRADD9A primitive.

Table 814:

Port Name	I/O	Description
CE[3:0]	I	Clock Enable Inputs
CLK[3:0]	I	Clock Inputs
RST[3:0]	I	Reset Inputs

Table 814:

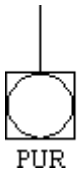
Port Name	I/O	Description
SOURCEA	I	Source Selector for Pre-adder Input A
PA[8:0]	I	Pre-adder Parallel Input A
PB[8:0]	I	Pre-adder Parallel Input B
SRIA[8:0]	I	Pre-adder Shift Input A
SRIB[8:0]	I	Pre-adder Shift Input A, backward direction
C[8:0]	I	Input used for high-speed option
SROA[8:0]	O	Pre-adder Shift Output A
SROB[8:0]	O	Pre-adder Shift Output B
PO[8:0]	O	Pre-adder Addition Output
OPPRE	I	Opcode for PreAdder

PUR

Power Up Set/Reset

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUT: PUR

ATTRIBUTES:

RST_PULSE: integer (default: 1)

Description

PUR is used to reset or set all register elements in your design upon device configuration/startup. The PUR component can be connected to a net from an input buffer or an internally generated net. It is active LOW and when pulsed will set or reset all register bits to the same state as the local set or reset functionality.

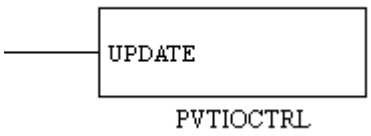
It is not necessary to connect signals for PUR to any register elements explicitly. The function will be implicitly connected globally.

PVTIOCTRL

PVT Monitor Circuit Controller

Architectures Supported:

- LatticeSC/M



INPUT: UPDATE

Description

The PVTIOCTRL primitive is used to generate a signal to control the PVT (Process, Voltage, and Temperature) monitor circuit. When UPDATE is 1, the PVT monitor circuit output will be updated. When UPDATE is 0, the last value of the PVT monitor circuit output is latched in.

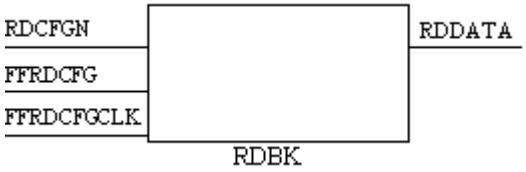
R

RDBK

Readback Controller

Architectures Supported:

- LatticeSC/M



INPUTS: RDCFGN, FFRDCFG, FFRDCFGCLK

OUTPUT: RDDATA

Description

RDBK is used to read back the configuration data and optionally the state of the PFU outputs. RDBK can be done while the FPGA is in normal system operation. To use RDBK, select options in the bit stream generator within the place and route tool.

- You can choose the option to prohibit readback, allow a single readback, or allow unrestricted readback. For more information on RDBK, refer to applicable technical notes or contact technical support.

RDCFGN: A high-to-low transition on this input initiates a readback operation. This pin must remain low during the readback operation.

RDDATA: Readback data is available at this output, which in turn is connected to the same pad as that used by TDO for boundary scan.

Note

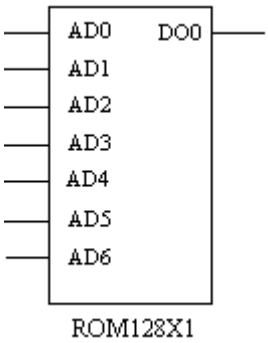
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

ROM128X1

128 Word by 1 Bit Positive Edge Triggered Read-Only Memory with Registered Data Outputs

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- Platform Manager



INPUTS: AD0, AD1, AD2, AD3, AD4, AD5, AD6

OUTPUT: DO0

ATTRIBUTES:

INITVAL: (*Verilog*) 128'hXXX...X (32-bit hex string for LatticeECP2 and LatticeXP2; 32-bit hex value for other devices)
(*VHDL*) 0xXXX...X (32-bit hex string for LatticeECP2 and LatticeXP2; 32-bit hex value for other devices)
Default: all zeros

Description

The ROM128X1 symbol represents a 128 word by1-bit read-only memory. This ROM can be used to implement a ORCALUT7 in a design. The read operation is asynchronous and is always active. The memory is always being read.

The INITVAL=<*value*> attribute is used to initialize the ROM. The <*value*> should consist of 128 one-bit binary or 32 hexadecimal data written into the

ROM from the highest address to the lowest address. For example, if the following attribute is specified:

INITVAL=0x0123456789ABCDEF0123456789ABCDEF (in hex)

or

INITVAL=00000001001000110100010101100111100010011010101111001101111011110000000100100011010001010110011110001001101010111100110111101111 (in binary)

it implies that the above data is loaded sequentially from location 127 to 0 (where location 127 would contain value 0 and location 0 value 1).

Truth Table

Table 815:

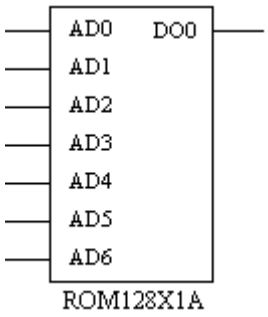
INPUTS	OUTPUTS	OPERATION
AD[5:0]	DO0	
AD[5:0]	MEM[AD[5:0]]	Read MEM[AD[5:0]]

ROM128X1A

128 Word by 1 Bit Positive Edge Triggered Read-Only Memory with Registered Data Outputs

Architectures Supported:

- ECP5
- LatticeECP3
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: AD6, AD5, AD4, AD3, AD2, AD1, AD0

OUTPUT: DO0

ATTRIBUTES:

INITVAL: (*Verilog*) 128'hXXX...X (32-bit hexadecimal value)
(*VHDL*) 0xXXX...X (32-bit hexadecimal value)
Default: all zeros

Description

PFU based distributed 128 Word by 1 Bit ROM primitive. See Memory Primitives Overview for individual port description.

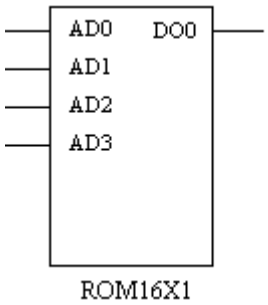
ROM16X1

16 Word by 1 Bit Read-Only Memory

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- Platform Manager



INPUTS: AD0, AD1, AD2, AD3

OUTPUT: DO0

ATTRIBUTES:

INITVAL: (*Verilog*) 16'hXXXX (4-bit hex string for LatticeECP2 and LatticeXP2; 4-bit hex value for other devices)
(*VHDL*) 0xXXXX (4-bit hex string for LatticeECP2 and LatticeXP2; 4-bit hex value for other devices)
Default: all zeros

Description

The ROM16X1 symbol represents a 16 word by 1 bit read-only memory. This ROM can be used to implement a ORCALUT4 in a design. The read operation is asynchronous and is always active. The memory is always being read.

The INITVAL=<*value*> attribute is used to initialize the ROM. The <*value*> should consist of 16 one-bit binary or 4 hexadecimal data written into the ROM from the highest address to the lowest address. For example, if the following attribute is specified:

INITVAL=0xF30A (in hex)

or

INITVAL=1111001100001010 (in binary)

it implies that the above data is loaded sequentially from location 15 to 0 (where location 15 would contain value 1 and location 0 value 0).

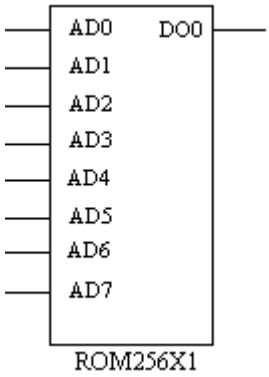
ROM256X1

256 Word by 1 Bit Positive Edge Triggered Read-Only Memory with Registered Data Outputs

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- Platform Manager



INPUTS: AD0, AD1, AD2, AD3, AD4, AD5, AD6, AD7

OUTPUT: DO0

ATTRIBUTES:

INITVAL: (*Verilog*) 256'hXXX...X (64-bit hex string for LatticeECP2 and LatticeXP2; 64-bit hex value for other devices)
(*VHDL*) 0xXXX...X (64-bit hex string for LatticeECP2 and LatticeXP2; 64-bit hex value for other devices)
Default: all zeros

Description

The ROM256X1 symbol represents a 256 word by1-bit read-only memory. This ROM can be used to implement a ORCALUT8 in a design. The read operation is asynchronous and is always active. The memory is always being read.

The INITVAL=<*value*> attribute is used to initialize the ROM. The <*value*> should consist of 256 one-bit binary or 64 hexadecimal data written into the ROM from the highest address to the lowest address. For example, if the following attribute is specified:

INITVAL=0x0123456789ABCDEF0123456789ABCDEF0123456789ABCDEF 0123456789ABCDEF (in hex)

or

INITVAL=0000000100100011010001010110011111000100110101010111100110 1111011110000000100100011010001010110011111000100110101011110011 0111101111000000010010001101000101011001111000100110101011110011 1011110111100000001001000110100010101100111100010011010101111001 101111011110000000100100011010001010110011111000100110101011110011 0110111101111 (in binary)

it implies that the above data is loaded sequentially from location 255 to 0 (where location 255 would contain value 0 and location 0 value 1).

Truth Table

Table 817:

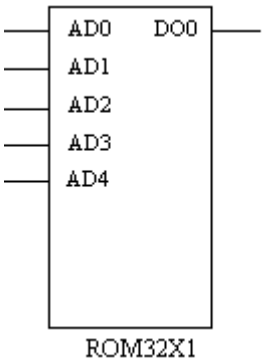
ROM32X1

32 Word by 1 Bit Read-Only Memory

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- Platform Manager



INPUTS: AD0, AD1, AD2, AD3, AD4

OUTPUT: DO0

ATTRIBUTES:

INITVAL: (*Verilog*) 32'hXXXXXXXX (8-bit hex string for LatticeECP2 and LatticeXP2; 8-bit hex value for other devices)
(*VHDL*) 0xXXXXXXXX (8-bit hex string for LatticeECP2 and LatticeXP2; 8-bit hex value for other devices)
Default: all zeros

Description

The ROM32X1 symbol represents a 32 word by 1 bit read-only memory. This ROM can be used to implement a ORCALUT5 in a design. The read operation is asynchronous and is always active. The memory is always being read.

The INITVAL=<*value*> attribute is used to initialize the ROM. The <*value*> should consist of 32 one-bit binary or 8 hexadecimal data written into the ROM from the highest address to the lowest address. For example, if the following attribute is specified:

INITVAL=0xF30A1234 (in hex)

or

INITVAL=11110011000010100001001000110100 (in binary)

it implies that the above data is loaded sequentially from location 31 to 0 (where location 31 would contain value 1 and location 0 value 0).

Truth Table

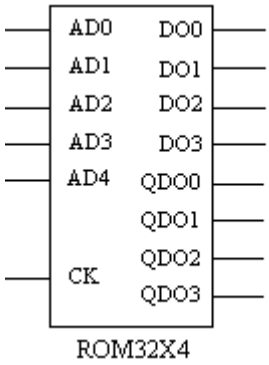
ROM32X4

32 Word by 4 Bit Positive Edge Triggered Read-Only Memory with Registered Data Outputs

Architectures Supported:

- LatticeSC/M



INPUTS: AD0, AD1, AD2, AD3, AD4, CK

OUTPUTS: DO0, DO1, DO2, DO3, QDO0, QDO1, QDO2, QDO3

ATTRIBUTES:

INITVAL: (*Verilog*) 128'hXXX...X (32-bit hexadecimal value)
(*VHDL*) 0xXXX...X (32-bit hexadecimal value)
Default: all zeros

Description

The ROM32X4 symbol represents a 32 word by 4 bit read-only memory. The read operation is asynchronous and is always active. The memory is always being read.

This ROM also has registered data outputs (QDO[0:3]), which are registered on the rising edge of the clock.

The INITVAL=<*value*> attribute is used to initialize the ROM. The <*value*> should consist of 32 four-bit binary or 32 hexadecimal data written into the ROM from the highest address to the lowest address. For example, if the following attribute is specified:

INITVAL=0x0123456789ABCDEF0123456789ABCDEF (in hex)

or

INITVAL=00000001001000110100010101100111100010011010101111001101111101111000000010010001101000101011001111000100110101011110011101111101111 (in binary)

it implies that the above data is loaded sequentially from location 127 to 0 (where location 127 would contain value 0 and location 0 value 1).

Truth Table

Table 819:

INPUTS		OUTPUTS		OPERATION

X = Don’t care

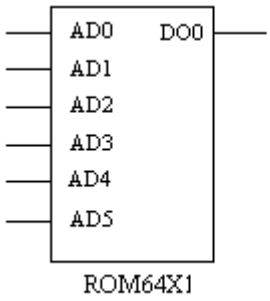
When GSR=0, QDO[3:0]=0

ROM64X1

64 Word by 1 Bit Positive Edge Triggered Read-Only Memory with Registered Data Outputs

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeSC/M
- LatticeXP
- LatticeXP2
- MachXO
- Platform Manager



INPUTS: AD0, AD1, AD2, AD3, AD4, AD5

OUTPUT: DO0

ATTRIBUTES:

INITVAL: (*Verilog*) 64'hXXXXXXXXXXXXXXXX (16-bit hex string for LatticeECP2 and LatticeXP2; 16-bit hex value for other devices)
(*VHDL*) 0xXXXXXXXXXXXXXXXX (16-bit hex string for LatticeECP2 and LatticeXP2; 16-bit hex value for other devices)
Default: all zeros

Description

The ROM64X1 symbol represents a 64 word by 1-bit read-only memory. This ROM can be used to implement a ORCALUT6 in a design. The read operation is asynchronous and is always active. The memory is always being read.

The INITVAL=<*value*> attribute is used to initialize the ROM. The <*value*> should consist of 64 one-bit binary or 16 hexadecimal data written into the ROM from the highest address to the lowest address. For example, if the following attribute is specified:

INITVAL=0x0123456789ABCDEF (in hex)

or

INITVAL=0000000100100011010001010110011110001001101010111100110111101111 (in binary)

it implies that the above data is loaded sequentially from location 63 to 0 (where location 63 would contain value 0 and location 0 value 1).

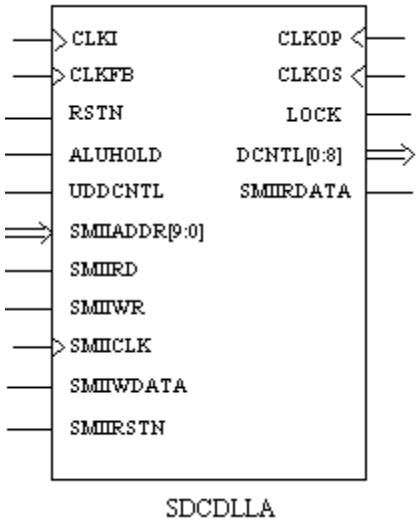
S

SDCDLLA

Single Delay Cell DLL

Architectures Supported:

- LatticeSC/M



INPUTS: CLKI, CLKFB, RSTN, ALUHOLD, UDDCNTL, SMIADDR9, SMIADDR8, SMIADDR7, SMIADDR6, SMIADDR5, SMIADDR4, SMIADDR3, SMIADDR2, SMIADDR1, SMIADDR0, SMIRD, SMIWR, SMICLK, SMIWDATA, SMIRSTN

OUTPUTS: CLKOP, CLKOS, LOCK, DCNTL0, DCNTL1, DCNTL2, DCNTL3, DCNTL4, DCNTL5, DCNTL6, DCNTL7, DCNTL8, SMIRDATA

ATTRIBUTES:

CLKOS_FPHASE: 0 (default), 11, 22, 45

CLKI_DIV: 1 (default), 2, 4

CLKOS_DIV: 1 (default), 2, 4

GSR: "DISABLED" (default), "ENABLED"

CLKOS_FDEL_ADJ: "DISABLED" (default), "ENABLED'

ALU_LOCK_CNT: integers 3~15 (default: 3)

ALU_UNLOCK_CNT: integers 3~15 (default: 3)

GLITCH_TOLERANCE: integers 0~7 (default: 0)

DCNTL_ADJVAL: integers -127~127 (default: 0)

ALU_INIT_CNTVAL: 0, 4, 8, 12, 16, 32, 48, 64, 72 (default: 0)

LOCK_DELAY: integers 0~1000 (in ns) (default: 100)

SMI_OFFSET: 0x400~0x7FF (default: 12'h410)

MODULE_TYPE: "SDCDLLA"

IP_TYPE: "SDCDLLA"

Description

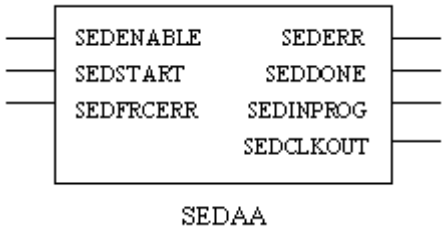
The single delay cell corrects for clock injection and enables the 9-bit ALU output. The primitive features a single clock output, lock achieved starting from minimum delay, output control bits, and allows +/- delay on output control bits. Its requirements are a maximum frequency of 700 MHz and a minimum frequency of 300 MHz.

SEDAA

SED (Soft Error Detect) Basic

Architectures Supported:

- LatticeECP2/M



INPUTS: SEDENABLE, SEDSTART, SEDFRCERR

OUTPUTS: SEDERR, SEDDONE, SEDINPROG, SEDCLKOUT

ATTRIBUTES:

OSC_DIV: 1 (default), 2, 4, 8, 16, 32, 64, 128, 256

CHECKALWAYS: "DISABLED" (default), "ENABLED"

MCCLK_FREQ: "2.5" (default), "4.3", "5.4", "6.9", "8.1", "9.2", "10.0", "13", "15", "20", "26", "30", "34", "41", "45", "55", "60", "130"

DEV_DENSITY: (ECP2) "35K" (default), "6K", "12K", "20K", "50K", "70K"

DEV_DENSITY: (ECP2M) "M35K" (default), "M20K", "M50K", "M70K", "M100K"

ENCRYPTION: "OFF" (default), "ON"

Description

SEDAA is the basic SED primitive for LatticeECP2 devices. Soft errors occur when high-energy charged particles alter the stored charge in a memory cell in an electronic circuit. There are customer selectable software features in Lattice Diamond to support Soft Error Detect (SED) IP features. This is only applicable to devices that support SED in their architecture.

This primitive should be instantiated in the user's source code in VHDL or Verilog.

See the following table for port definition.

Table 821:

Port Name	I/O	Description
SEDSTART	I	Error detection start (sampled at positive clock edge).
SEDENABLE	I	SED enable (a Low clears the SED).
SEDFRCERR	I	Force an SED error flag (e.g. for testing), active high.
SEDINPROG	O	SED cycle is in progress, asserts high.
SEDDONE	O	SED cycle is complete, asserts high.
SEDERR	O	SED error flag, asserts high.
SEDCLKOUT	O	Optional clock output.

You can refer to the following technical note on the Lattice web site for more information and usage.

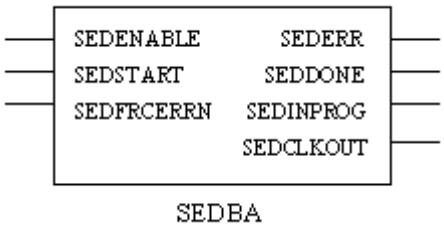
- TN1113 - LatticeECP2/M Soft Error Detection (SED) Usage Guide

SEDBA

Basic SED (Soft Error Detect)

Architectures Supported:

- LatticeXP2



INPUTS: SEDENABLE, SEDSTART, SEDFRCERRN

OUTPUTS: SEDERR, SEDDONE, SEDINPROG, SEDCLKOUT

ATTRIBUTES:

OSC_DIV: 1 (default), 2, 4, 8, 16, 32, 64, 128, 256

CHECKALWAYS: "DISABLED" (default), "ENABLED"

MCCLK_FREQ: "3.1" (default), "2.5", "4.3", "5.4", "6.9", "8.1", "9.2", "10.0", "13", "15", "26", "32", "40", "54"

DEV_DENSITY: "17K" (default), "5K", "8K", "30K", "40K"

BOOT_OPTION: "INTERNAL" (default), "EXTERNAL"

Description

SEDBA is the basic soft error detect (SED) primitive for LatticeXP2 devices. Soft errors occur when high-energy charged particles alter the stored charge in a memory cell in an electronic circuit. There are customer selectable software features in Lattice Diamond to support SED IP features. This is only applicable to devices that support SED in their architecture. LatticeXP2devices have built-in SED circuitry to detect soft errors.

The SED primitive should be instantiated in user's VHDL or Verilog source code. There are two types of LatticeXP2 modules: Basic SED (SEDBA) and One Shot SED (SEDBB).

See the following table for port description

Table 822:

Port Name	I/O	Description
SEDSTART	I	Error detection start (sampled at positive clock edge).
SEDENABLE	I	SED enable (a Low clears the SED).
SEDFRCERRN	I	Force an SED error flag (e.g. for testing), active low.
SEDINPROG	O	SED cycle is in progress, asserts high.
SEDDONE	O	SED cycle is complete, asserts high.

Table 822:

Port Name	I/O	Description
SEDERR	O	SED error flag, asserts high.
SEDCLKOUT	O	Optional clock output.

You can refer to the following technical note on the Lattice web site for more information and usage.

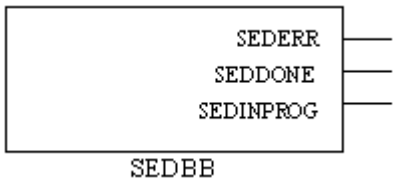
- TN1130 - LatticeXP2 Soft Error Detection (SED) Usage Guide

SEDBB

One Shot SED (Soft Error Detect)

Architectures Supported:

- LatticeXP2



OUTPUTS: SEDERR, SEDDONE, SEDINPROG

Description

SEDBB is the one shot soft error detect (SED) primitive for LatticeXP2 devices. Soft errors occur when high-energy charged particles alter the stored charge in a memory cell in an electronic circuit. There are customer selectable software features in Lattice Diamond to support SED IP features. This is only applicable to devices that support SED in their architecture. LatticeXP2 devices have built-in SED circuitry to detect soft errors.

The SED primitive should be instantiated in user's VHDL or Verilog source code. There are two types of LatticeXP2 modules: Basic SED (SEDBA) and One Shot SED (SEDBB).

See the following table for port description.

Table 823:

Port Name	I/O	Description
SEDINPROG	O	SED cycle is in progress, asserts high.
SEDDONE	O	SED cycle is complete, asserts high.
SEDERR	O	SED error flag, asserts high.

You can refer to the following technical note on the Lattice web site for more information and usage.

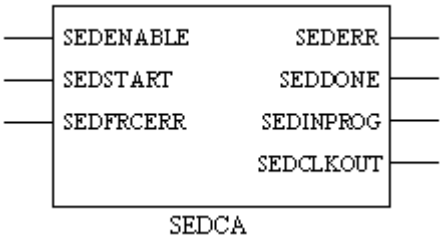
- TN1130 - LatticeXP2 Soft Error Detection (SED) Usage Guide

SEDCA

Basic SED (Soft Error Detect)

Architectures Supported:

- LatticeECP3



INPUTS: SEDENABLE, SEDSTART, SEDFRCERR

OUTPUTS: SEDERR, SEDDONE, SEDINPROG, SEDCLKOUT

ATTRIBUTES:

OSC_DIV: 1 (default), 2, 4, 8, 16, 32, 64, 128, 256

CHECKALWAYS: "DISABLED" (default), "ENABLED"

MCCLK_FREQ: "2.5" (default), "4.3", "5.4", "6.9", "8.1", "9.2", "10.0", "13", "15", "20", "26", "30", "34", "41", "45", "55", "60", "130"

DEV_DENSITY: "95K" (default)

Description

SEDCA is the basic Soft Error Detect primitive. Basic SED runs on all bits only. It checks the CRC for all the bitstreams that include both “Care” and “Don’t Care” bits.

See the following table for port definition.

Table 824:

Port Name	I/O	Description
SEDENABLE	I	SED enable (a Low clears the SED).
SEDSTART	I	Error detection start (sampled at positive clock edge).

Table 824:

Port Name	I/O	Description
SEDFRCERR	I	Force an SED error flag (e.g. for testing), active high.
SEDINPROG	O	SED cycle is in progress, asserts High.
SEDDONE	O	SED cycle is complete, asserts High.
SEDERR	O	SED error flag, asserts High.
SEDCLKOUT	O	Optional clock output.

You can refer to the following technical note on the Lattice web site for more information and usage.

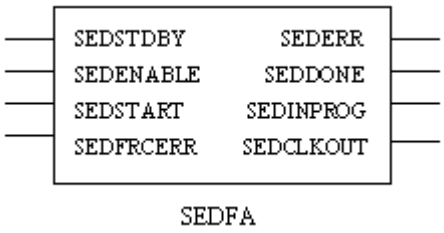
- TN1184 - LatticeECP3 Soft Error Detection (SED) Usage Guide

SEDFA

Soft Error Detect in Basic Mode

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: SEDSTDBY, SEDENABLE, SEDSTART, SEDFRCERR

OUTPUTS: SEDERR, SEDDONE, SEDINPROG, SEDCLKOUT

ATTRIBUTES:

SED_CLK_FREQ: "2.08", "2.15", "2.22", "2.29", "2.38", "2.46", "2.56", "2.66", "2.77", "2.89", "3.02", "3.17", "3.33", "3.5" (default), "3.69", "3.91", "4.16", "4.29", "4.43", "4.59", "4.75", "4.93", "5.12", "5.32", "5.54", "5.78", "6.05", "6.33", "6.65", "7", "7.39", "7.82", "8.31", "8.58", "8.87", "9.17", "9.5", "9.85", "10.23", "10.64", "11.08", "11.57", "12.09", "12.67", "13.3", "14", "14.78", "15.65", "16.63", "17.73", "19", "20.46", "22.17", "24.18", "26.6", "29.56", "33.25", "38", "44.33", "53.2", "66.5", "88.67", "133"

CHECKALWAYS: "DISABLED" (default), "ENABLED"

DEV_DENSITY:

MachXO2: "256L", "640L", "1200L", "2000L", "4000L", "7000L", "10000L", "640U", "1200U", "2000U", "4000U"

MachXO3D: "4300L", "9400L"

MachXO3L: "640L_121P", "1300L", "2100L", "4300L", "1300L_256P", "2100L_324P", "4300L_400P", "6900L"

Description

The Soft-Error Detect (SED) circuitry provides a method for the device to check its configuration data for soft-errors. SEDFA is used for SED basic mode.

See the following table for port description.

Table 825:

Port Name	I/O	Description
SEDSTDBY	I	SED standby.
SEDENABLE	I	SED enable (a Low clears the SED).
SEDSTART	I	Error detection start (sampled at positive clock edge).
SEDFRCERR	I	Force an SED error flag (e.g. for testing), active high.
SEDINPROG	O	SED cycle is in progress, asserts High.
SEDDONE	O	SED cycle is complete, asserts High.
SEDERR	O	SED error flag, asserts High.
SEDCLKOUT	O	Optional clock output.

You can refer to the following technical note on the Lattice web site for more information and usage.

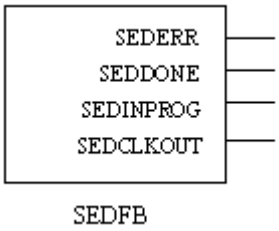
- TN1206 - MachXO2 Soft Error Detection (SED) Usage Guide

SEDFB

Soft Error Detect in One Shot Mode

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



OUTPUTS: SEDERR, SEDDONE, SEDINPROG, SEDCLKOUT

Description

The Soft-Error Detect (SED) circuitry provides a method for the device to check its configuration data for soft-errors. SEDFB is used for One Shot SED mode.

See the following table for port description.

Table 826:

Port Name	I/O	Description
SEDINPROG	O	SED cycle is in progress, asserts High.
SEDDONE	O	SED cycle is complete, asserts High.
SEDERR	O	SED error flag, asserts High.
SEDCLKOUT	O	Optional clock output.

You can refer to the following technical note on the Lattice web site for more information and usage.

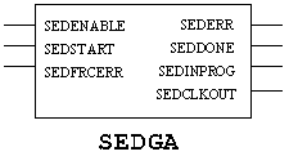
- TN1206 - MachXO2 Soft Error Detection (SED) Usage Guide

SEDGA

Soft Error Detect

Architectures Supported:

- ECP5



INPUTS: SEDENABLE, SEDSTART, SEDFRCERR

OUTPUTS: SEDERR, SEDDONE, SEDINPROG, SEDCLKOUT

Description

The Soft-Error Detect (SED) circuitry provides a method for the device to check its configuration data for soft-errors.

See the following table for port description.

Table 827:

Port Name	I/O	Description
SEDENABLE	I	SED enable (a Low clears the SED).
SEDSTART	I	Error detection start (sampled at positive clock edge).
SEDFRCERR	I	Force an SED error flag (e.g. for testing), active high.
SEDINPROG	O	SED cycle is in progress, asserts High.
SEDDONE	O	SED cycle is complete, asserts High.
SEDERR	O	SED error flag, asserts High.
SEDCLKOUT	O	Optional clock output.

You can refer to the following technical note on the Lattice web site for more information and usage.

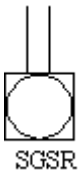
- TN1268 - ECP5 Soft Error Detection (SED) Usage Guide

SGSR

Synchronous Release Global Set/Reset Interface

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: GSR, CLK

Description

SGSR is used to reset or set all register elements in your design. The SGSR component can be connected to a net from an input buffer or an internally generated net. It is active LOW and when pulsed will set or reset all flip-flops, latches, registers, and counters to the same state as the local set or reset functionality. When input GSR is HIGH, the global signal is released at the positive edge of the clock (CLK).

It is not necessary to connect signals for SGSR to any register elements explicitly. The function will be implicitly connected globally. The functionality of the SGSR for sequential cells without a local set or reset are described in the appropriate library help page.

Note

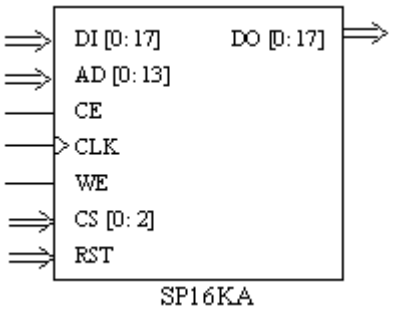
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

SP16KA

16K Single Port Block RAM

Architectures Supported:

- LatticeSC/M



INPUTS: DI0, DI1, DI2, DI3, DI4, DI5, DI6, DI7, DI8, DI9, DI10, DI11, DI12, DI13, DI14, DI15, DI16, DI17, AD0, AD1, AD2, AD3, AD4, AD5, AD6, AD7, AD8, AD9, AD10, AD11, AD12, AD13, CE, CLK, WE, CS0, CS1, CS2, RST

OUTPUTS: DO0, DO1, DO2, DO3, DO4, DO5, DO6, DO7, DO8, DO9, DO10, DO11, DO12, DO13, DO14, DO15, DO16, DO17

ATTRIBUTES:

DATA_WIDTH: 1, 2, 4, 9, 18 (default)

REGMODE: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE: any 3-bit binary value (default: 3'b000)

WRITEMODE: "NORMAL" (default), "WRITETHROUGH"

GSR: "DISABLED" (default), "ENABLED"

INITVAL_00 to INITVAL_3F: (*Verilog*) 320'hXXX...X (80-bit hexadecimal value)
(*VHDL*) 0xXXX...X (80-bit hexadecimal value)
Default: all zeros

Description

You can refer to the following technical note on the Lattice web site for EBR port definition, attribute definition and usage.

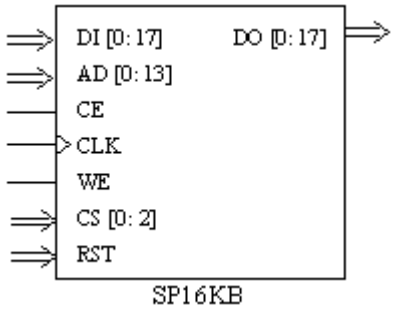
- TN1094 - On-Chip Memory Usage Guide for LatticeSC Devices

SP16KB

Single Port Block RAM

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



INPUTS: DI0, DI1, DI2, DI3, DI4, DI5, DI6, DI7, DI8, DI9, DI10, DI11, DI12, DI13, DI14, DI15, DI16, DI17, AD0, AD1, AD2, AD3, AD4, AD5, AD6, AD7, AD8, AD9, AD10, AD11, AD12, AD13, CE, CLK, WE, CS0, CS1, CS2, RST

OUTPUTS: DO0, DO1, DO2, DO3, DO4, DO5, DO6, DO7, DO8, DO9, DO10, DO11, DO12, DO13, DO14, DO15, DO16, DO17

ATTRIBUTES:

DATA_WIDTH:1, 2, 4, 9, 18 (default)

REGMODE: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE: any 3-bit binary value (default: 0b000)

WRITEMODE: "NORMAL" (default), "WRITETHROUGH"

GSR: "DISABLED" (default), "ENABLED"

INITVAL_00 to INITVAL_3F: "0xXXX...X" (80-bit hex string) (default: all zeros)

Description

Single Port Block RAM primitive. See Memory Primitives Overview for more information.

You can also refer to the following technical notes on the Lattice web site for port definition, attributes and usage.

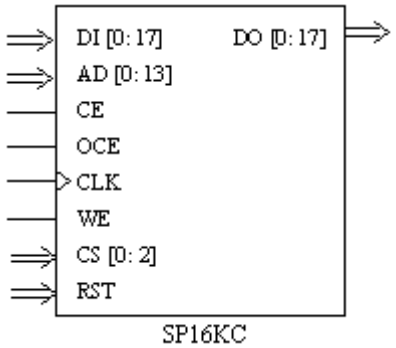
- TN1104 - LatticeECP2/M Memory Usage Guide
- TN1137 - LatticeXP2 Memory Usage Guide

SP16KC

Single Port Block RAM

Architectures Supported:

- LatticeECP3



INPUTS: DI17, DI16, DI15, DI14, DI13, DI12, DI11, DI10, DI9, DI8, DI7, DI6, DI5, DI4, DI3, DI2, DI1, DI0, AD13, AD12, AD11, AD10, AD9, AD8, AD7, AD6, AD5, AD4, AD3, AD2, AD1, AD0, CE, OCE, CLK, WE, CS2, CS1, CS0, RST

OUTPUTS: DO17, DO16, DO15, DO14, DO13, DO12, DO11, DO10, DO9, DO8, DO7, DO6, DO5, DO4, DO3, DO2, DO1, DO0

ATTRIBUTES:

DATA_WIDTH: 1, 2, 4, 9, 18 (default)

REGMODE: "NOREG" (default), "OUTREG"

CSDECODE: any 3-bit binary string (default: "0b000")

WRITEMODE: "NORMAL" (default), "WRITETHROUGH"

GSR: "DISABLED" (default), "ENABLED"

INITVAL_00 to INITVAL_3F: "0xXXX...X" (80-bit hex string) (default: all zeros)

Description

You can refer to the following technical note on the Lattice web site for EBR port definition, attribute definition and usage.

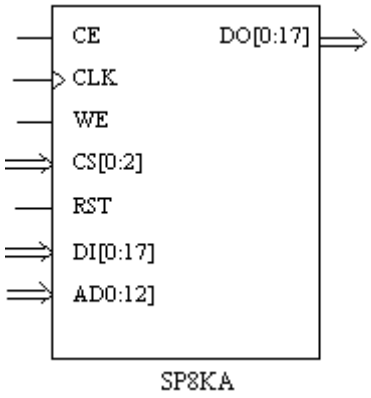
- TN1179 - LatticeECP3 Memory Usage Guide

SP8KA

8K Single Port Block RAM

Architectures Supported:

- LatticeECP/EC
- LatticeXP



INPUTS: CE, CLK, WE, CS0, CS1, CS2, RST, DI0, DI1, DI2, DI3, DI4, DI5, DI6, DI7, DI8, DI9, DI10, DI11, DI12, DI13, DI14, DI15, DI16, DI17, AD0, AD1, AD2, AD3, AD4, AD5, AD6, AD7, AD8, AD9, AD10, AD11, AD12

OUTPUTS: DO0, DO1, DO2, DO3, DO4, DO5, DO6, DO7, DO8, DO9, DO10, DO11, DO12, DO13, DO14, DO15, DO16, DO17

ATTRIBUTES:

REGMODE: "NOREG" (default), "OUTREG"

GSR: "DISABLED" (default), "ENABLED"

WRITEMODE: "NORMAL" (default), "WRITETHROUGH"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE: any 3-bit binary value (default: 111)

DATA_WIDTH: 1, 2, 4, 9, 18 (default)

INITVAL_00 to INITVAL_1F: (*Verilog*) 320'hXXX...X (80-bit hexadecimal value)
(*VHDL*) 0xXXX...X (80-bit hexadecimal value)
Default: all zeros

Description

You can refer to the following technical note on the Lattice web site for EBR port definition, attribute definition and usage.

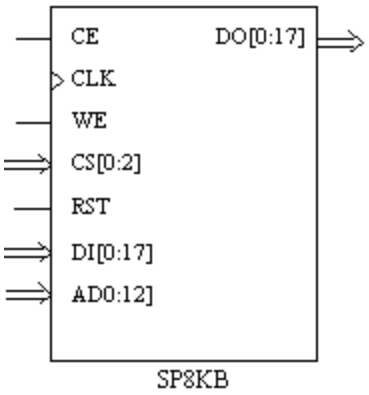
- TN1051 - Memory Usage Guide for LatticeECP/EC and LatticeXP Devices

SP8KB

8K Single Port Block RAM

Architectures Supported:

- MachXO
- Platform Manager



INPUTS: CE, CLK, WE, CS0, CS1, CS2, RST, DI0, DI1, DI2, DI3, DI4, DI5, DI6, DI7, DI8, DI9, DI10, DI11, DI12, DI13, DI14, DI15, DI16, DI17, AD0, AD1, AD2, AD3, AD4, AD5, AD6, AD7, AD8, AD9, AD10, AD11, AD12

OUTPUTS: DO0, DO1, DO2, DO3, DO4, DO5, DO6, DO7, DO8, DO9, DO10, DO11, DO12, DO13, DO14, DO15, DO16, DO17

ATTRIBUTES:

DATA_WIDTH: 1, 2, 4, 9, 18 (default)

REGMODE: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE: any 3-bit binary value (default: 3’b000)

WRITEMODE: "NORMAL" (default), "WRITETHROUGH"

GSR: "DISABLED" (default), "ENABLED"

INITVAL_00 to INITVAL_1F: (*Verilog*) "320'hXXX...X" (80-bit hex string)
(*VHDL*) "0xXXX...X" (80-bit hex string)
Default: all zeros

Description

8K Single Port Block RAM primitive. See Memory Primitives Overview for more information.

You can also refer to the following technical note on the Lattice web site for port definition, attributes and usage.

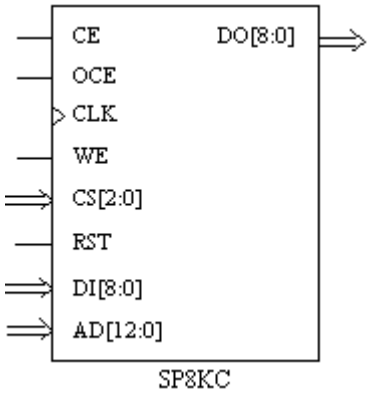
- TN1092 - MachXO Memory Usage Guide

SP8KC

8K Single Port Block RAM

Architectures Supported:

- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: CE, OCE, CLK, WE, CS0, CS1, CS2, RST, DI0, DI1, DI2, DI3, DI4, DI5, DI6, DI7, DI8, DI9, DI10, DI11, DI12, DI13, DI14, DI15, DI16, DI17, AD0, AD1, AD2, AD3, AD4, AD5, AD6, AD7, AD8, AD9, AD10, AD11, AD12

OUTPUTS: DO0, DO1, DO2, DO3, DO4, DO5, DO6, DO7, DO8, DO9, DO10, DO11, DO12, DO13, DO14, DO15, DO16, DO17

ATTRIBUTES:

DATA_WIDTH: 1, 2, 4, 9 (default)

REGMODE: "NOREG" (default), "OUTREG"

RESETMODE: "SYNC" (default), "ASYNC"

CSDECODE: any 3-bit binary value (default: all zeros)

WRITEMODE: "NORMAL" (default), "WRITETHROUGH", "READBEFOREWRITE"

GSR: "ENABLED" (default), "DISABLED"

INIT_DATA: "STATIC" (default), "DYNAMIC"

INITVAL_00 to INITVAL_1F: (*Verilog*) "320'hXXX...X" (80-bit hex string)
(*VHDL*) "0xXXX...X" (80-bit hex string)
Default: all zeros

Description

8K Single Port Block RAM primitive. See the below table for I/O port description.

Table 828:

Port Name	I/O	Definition
CLK	I	Clock
CE	I	Clock enable
OCE	I	Output clock enable
AD[12:0]	I	Address bus
DI[8:0]	I	Input data
WE	I	Write enable
CS[2:0]	I	Chip select
RST	I	Reset
DO[8:0]	O	Output data

You can also refer to the following technical note on the Lattice web site for port definition, attributes and usage.

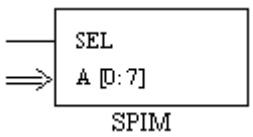
- TN1201 - Memory Usage Guide for MachXO2 Devices

SPIM

SPIM Primitive Distributed RAM

Architectures Supported:

- LatticeECP2/M
- LatticeECP3



INPUTS: SEL, A0, A1, A2, A3, A4, A5, A6, A7

Description

Some devices have a built-in SPI CIB interface that is embedded into the hardware. The SPI CIB interface allows the user to control the dual-boot flash support based on the user's logic. Users can interface with this hardwired SPI controller through the use of the SPIM primitive. The SPIM primitive have 9 input ports only. The SEL line indicates which SPI Flash device to boot from and the signals [A0..A7] indicate the address from where the device will reboot during reconfiguration.

For further information on SPIm Mode, refer to the following technical notes on the Lattice web site:

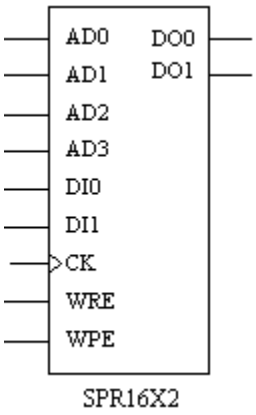
- TN1169 - LatticeECP3 sysCONFIG Usage Guide
- TN1108 - LatticeECP2/M sysCONFIG Usage Guide

SPR16X2

Distributed Single Port RAM

Architectures Supported:

- LatticeSC/M



INPUTS: AD0, AD1, AD2, AD3, DI0, DI1, CK, WRE, WPE

OUTPUTS: DO0, DO1

ATTRIBUTES:

INITVAL: (*Verilog*) 64'hXXXXXXXXXXXXXXXX (16-bit hexadecimal value)
(*VHDL*) 0xXXXXXXXXXXXXXXXX (16-bit hexadecimal value)
Default: all zeros

GSR: "ENABLED" (default), "DISABLED"

Description

The SPR16X2 symbol represents a 16 word by 2 bit asynchronous single port RAM. It has two data inputs DI[1:0], a positive Write Enable (WRE), one positive Write Port Enables (WPE), and one set of address inputs.

The WRE and WPE must be HIGH for the rising clock edge if the write to the RAM is occurring on the falling edge. The data is written into the locations specified by the write address lines AD[3:0] on the next negative clock (CK) edge. The data read operation is always performed asynchronously, with the memory contents specified by the address inputs AD[3:0] output on the data output signals DO[1:0].

In other words, the read operation is asynchronous and is always active. The write operation is synchronous and only occurs when there is a falling edge of the clock and the write enables are high prior to that falling edge.

If desired, the contents of the SPR16X2 can be assigned an initial value, which is loaded into the RAM during configuration. The INITVAL=<*value*> attribute is used to assign the initial value. The <*value*> should consist of 16 hexadecimal data written into the RAM from the highest address to the lowest address. For example, if the following attribute is specified:

INITVAL=0x0123012301230123 (in hex)

it implies that the above data is loaded sequentially from location FH to 0H (where FH would contain the 0 and 0H the 3). If no INITVAL attribute is specified, the RAM is initialized with zeros on configuration.

If the INITVAL is specified as a hex string of 16 values, the values should not be greater than 3, since 3 is setting both memory locations to 1. If a value greater than 3 is used for synthesis or mapping, only the last two (least significant) bits are used for initialization by the mapper.For example,

INITVAL=0x00000000ffffffff

is equivalent to

INITVAL=0x0000000033333333

for mapping purposes, since the first two bits of the "f" are ignored.

You can refer to the following technical note on the Lattice web site for more information and usage.

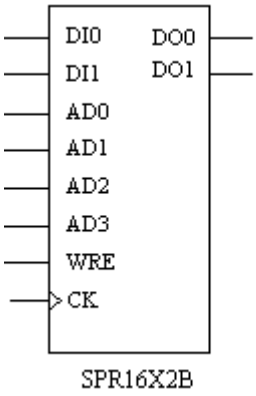
- TN1094 - On-Chip Memory Usage Guide for LatticeSC Devices

SPR16X2B

16 Word by 2 Bit Positive Edge Triggered Write Synchronous Single Port RAM Memory with Positive Write Enable and Positive Write Port Enable (1-Slice)

Architectures Supported:

- LatticeECP/EC
- LatticeXP
- MachXO
- Platform Manager



INPUTS: DI0, DI1, AD0, AD1, AD2, AD3, WRE, CK

OUTPUTS: DO0, DO1

Description

Refer to SPR16X2 for functionality. You can also refer to the following technical notes on the Lattice web site for EBR port definition, attribute definition, and use.

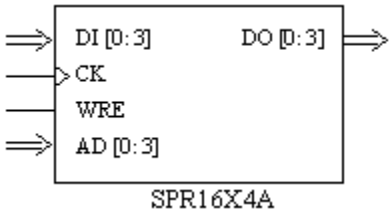
- TN1051 - Memory Usage Guide for LatticeECP/EC and LatticeXP Devices
- TN1092 - MachXO Memory Usage Guide

SPR16X4A

Distributed Single Port RAM

Architectures Supported:

- LatticeECP2/M
- LatticeXP2



INPUTS: DI0, DI1, DI2, DI3, AD0, AD1, AD2, AD3, CK, WRE

OUTPUTS: DO0, DO1, DO2, DO3

Description

PFU based distributed pseudo single port RAM primitive. See Memory Primitives Overview for more information.

You can also refer to the following technical notes on the Lattice web site for port definition, attributes, and use.

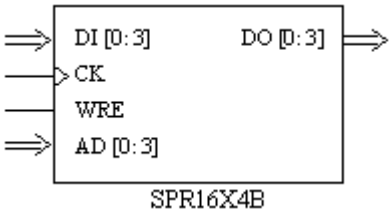
- TN1104 - LatticeECP2/M Memory Usage Guide
- TN1137 - LatticeXP2 Memory Usage Guide

SPR16X4B

Distributed Single Port RAM

Architectures Supported:

- LatticeXP2



INPUTS: DI0, DI1, DI2, DI3, AD0, AD1, AD2, AD3, CK, WRE

OUTPUTS: DO0, DO1, DO2, DO3

ATTRIBUTES:

INITVAL: (*Verilog*) "64'hXXXXXXXXXXXXXXXX" (16-bit hex string)
(*VHDL*) "0xXXXXXXXXXXXXXXXX" (16-bit hex string)
Default: all zeros

Description

PFU based distributed pseudo single port RAM primitive. See Memory Primitives Overview for more information.

You can also refer to the following technical note on the Lattice web site for port definition, attributes, and use.

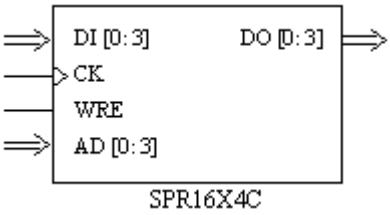
- TN1137 - LatticeXP2 Memory Usage Guide

SPR16X4C

Distributed Single Port RAM

Architectures Supported:

- ECP5
- LatticeECP3
- LIFMD
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUTS: DI3, DI2, DI1, DI0, AD3, AD2, AD1, AD0, CK, WRE

OUTPUTS: DO3, DO2, DO1, DO0

ATTRIBUTES:

INITVAL: "0xXXXXXXXXXXXXXXXX" (16-bit hex string) (default: all zeros)

Description

PFU based distributed Single Port RAM primitive. See Memory Primitives Overview for individual port description.

You can also refer to the following technical notes on the Lattice web site for port definition, attribute definition, and use.

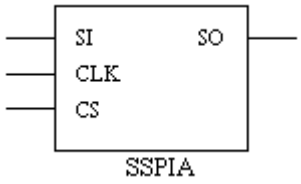
- TN1201 - Memory Usage Guide for MachXO2 Devices
- TN1179 - LatticeECP3 Memory Usage Guide

SSPIA

SSPI TAG Memory

Architectures Supported:

- LatticeXP2



INPUTS: SI, CLK, CS

OUTPUT: SO

ATTRIBUTES:

TAG_INITSIZE: 448, 632, 768, 2184 (default), 2488, 2640, 3384, 3608

TAG_INITIALIZATION: "DISABLED" (default), "ENABLED"

TAG_INITVAL_00 to TAG_INITVAL_0C: "0xXXX...X" (80-bit hex string) (default: all zeros)

Description

Implements the dedicated “TAG Memory” block, which is a one page FLASH non-volatile memory accessible by the hardwired Serial Peripheral Interface port or the JTAG port. This stand-alone TAG memory is ideal for scratch pad memory for mission critical data, board serialization, board revision log and programmed pattern identification.

The LatticeXP2 family of devices provides dedicated TAG memory ranging from 632 to 3384 bits depending on device density. The user can read and write to the TAG memory either through the SPI port (External Slave SPI) or the CIB interface (Internal Slave SPI) by setting the SLAVE_SPI_PORT attribute. The software default for access to the Tag memory is the CIB interface. The TAG memory initialization file format is similar to that of EBR.

- The TAG interface through the SPI port (External Slave SPI): When the TAG interface is set for the SPI port, four SPI pins will be reserved for the TAG access through the SPI port.
- The TAG interface through the CIB interface (Internal Slave SPI): When the TAG interface is set for the CIB interface, the user can select any four general purpose IO pins to access the TAG memory using the SPI commands. The four SPI pins on each LatticeXP2 device are considered general purpose IOs if they are not reserved using SLAVE_SPI_PORT attribute.

SSPIA Port Description

Table 829:

Port Name	I/O	Description
SI	I	Data input
CLK	I	Clock
CS	I	Chip select
SO	O	Data output

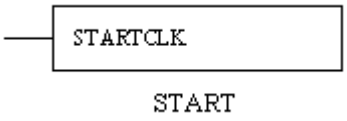
You can refer to LatticeXP2 technical notes on the Lattice web site for more details.

START

Startup Controller

Architectures Supported:

- ECP5
- LatticeECP3
- LatticeXP2
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager 2



INPUT: STARTCLK

Description

This primitive determines the user clock for the Wake up sequence. You can instantiate this module in your HDL source to tie a specific user clock to be used in the wake-up sequence instead of the TCK (JTAG), BCLK (SDM), or MCLK/CCLK (sysCONFIG).

START Usage with Verilog HDL

```
module START (STARTCLK);
input  STARTCLK;
endmodule
```

START Usage with VHDL

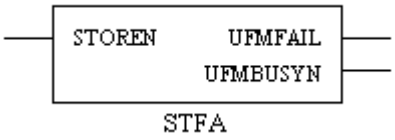
```
COMPONENT START
   PORT(
        STARTCLK    :  IN STD_ULOGIC
       );
END COMPONENT;
```

STFA

Store to Flash Primitive

Architectures Supported:

- LatticeXP2



INPUT: STOREN

OUTPUTS: UFMFAIL, UFMBUSYN

Description

The LatticeXP2 store-to-flash primitive is for user flash module (UFM) operations. The main function of a UFM is to protect the user data from being lost when the system is powered OFF. The user data in the UFM will be used by the system for initialization when the power comes back. To emulate the UFM capability, the users can use the EBR (shadow flash) memory configurations and then transfer the data to UFM through Store-to-Flash operation. The store-to-flash operation is a single-command-two-operation process. When the store-to-flash operation is initiated, an erase-UFM-Flash CIB signal will be enabled to erase the Flash, followed by the transfer-to-flash operation. Once the transfer is done, the flash controller will send a transfer-done signal back to the user logic. During the Store-to-Flash operation, the EBR's are not accessible. There is no difference between regular EBR RAM configuration and shadow flash (UFM) EBR RAM configuration in Lattice Diamond GUI. The presence of a STFA primitive in the design determines EBR RAM configuration. Due to a silicon limitation, the user cannot use the Store-to-Flash operation if the SED is operating in an Always mode. Only one STFA instance in the design is allowed.

STFA Port Description

Table 830:

Port Name	Corresponding Hardware Port Name	I/O	Description
STOREN	storecmdn	I	Initiates to store the EBR content to Flash
UFMFAIL	ufm_fail	O	Store to Flash operation failed
UFMBUSYN	fl_busyn	O	Tells the user whether the FLASH is in busy state or not

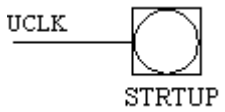
You can refer to LatticeXP2 technical notes on the Lattice web site for more information.

STRTUP

Startup Controller

Architectures Supported:

- LatticeECP/EC
- LatticeECP2/M
- LatticeSC/M



INPUT: UCLK

Description

After configuration, the FPGA enters the start-up phase, which is the transition between the configuration and operational states. Normally, the relative timing of the following three events is triggered by the configuration clock (CCLK): DONE going high, release of the set/reset of internal FFs, and activation of user I/Os. The three events can also be triggered by a user clock, UCLK. This allows the start-up to be synchronized by a known system clock. For more detailed information refer to an available data book or contact technical support.

Another set of bitstream options for the STRTUP block allows the DONE pin to be held low and then released to be used with either CCLK or UCLK to control the release of the set/reset of internal FFs and the activation of user I/Os. This allows the synchronization of the start-up of multiple FPGAs.

UCLK: User defined clock to trigger DONE going high, release of set/reset of internal FFs, and activation of user I/Os.

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in Schematic Editor.

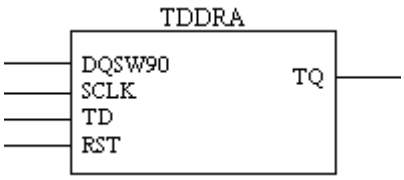
T

TDDRA

Tristate for DQ/DQS of PIC Cell

Architectures Supported:

- MachXO2
- Platform Manager 2



INPUTS: DQSW90, SCLK, TD, RST

OUTPUT: TQ

ATTRIBUTES:

GSR: "ENABLED" (default), "DISABLED"

DQSW90_INVERT: "DISABLED" (default), "ENABLED"

Description

TDDRA is the tristate for DQ/DQS of the PIC cell. It is used for right side only. See the below table for the port description.

Table 831:

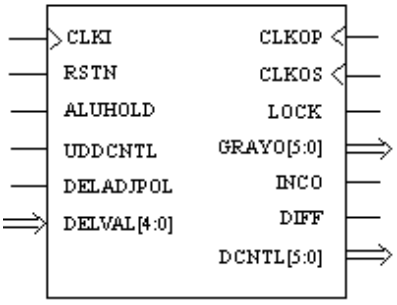
Signal	I/O	Description
DQSW90	I	Shifts the DQS signal by 90 degree
SCLK	I	Clock from the CIB
TD	I	Tristate signal
RST	I	RESET to this block from the CIB
TQ	O	Tristate output for DQ

TR1DLLB

Time Reference DLL with Dynamic Delay Adjustment

Architectures Supported:

- LatticeECP3



INPUTS: CLKI, RSTN, ALUHOLD, UDDCNTL, DELADJPOL, DELVAL4, DELVAL3, DELVAL2, DELVAL1, DELVAL0

OUTPUTS: CLKOP, CLKOS, LOCK, INCO, DIFF, GRAYO5, GRAYO4, GRAYO3, GRAYO2, GRAYO1, GRAYO0, DCNTL5, DCNTL4, DCNTL3, DCNTL2, DCNTL1, DCNTL0;

ATTRIBUTES:

CLKOP_PHASE: 0 (default), 90, 180, 270, 360

CLKOS_PHASE: 0 (default), 90, 180, 270, 360

CLKOS_FPHASE: 0, 11, 22, 33, 45, 56, 67, 78, 90, 101 (default), 112, 123, 135, 146, 157, 169, 191, 202, 214, 225, 236, 247, 259, 281, 292, 304, 315, 326, 337, 349

CLKOS_DIV: 1 (default), 2, 4

GSR: "DISABLED" (default), "ENABLED"

CLKOS_FPHASE _ADJVAL: integers -20~20 (default: 0)

ALU_LOCK_CNT: integers 3~15 (default: 3)

ALU_UNLOCK_CNT: integers 3~15 (default: 3)

GLITCH_TOLERANCE: integers 0~7 (default: 2)

LOCK_DELAY: integers 0~1000 (in ns) (default: 100)

CLKOP_DUTY50: "DISABLED" (default), "ENABLED"

CLKOS_DUTY50: "DISABLED" (default), "ENABLED"

Description

TRDLLB specifies the Time Reference operation mode for the general purpose DLL (GDLL). It supports the 1G SPI4.2 interface. The feedback connection is not required for this mode and hence the CLKFB is not captured on the TRDLLB primitive. In this mode, the CLKFB should be tied to GND.

Port Description

Table 832:

Port Name	Optional	Logical Capture Port Name
ALUHOLD	YES	HOLD
RSTN	YES	RSTN
UDDCNTL	YES	UDDCNTL
CLKI	NO	CLKI
CLKOP	YES	CLKOP
CLKOS	YES	CLKOS
LOCK	NO	LOCK
GRAYO[5:0]	YES	GRAY_OUT[5:0]
INCO	YES	INC_OUT
DIFF	YES	DIFF
DCNTL[5:0]	NO	DCNTL[5:0]
DELADJPOL	YES	DELADJPOL
DELVAL[4:0]	YES	DELVAL[4:0]

For more information, refer to the following technical note on the Lattice web site:

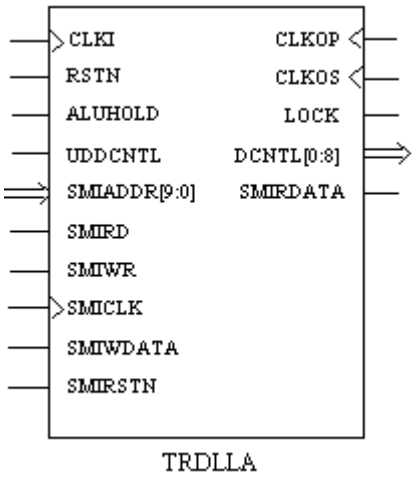
- TN1178 - LatticeECP3 sysCLOCK PLL/DLL Design and Usage Guide

TRDLLA

Time Reference Delay

Architectures Supported:

- LatticeECP2/M
- LatticeSC/M



INPUTS: CLKI, RSTN, ALUHOLD, UDDCNTL, SMIADDR9, SMIADDR8, SMIADDR7, SMIADDR6, SMIADDR5, SMIADDR4, SMIADDR3, SMIADDR2, SMIADDR1, SMIADDR0, SMIRD, SMIWR, SMICLK, SMIWDATA, SMIRSTN

OUTPUTS: CLKOP, CLKOS, LOCK, DCNTL0, DCNTL1, DCNTL2, DCNTL3, DCNTL4, DCNTL5, DCNTL6, DCNTL7, DCNTL8, SMIRDATA

ATTRIBUTES:

CLKOP_PHASE: 0 (default), 90, 180, 270, 360

CLKOS_PHASE: (0, 90, 180, 270, 360) + (0, 11, 22, 45) (default: 0)

CLKOS_FPHASE: 0 (default), 11, 22, 45

CLKOP_DUTY50: "DISABLED" (default), "ENABLED"

CLKOS_DUTY50: "DISABLED" (default), "ENABLED"

CLKOS_DIV: 1 (default), 2, 4

GSR: "DISABLED" (default), "ENABLED"

CLKOS_FDEL_ADJ: "DISABLED" (default), "ENABLED"

CLKOS_FPHASE _ADJVAL: integers -127~127 (default: 0)

ALU_LOCK_CNT: integers 3~15 (default: 3)

ALU_UNLOCK_CNT: integers 3~15 (default: 3)

GLITCH_TOLERANCE: integers 0~7 (default: 2 for LatticeECP2/M, 0 for LatticeSC/M)

LOCK_DELAY: integers 0~1000 (in ns) (default: 100)

(*LatticeSC/M only*) DCNTL_ADJVAL: integers -127~127 (default: 0)

(*LatticeSC/M only*) SMI_OFFSET: 0x400~0x7FF (default: 12'h410)

(*LatticeSC/M only*) MODULE_TYPE: "TRDLLA"

(*LatticeSC/M only*) IP_TYPE: "TRDLLA"

Description

TRDLLA will generate four phases of the clock, 0, 90, 180, 270 degrees, along with the control setting used to generate these phases. This mode features registered control bit output with separate enable, addition and subtraction on the outgoing control bits, lock achieved starting from minimum delay which guarantees lock to first harmonic (fundamental frequency), and four available output phases (0, 90, 180, 270) degrees. This requires internal feedback only, a maximum frequency 700MHz, and a minimum frequency 100MHz.

For more information, see the following technical notes on the Lattice web site:

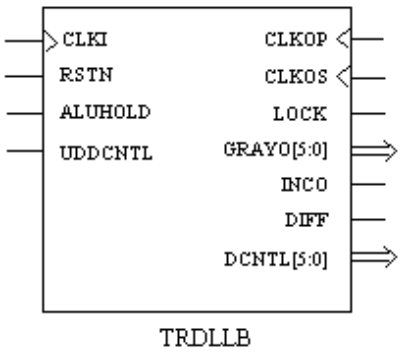
- TN1098 - LatticeSC sysCLOCK and PLL/DLL User's Guide
- TN1103 - LatticeECP2 sysCLOCK PLL Design and Usage Guide

TRDLLB

Time Reference DLL

Architectures Supported:

- LatticeECP3



INPUTS: CLKI, RSTN, ALUHOLD, UDDCNTL

OUTPUTS: CLKOP, CLKOS, LOCK, INCO, DIFF, GRAYO5, GRAYO4, GRAYO3, GRAYO2, GRAYO1, GRAYO0, DCNTL5, DCNTL4, DCNTL3, DCNTL2, DCNTL1, DCNTL0

ATTRIBUTES:

CLKOP_PHASE: 0 (default), 90, 180, 270, 360

CLKOS_PHASE: 0 (default), 90, 180, 270, 360

CLKOS_FPHASE: 0, 11, 22, 33, 45, 56, 67, 78, 90, 101 (default), 112, 123, 135, 146, 157, 169, 191, 202, 214, 225, 236, 247, 259, 281, 292, 304, 315, 326, 337, 349

CLKOS_DIV: 1 (default), 2, 4

GSR: "DISABLED" (default), "ENABLED"

CLKOS_FPHASE _ADJVAL: integers -20~20 (default: 0)

ALU_LOCK_CNT: integers 3~15 (default: 3)

ALU_UNLOCK_CNT: integers 3~15 (default: 3)

GLITCH_TOLERANCE: integers 0~7 (default: 2)

LOCK_DELAY: integers 0~1000 (in ns) (default: 100)

CLKOP_DUTY50: "DISABLED" (default), "ENABLED"

CLKOS_DUTY50: "DISABLED" (default), "ENABLED"

Description

TRDLLB specifies the Time Reference operation mode for the general purpose DLL (GDLL). The feedback connection is not required for this mode and hence the CLKFB is not captured on the TRDLLB primitive. In this mode, the CLKFB should be tied to GND.

Port Description

Table 833:

Port Name	Optional	Logical Capture Port Name
ALUHOLD	YES	HOLD
RSTN	YES	RSTN
UDDCNTL	YES	UDDCNTL
CLKI	NO	CLKI
CLKOP	YES	CLKOP
CLKOS	YES	CLKOS
LOCK	NO	LOCK
GRAYO[5:0]	YES	GRAY_OUT[5:0]
INCO	YES	INC_OUT
DIFF	YES	DIFF
DCNTL[5:0]	NO	DCNTL[5:0]

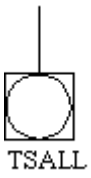
TSALL

Global Tristate Interface

Architectures Supported:

- LatticeSC/M
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUT: TSALL (TSALLN for LatticeSC/M)

Description

TSALL is used to tristate buffers in your design. The TSALL component is connected to a net to drive all output and bidirectional buffers into a HIGH impedance state when active HIGH.

It is not necessary to connect signals to buffers explicitly. The function will be implicitly connected globally.

Note

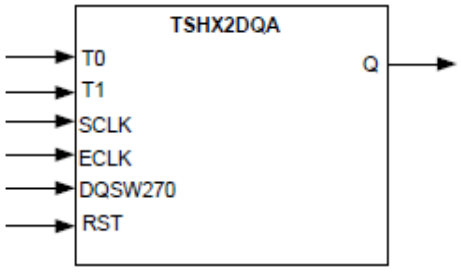
- The TSALL component may be driven by general FPGA logic or by the read-configuration block. In the latter case, the TSALL block must be driven by a buffer located at the RDCGFN pin. When locating the TSALL to the RDCFGN, you must do this by explicitly designating “RDCFGN” in the attribute. Check with customer support or with FAEs for more details.
- This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

TSHX2DQA

Generates the tristate control for DQ data output for DDR2 and DDR3 memory

Architectures Supported:

- ECP5



INPUTS: T0, T1, SCLK, DQSW270, RST

OUTPUT: Q

Description

This primitive is used to generate the tristate control for DQ data output for DDR2 and DDR3 memory.

Table 834:

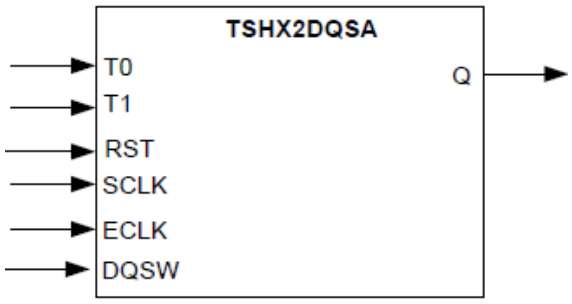
Signal	I/O	Description
T0, T1	I	Tristate input
ECLK	I	ECLK input (2x speed of SCLK)
DQSW270	I	Clock that is 90 degree ahead of clock used to generate the DQS output
SCLK	I	SLCK input
RST	I	Reset input
Q	O	Tristate output

TSHX2DQSA

Generates the tristate control for DQS output

Architectures Supported:

- ECP5



INPUTS: T0, T1, SCLK, DQSW, ECLK, RST

OUTPUT: Q

Description

This primitive is used to generate the tristate control for DQS output.

Table 835:

Signal	I/O	Description
T0, T1	I	Tristate input
ECLK	I	ECLK input (2x speed of SCLK)

Table 835:

Signal	I/O	Description
DQSW	I	DQSW includes write leveling phase shift from ECLK
SCLK	I	SLCK input
RST	I	Reset input
Q	O	Tristate output

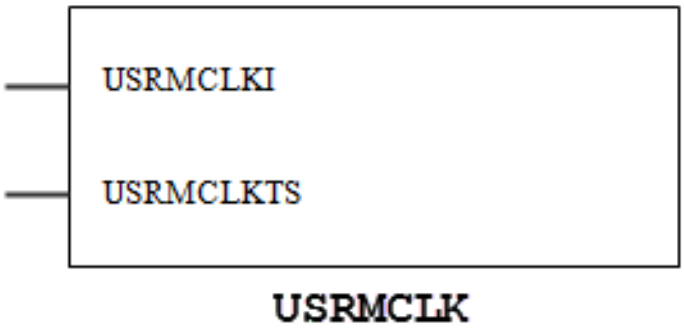
U

USRMCLK

Allows User Function to Access SPI PROM

Architectures Supported:

- ECP5



INPUTS: USRMCLKI, USRMCLKTS

Description

A primitive to allow the user function to access the SPI PROM. It has two inputs. This feature allows the user to tie a specific user clock to be used as MCLK. Without this instantiation the device will use the CFG MCLK as MCLK. This primitive can only be instantiated if the device is in MSPI mode. DRC error will be issued if this primitive be instantiated in any mode other than MSPI. The table below describes the ipnputs of the USRMCLK primitive.

Table 836:

Port	I/O	Function
USRMCLKI	I	User defined MCLK.
USRMCLKTS	I	User defined MCLK tri-state.

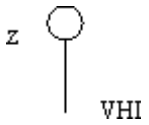
V

VHI

Logic High Generator

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



OUTPUT: Z

Note

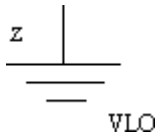
- It is possible that this primitive will be optimized by the back-end tool before place and route.
- This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

VLO

Logic Low Generator

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- Platform Manager
- Platform Manager 2



OUTPUT: Z

Note

- It is possible that this primitive will be optimized by the back-end tool before place and route.
- This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

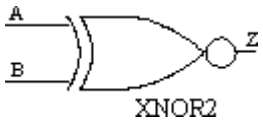
X

XNOR2

2-Input Exclusive NOR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B

OUTPUT: Z

Note

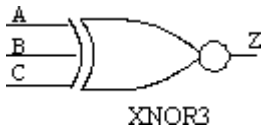
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

XNOR3

3-Input Exclusive NOR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C

OUTPUT: Z

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

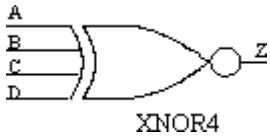
XNOR4

4-Input Exclusive NOR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC

- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C, D

OUTPUT: Z

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

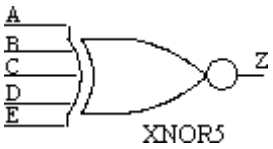
XNOR5

5-Input Exclusive NOR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD

- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C, D, E

OUTPUT: Z

Note

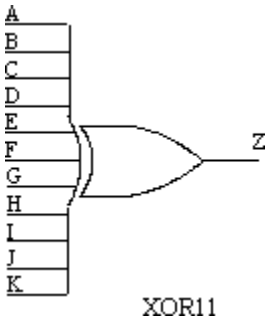
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

XOR11

11-Input Exclusive OR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C, D, E, F, G, H, I, J, K

OUTPUT: Z

Note

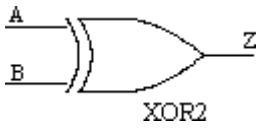
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

XOR2

2-Input Exclusive OR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B

OUTPUT: Z

Note

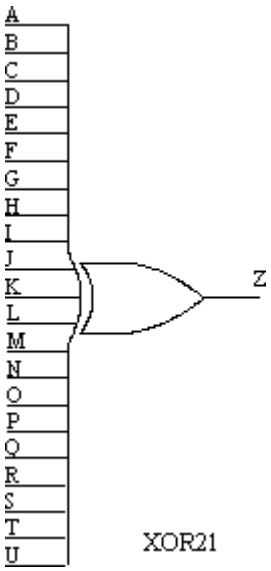
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

XOR21

21-Input Exclusive OR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C, D, E, F, G, H, I, J, K, L, M, N, O, P, Q, R, S, T, U

OUTPUT: Z

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

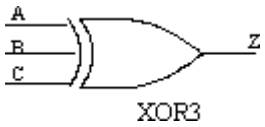
XOR3

3-Input Exclusive OR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L

- Platform Manager
- Platform Manager 2



INPUTS: A, B, C

OUTPUT: Z

Note

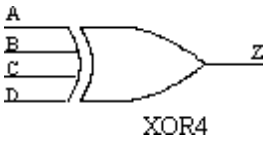
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

XOR4

4-Input Exclusive OR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- MachXO3D
- MachXO3L
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C, D

OUTPUT: Z

Note

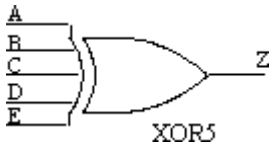
This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

XOR5

5-Input Exclusive OR Gate

Architectures Supported:

- ECP5
- LatticeECP/EC
- LatticeECP2/M
- LatticeECP3
- LatticeSC/M
- LatticeXP
- LatticeXP2
- LIFMD
- MachXO
- MachXO2
- Platform Manager
- Platform Manager 2



INPUTS: A, B, C, D, E

OUTPUT: Z

Note

This primitive is also available as a schematic symbol. You can add it to your schematic using the Add > Symbol command in the Schematic Editor.

Primitive-Specific HDL Attributes

The following is a comprehensive list of HDL attributes that are commonly set automatically during module generation and are associated with specific primitives. We list these attributes here mainly for purposes of identification.

In almost all cases, it is not recommended that any of these attributes be edited manually. They should appear in your source as a result of module generation in IPexpress only. There are many interdependencies that exist between certain related attributes and their valid values on an architecture or device basis. These interdependencies make it impractical to simply edit the source HDL. If you were to do so, its very likely an invalid value may result in a failure in your design.

List of Primitive-Specific HDL Attributes

The below table lists all the primitive-specific attributes in alphabetic order.

Table 837:

Attribute	Type	Allowed Values	Default	Description
AEPOINTER	Binary	(*LatticeSCM*) 15-bit binary value; (*MachXO/Platform Manager*) 14-bit binary value	All zeros	Specifies the Almost Empty Flag Pointer. AEPOINTER1 refers to the Almost Empty Flag Pointer 1.
AFPOINTER	Binary	(*LatticeSCM*) 15-bit binary value; (*MachXO/Platform Manager*) 14-bit binary value	All zeros	Specifies the Almost Full Flag Pointer. AFPOINTER1 refers to the Almost Full Flag Pointer 1.
ALU_INIT_CNTVAL	Integer	(*LatticeECP3*) 0 to 31; (*Others*) 0, 4, 8, 12, 16, 32, 48, 64, 72 (0 = DISABLED)	0	Specifies the minimum number of delay taps that ALU will count for. This forces the ALU to count for a minimum number of delay taps before it can find lock, and prevents the DLL finding lock at the minimum possible delay setting and then “falling off the end” of the delay chain if the input clock has jitter. Used in all clock injection cancellation modes where the lock point is not predictable.
ALU_LOCK_CNT	Integer	3 to 15	3	Specifies the Lock Count Cycles. Attached to a DLL-type primitive.
ALU_UNLOCK_CNT	Integer	3 to 15	3	Specifies the Unlock Count Cycles. Attached to a DLL-type primitive.
ASYNC_RESET_RELEASE	String	SYNC, ASYNC	SYNC	Specifies reset release when the reset mode is ASYNC.

Table 837:

Attribute	Type	Allowed Values	Default	Description
BANKID	Integer	0, 1, 2, 3, 4, 5	0	Specifies the ID of the bank that enables dynamic InRD control for the BCINRD primitive.
BGOFF	Boolean	TRUE, FALSE	FALSE	Turns on or off Bandgap when in standby.
BOOT_OPTION	String	INTERNAL, EXTERNAL	INTERNAL	Specifies device boot from external SPI flash or internal flash.
CAS_MATCH_REG	Boolean	TRUE, FALSE	FALSE	Specifies the Cascade Match Register option. Attached to DSP primitives such as MULT9X9C and MULT18X18C.
CFGx_INIT_PAGES	Integer	0 to Max Number of Pages in UFM array.	0	Specifies the number of pages with initialization data, where x holds value of 0 or 1. If the user doesn't enter a value, it is set to 0.
CFGx_INIT_START_PAGE	Integer	Calculated by Software.	0	Software calculates and displays the starting page of the init data in the CFG array, where x holds value between 0 to 1. Read only field.
CFGx_INIT_ALL_ZEROS	Boolean	ENABLED, DISABLED	ENABLED	Specifies that the CFG is initialized with all 0s. x can hold a value between 0 to 1. By default, the radio button is selected.
CFGx_INIT_FILE_NAME	String	String	None	Uploads the CFG Initialization data file, where x holds value between 0 to 1. By default, the radio button is not selected. The browse button is not enabled if the radio button is not selected.
CFGx_INIT_FILE_FORMAT	String	HEX, BIN	HEX	Specifies the selection of file format, either Binary or Hexadecimal, x holds a value between 0 and 1.
CHECKALWAYS	Boolean	ENABLED, DISABLED	DISABLED	When set to ENABLED, makes the SED (Soft Error Detect) run automatically every time upon power up and after device configuration. The software will set signals from the SED IP that puts it in an "Always Running" state.
CLKFB_DIV	Integer	Vary	1	Specifies the CLKFB N Divider setting. Attached to a PLL-type primitive (such as EHXPLLB).
CLKFB_FDEL	Integer	0, 100, 200, ..., 700	0	Specifies the CLKFB Fine Delay setting for the EHXPLLA primitive.

Table 837:

Attribute	Type	Allowed Values	Default	Description
CLKI_DIV	Integer	Vary	1	Specifies the CLKI M Divider setting. Attached to a PLL or DLL primitive (such as EHXPLLB and CIDDLLA).
CLKI_FDEL	Integer	0, 100, 200, ..., 700	0	Specifies the CLKI Fine Delay setting for the EHXPLLA primitive.
CLKMODE	String	ECLK, SCLK	ECLK	Specifies the edge clock or system clock for the CLKCNTL primitive.
CLKOK_BYPASS	Boolean	ENABLED, DISABLED	DISABLED	Enables or disables the GPLL clock bypass feature. When enabled, this feature allows the input reference clock (CLK) to bypass the PLL and directly drive CLKOP, CLKOS, and CLKOK. If CLKOP is used for bypass, the PLL is no longer functional and cannot be used as a PLL. The CLKOS and CLKOK can be used for bypass without affecting the operation of the loop. IPexpress includes selections for CLKOP, CLKOS, and CLKOK bypass.
CLKOK_DIV	Integer	Even integers from 2 to 128	2	Specifies the CLKOK K Divider setting. Attached to a PLL-type primitive (such as EHXPLLB).
CLKOK_INPUT	String	CLKOP, CLKOS	CLKOP	Specifies the CLKOK divider input. Attached to a PLL-type primitive. (such as EHXPLLF).
CLKOP_BYPASS	Boolean	ENABLED, DISABLED	DISABLED	Enables or disables the GPLL clock bypass feature. When enabled, this feature allows the input reference clock (CLK) to bypass the PLL and directly drive CLKOP, CLKOS, and CLKOK. If CLKOP is used for bypass, the PLL is no longer functional and cannot be used as a PLL. The CLKOS and CLKOK can be used for bypass without affecting the operation of the loop. IPexpress includes selections for CLKOP, CLKOS, and CLKOK bypass.
CLKOP_DIV	Integer	Vary	1 or 8	Specifies the CLKOP V Divider setting. Attached to a PLL-type primitive (such as EHXPLLB). **Note**: CLKOP_DIV value must be calculated to maximize the FVCO within the specified range based on CLKI_DIV and CLKFB_DIV values for optimum performance.

Table 837:

Attribute	Type	Allowed Values	Default	Description
CLKOP_DUTY50	Boolean	ENABLED, DISABLED	DISABLED	Enables or disables the CLKOP Duty Cycle. Attached to a PLL-type primitive (such as EHXPLLA).
CLKOP_MODE	String	BYPASS, FDEL0, VCO, DIV	BYPASS	Specifies the CLKOP Select for the EHXPLLA primitive.
CLKOP_PHASE	Integer	0, 90, 180, 270, 360	0	Specifies the CLKOP Phase setting. Attached to a DLL-type primitive (such as TRDLLA).
CLKOP_TRIM_DELAY	Integer	0 to 7	0	Specifies the CLKOP Duty Trim Polarity Delay. Attached to a PLL-type primitive.
CLKOP_TRIM_POL	String	FALLING, RISING	FALLING for LatticeXP2; RISING for LatticeECP 3	Specifies the CLKOP Duty Trim Polarity. Attached to a PLL-type primitive.
CLKOS_BYPASS	Boolean	ENABLED, DISABLED	DISABLED	Enables or disables the GPLL clock bypass feature. When enabled, this feature allows the input reference clock (CLK) to bypass the PLL and directly drive CLKOP, CLKOS, and CLKOK. If CLKOP is used for bypass, the PLL is no longer functional and cannot be used as a PLL. The CLKOS and CLKOK can be used for bypass without affecting the operation of the loop. IPexpress includes selections for CLKOP, CLKOS, and CLKOK bypass.
CLKOS_DIV	Integer	1, 2, 4 for DLL primitives; 1 to 64 for PLL primitives	1	Specifies the CLKOS Divider setting. Attached to a PLL- or DLL-type primitive (such as EHXPLLA and CIDDLLA).
CLKOS_DUTY50	Boolean	ENABLED, DISABLED	DISABLED	Enables or disables the CLKOS Duty Cycle. Attached to a PLL-type primitive (such as EHXPLLA).
CLKOS_FDEL	Integer	0, 100, 200, ..., 700	0	Specifies the CLKOS Fine Delay setting for the EHXPLLA primitive.
CLKOS_FDEL_ADJ	Boolean	ENABLED, DISABLED	DISABLED	Specifies the CLKOS DEL Manual Setting Adjust Value. Attached to a DLL-type primitive (such as TRDLLA).
CLKOS_FPHASE	Integer	Vary	0	Specifies the CLKOS Fine Phase setting. Attached to a DLL-type primitive (such as TRDLLA).

Table 837:

Attribute	Type	Allowed Values	Default	Description
CLKOS_FPHASE _ADJVAL	Integer	-20 to 20	0	Specifies the CLKOS Fine Phase Adjust Value. Attached to a DLL-type primitive (such as TRDLLA).
CLKOS_MODE	String	BYPASS, FDEL, VCO, DIV	BYPASS	Specifies the CLKOS Select for the EHXPLLA primitive.
CLKOS_PHASE	Integer	Vary	0	Specifies the CLKOS Phase setting. Attached to a DLL-type primitive (such as TRDLLA).
CLKOS_TRIM_DELAY	Integer	0 to 3	0	Specifies the CLKOS Duty Trim Polarity Delay. Attached to a PLL-type primitive.
CLKOS_TRIM_POL	String	RISING, FALLING	RISING	Specifies the CLKOS Duty Trim Polarity Delay. Attached to a PLL-type primitive.
CLKOS_VCODEL	Integer	0 to 31	0	Specifies the CLKOS VCO Delay setting for the EHXPLLA primitive.
CRUDIV	Integer	1.0, 2.0, 3.5, 4.0, 5.0	5.0	Sets the divider setting for the DIVCLK output.
CSDECODE	Binary	2- or 3-bit binary value	Vary	Attached to a single-port block RAM primitive. The CSDECODE value determines the decoding value of CS[2:0]. A value set to “000” means that the memory is selected if CS[2:0]=1’B000.
DATA_WIDTH	Integer	1, 2, 4, 9, 18 for DATA_WIDTH, DATA_WIDTH_A, and DATA_WIDTH_B; 1, 2, 4, 9, 18, 36 for DATA_WIDTH_R and DATA_WIDTH_W	9, 18, or 36	Specifies the Data Word Width. Attached to a memory type primitive.
DCNTL_ADJVAL	Integer	-127 to 127	0	Specifies the Adjust Delay Control. Attached to a DLL-type primitive.
DCSMODE	String	NEG, POS, HIGH_LOW, HIGH_HIGH, LOW_LOW, LOW_HIGH, CLK0, CLK1	NEG	Sets the particular mode for the DCS primitive. Refer to DCSMODE Values for more information.
DEL_ADJ	String	PLUS, MINUS	PLUS	Specifies the delay adjustment sign bit.
DEL_VAL	Integer	0 to 127 if DEL_ADJ=PLUS; 1 to 128 if DEL_ADJ=MINUS	0	Specifies the delay adjustment offset.
DEL[0,1,2,3,4]_GRAY	Boolean	ENABLED, DISABLED	DISABLED	Specifies gray in for DEL0, DEL1, DEL2, DEL3, and DEL4. Attached to a DLL-type primitive.

Table 837:

Attribute	Type	Allowed Values	Default	Description
DEL_MODE	String	SCLK_ZEROHOLD, ECLK_ALIGNED, ECLK_CENTERED, ECLK_CENTERED_MIPI, ECLK_CENTERED_SLVS, SCLK_ALIGNED, SCLK_CENTERED, USER_DEFINED	USER_DEFINED	Controls whether the fixed delay value is dependent on a certain interface or user-defined delay value.
DEL_VALUE	String	DELAY0, DELAY1, DELAY2, ..., DELAY31	DELAY0	Specifies user-defined delay value.
DELAY_CNTL	String	DYNAMIC, STATIC	STATIC	Specifies the Delay Control mode. Attached to a PLL-type primitive (such as EHXPLLB). The DYNAMIC mode switches delay control between DYNAMIC and STATIC depending upon the input logic of the DDAMODE pin. In the STATIC mode, delay inputs are ignored.
DELAY_PWD	Boolean	ENABLED, DISABLED	DISABLED	Enables or disables the CLKOS Fine Delay Powerdown. Attached to a PLL-type primitive. When set to ENABLED, the f_fdelay_pwd fuse will be set to HIGH to disable the fine delay circuitry for power saving. When set to DISABLED, the f_fdelay_pwd fuse will be set to LOW to enable the fine delay circuitry.
DELAY_VAL	Integer	0 to 15	0	Specifies the CLKOS Fine Delay Value. Attached to a PLL-type primitive.
DEV_DENSITY	String	Vary	Vary	Specifies the device density.
DIV	Integer	1, 2, 4 (1:off) for the CLKDIV primitive; 2.0, 3.5, 4.0 for the CLKDIVC primitive; 1, 2, 4, 8, 16, 32, 64, 128 for the OSCA primitive	1 or 2 or 2.0	Specifies the Divider setting.
DQS_LI_DEL_ADJ	String	PLUS, MINUS	Vary	Adjusts the sign delay offset direction for input DDR. For DQSBUFH, it adjusts the sign bit for the READ delay.

Table 837:

Attribute	Type	Allowed Values	Default	Description
DQS_LI_DEL_VAL	Integer	0 to 63 or 0 to 127 if DQS_LI_DEL_ADJ=PLUS; 1 to 64 or 1 to 128 if DQS_LI_DEL_ADJ =MINUS	Vary	Specifies the delay value for input DDR.
DQS_LO_DEL_ADJ	String	PLUS, MINUS	PLUS	Adjusts the sign delay offset direction for output DDR. For DQSBUFH, it adjusts the sign bit for the WRITE delay.
DQS_LO_DEL_VAL	Integer	0 to 63 or 0 to 127 if DQS_LO_DEL_ADJ=PLUS; 1 to 64 or 1 to 128 if DQS_LO_DEL_ADJ=MINUS	0	Specifies the delay value for output DDR.
DQSW90_INVERT	String	DISABLED, ENABLED	DISABLED	Selects the clock polarity for the second FF of the tristate cell for the DQS pin. Only used for the DQS during DDR write.
DR_CONFIG	String	DISABLED, ENABLED	DISABLED	Indicates whether the primitive is used for data recovery configuration or not. If it is for data recovery configuration then the correct GBB timing will be set. This attribute is required for mapper and is not required for simulation.
DUTY	Integer	Vary	4 or 8	Specifies the duty cycle floating point percentage value. Used to control the duty cycle modes of PLL primitives such as EHXPLLB.
DYNDEL_CNTL	String	STATIC, DYNAMIC	DYNAMIC	Enables the static or dynamic delay. Attached to a DQSBUF primitive (such as DQSBUFB).
DYNDEL_TYPE	String	NORMAL, SHIFTED	NORMAL	Specifies the value of the Static Delay input to the write portion of the DQSBUFD or DQSBUFE module that controls the clock inversion. NORMAL: 0-degree phase shift; SHIFTED: 180-degree phase shift through clock inversion.
DYNDEL_VAL	Integer	0 to 127	0	Specifies the value of the Static Delay input to the write portion of the DQSBUFD or DQSBUFE module.
EFB_I2C1	Boolean	DISABLED, ENABLED	DISABLED	Enables I2C Primary User Port.
EFB_I2C2	Boolean	DISABLED, ENABLED	DISABLED	Enables I2C Secondary User Port.

Table 837:

Attribute	Type	Allowed Values	Default	Description
EFB_SPI	Boolean	DISABLED, ENABLED	DISABLED	Enables the SPI Port.
EFB_TAMPER_TYPE_PASSWORD	Boolean	DISABLED, ENABLED	DISABLED	Enables the detection of the unauthorized access to password protection.
EFB_TAMPER_TYPE_LOCKED_FLASH_SRAM	Boolean	DISABLED, ENABLED	DISABLED	Enables the action detection of unauthorized access to locked flash sector or SRAM.
EFB_TAMPER_TYPE_MANUFACTURE_MODE	Boolean	DISABLED, ENABLED	DISABLED	Enables the detection of entering manufacture mode.
EFB_TAMPER_SRC_JTAG	Boolean	DISABLED, ENABLED	DISABLED	Enables the threat detection for JTAG port.
EFB_TAMPER_SRC_SSPI	Boolean	DISABLED, ENABLED	DISABLED	Enables the threat detection for SSPI port.
EFB_TAMPER_SRC_SI2C	Boolean	DISABLED, ENABLED	DISABLED	Enables the threat detection for SI2C port.
EFB_TAMPER_SRC_WB	Boolean	DISABLED, ENABLED	DISABLED	Enables the threat detection for WB port.
EFB_TAMPER_PORT_LOCK	Boolean	DISABLED, ENABLED	DISABLED	Enables the detection of accessing port lock function.
EFB_TAMPER_DETECTION_RESPONSE	Boolean	DISABLED, ENABLED	DISABLED	
EFB_TC	Boolean	DISABLED, ENABLED	DISABLED	Enables Timer/Counter port.
EFB_TC_PORTMODE	String	WB, NO_WB	NO_WB	Determined by T/C Static and Dynamic radio buttons. Selecting “Use static ...” sets it to NO_WB “Dynamic register ...” sets it to WB and enables WB port. It brings the primitive port TCIC to the top level.
EFM_UFM_BOOT	String	INT_SINGLE_BOOT_CFG0 INT_SINGLE_BOOT_CFG0_UFM0 INT_DUAL_BOOT_CFG0_CFG1 INT_DUAL_BOOT_CFG0_UFM0_CFG1 INT_DUAL_BOOT_CFG0_CFG1_UFM1 INT_DUAL_BOOT_CFG0_UFM0_CFG1_UFM1 EXTERNAL_BOOT	INT_SINGLE_BOOT_CFG0	Specifies the UFM boot setting.

Table 837:

Attribute	Type	Allowed Values	Default	Description
EFB_UFM	Boolean	DISABLED, ENABLED	DISABLED	Indicates that the user wants to use one of UFM0, UFM1, UFM2, UFM3, CFG0, or CFG1.
EFB_UFMx	Boolean	DISABLED, ENABLED	DISABLED	Indicates that the user wants to address the UFMx through WB, where x is a value between 0 and 3. It enables WB port and WBCUFMIRQ port.
EFB_CFGx	Boolean	DISABLED, ENABLED	DISABLED	Indicates that the user wants to address the CFGx through WB, where x is a value between 0 and 1. It enables WB port and WBCUFMIRQ port.
EFB_WB_CLK_FREQ	Integer	0 to 133	50	Used by SPI and I2C to derive frequency.
ENCRYPTION	String	ON, OFF	OFF	Specifies the encryption feature.
ER1, ER2	Boolean	ENABLED, DISABLED	ENABLED	Lattice supports two private JTAG instructions ER1 (0x32) and ER2 (0x38). If the ER1 instruction is shifted into the JTAG instruction register, JRTI1 will go high when the TAP controller is in the Run-Test/Idle state. If the ER2 instruction is shifted into the JTAG instruction register, JRTI2 will go high when the TAP controller is in the Run-Test/Idle state.
FB_MODE	String	INTERNAL, CLOCKTREE, EXTERNAL	CLOCKTREE	Defines PLL clock resources in the feedback mode.
FDEL	Integer	-8 to 8	0	Specifies the fine delay adjust setting. Attached to a PLL-type primitive (such as EHXPLLB).
FIN	Real	Vary (in MHz)	100.0	Specifies the input frequency (MHz) designation for a PLL/DLL primitive (such as EHXPLLB, DQSDLLC).
FORCE_MAX_DELAY	Boolean	YES, NO	NO	Used to bypasses the DLL-locking procedure at low frequency. When FIN ≤ 30 MHz (pending PDE result), the software sets this attribute to YES. Then DQSDLL will not go through the locking procedure but will be locked to the maximum delay steps.
FORCE_ZERO_BARREL_SHIFT	Boolean	ENABLED, DISABLED	DISABLED	When set to ENABLED, forces zeros to 18 MSB of shift for barrel shift. Attached to the ALU54A primitive.
FWFT	Boolean	ENABLED, DISABLED	DISABLED	First word fall through.

Table 837:

Attribute	Type	Allowed Values	Default	Description
FULLPOINTER	Binary	(*LatticeSC/M*) 15-bit binary value; (*MachXO/Platform Manager*) 14-bit binary value	All zeros	Specifies the Full Flag Pointer. Attached to a FIFO primitive (such as FIFO8KA). FULLPOINTER1 refers to the Full Flag Pointer 1.
GEARING_MODE	String	X2, X4	X2	Sets gearing mode required.
GLITCH_TOLERANCE	Integer	0 to 7	2	Specifies the Programmable Glitch Tolerance. Attached to a DLL-type primitive.
GSR	Boolean	ENABLED, DISABLED	Vary	Enables or disables the Global Set/ Reset (GSR) for all registered primitives. Applicable to registers, PLLs, and memories such as SP8KA, DP8KA and the like.
INIT	Hexadecimal	Hex value or string	All zeros	Initializes the look-up table values. INIT is required to specify the look-up table values for the LUT primitives (ORCALUT4, 5, 6, 7, or 8). See ORCALUT4 for more information on INIT attribute usage.
INIT_DATA	String	STATIC, DYNAMIC	STATIC	Defines whether or not the memory file can be updated. STATIC – Memory values are stored in the User Flash Memory (UFM) or bitstream but can be shared and can not be updated. DYNAMIC– Memory values are stored in the UFM and can be updated by user logic knowing the EBR address locations.
INITVAL	Hexadecimal	Hex value or string	All zeros	Specifies the initialization value for RAM type primitives (such as SPR16X2 and DPR16X2). These primitives carry prescribed initialization values, for example, DPR16X2 has an initialization value of 0x0000000000000000.
INJECT	Boolean	YES, NO	YES	This injection attribute is not a user selection. It is for software use only. Attached to a Carry Chain primitive.
IP_TYPE	String	EHXPLLA, CIDDLLA, CIMDLLA, TRDLLA, SDCDLLA	Vary	This attribute is not a user selection. It is for software use only. Attached to a PLL- or DLL-type primitive.

Table 837:

Attribute	Type	Allowed Values	Default	Description
I2Cx_ADDRESSING	String	7BIT, 10BIT	7BIT	Specifies the addressing scheme for i2c module: selects between 7-bit addressing and 10-bit addressing in i2c module. The value x represents an index: index 1 is for primary i2c module while index 2 is for the secondary i2c module
I2Cx_SLAVE_ADDR	Binary	Any 7-bit binary value, Any 10-bit binary value	0b0001000 001 (for primary module) 0b0001000 010 (for secondary module)	Specifies a default slave address during i2c hard IP generation. The last 2 bits of the 7-bit addressing and 10-bit addressing are hard-coded. ▶ Address ends xxxxx01 or xxxxxxxx01 for Primary module in user mode. ▶ Address ends xxxxx10 or xxxxxxxx10 for Secondary module.
I2Cx_BUS_PERF		50 kHz, 100kHz, 400 kHz	100 kHz	Master only. No software DRC for Master/Slave mode.
I2Cx_CLK_DIVIDER	Integer	1 to 1024	1	Read-Only display of I2Cx_CLK_DIVIDER value.
I2Cx_GEN_CALL	Boolean	ENABLED, DISABLED	DISABLED	Enables the generic call response in Slave. The attribute is disabled by default.
I2Cx_WAKEUP	Boolean	ENABLED, DISABLED	DISABLED	Enables/disables the i2c core to send a wake up signal to the on chip power manager to wake up the part from standby/sleep mode when the slave address matches. Default is disabled so that the device is in lower power mode
ISI_CAL	String	BYPASS, DEL1, DEL2, DEL3, DEL4, DEL5, DEL6, DEL7	BYPASS	Sets the ISI correction values in the ODDRX2D and ODDRX2DQSA blocks.
JTAG_FLASH_PRGRM	Boolean	ENABLED, DISABLED	ENABLED	When set to ENABLED, enables the use of the ispJTAG interface to program or write to Flash devices. Refer to TN1100 - SPI Serial Flash Programming Using ispJTAG in LatticeSC Devices on the Lattice Web site for more information.
LEGACY	Boolean	ENABLED, DISABLED	DISABLED	This attribute is required to support LatticeECP2 to LatticeECP3 mapping. Attached to the ALU54A primitive.

Table 837:

Attribute	Type	Allowed Values	Default	Description
LOCK_CYC	Integer	Integer value	2	This lock cycle attribute is not a user selection. It is for software use only. Attached to a PLL- or DLL-type primitive.
LOCK_DELAY	Integer	0 to 1000 (in ns)	100	This is a PLL-lock time attribute used for simulation. If you wish to enter other than the default value of 100 ns, it can be done by adding this attribute in the DEFPARAM section of the code generated by IPexpress. You can also set this attribute in the Spreadsheet view.
LOCK_SENSITIVITY	String	HIGH, LOW	LOW	This DLL configuration attribute selects greater or less sensitivity to the jitter. **Note**: There is a known issue for the LatticeXP family. The DQSDLL attribute LOCK_SENSITIVITY will always be set to LOW even if you attempt to set it to HIGH. Devices impacted are LFXP20E/C, LFXP15E/C, LFXP10E/C, LFXP6E/C and LFXP3E/C.
LPDDR	String	ENABLED, DISABLED	DISABLED	Turns the LPDDR feature on or off.
LSRMODE	String	EDGE, LOCAL	LOCAL	Attached to DDR and ISR primitives (such as IDDRA and ISRX1A), this attribute takes the EDGE and LOCAL mode options, which allows you to choose Local Set Reset or the Edge Set Reset.
MASK_ADDR	Hexadecimal	Any 4-bit hex value	All zeros	Specifies the starting mask address for the “care bits” mask. Attached to a SED-type primitive.
MASK01	Hexadecimal	Any 14-bit hex value	All zeros	Specifies the mask for EQZM/EQOM. Attached to the ALU54A primitive.
MASKPAT	Hexadecimal	Any 14-bit hex value	All zeros	Specifies the mask for EQPAT/EQPATB. Attached to the ALU54A primitive.
MASKPAT_SOURCE	String	STATIC, DYNAMIC	STATIC	Specifies the EQPAT/EQPATB source setting. Attached to the ALU54A primitive. MASKPAT_SOURCE and MCPAT_SOURCE cannot be DYANMIC at the same time.
MCCLK_FREQ	String	Vary	2.5 or 3.1	Controls the master clock frequency.
MCPAT	Hexadecimal	Any 14-bit hex value	All zeros	Specifies the MEM Cell Pattern. Attached to the ALU54A primitive.

Table 837:

Attribute	Type	Allowed Values	Default	Description
MCPAT_SOURCE	String	STATIC, DYNAMIC	STATIC	Specifies the MEM Cell Pattern source setting. Attached to the ALU54A primitive. MASKPAT_SOURCE and MCPAT_SOURCE cannot be DYANMIC at the same time.
MEMMODE	String	DISABLED, ENABLED	DISABLED	Indicates the memory mode or generic mode.
MODULE_TYPE	String	EHXPLLA, CIDDLLA, CIMDLLA, TRDLLA, SDCDLLA	Vary	This attribute is not a user selection. It is for software use only. Attached to a PLL- or DLL-type primitive.
MULT_BYPASS	Boolean	ENABLED, DISABLED	DISABLED	Enables or disables Multiplier Output Bypass. Attached to DSP primitives such as MULT9X9C and MULT18X18C.
MULT9_MODE	Boolean	ENABLED, DISABLED	DISABLED	Enables or disables the operation in the Mult9 mode. Attached to the ALU54A primitive.
NOM_FREQ	Real	Vary	Vary	Specifies the nominal frequency (in MHz) for oscillator primitives.
NRZMODE	String	DISABLED, ENABLED	DISABLED	Specifies NRZMODE for DDR3_MEM mode for the DQSBUFD primitive.
OSC_DIV	Integer	1, 2, 4, 8, 16, 32, 64, 128, 256	1	Used for the Soft Error Detect (SED). As an attribute for the internal oscillator, OSC_DIV specifies the divisor of the CCLK frequency to be used in the SED module or corresponding primitives.
PHASE_CNTL	String	DYNAMIC, STATIC	STATIC	Specifies the Phase Adjustment Select mode. When this is set to DYNAMIC, the Phase Adjustment Select control switches between Dynamic and Static depending upon the input logic of the DPAMODE pin. If the attribute is set to STATIC, Dynamic Phase Adjustment Select inputs are ignored.
PHASE_DELAY_CNTL	String	DYNAMIC, STATIC	STATIC	Specifies the CLKOS Phase and Duty Control/Duty Trimming mode. Attached to a PLL-type primitive.
PHASE_SHIFT	Integer	45, 57, 68, 79, 90, 101, 112, 123, 135	90	Phase shift value used. This is required for Simulation. DRC Check: This should match the PHASE_SHIFT value set in the DDRDLLA.

Table 837:

Attribute	Type	Allowed Values	Default	Description
PHASEADJ	Real	Vary	0	Specifies the Coarse Phase Shift setting. Attached to a PLL-type primitive (such as EHXPLLB).
PLLCAP	String	ENABLED, DISABLED, AUTO	DISABLED	Enables or disables the external capacitor pin. Attached to a PLL-type primitive. This attribute value will be usedand updated by MPAR. MPAR converts AUTO to DISABLED or ENABLED as per the placement. This attribute has no impact on the simulation.
PLLTYPE	String	AUTO, SPLL, GPLL	AUTO	Specifies the PLL configuration mode. Applicable only for the EPLLD primitive. This attribute value will be used by MPAR. It has no impact on simulation or bit generation.
POROFF	Boolean	TRUE, FALSE	FALSE	Turns on or off POR when in standby.
REG_<*RegisterType*> _<*RegisterName*>	String	Vary	Vary	This attribute applies to DSP block multipliers to enable various registers, such as Input Registers, Pipeline Registers, Output Registers, Signed Registers, Signed Pipeline Registers, and Accumulator Load Pipeline Registers. Attribute value is the register name. For clocks, you can also assign “NONE” to the attribute. Refer to appropriate DSP User Guide on the Lattice Web site for more details.
REGMODE	String	NOREG, OUTREG	NOREG	Specifies the register mode for pipelining.
REGSET	String	SET, RESET	RESET	Sets the output to either SET or RESET for input and output DDR and shift register elements.
RESETMODE	String	ASYNC, SYNC	Vary	Specifies the reset type. This attribute is attached to a block RAM-type primitive that has a memory size smaller than 9 bits. When set to SYNC, the memory reset is synchronized with the clock. When set to ASYNC, the memory reset is asynchronous to the clock.
RNDPAT	Hexadecimal	Any 14-bit hex value	All zeros	Specifies the Rounding Pattern. Attached to the ALU54A primitive.
RST_PULSE	Integer	Integer value	1	Specifies the required reset pulse length. Attached to the Power Up Reset (PUR) primitive.

Table 837:

Attribute	Type	Allowed Values	Default	Description
SCLKLATENCY	Integer	1, 2 (on the top only 1 is valid)	1	Adjusts SCLK latency. For simulation only.
SED_CLK_FREQ	String	2.08, 2.15, 2.22, 2.29, 2.38, 2.46, 2.56, 2.66, 2.77, 2.89, 3.02, 3.17, 3.33, 3.5, 3.69, 3.91, 4.16, 4.29, 4.43, 4.59, 4.75, 4.93, 5.12, 5.32, 5.54, 5.78, 6.05, 6.33, 6.65, 7, 7.39, 7.82, 8.31, 8.58, 8.87, 9.17, 9.5, 9.85, 10.23, 10.64, 11.08, 11.57, 12.09, 12.67, 13.3, 14, 14.78, 15.65, 16.63, 17.73, 19, 20.46, 22.17, 24.18, 26.6, 29.56, 33.25, 38, 44.33, 53.2, 66.5, 88.67, 133	3.5	Specifies the SED clock frequency.
SHIFT_IN	Boolean	TRUE, FALSE	FALSE	Specifies shift for data. Attached to a DSP multiplier primitive.
SMI_OFFSET	Hexadecimal	Hex value	0x410, 12'h410	Specifies Serial Management Interface offset. Attached to a PLL or DLL primitive.
SPI_MODE	String	SLAVE, BOTH	SLAVE	This option allows the user to select between Slave or Both mode for the initial state of the SPI block.
SPI_CLK_DIVIDER	Integer	1 to 64	1	Allows the user to specify a desired master clock frequency. Applies to SLAVE or BOTH operation mode.
SPI_LSB_FIRST	Boolean	ENABLED, DISABLED	DISABLED	Allows for programmable data order (MSB or LSB first) in the SPI core.
SPI_CLK_INV	Boolean	ENABLED, DISABLED	DISABLED	Allows to program the clock polarity used to sample and output data withing the SPI core.
SPI_PHASE_ADJ	Boolean	ENABLED, DISABLED	DISABLED	Allows the user to specify a phase change to match the application. An alternate clock-data relationship is available for SPI devices with particular requirements.
SPI_SLAVE_HANDSHAKE	Boolean	ENABLED, DISABLED	DISABLED	Enables the core to insert certain values into the data stream to inform the external master when data can be sent.

Table 837:

Attribute	Type	Allowed Values	Default	Description
SPI_INTR_TXRDY	Boolean	ENABLED, DISABLED	DISABLED	The core has configurable reset generation for data buffer conditions. The user can specify which of these options is desired.
SPI_INTR_RXRDY	Boolean	ENABLED, DISABLED	DISABLED	The core has configurable reset generation for data buffer conditions. The user can specify which of these options is desired.
SPI_INTR_TXOVR	Boolean	ENABLED, DISABLED	DISABLED	The core has configurable reset generation for data buffer conditions. The user can specify which of these options is desired.
SPI_INTR_RXOVR	Boolean	ENABLED, DISABLED	DISABLED	The core has configurable reset generation for data buffer conditions. The user can specify which of these options is desired.
SPI_WAKEUP	Boolean	ENABLED, DISABLED	DISABLED	Allows the user to enable this feature where the core can optionally provide a wakeup signal to the device to resume from low-power modes. Applies to SLAVE or BOTH operation mode.
STDBYOPT	String	USER, CFG, USER_CFG	USER_CFG	Specifies the entry option for entry signals.
TAG_INITIALIZATION	Boolean	ENABLED, DISABLED	DISABLED	Attached to the SSPIA primitive. When this attribute is set to DISABLED, the TAG configuration will be generated without an initialization file, and TAG_INITVAL_* will be all zeros. When this is set to ENABLED, the TAG configuration will be generated with an initialization file, and TAG_INITVAL_* will contain the initialization data. Any un-initialized byte word will default to 00000000 (software default).
TAG_INITSIZE	Integer	448, 632, 768, 2184, 2488, 2640, 3384, 3608	2184	Specifies the TAG Memory size. Attached to the SSPIA primitive.
TAG_INITVAL	Hexadecimal	Any 80-bit hex value	All zeros	Specifies the TAG initialization value. The 80-bit hex string corresponds to the 320 TAG bits. Attached to the SSPIA primitive.
TC_MODE	String	WATCHDOG, CTCM, FASTPWM, PFCPWM	CTCM	Timer/Counter Mode Setting.

Table 837:

Attribute	Type	Allowed Values	Default	Description
TC_SCLK_SEL	String	PCLOCK, POSC, NCLOCK, NOSC	PCLOCK	Timer/Counter Input Clock Setting.
TC_CCLK_SEL	Integer	0, 1, 8, 64, 256, 1024	1	Timer/Counter Input Clock Divider Setting.
TC_TOP_SET	Integer	0 to 65535	65535	Specifies the Timer/Counter Top Set value.
TC_OCR_SET	Integer	0 to 65535	32767	Specified the Timer/Counter OCR Set value.
TC_OC_MODE	String	STATIC, TOGGLE, WAVE_GENERATOR, INV_WAVE_GENERATOR	TOGGLE	Mode Selection on TC_OC waveform generation.
TC_RESETN	Boolean	ENABLED, DISABLED	ENABLED	Timer/Counter reset enable.
TC_TOP_SEL	Boolean	ON, OFF	ON	Sets Top Counter value.
TC_OV_INT	Boolean	ON, OFF	OFF	Timer/Counter overflow interrupt request.
TC_OCR_INT	Boolean	ON, OFF	OFF	Timer/Counter interrupt request.
TC_ICR_INT	Boolean	ON, OFF	OFF	The input capture interrupt.
TC_OVERFLOW	Boolean	ENABLED, DISABLED	ENABLED	Enables Timer/Counter for an overflow tag.
TC_ICAPTURE	Boolean	ENABLED, DISABLED	DISABLED	Enables Timer/Counter for input capture.
TIMEOUT	String	BYPASS, USER, COUNTER	BYPASS	Specifies the stop to standby delay.
UDS_TRN	128-bit value	Any 128-bit value	0	Unique Device Secret. Setting to all 0s disables the UDS feature.
UDS_TRN_FORMAT		BIN, HEX, ASCII	ASCII	Format for Unique Device Secret.
UFMx_INIT_PAGES	Integer	0 to Max Number of Pages in UFM array.	0	Specifies the number of pages with initialization data for UFMx, where x holds value between 0 to 3. If the user doesn’t enter a value, it is set to 0.
UFMx_INIT_START_PAGE	Integer	Calculated by software.	0	Software calculates and displays the starting page of the init data in the UFM array, where x holds value between 0 to 3. Read only field.
UFMx_INIT_ALL_ZEROS	Boolean	ENABLED, DISABLED	ENABLED	Specifies that the User Flash Memory is initialized with all 0s. x can hold a value between 0 to 3. By default, the radio button is selected.

Table 837:

Attribute	Type	Allowed Values	Default	Description
UFMx_INIT_FILE_NAME	String	String	None	Uploads the User Flash Memory Initialization data file, where x holds value between 0 to 3. By default, the radio button is not selected. The browse button is not enabled if the radio button is not selected.
UFMx_INIT_FILE_FORMAT	String	HEX, BIN	HEX	Specifies the selection of file format, either Binary or Hexadecimal, x holds a value between 0 and 3.
UPDT	String	POS, NEG	POS	Attached to a DDR-type primitive (such as ODDRX4A), the UPDT attribute takes the POS and NEG options, which allows you to update block output.
WAIT_FOR_EDGE	Boolean	ENABLED, DISABLED	ENABLED	Wait for edge.
WAKE_ON_LOCK	Boolean	ON, OFF	ON, OFF	This is a legacy attribute and not supported for new configurations. Attached to a PLL-type primitive.
WAKEUP	String	USER, CFG, USER_CFG	USER_CFG	Specifies the wake option for wake signals. There are three options. ▶ USER: In this case, MAP checks for the connection to the USERSTDBY pin only. If the pin is not driven by a signal that can be toggled, MAP issues error with DRC for this case only. ▶ CFG: In this case, MAP checks for JTAG, I2C, and SLAVE_SPI. If all are disabled, MAP errors out with config mode error. ▶ USER_CFG: In this case, MAP checks the USERSTDBY pin connection and JTAG, I2C, and SLAVE_SPI. Map errors out only when the USERSTDBY pin is not driven by live signal and all settings are disabled.

Table 837:

Attribute	Type	Allowed Values	Default	Description
WRITEMODE	String	NORMAL, WRITETHROUGH, READBEFORE	NORMAL	Specifies Read/Write mode. Attached to a dual- and single-port RAM primitive. WRITEMODE_A and WRITEMODE_B are used for dual-port RAM primitives and refer to the A and B ports.
WRITE_LEVELING	String	0T, 1T, 2T	2T	Sets the Write Leveling. 0T: for DDR2, or DDR3 without WL. 1T: For DDR3 with 1T. 2T: for DDR3 with 2T range.

Chapter 20

Command Line Reference Guide

This help guide contains information necessary for running the core design flow development from the command line. For tools that appear in the Diamond graphical user interface, use Tcl commands to perform commands that are described in the “Tcl Command Reference Guide” on page 2554.

Command Line Program Overview

Lattice FPGA command line programs can be referred to as the FPGA flow core tools. These are tools necessary to run a complete design flow and are used for tasks such as module generation, design implementation, design verification, and design configuration. This topic provides an overview of those tools, their functions, and provides links to detailed usage information on each tool.

Each command line program provides multiple options for specifying device information, applying special functions using switches, designating desired output file names, and using command files. The programs also have particular default behavior often precludes the need for some syntax, making commands less complex. See “Command Line General Guidelines” on page 2435 and “Command Line Syntax Conventions” on page 2437.

To learn more about the applications, usage, and syntax for each command line program, click on the hyperlink of the command line name in the section below.

Note

Many of the command line programs described in this topic are run in the background when using the tools you run in the Diamond environment. Please also note that in some cases, command line tools described here are used for earlier FPGA architectures only, are not always recommended for command line use, or are only available from the command line.

Design Implementation Using Command Line Tools The table below shows all of the command line tools used for various design functions, their

graphical user interface counterparts, and provides functional descriptions of each.

Table 838: Diamond Core Design and Tool Chart

Design Function	Command Line Tool	Diamond Process	Description
Core Implementation and Auxiliary Tools			
Simulation	cmpl_libs.tcl	Simulation	Simulation libraries compilation.
Synthesis	SYNTHESIS	Synthesis Design	(*MachXO/XO2 Only*) Runs input source files though synthesis based on Lattice Synthesis Engine options set in Strategies.
Synthesis	synpwrap	Synthesis Design	Used to manage Synplicity Synplify and Synplify Pro synthesis programs.
Netlist Translation and Conversion	EDIF2NGD NGDBUILD	Translate Database	Converts netlists into generic databases which use native primitive terms that the system can interpret and implement.
Mapping	MAP	Map Design	Converts a design represented in logical terms into a network of physical components or configurable logic blocks.
Placement and Routing	PAR	Place & Route Design	Assigns physical locations to mapped components and creates physical connections to join components in an electrical network.
Static Timing Analysis	TRCE	MAP TRACE Report, Place & Route TRACE Report	Generates reports that can be used for static timing analysis. Also known as TRACE.
I/O Timing Analysis	IOTIMING	I/O Timing Analysis	Generates a report that provides port information regarding setup/hold time requirements and min/max clock-to-out delay. Also determines the clocks and their associated data ports.
I/O SSO (Simultaneous Switching Output) Analysis	SSOANA	SSO Analysis	Generates an SSO analysis report (.sso) based on the SSO preferences you specified in your LPF file.

Table 838: Diamond Core Design and Tool Chart

Design Function	Command Line Tool	Diamond Process	Description
Backannotation	LDBANNO	Tool does not exist in Diamond interface as process but employed in file export.	Distributes the physical design information back to the logical design to generate a timing simulation file.
Convert Logical PCS Attributes to Physical PCS Attributes (LatticeEPC3 only)	LTXT2PTXT	Not applicable.	Converts Logical PCS Attributes to Physical PCS Attributes (LatticeEPC3 only)
Bitstream Generation	BITGEN	Bitstream	Converts a fully routed physical design into configuration bitstream data.
Device Programming	PGRCMD	Device Programming	Downloads data files to an FPGA device.
Deployment Tool	DDTCMD	Deployment Tool	Converts data files to other formats. Also, uses the data files produced to generate other data file formats.

Command Line Basics

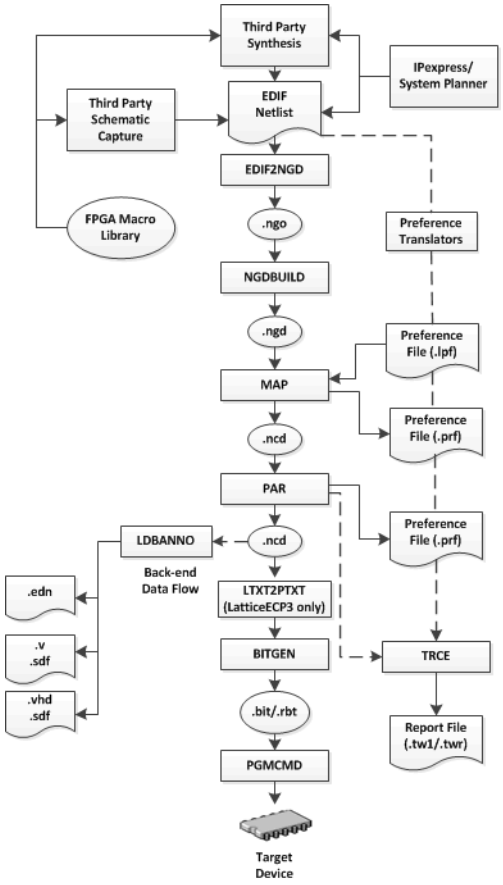
This section provides basic instructions for running any of the core design flow development and tools from the command line.

Topics include:

Command Line Data Flow

The following chart illustrates the FPGA command line tool data flow through a typical design cycle.

Command Line Tool Data Flow



See Also ▶"Command Line Reference Guide" on page 2432

- "Command Line General Guidelines" on page 2435

Command Line General Guidelines

You can run the FPGA family Diamond design tools from the command line. The following are general guidelines that apply.

- Files are position-dependent. Generally, they follow the convention [options] <infile> <outfile> <preference_file> (although order of <outfile> and <infile> are sometimes reversed). Use the **-h** command line option to check the exact syntax; for example, **par -h**.

- For any Diamond FPGA command line program, you can invoke help on available options with the **-h** or **-help** command. See "Invoking Core Tool Command Line Programs" on page 2439 for more information.
- Command line options are entered on the command line in any order, preceded by a hyphen (-), and separated by spaces.
- Most command line options are case-sensitive and must be entered in lowercase letters. When an option requires an additional parameter, the option and the parameter must be separated by spaces or tabs (i.e., **-l 5** is correct, **-l5** is not).
- Options that do not require an additional parameter may be grouped together preceded by a single hyphen (i.e., **-arw** is the same as **-a -r -w**).
- Options can appear anywhere on the command line. Arguments that are bound to a particular option must appear after the option (i.e., **-f** <command_file> is legal; <command_file> **-f** is not).
- For options that may be specified multiple times, in most cases the option letter must precede each parameter. For example, **-b romeo juliet** is not acceptable, while **-b romeo -b juliet** is acceptable.
- If you enter the FPGA family Diamond application name on the command line with no arguments and the application requires one or more arguments (**par,** for example), you get a brief usage message consisting of the command line format string.
- For any Diamond FPGA command line program, you can store program commands in a command file. Execute an entire batch of arguments by entering the program name, followed by the **–f** option, and the command file name. This is useful if you frequently execute the same arguments each time you execute a program or to avoid typing lengthy command line arguments. See "Using Command Files" on page 2550.

Command Line Syntax Conventions

The following conventions are used when commands are described:

Table 839: Command Line Syntax Conventions

Convention	Meaning
( )	Encloses a logical grouping for a choice between sub-formats.
[ ]	Encloses items that are optional. (Do not type the brackets.) Note that <infile[**.ncd**]> indicates that the .ncd extension is optional but that the extension must be NCD.
{ }	Encloses items that may be repeated zero or more times.
|	Logical OR function. You must choose one or a number of options. For example, if the command syntax says **pan up | down | right | left** you enter **pan up** or **pan down** or **pan right** or **pan left**.
< >	Encloses a variable name or number for which you must substitute information.
, (comma)	Indicates a range for an integer variable.
- (dash)	Indicates the start of an option name.
:	The bind operator. Binds a variable name to a range.
bold text	Indicates text to be taken literally. You type this text exactly as shown (for example, “Type **autoroute -all -i 5** in the command area.”) Bold text is also used to indicate the name of an EPIC command, a UNIX command, or a DOS command (for example, “The **playback** command is used to execute the macro you created.”).
Italic text or text enclosed in angle brackets <>	Indicates text that is not to be taken literally. You must substitute information for the enclosed text. Italic text is also used to show a file directory path, for example, “the file is in the /cd/data/diamond directory”).
Monospace	Indicates text that appears on the screen (for example, “File already exists.”) and text from UNIX or DOS text files. Monospace text is also used for the names of documents, files, and file extensions (for example, “Edit the autoexec.bat file” or “Native Circuit Description (.ncd) files.”

Setting Up the Environment to Run Command Line

For Windows The environments for both the Diamond Tcl Console window or Diamond Standalone Tcl Console window (pnmainc.exe) are already set. You can start entering Tcl tool command or core tool commands in the console and the software will perform them.

When running Diamond from the Windows command line (via cmd.exe), you will need to add the appropriate values to the following environment variables:

- PATH (for 32-bit systems)

  `<Install_directory>\bin\nt;<Install_directory>\ispfpga\bin\nt;`

  Example:

  `c:\lscc\diamond\3.10\bin\nt;c:\lscc\diamond\3.10\ispfpga\bin\nt;`

- PATH (for 64-bit systems)

  `<Install_directory>\bin\nt64;<Install_directory>\ispfpga\bin\nt64;`

  Example:

  `c:\lscc\diamond\3.10\bin\nt64;c:\lscc\diamond\3.10\ispfpga\bin\nt64;`

- FOUNDRY (all systems)

  `<Install_directory>\ispfpg`

  Example:

  `set FOUNDRY = c:\lscc\diamond\3.10_x64\ispfpga`

For Linux On Linux, Diamond software provides a similar standalone Tcl Console window (pnmainc) that sets the environment. The user can enter Tcl commands and core tool commands in it.

If you do not use the Tcl Console window, before running any of the command line programs, you need to run the following command:

- For CSH (64-bit systems):

  ```
  cd <install_path>/diamond/3.10/bin/lin64
  source setupenv
  ```

- For BASH (64-bit):

  ```
  export bindir=<Install_directory>/bin/lin64
  source $bindir/diamond_env
  ```

After setting up for either Windows or PC, you can run the Diamond executable files directly. For example, you can invoke the Place and Route program by:

```
par -w test_map.ncd test.ncd test.prf
```

Invoking Core Tool Command Line Programs

This topic provides general guidance for running the Diamond FPGA flow core tools. Refer to "Command Line Program Overview" on page 2432 to see what these tools include and for further information.

For any Diamond FPGA command line programs, you begin by entering the name of the command line program followed by valid options for the program separated by spaces. Options include switches (**-f**, **-p**, **-o**, etc.), values for those switches, and file names, which are either input or output files. You start command line programs by entering a command in the UNIX™ or DOS™ command line. You can also run command line scripts or command files.

See the table in the section Design Implementation Using Command Line Tools in "Command Line Reference Guide" on page 2432 for details and links to specific information on usage and syntax. You will find all of the usage information on the command line in the **Running FPGA Tools from the Command Line > Command Line Tool Usage** book topics.

See Also ▶"Command Line Reference Guide" on page 2432

- "Command Line Syntax Conventions" on page 2437

- "Setting Up the Environment to Run Command Line" on page 2438
- "Using Command Files" on page 2550

Invoking Core Tool Command Line Tool Help

To get a brief usage message plus a verbose message that explains each of the options and arguments, enter the FPGA family Diamond application name on the command line followed by **-help** or **-h**. For example, enter **bitgen -h** for option descriptions for the **bitgen** program.

To redirect this message to a file (to read later or to print out), enter this command:

command_name -help | -h > filename

The usage message is redirected to the filename that you specify.

For those FPGA family Diamond applications that have architecture-specific command lines (e.g., or2c00a), you must enter the application name, **-help** (or **-h**), and the architecture to get the verbose usage message specific to that architecture. If you fail to specify the architecture, you get a message similar to the following:

Use '<appname> -help <architecture>' to get detailed usage for a particular architecture.

Reading NCD Files

If you need to read a Native Circuit Description (.ncd) file, that is a physical design NCD file, you can use the NCDREAD utility program that is available in the <install_dir>\ispFPGA\bin\nt | sol file path for PC and UNIX/Linux platforms respectively. This utility is only available from the command line.

NCD files represent your design as a network of device-specific components (e.g., PFUs, PFFs, and EBRs) or configurable logic blocks in the form of a physical design (NCD). These files are the output of the **Map Design** (**map**) and **Place & Route Design** (**par**) processes in Diamond.

Using NCDREAD, you can quickly generate an ASCII (text) file based on the data found in one or more NCD files.

To run NCDREAD from the UNIX or DOS command line:

- Type in the **ncdread** command with valid options and enter. Syntax for this utility is as follows:

ncdread [**–o** <outfile_name>] <infile1[.**ncd**]> {<infile2[.**prf**]> ...}

where the .prf file is the project preference file.

Note

If you do not specify the **–o** option to write the output to a file, standard output goes to your screen.

Example 1 An example of an actual command line argument might be as follows:

ncdread –o readfile.txt arcrad4.ncd ramus256.prf

Example 2 You may want to find an HDL instance name of a given memory, you could use the NCDREAD program utility on your NCD file to generate a text file containing those names. Note however that the Memory Generation Tool in Diamond automates this process. For example,

ncdread rom8x8.ncd -o rom8x8.out

In the above command line, an NCD file named **rom8x8** is used as input for NCDREAD, outputting a text file called **rom8x8.out**.

Now, look in the **rom8x8.out** text file for the instance name using a text editing tool to search on the word “INITVAL” in the Config String. When you find an occurrence of INITVAL, look for the corresponding COMP name in the line right above it as shown in the example below:

```
NC_COMP:20 - <TEST/rom8x8_0_0_0>, site = EBR_R10C6
```

In the above COMP name, **TEST** is the instance name. The **rom8x8_0_0_0** value is generated during module generation and is based upon how many EBRs this particular memory takes. So, if the memory takes two EBRs, then there will be two NC_COMPs with the name values of **TEST/rom8x8_0_0_0** and **TEST/rom8x8_0_0_1**. In this case, the instance name would be still be **TEST**. See “Sample Text-Converted NCD File” on page 2441if you wish to test this search on INITVAL.

Command Line Tool Usage

This section contains usage information of all of the command line tools and valid syntax descriptions for each.

Topics include:

Running cmpl_lib.tcl from the Command Line

The cmpl_lib.tcl command allows you to perform simulation library compliation from the command line.

The following information is for running cmpl_libs.tcl from the command line using the tclsh application. The supported TCL version is 8.5 or higher.

If you don't have TCL installed, or you have an older version, perform the following:

- Add <*Diamond_install_path*>/tcltk/bin to the front of your PATH, and

- For Linux users only, add <*Diamond_install_path*>/tcltk/lib to the front of your LD_LIBRARY_PATH

Note

The default version of TCL on Linux could be older and may cause the script to fail. Ensure that you have TCL version 8.5 or higher.

To check TCL version, type:

```
tclsh
% info tclversion
% exit
```

For script usage, type:

```
tclsh cmpl_libs.tcl [-h|-help|]
```

Note

If Modelsim/Questa is already in your PATH and preceding any Aldec tools, you can use:

'-sim_path .' for simplification; '.' will be added to the front of your PATH.

Note

Ensure the FOUNDRY environment variable is set. If the FOUNDRY environment variable is missing, then you need to set it before running the script. For details, refer to "Setting Up the Environment to Run Command Line" on page 2438.

Check log files under <*target_path*> (defualt = .) for any errors, as follows:

- For Linux, type:

  ```
  grep -i error *.log
  ```

- For Windows, type:

  ```
  find /i "error" *.log
  ```

Subjects included in this topic:

Running compl_lib.tcl cmpl_libs.tcl allows you to compile simulation libraries from the command line.

Command Line Syntax tclsh <*diamond_install_path*>/cae_library/simulation/script/cmpl_libs.tcl -sim_path <sim_path> [-sim_vendor {mentor<default>}] [-lang {verilog|vhdl|all<default>}] [-device {sc|scm|ec|xp|ecp|machxo|ecp2|ecp2m|xp2|ecp3|machxo2|machxo3d|machxo3l|lptm|lptm2|ecp5u|ecp5um|lifmd|all<default>}] [-target_path <target_path>]

cmpl_lib.tcl Options The table below contains all valid options for cmpl_libs.tcl

Table 840: cmpl_lib.tcl Command Line Options

Option	Description
-sim_path <sim_path> [-sim_vendor {mentor<default>}] [-lang {verilog|vhdl|all<default>}] [-device {sc|scm|ec|xp|ecp|machxo|ecp2|ecp2m|xp2|ecp3|machxo2|machxo3d|machxo3l|lptm|lptm2|ecp5u|ecp5um|lifmd|all<default>}] [-target_path <target_path>]	▶ The -sim_path argument specifies the path to the simulation tool executable (binary) folder. This option is mandatory. Currently only Modelsim and Questa simulators are supported. NOTE: If <*sim_path*> has spaces, then it must be surrounded by " ". Do not use { }. ▶ The -sim_vendor argument is optional, and intended for future use. It currently supports only Mentor Graphics simulators (Modelsim / Questa). ▶ The -lang argument specifies the HDL type of the compiled libraries. This argument is optional, and the default is to compile both types of libraries. ▶ The -device argument specifies the Lattice FPGA device to compile simulation libraries for. This argument is optional, and the default is to compile libraries for all the Lattice FPGA devices. ▶ The -target_path argument specifies the target path, where you want the compiled libraries and modelsim.ini file to be located. This argument is optional, and the default target path is the current folder. NOTES: (1) This argument is recommended if the current folder is the Diamond's startup (binary) folder, or if the current folder is write-protected. (2) If <*target_path*> has spaces, then it must be surrounded by " ". Do not use { }.

Examples This section illustrates and describes a few examples of Simulation Libraries Compilation Tcl command.

Example 1 The following command will compile all the Lattice FPGA libraries for both Verilog and VHDL simulation, and place them under the folder specified by -target_path. The path to Modelsim is specified by -sim_path.

```
tclsh <Diamond_install_path>/cae_library/simulation/script/
cmpl_libs.tcl -sim_path C:/modeltech64_10.0c/win64 -target_path
c:/mti_libs
```

Example 2 The following command will compile the LatticeECP3 libraries for Verilog simulation only, and place them under the current folder. The path to Modelsim is specified by -sim_path.

```
tclsh <Diamond_install_path>/cae_library/simulation/script/
cmpl_libs.tcl -sim_path C:\modeltech_6.6d\win32 -device ecp3 -
lang verilog
```

Note

Backslash (\) is for Windows paths only. For Linux, use forward slash (/).

Running SYNTHESIS from the Command Line

The Lattice synthesis tool SYNTHESIS allows you to synthesize source schematics, Verilog and VHDL HDL source files into netlists for design entry into the Diamond environment. Based on your strategy settings you specify in Diamond, a synthesis project (.synproj) file is created and then used by SYNTHESIS using the -f option. Diamond translates strategy options into command line options described in this topic.

Verilog source files are passed to the program using the **-ver** option and VHDL source files are passed using the **-vhd** option. For mixed language designs the language type is automatically determined by SYNTHESIS based on the top module of the design. For IP design, you must also specify IP location (**-ip_dir)**, IP core name (**-corename**), and encrypted RTL file name (**-ertl_file**).

For synthesis output, NGD and NGO formats cannot be used together in the same command. You must specify one or the other format. If NGO output is selected, the NGD file must be generated separately using the NGDBUILD command together with any other NGO files that may be required (e.g., PMIs).

Subjects included in this topic:

Running SYNTHESIS SYNTHESIS will convert your input netlist (.ed*, .v, .ngo) file into an .ngo file that is used for input for NGDBUILD.

- To run SYNTHESIS, type **synthesis** on the command line with valid options. A sample of a typical SYNTHESIS command would be as follows:

  synthesis -ngd v_top.ngd

There are many command line options that give you control over the way SYNTHESIS processes the output file. Please refer to the rest of the subjects in this topic for more details. See examples.

Command Line Syntax **synthesis** [**-a** <arch>] [**-d** <device>] [**-f** <file_name>][**-t** <package>] [**-p** <searchpath>] [**-top** <module_name>] [**-lib** <VHDL lib name>] [**-vhd** <VHDL files>] [**-ver** <Verilog files>] [**-hdl_param** <name,value>] [**-ngd** <file_name.ngd>] [**-ngo** <file_name.ngo>] [**-optimization_goal** <balanced | area | timing>] [**-force_gsr** <auto | yes | no>] [**-ramstyle** <auto | distributed | block_ram | registers>] [**-romstyle** <auto | logic | EBR>] [**-output_edif** <file_name.edf>] [**-sdc** <sdc_file.ldc>] [**-lpf** <pref_file.lpf>] [**-loop_limit** <value>] [**-logfile** <file_name>] [**-frequency** <value>] [**-max_fanout** <value>] [**-fsm_encoding_style** <binary | one-hot | gray>][**-bram_utilization** <value>] [**-mux_style** <auto | pfu_mux | L6Mux_single | L6Mux_multiple>] [**-use_carry_chain** <0|1>] [**-carry_chain_length** <chain_length>] [**-use_io_insertion** <0|1>] [**-use_io_reg** <0|1>] [**-resource_sharing** <0|1>] [**-propagate_constants** <0|1>] [**-remove_duplicate_regs** <0|1>] [**-ip_dir** <dir_name>] [**-corename** <core_name>] [**-ertl_file** <file_name>] [**-twr_paths** <num_paths >] [**-ifd**] [**-dt**] [**-fix_gated_clocks** <fix_gated_clocks_value>] [**-vh2008**] [**-key** <key_file>]

SYNTHESIS Options The table below contains descriptions of all valid options for SYNTHESIS.

Table 841: SYNTHESIS Command Line Options

Option	Description
-a <arch>	Sets the FPGA architecture. This synthesis option must be specified and if the value is set to any unsupported FPGA device architecture the command will fail.
-d <device>	Specifies the device type for the architecture (optional).
-f <file_name>	Specifies the synthesis project file name (.synproj). The project file can be edited by the user to contain all desired command line options.
-s <device>	Specifies the device peformance grade for the architecture (optional).
-t <package>	Specifies the package type of the device.
-p <searchpath>	Add searchpath for NGO files, Verilog “include” files (optional).
-top <module_name>	Name of top module (optional, but better to have to avoid ambiguity).
-lib <VHDL lib name>	Name of VHDL library (optional).
-vhd <VHDL files>	Names of VHDL design files (must have, if language is VHDL or mixed language).
-ver <Verilog files>	Names of Verilog design files (must have, if language is Verilog, or mixed language).
-hdl_param <name, value>	Allows you to override HDL parameter pairs in the design file.

Table 841: SYNTHESIS Command Line Options

Option	Description
-ngd <ngd_file>	Specifies the name of the NGD file output.
-ngo <ngo_file>	Specifies the name of the NGO file output. This is an optional switch that cannot be used in conjunction with the **-ngd** option.
-optimization_goal <balanced | area | timing>	The synthesis tool allows you to choose among the following optimization options: ▶ **balanced** balances the levels of logic. ▶ **area** optimizes the design for area by reducing the total amount of logic used for design implementation. ▶ **timing** optimizes the design for timing. The default setting depends on the device type. Smaller devices, such as MachXO and Platform Manager, default to balanced. Larger devices—ECP5U, ECP5UM, LatticeECP2, LatticeECP3, and LatticeXP2—default to timing.
-force_gsr <auto | yes | no>	Enables (**yes**) or disables (**no**) forced use of the global set/reset routing resources. When the value is auto, the synthesis tool decides whether to use the global set/reset resources. The default behavior is determined by the switch settings: When **-ngo** or **-output_edif** then the default is no. When **-ngd** then default is auto.

Table 841: SYNTHESIS Command Line Options

Option	Description
-ramstyle <auto | distributed | block_ram | registers>	Sets the type of random access memory globally to *distributed*, *embedded block RAM*, or *registers*.The default is auto which attempts to determine the best implementation, that is, synthesis tool will map to technology RAM resources (EBR/Distributed) based on the resource availability. This option will apply a syn_ramstyle attribute globally in the source to a module or to a RAM instance. To turn off RAM inference, set its value to registers. ▶ **registers** causes an inferred RAM to be mapped to registers (flip-flops and logic) rather than the technology-specific RAM resources. ▶ **distributed** causes the RAM to be implemented using the distributed RAM or PFU resources. ▶ **block_ram** causes the RAM to be implemented using the dedicated RAM resources. If your RAM resources are limited, for whatever reason, you can map additional RAMs to registers instead of the dedicated or distributed RAM resources using this attribute. ▶ **no_rw_check** (Certain technologies only). You cannot specify this value alone. Without no_rw_check, the synthesis tool inserts bypass logic around the RAM to prevent the mismatch. If you know your design does not read and write to the same address simultaneously, use no_rw_check to eliminate bypass logic. Use this value only when you cannot simultaneously read and write to the same RAM location and you want to minimize overhead logic.

Table 841: SYNTHESIS Command Line Options

Option	Description
-romstyle <auto | logic | EBR>	Allows you to globally implement ROM architectures using *dedicated* , *distributed ROM*, or a *combination of the two* (auto). This applies the syn_romstyle attribute globally to the design by adding the attribute to the module or entity. You can also specify this attribute on a single module or ROM instance. Specifying a syn_romstyle attribute globally or on a module or ROM instance with a value of: ▶ **auto** allows the synthesis tool to choose the best implementation to meet the design requirements for peformance, size, etc. ▶ **logic** causes the ROM to be implemented using the distributed ROM or PFU resources. Specifically, the logic value will implement ROM to logic (LUT4) or ROM technology primitives (e.g., ROM16X1, ROM32X1, ROM64X1 and so on). ▶ **EBR** causes the ROM to be mapped to dedicated EBR block resources. ROM address or data should be registered to map it to an EBR block. If your ROM resources are limited, for whatever reason, you can map additional ROM to registers instead of the dedicated or distributed RAM resources using this attribute. Infer ROM architectures using a CASE statement in your code. For the synthesis tool to implement a ROM, at least half of the available addresses in the CASE statement must be assigned a value. For example, consider a ROM with six address bits (64 unique addresses). The case statement for this ROM must specify values for at least 32 of the available addresses.
-output_edif <file_name.edf>	Specifies the name of the output EDIF netlist file.
-sdc <sdc_file.ldc>	Specifies a Synopsys design constraint (.ldc) file input.
-lpf <pref_file.lpf>	Specifies whether the logical preference file (.lpf) is written or is not written. 0 or False = .lpf file not written 1 or True = .lpf file is written The default value is 1 or True.

Table 841: SYNTHESIS Command Line Options

Option	Description
-loop_limit <value>	Specifies the iteration limits for “for” and “while” loops in the user RTL for loops that have the loop index as a variable and not a constant. The higher the loop_limit, the longer the run time. Also, for some designs, a higher loop limit may cause stack overflow during some of the optimizations during compile/synthesis. The default value is 1950. Setting a higher value may cause stack overflow during some of the optimizations during synthesis.
-logfile <file_name>	Specifies the name of the synthesis log file in ASCII format. If you do not specify a name, SYNTHESIS will output a file named synthesis.log by default.
-frequency <value>	Specifies the target frequency setting. Default frequency value is 200.0 MHz.
-max_fanout <value>	Specifies maximum global fanout limit to the entire design at the top level. Default value is 1000 fanouts.
-bram_utilization <value>	Specifies block RAM utilization target setting in percent of total vacant sites. Default is 100 percent.
-mux_style <auto | pfu_mux | L6Mux_single | L6Mux_multiple>	Specifies the MUX style setting. The -mux_style option controls the way the macrogenerator implements the multiplexer macros. Valid options are *auto*, *pfu_mux*, *L6Mux_single*, and *L6Mux_multiple*. The default value is auto, meaning that the tool looks for the best implementation for each considered macro.
-fsm_encoding_style <auto | one-hot | gray | binary>	Specifies One-Hot, Gray, or Binary style. The -fsm_encoding_style. Allows the user to determine which style is faster based on specific design implementation. Valid options are *auto*, *one-hot*, *gray*, and *binary*. The default value is auto, meaning that the tool looks for the best implementation.
-use_carry_chain <0|1>	Turns on (1) or off (0) carry chain implementation for adders. The 1 or true setting is the default.
-carry_chain_length <chain_length>	Specifies the maximum length of the carry chain.
-use_io_insertion <0|1>	Specifies the use of I/O insertion. The 1 or true setting is the default.

Table 841: SYNTHESIS Command Line Options

Option	Description
-use_io_reg <0|1>	Packs registers into I/O pad cells based on timing requirements for the target Lattice families. The value 1 enables and 0 disables (default) register packing. This applies it globally forcing the synthesis tool to pack all input, output, and I/O registers into I/O pad cells. NOTE: You can place the syn_useioff attribute on an individual register or port. When applied to a register, the synthesis tool packs the register into the pad cell, and when applied to a port, packs all registers attached to the port into the pad cell. The syn_useioff attribute can be set on a: ▶ top-level port ▶ register driving the top-level port ▶ lower-level port, only if the register is specified as part of the port declaration
-resource_sharing <0|1>	Specifies the resource sharing option. The 1 or true setting is the default.
-propagate_constants <0|1>	Prevents sequential optimization such as constant propagation, inverter push-through, and FSM extraction. The 1 or true setting is the default.
-remove_duplicate_regs <0|1>	Specifies the removal of duplicate registers. The 1 or true setting is the default.
-twr_paths <timing_path_cnt>	Specifies the number of critical paths.
-dt	Disables the hardware evaluation capability.
-ip_dir <dir_name>	Switch option used for specially licensed IP core source input. Specifies the IP installation directory that contains the decoding key for the encyrpted file. NOTE: The tool does not work with IP for MachXO devices.
-corename <core_name>	Switch option used for specially licensed IP core source input. Specifies the name of IP core which should match the correpsponding name in IPexpress.
-ertl_file <file_name>	Switch option used for specially licensed IP core source input. Specifies the name of encrypted IP RTL file.
-ifd	Sets option to dump intermediate files. If you run the tool with this option, it will dump about 20 intermediate encrypted Verilog files. If you supply Lattice with these files, they can be decrypted and analyzed for problems. This option is good to for analyzing simulation issues.
-fix_gated_clocks <fix_gated_clocks_value>	Allows you to enable/disable gated clock optimization. By default, the option is enabled.
-vh2008	Enables VHDL 2008 support.
-key <key_file>	Specifies key file to encrypted IP RTL file(s).

Examples Following are a few examples of SYNTHESIS command lines and a description of what each does.

Example 1 The following command is a simple example with Verilog and VHDL file inputs.

synthesis -a MachXO2 -d LCMXO256E -top top_name -vhd f1.vhd f2.vhd f3.vhd -ver file1.v file2.v -ngd file.ngd

Example 2 The following example illustrates the usage of a search path **-p** option for IP .ngo files or include files.

synthesis -a MachXO2 -d LCMXO256E -p c:/rel/tmp c:/dir1/dir2 -top top_name -vhd f1.vhd f2.vhd f3.vhd -ver file1.v file2.v -ngd file.ngd

Example 3 The following example shows VHDL library usage with the **-lib** option.

synthesis -a MachXO2 -d LCMXO256E -top top -lib work -vhd top.vhd -lib pck -vhd ff.vhd -ngd file.ngd

Example 4 The following example illustrates the usage of both the -hdl_param and -optimization_goal options.

synthesis -a MachXO2 -d LCMXO256E -hdl_param width 7 depth 5 -optimization_goal timing -ver test1.v.v f2.v -ngd file.ngd

Example 5 This is an example of a command line with encrypted RTL for IP designs.

synthesis -a MachXO2 -d LCMXO256E -corename file_datapath -ertl_file source/file_datapath_enc.vhd -ip_dir encryption -ngd file.ngo

Example 6 This example shows miscellaneous commands for illustrating various syntax structures.

synthesis -vhd source/ora.vhd source/top.vhdl source/anda_vhd.vhd

synthesis -ver source/anda.v source/v_top.v

synthesis -a MachXO2 -d LCMXO256E -force_gsr auto -ver top.v mid.v prim.v -vhd count.vhd

synthesis -lib ..\include_lib.v -o top.ngd -lpf top.lpf -sdc top.ldc

Running EDIF2NGD from the Command Line

The **Translate Design** process in the Diamond environment can also be run through the command line using two separate programs in the following process order: **edif2ngd** and **ngdbuild**. This topic describes how to use

EDIF2NGD from the command line. Refer to "Running NGDBUILD from the Command Line" on page 2460 to complete the Translate Design process using command line tools.

EDIF2NGD is used in netlist translation. Specifically, it is a netlist reader tool that converts a netlist (.ed*, .v, .vhd) file to an .ngo file. An .ngo file is a binary file describing the design in terms of the components and hierarchy specified in the input design file. EDIF2NGD accepts FPGA properties if they appear within the input file and passes them through to the output .ngo file. All other properties are ignored and are not written to the .ngo file.

Note

Acceptable extensions for EDIF files are .edn, .edf, and .edif.

Subjects included in this topic:

- Running EDIF2NGD
- Command Line Syntax
- EDIF2NGD Options
- Examples

Running EDIF2NDG EDIF2NGD converts your input netlist (.ed*, .v, .ngo) file into an .ngo file that is used for input for NGDBUILD.

- To run EDIF2NGD, type **edif2ngd** on the command line with, at minimum, the library name with the **-l** option, your input netlist and the name of your output Native Generic Object (.ngo) file. A sample of a typical EDIF2NGD command would be as follows:

  edif2ngd -l ep5g00 design.edn design.ngo

There are many command line options that give you control over the way EDIF2NGD processes the output file. Please refer to the rest of the subjects in this topic for more details. See examples.

Command Line Syntax **edif2ngd** [**-l** <libname> [**-d** <device>] [**-ip** <ippath>] [**-ic** <ipcore>] [**-nopropwarn**] [**-cbn** <format>] [**-r**] [**-f** <command_file>] <edif_file[.**edn**]> [<outfile[.**ngo**]>] [**-mc**]

EDIF2NGD Options The table below contains descriptions of all valid options for EDIF2NGD.

Table 842:

Option	Description
-l <libname>	Specifies libraries to search when determining what library components were used to build the design. NGDBUILD uses this information to resolve the components to Lattice FPGA primitives. A list of valid library names displays when you use the **edif2ngd -h** command. These names are case sensitive. Valid libraries include the following: ▶ Platform Manager 2 ▶ Platform Manager ▶ MachXO3D ▶ MachXO3LF ▶ MachXO3L ▶ MachXO2 ▶ MachXO ▶ LatticeXP2 ▶ LatticeXP ▶ LatticeSCM ▶ LatticeSC ▶ LatticeECP3 ▶ LatticeECP2M ▶ LatticeECP2 ▶ LatticeECP ▶ LatticeEC ▶ LIFMD ▶ ECP5UM5G ▶ ECP5UM ▶ ECP5U
-d <device>	Specifies a device name. The device name option can be used as an alternative to the **-l** <libname> option. These device names are case sensitive. An example of a valid device name would be **LFECP6E**. This is a LatticeECP device example. Device names are the first half of a valid part name. For example, for a specific LatticeECP part named LFECP6ETQFP144, **LFECP6E** is the device name and **TQFP144** is the name of the package type. For more information on part names see "Selecting Valid Part Names" on page 2472 in the topic on running the **map** tool from the command line. In Diamond, device names are shown in the device selector and also will appear in the EPIC Device Editor.

Table 842:

Option	Description
-ip <ippath>	Specifies a path to a Synplify encrypted EDIF formatted IP module to be read by EDIF2NGD. When Synplify reads encrypted RTL, it generates encrypted EDIF. This option is needed for “User Configurable IP”. Used in conjunction with the **-ic** option to provide the directory and name of the IP core associated with the EDIF file.
-ic <ipcore>	Specifies a path to a Synplify encrypted EDIF formatted IP core to be read by EDIF2NGD. When Synplify reads encrypted RTL, it generates encrypted EDIF. This option is needed for “User Configurable IP”. Used in conjunction with the **-ip** option to provide the directory and name of the IP EDIF file for which the core is associated.
-nopropwarn	Turns off warning messages on properties. This option is useful mostly for troubleshooting and testing a design to avoid long warning messages that you might expect after running the process.
-cbn <format>	Turns on the Consistent Bus Name Conversion property taking the values **lattice**, **synplify**, or **precision**. These are not case sensitive. When this property is set to **lattice**, it converts the “( )“, “[ ]“, “< >”, “{ }“ in the bus signal names to underscores “_”. For example, the bus name **aq[i]** is converted to **aq_i_**, **bq(i)** is converted to **bq_i_**, **cq<i>** is converted to **cq_i_**, **dq{i}** is converted to **dq_i_**, and so on. If given the value **synplify** or **precision**, bus signals names will be converted to match that format. Verilog and VHDL bus signal preferences will then be honored by Synplify and Precision RTL synthesis. Verilog or VHDL bus signal preferences set for Synplify will not be honored by Precision, and vice versa. If option does not appear in the command line, conversion of bus signal names does not take place.
-r	Filters out all LOCATION properties (LOC=) from the design. This can be used when you are migrating to a different device or architecture.
-f <command_file>	Executes the command line arguments in the specified command_file. See “The –f Option” on page 2551, “Command File Example” on page 2550, and “Using the Command File” on page 2551.

Table 842:

Option	Description
<edif_file[.**edn**] | [.**edf**]>	Name of the input netlist file in EDIF 2 0 0 format. If the file has an extension, you must enter the extension as part of edif_file. If you enter a filename without an extension, EDIF2NGD looks for an .edn file with the name you specified.
<outfile[.**ngo**]>	Output design file in .ngo format. The output filename, its extension, and its location are determined in this way: ▶ No output filename specified: The output file has the same name as the input file, with an .ngo extension. ▶ Output filename specified but with no extension: EDIF2NGD appends the .ngo extension to the filename. ▶ Output filename specified with an extension other than .ngo: Produces an error message and EDIF2NGD will not run. ▶ No full pathname: The output file is placed in the directory from which you ran EDIF2NGD. If the output file already exists, it will be overwritten with the new file.

Examples Following are a few examples of EDIF2NGD command lines and a description of what each does.

Example 1 The following command converts the netlist top.edn which uses the LatticeEC library to an .ngo file.

edif2ngd -l ep5g00 top.edn mapped.ngo

Example 2 The following command converts the netlist top.edn which uses the LatticeECP library to an .ngo file but uses the **-r** option to filter out all location attributes (LOC=) from the input netlist. This filtering option is useful when migrating to a different device or architecture.

edif2ngd -l ep5g00p -r top.edn mapped.ngo

Example 3 This example shows **edif2ngd** running a file command script file that is specified with the **-f** command. The command file is named edif2ngd.command.

edif2ngd -f edif2ngd.command

For example, this command file may contain several command options pertaining to multiple input netlists.

-l LatticeEC top.edn mapped.ngo
-l LatticeEC state.edn state.ngo
-l LatticeEC rom.edn rom.ngo

Example 4 This example shows **edif2ngd** using the consistent bus notation feature (-cbn) to convert bus signal names to match that synthesis format for a LatticeSC design. This ensures that during synthesis any bus signal preferences in the design are honored by the synthesis tool.

edif2ngd -l LatticeSC my.edif my.ngo -cbn synplify

- "Command Line Program Overview" on page 2432

Running NGDBUILD from the Command Line

The **Translate Design** process in the Diamond environment can also be run through the command line using two separate programs in the following process order: **edif2ngd** and **ngdbuild**. This topic describes how to use NGDBUILD from the command line. Refer to "Running EDIF2NGD from the Command Line" on page 2455 to complete the Translate Design process using command line tools.

The **ngdbuild** program translates one or more .ngo files and combines each component in the design to its equivalent Lattice FPGA primitives. Before you run **ngdbuild**, you must convert the top-level design file, and all files referenced in the top-level file, to .ngo format. This is done using the **edif2ngd** program.

Subjects included in this topic:

Running NDGBUILD NGDBUILD converts your input Native Generic Object (.ngo) file into a Native Generic Database (.ngd) file that can be used for input for MAP.

- To run NGDBUILD, type **ngdbuild** on the command line with, at minimum, the architecture name with the **-a** option, your input .ngo file, and the name of your output .ngd file. A sample of a typical NGDBUILD command would be as follows:

  ngdbuild -a ep5g00 design.ngo design.ngd

There are many command line options that give you control over the way NGDBUILD processes the output file. Please refer to the rest of the subjects in this topic for more details. See examples.

Command Line Syntax **ngdbuild -a** <architecture> {**-p** <search_path>} [**-f** <command_file>] [<ngo_file.[**ngo**]>] [<outfile.[**ngd**]>] [**-cbn**] [**-mc** | **-mc**

<module_name>] [**-assemble**] | [**-h** [<architecture>] | **-help** [<architecture>] | [**-f** <command_file>]

NGDBUILD Options The table below contains descriptions of all valid options for NGDBUILD.

Table 843: NGDBUILD Command Line Options

Option	Description
-a <architecture>	Specifies the architecture of the device to which your design will be mapped (and into which the design will eventually be programmed). When you specify the architecture, the output .ngd file is optimized for mapping into that architecture. A list of valid architectures displays when you use the **ngdbuild -h** command. These names are case sensitive. Valid architecture names include the following: ▶ Platform Manager 2 ▶ Platform Manager ▶ MachXO3D ▶ MachXO3LF ▶ MachXO3L ▶ MachXO2 ▶ MachXO ▶ LatticeXP2 ▶ LatticeXP ▶ LatticeSCM ▶ LatticeSC ▶ LatticeECP3 ▶ LatticeECP2M ▶ LatticeECP2 ▶ LatticeECP ▶ LatticeEC ▶ LIFMD ▶ ECP5UM5G ▶ ECP5UM ▶ ECP5U For backwards compatibility, the software allows you to use older architecture names for Lattice FPGA series architectures. Older Lattice FPGA architecture names are as follows: **or5s00** (LatticeSC), **mg5g00** (LatticeXP), **ep5g00** (LatticeEC), **ep5g00p** (LatticeECP). Check for availability of these devices using **-h** or by contacting support. Also see subsection "Selecting Valid Part Names" on page 2472 in "Running MAP from the Command Line" on page 2463 topic.
-dt	Disables the hardware evaluation capability.

Table 843: NGDBUILD Command Line Options

Option	Description
-f <command_file>	Execute command line arguments in the specified command file. See See "The –f Option" on page 2551, "Command File Example" on page 2550, and "Using the Command File" on page 2551.
-h [<architecture>] or **-help** <architecture>	Displays all of the available NGDBUILD command options for mapping to the specified architecture. Values for architecture are the same as for the **-a** option. If an **ngdbuild -h** command is issued without an architecture, general help is invoked.
<ngo_file[.**ngo**] >	Name of the input top-level design file in .ngo format. If you enter a filename with no extension, **ngdbuild** looks for an .ngo file with the name you specify. If you specify a filename with an extension other than .ngo, you get an error message and **ngdbuild** will not run.
<outfile[.**ngd**]>	Output design file in .ngd format. The output filename, its extension, and its location are determined in this way: ▶ No output filename specified: The output file has the same name as the input file, with an .ngd extension. ▶ Output filename specified but with no extension: EDIF2NGD appends the .ngd extension to the filename. ▶ Output filename specified with an extension other than .ngd. Produces an error message and NGDBUILD will not run. If the output file already exists, it will be overwritten with the new file.
-d <device_name>	Specifies the device type for the architecture.
-p <search_path>	Adds the specified search_path to the list of directories to search when resolving file references (i.e., files specified in the design with a FILE= filename attribute). You need not specify a search path if the necessary .ngo or .nmc file is in the directory containing the top-level .ngo file or if the FILE attribute in the design gives a complete path name for the file (instead of a relative path name). To specify multiple **-p** options, precede each with **-p**; or combine multiple search_path specifiers after one **-p**. The syntax for combining multiple search_path specifiers for a given macro search path is as follows where dir is the directory search path: **-p** dir1;dir2;dir3 (for Windows) **-p** dir1:dir2:dir3 (for UNIX)

Examples Following are a few examples of NGDBUILD command lines and a description of what each does.

Example 1 The following command translates the input netlist reader file named mapped.ngo into a Native Generic Database file named mapped.ngd.

ngdbuild -a LatticeEC mapped.ngo mapped.ngd

See Also ▶"Command Line Data Flow" on page 2435

▶ "Command Line Program Overview" on page 2432

Running MAP from the Command Line

The **Map Design** process in the Diamond environment can also be run through the command line using the **map** program. The **map** program takes an input generic database (.ngd) file and converts this design represented as a network of device-independent components (e.g., gates and flip-flops) into a network of device-specific components (e.g., PFUs, PFFs, and EBRs) or configurable logic blocks in the form of a Native Circuit Description (.ncd) file.

Subjects included in this topic:

- Running MAP
- Command Line Syntax
- MAP Options
- Examples

Running MAP MAP uses the generic database (.ngd) file that was the output of the **Translate Design** process (**edif2ngd** and **ngdbuild** programs) and outputs a mapped Native Circuit Description (.ncd) file and a preference file which is automatically generated if you do not specify one. The output preference file takes the name of the output NCD file.

- To run MAP, type **map** on the command line with, at minimum, the required options to describe your target technology (i.e., architecture, device, package, and peformance grade), the input .ngd along with the input .lpf file. The output .ncd file specified by the **-o** option. A sample of a typical MAP command would be as follows:

  map -p LFEC20E -t FPBGA484 -s 3 input.ngd -o output.ncd input.lpf -pr output.prf

Note

The **-a** (architecture) option is not necessary when you supply the part number with the **-p** option. There is also no need to specify the preference file here, but if you do, it must be specified after the input .ngd file name. The preference file automatically takes the name "**output**" in this case, which is the name given to the output .ncd file. If the output file was not specified with the **-o** option as shown in the above case, **map** would place a file named input.ncd into the current working directory, taking the name of the input file. If you specify the input.lpf file and it is not there, map will error out.

There are many command line options that give you control over the way MAP processes the output file. Please refer to the rest of the subjects in this topic for more details. See examples.

Command Line Syntax **map** [[**-a** <architecture> **-p** <device> **-t** <pkgname> **-s** <performance> **-hier -u -m -noinferGSR -ioreg** <packing> **-pe -pr** <oprffile[**.prf**]> **-fc -c** [<packfactor>:0-100] **-retime** [<option=value:+] [**-tdm** <pref_file> **-split_node -td_pack** [<infile[**.ngd**]>] [**-o** <outfile[**.ncd**]>] [<pref_file[**.prf**]>] [<logpref_file[**.lpf**]>] | [**-h** [<architecture>] | **-help** [<architecture>] | [**-f** <command_file>]]

MAP Options The table below contains descriptions of all valid options for MAP.

Table 844: MAP Command Line Options

Option	Description
-a <architecture>	Specifies the architecture of the device to which you will map the design. The **-a** overrides the architecture specified in the input NGD file, if any. Note that this is unnecessary to specify if you use the **-p** option. A list of valid architectures displays when you use the **map -h** command. These names are case sensitive. Valid architecture names include the following: ▶ Platform Manager 2 ▶ Platform Manager ▶ MachXO3D ▶ MachXO3LF ▶ MachXO3L ▶ MachXO2 ▶ MachXO ▶ LatticeXP2 ▶ LatticeXP ▶ LatticeSCM ▶ LatticeSC ▶ LatticeECP3 ▶ LatticeECP2M ▶ LatticeECP2 ▶ LatticeECP ▶ LatticeEC ▶ LIFMD ▶ ECP5UM5G ▶ ECP5UM ▶ ECP5U
	Note: For backwards compatibility, the software allows you to use older architecture names for Lattice FPGA series architectures. Older Lattice FPGA architecture names are as follows: **or5s00** (LatticeSC), **mg5g00** (LatticeXP), **ep5g00** (LatticeEC), **ep5g00p** (LatticeECP)**ep5m00** (LatticeECP2/M), **mj5g00** (MachXO). Check for availability of these devices using **-h** or by contacting support. Also see "Selecting Valid Part Names" on page 2472.

Table 844: MAP Command Line Options

Option	Description
-c [<packfactor>:0-100]	Allows you to set a packing factor to map to a given percentage of PFU slices in your design (1-100 percent). The value range is 0-100 percent (100 = minimum packing; 0 = maximum density). This option has great control of the packing density. It sets the relative packing density of available slices within a device in terms of a percentage of the available slices in the device. If not specified, mapping will be performed to a specific density of 97 percent. The result will be a less dense packing, depending on the size of the design relative to the number of available slices in the device. If the design is large compared with the number of available slices in the device, the mapper will make a reasonable effort to pack the design so that it fits in the device. When you specify a density percent value, the mapper attempts to pack the device to that density. The “0” setting results in the densest mapping. If the design is large compared with the target density, the mapper will make an aggressive packing effort to meet your target. However, this may adversely impact the design's f_{MAX} performance.
-f <command_file>	Executes the command line arguments in the specified command_file. See “The –f Option” on page 2551, “Command File Example” on page 2550, and “Using the Command File” on page 2551.
-h [<architecture>] or **-help** [<architecture>]	Displays all of the available MAP command options for mapping to the specified architecture. Values for architecture are the same as for the **-a** option. If an **map -h** command is issued without an architecture, general help is invoked.
-hier	Use the **-hier** option to designate hierarchical mapping instead of flat mapping. With the option designated, MAP will not pack components from different top level modules into the same PFU. This affords PAR better placement choices through improved logic grouping. Keep the following in mind when using the **-hier** option: The hierarchical mapping option will override signal sharing packing of inputs or outputs. SWLs or direct connections have higher priority than **-hier** option. The default is flat mapping, same as in previous releases. In addition, the COMP= properties will now have hierarchical paths appended to their data strings. This allows the multiple instantiation of blocks with COMP= properties to be unique and separate.

Table 844: MAP Command Line Options

Option	Description
<infile[.**ngd**]>	The design file (in .ngd format) to be mapped. You must enter an input design, but the .ngd extension is optional.
-ioreg <packing>	Direct I/O register packing. Valid packing options are **i**, **o**, **b**, and **n**. The packing options function as follows: ▶ The **i** option packs input registers only. ▶ The **o** option packs output register only. ▶ The **b** option packs both input and output registers whenever possible. ▶ The **n** option does not pack I/O registers but uses PFF/PFU resources only. This is a global option and overrides the register types in the Native Generic Database (NGD) file. Use USE DIN or USE DOUT preferences in your LPF file to override the **-ioreg** option. *This option is not applicable to MachXO devices*.
-lp <logpref_file[.lpf]>	Specifies the name of the input logical preference (.lpf) file. Backwards compatibility: If **map** does not find this file, it will error out. See Example 3 for **map** behavior in regard to the preference flow for 5.1 or higher and backwards compatibility.
-m	Allow overmapped NCDs.
-noinferGSR	Suppress GSR inferencing. By default if the input design (NGD) does not include a GSR buffer, MAP will infer one based on the signal that drives the most set/reset loads. If **-noinferGSR** is applied all GSR_NET preferences of the logical preference file (LPF) will be ignored.

Table 844: MAP Command Line Options

Option	Description
-o <outfile[**.ncd**]>	Specifies the output design file name in .ncd format. The .ncd extension is optional. If the output file already exists, it is overwritten with the new .ncd file. The output file name and its location are determined as follows: ▶ When not specified, by default the output file takes the same name as the input .ngd file, with an .ncd extension. The file is placed in the input file's directory. ▶ Output file name specified with no path (for example, cpu_dec.ncd instead of /home/designs/cpu_dec.ncd) the .ncd file is placed in the current working directory. ▶ Output file name specified with a full path (for example, / home/designs/cpu_dec.ncd) the output file is placed in the specified directory. ▶ Output file name of the physical preference (.prf) file will be the same as this output .ncd.

Table 844: MAP Command Line Options

Option	Description
-p <device>	Specifies the part number for the device. These part names are case sensitive. May be used in either of two ways: ▶ Device name only (e.g., **LFECP6E**). This is a LatticeECP device example. ▶ Part number (e.g., **LFECP6ETQFP144**) specifies both a device and a package, so you do not have to enter the **-t** option to specify the package. If you do not specify a part number using the **-p** option, MAP selects a part in this way: ▶ If the design's netlist contains properties that define a device, MAP selects the part specified by the properties. ▶ If no device properties were specified, MAP uses the default part number. ▶ Device names and part numbers are listed in the device selection in Diamond (includes part name and package name), in EPIC Device Editor, or can be obtained from technical support. Also see "Selecting Valid Part Names" on page 2472 for information on device and package selection. Examples of valid part names for various architectures include the following: ▶ **LFSC3GA15EFPBGA256** (LatticeSC) ▶ **LFXP10EFPBGA256** (LatticeXP) ▶ **LFEC20EFPBGA484** (LatticeEC) ▶ **LFECP10EPQFP208** (LatticeECP) **Note:** You can only enter a part number or device name from a device library you have installed on your system.
-pe	This option terminates the **map** process if preference errors are found.
-pr <oprffile[**.prf**]>	Optional preference file output. Prevents changing the input preference file.

Table 844: MAP Command Line Options

Option	Description
<preffile[.**prf**]>	(For ispLEVER 5.0 and below) The input physical preference file in .prf format which contains preferences written in logical preference syntax. This option remains for purposes of backwards compatibility of designs of legacy Lattice software. The previous preference flow used the PRF file to read in previous logical preference syntax allowable in the .prf file. These logical preferences used block names present in the logical netlist in their syntax and were typically LOCATE or IOBUF preferences. A physical preference file name is optional on the command line, but if one is entered it must be entered after the input NGD file name. You need not enter the .prf extension. See Example 3 for **map** behavior in regard to the preference flow for 5.1 or higher and backwards compatibility. The .mrp and .ngm files produced by a **map** run both have the same name as the output file, with the proper extension. If the .mrp or .ngm (.ldb) files already exist, they are overwritten by the new files.

Table 844: MAP Command Line Options

Option	Description
-retime or **-retime** [<option=value>]	Enables the register re-timing feature that can be used to help optimize the design to meet timing. See "Map Register Retiming" on page 596 for details of what this switch does. This option is turned off by default when **-retime** does not appear in the command line and should not be used on the initial run until you have determined whether or not it could be used to optimized your design to meet timing. If **-retime** appears in the command line, -retime TRUE is assumed and you do not have to specify the TRUE parameter. The **-retime** switch takes the following options: EFFORT Re-timing Level of Effort option. Takes integer values **1-6**, with **1** being the least effort and **6** the most. Default value for all devices is **4**. Syntax: **map** <map_options> **-retime** <option=value> For example, **-retime** EFFORT=2 The above **-retime** options are separated by a colon and should not contain any spaces in between them. **Note**: You may encounter error messages if you do not use a colons as a delimiter and if your parameters contain spaces. Here a few examples show the default behavior if you do not set both values: **map** <map_options> **-retime** If no options are specified as above, it is equivalent to -retime TRUE and the default option settings are used. *Not compatible with NCD Guide File*.
-s <performance>	Specifies the performance grade (toggle rate) of the part. Applicable performance grades are given in the Devices appendix. If not specified, MAP selects the performance as follows: ▶ If the designs netlist file contains a attribute that defines the device peformance, MAP selects the peformance specified by the attribute. ▶ If no device peformance attribute is specified, MAP uses the default peformance.

Table 844: MAP Command Line Options

Option	Description
-split_node	Activates timing-driven node replication. This mode replicates a LUT4 that has multiple fanout to FFs adding a LUT for each FF if the LUT belongs to the timing path. It allows packing LUT/FF in the same slice for all FFs. *Not supported by LatticeSC/M and not compatible with NCD Guide File*.
-t <pkgname>	Specifies the package (e.g., **PQFP208**, **TQFP100**, or **FPBGA484**) for the device to which you will map. These package names are case sensitive. See "Selecting Valid Part Names" on page 2472 for information on device and package selection.
-td_pack	Activates timing-driven packing of LUT/FF, FF/LUT, LUT/LUT in the same slice. *Not supported by LatticeSC/M and not compatible with NCD Guide File*.
-tdm <pref_file>	Activates timing-driven mapping for a given design flow. If you do not specify a logical preference (.lpf), by default **map** will first use the <design_name>.lpf. You can specify any other preference file you wish. If an LPF file does not exist, **map** will attempt to find a <design_name>.prf file for the backward compatibility. See example below for details. *Not compatible with NCD Guide File*.
-u	Do not remove unused logic. Note that you must use the **-u** switch in the I/O Assistant command line flow to prevent unused I/O logic from being removed since an I/O design is only partial, that is, it contains only disconnected I/O logic. This option is also especially useful when you are working with designs that have high I/O signal counts going off and coming onto your device. Unless you specify the **-u** option, the mapper will remove this unused logic from your design which will likely be undesirable.
-xref_sig	Reports signal cross references in the Map report (MRP) file. Signal cross references show where nets in the logical design were mapped in the physical design (NCD file).
-xref_sym	Reports symbol cross references in the Map report (MRP) file. Symbol cross references show where symbols in the logical design were mapped in the physical design (NCD file).

Examples Following are some examples of MAP command lines and a description of what each does.

Example 1 The following command maps an input generic database file named mapped.ngd and outputs a mapped Native Circuit Description file named mapped.ncd.and an output physical preference (.prf) file named mapped.prf. The example targets a LatticeXP device, part number lfxp3c, package PQFP208, at a -5 peformance grade.

map -a LatticeXP -p LFXP3C -t PQFP208 -s 5 mapped.ngd -o mapped.ncd my.lpf -pr mapped.prf

Example 2 The following command maps an input generic database file named mod1.ngd and outputs a mapped Native Circuit Description file named mod1.ncd by default when the output file is not specified into the current working directory. The example targets a MachXO device, part number lcmxo640c, taking default package and peformance grade because these options are not specified. The **-a** architecture is implied by the part number and is unnecessary to specify.

map -p LCMXO640C mod1.ngd

Example 3 These examples show the **map** program behavior associated with reading in logical (.lpf).

If an .lpf file is specified, **map** looks for the LPF and processes it. If the file is not found, map issues an information message that tells you that map could not open the specified preference file. Any input physical (.prf) files that are present would be ignored. Here is an example,

map -p LFEC1ETQFP100 lev1.ngd -o lev1.ncd lev1.lpf

If no .lpf or .prf file is specified, **map** looks for an LPF. If **map** does not find an .lpf file, it looks for .prf file and processes it.

map -p LFEC1ETQFP100 lev1.ngd -o lev1.ncd

Example 4 The **map** program runs with timing-driven mapping activated, using the default <design_name>.lpf file as the input preference file. If an LPF file does not exist, then **map** will look for an existing <design_name>.prf.

map -tdm

Selecting Valid Part Names Part names include both the device name and package name and can be specified in the **map** command line using the **-p** and **-t** options or by using the **-p** option with the complete part name (device name and package name with no spaces or dashes). See above examples for usage.

So, you can break down a part name into two components, the device name comes first and the package name second. For example, for a specific LatticeECP part named LFECP6ETQFP144, **LFECP6E** is the device name and **TQFP144** is the name of the package type.

- You can access the latest data sheets on www.latticesemi.com.
- In the software interface, you can view valid device and package names in the Device Selector dialog box in the Diamond environment. Please note

that in the graphical interface, these names may appear with spaces or dashes in them. Only use an alpha-numeric convention with no spaces in the command line when specifying these parts.

- Although in some cases lowercase is allowable when specifying part and package names in the command line, as a rule you should specify these names in uppercase characters. The UNIX/Linux command line is case sensitive and will not accept some part and package number arguments that use lowercase.

See Also "Command Line Data Flow" on page 2435

"Command Line Program Overview" on page 2432

Running PAR from the Command Line

The **Place & Route Design** process in the Diamond environment can also be run through the command line using the **par** program. The **par** program takes an input mapped Native Circuit Description (.ncd) file and further places and routes the design, assigning locations of physical components on the device and adding the inter-connectivity, outputting a placed and routed .ncd file.

The are special PAR Explorer (**-exp**) options available for newer Lattice FPGA architectures that help improve both placement and routing with various options for this switch described in a separate section. The Implementation Engine multi-tasking option available in UNIX is explained in detail here because the option is not available for PCs.

Subjects included in this topic:

Running PAR PAR uses your mapped Native Circuit Description (.ncd) file and associated preference (.prf) file that were the outputs of the **Map Design** process or the **map** program. With these inputs, **par** outputs a new placed-and-routed .ncd file, a PAR report (.par) file, and a PAD Specification (.pad) file that contains I/O placement information.

- To run PAR, type **par** on the command line with at minimum, the name of the input .ncd file and the desired name of the output .ncd file. While a physical preference (input.prf) file need not be specified, it is highly recommended to do so in the event there are several .prf files in the project directory. A sample of a basic PAR command would be as follows:

par input.ncd output.ncd input.prf

There are many command line options that give you control over PAR. Please refer to the rest of the subjects in this topic for more details. See examples.

Command Line Syntax **par** [general_options] [placement_options] [routing_options] <infile[.**ncd**]> <outfile[.**ncd** | **.dir**]> [<preffile[.**prf**]>]

Note

All filenames without special switches must be in the order <infile> <outfile> <preffile>. Options may exist in any order.

General Options

Table 845: General PAR Command Line Options

Option	Description
-k[**p**]	Skip constructive placement. Run only optimizing placement, then enter the router. Existing routes are ripped up before routing begins. Use only on a design that has already been placed. To run re-entrant routing (also called incremental routing), use the option **-kp** to skip placement (constructive and optimizing) and begin routing, leaving the existing routing in place.
-p	Do not run placement (constructive or optimizing) route only. Existing routes are ripped up before routing begins. To run re-entrant (also called incremental) routing, use the options **-kp** to skip placement and begin routing, leaving the existing routing in place.
-r	Prevents the design from being routed. With this option, PAR outputs a placed, but not routed, Native Circuit Description (.ncd) file.
-sp <speedgrade>	Overrides the default performance grade.
-w	If the specified output file already exists, over-write the existing file (including the input file). If the specified output is a directory, overwrite files in the directory. With this option, any files generated will overwrite existing files (e.g., any .par, .pad files).
-x	Do not use timing-driven option for this PAR run.
-y	Adds the Delay Summary Report in the .par file and creates the delay file (in .dly format) at the end of the **par** run.
-pe	Issues error if Map encounters any semantic errors in the syntax of the preferences in the preference file.

Table 845: General PAR Command Line Options

Option	Description
<infile[.**ncd**]>	The design file (in .ncd format) to be placed and routed. You must enter an input design, but the .ncd extension is optional.
<outfile>	The target design file which is written after PAR is finished. ▶ If options you specify yield a single output design file, outfile may have an extension of .ncd or .dir. An .ncd extension generates an output file in .ncd format; the .dir extension directs PAR to create a directory in which to place the output file (in .ncd format). ▶ If options you specify generate more than one place and route iteration (that is, the **-n** option described above), you must specify a .dir extension; the results of each iteration are written into a separate file in the directory. These multiple files are in .ncd format. If the file or directory you specify already exists, you get an error message and the operation does not run. You can override this protection and automatically overwrite existing files by using the **-w** option.
<preffile[.**prf**]>	The preference file in .prf format containing design constraints such as timing, path specification, locking, etc. If you do not enter the name of a preference file and the current directory contains an existing preference file with the infile name and a .prf extension, PAR will use it. A preference file name is optional on the command line, but if one is entered it must be entered after the input filename. You need not enter the .prf extension.
-f <command_file>	Execute command line arguments in the specified command_file. See "The –f Option" on page 2551, "Command File Example" on page 2550, and "Using the Command File" on page 2551.

Placement Options

Table 846: PAR Placement Command Line Options

Option	Description
-a	Automatic level skipping for constructive placement. When you use **-a**, the **-n** option controls the maximum number of iterations per level. You cannot use **-a** with **-m** or **-r** options.

Table 846: PAR Placement Command Line Options

-cs <strategy>	(LatticeECP/EC and LatticeXP) Turns on clock skew minimization with a given strategy on auto-selected non-global clock nets or selected clock nets with strategy values **1** and **2** (default). This option is the same as the **-exp** clockSkewMin=<strategy> explorer option. See ClockSkewMin explorer option for additional information. The **1** value strategy option routes from driver pin to each clock load with pre-computed delay lower bound for balance routing. This option may help when the candidate clock net has a very small span, for example, when a bounding box (BBOX) span is within two to three PLCs, it will have a smaller skew. If it creates a better result, then use this option instead. The **2** value strategy option routes a clock trunk first and then routes from the trunk to each clock load with pre-computed delay with lower bound for balanced routing. This option will usually create a better result in shorter time with less memory usage.
-io	Switch that is used in the I/O Assistant process flow. This switch instructs PAR to place only I/Os, PLLs, DLLs and other elements that affect board level pin-outs.
-l <1-5>	Specifies the effort level of the design from 1 (simplest designs) to 5 (most complex designs). The default is technology dependent.
-m <nodefile_name>	Multi-tasking option. Use to run multiple nodes/machines on more than one PAR job at the same time to reduce runtimes. Cannot use **-m** with **-a**. See "Using the PAR Multi-Tasking (-m) Option" on page 2487 for details on usage. If used in conjunction with the **-n** and **-stopzero** options, once PAR returns an iteration with a timing score of zero, it will finish any jobs in the queue that have been already issued, but it will stop any further jobs from being issued and run. If necessary, you can kill jobs manually, but you may risk the program unexpectedly quitting and erroring out.

Table 846: PAR Placement Command Line Options

-n <0-100>	(Cost tables). Sets the number of iterations (place and route passes) performed at the effort level specified by the **-l** option. Each iteration uses a different cost table during placement and will produce a different .ncd file. If you enter **-n 0**, PAR continues to run until solved, stopping either after the design is fully routed and all constraints are met or after completing the iteration at cost table 100 or 99 seeds. You cannot limit the maximum number of seeds using **-n 0**. If you use the **-stopzero** option along with -n <*number*>, it will stop PAR on the first iteration that returns a zero timing score or it will end processing at the <*number*> limit you specify whether or not you reach a timing score of zero. If you do not specify the **-n** option, one place and route iteration runs. If you specify a **-t** option, the iterations begin at the cost table specified by **-t**.
-s <1-100>	Save the number of best results for this run. If not used, all results are saved.
-stopzero	Stops multiple-seed router run when the timing score reaches zero while it allows you to specify a limit to the number of iterations you are running. The maximum number of seeds is set by the **-n** option, so, for example, if you apply “-n 20 -stopzero” to a PAR run, PAR will stop running after any iteration that hits a timing score of zero or it will stop after 20 iterations are run whether or not timing is reached. If -n is not used, or "**-n 0**" is used, the router will run up to 99 seeds if timing does not hit zero. See description for the **-m** option in regard to how -stopzero prevents jobs from running iterations after it has reached a timing score of zero.
-t <1-100>	Start placement at the specified cost table. Default is 1.

Routing Options

Table 847: PAR Routing Command Line Options

Option	Description
-c <number>	Run number of cost-based cleanup passes of the router.
-d <number>	Run number of delay-based cleanup passes of the router. To run delay-based cleanup passes only on designs that have been routed to completion (100% routed), use the **-e** option instead of **-d**.
-e <number>	Run number of delay-based cleanup passes of the router on completely-routed designs only.

Table 847: PAR Routing Command Line Options

Option	Description
-i <1-1000>	Run a maximum number of passes, stopping earlier only if the routing goes to 100 percent completion and all constraints are met. If not used, runs to completion or until router decides it cannot complete.
-u	Use this router cost table entry. Valid range varies by device. The default is 1.

PAR Explorer Options The PAR Explorer (**-exp**) options are specialized options that help improve both the placement and routing of a given design. The options are available for most Lattice FPGA designs. Generally, most explorer options are not available for the LatticeSC/M family unless stated otherwise. Use the **-h** option with the architecture argument in the PAR command line to determine what options are available per device family.

Table 848: PAR Explorer Command Line Options

Option	Description
-exp [<option=value>:+]	Explorer string to turn on or off special placement and routing options. Options and values are case-insensitive. You can also specify multiple options using a colon to indicate additional options in the following manner: Syntax: **-exp** [<option=value>:+] Example: **par -exp** option1=value:option2=value2 design.ncd *All valid -exp values are listed in the table rows below in alphabetical order.*
Valid -exp Values	

Table 848: PAR Explorer Command Line Options

ClockSkewMin=<strategy>	CLOCKSKEWMIN Clock Skew Minimization option. This is the same as the **-cs** option. The option is used minimize your clock skew on selected clock nets that warrant further optimization. Options are **1** and **2** (default) and are referred to as “strategies.” You turn this option on after you identified good candidate clock nets that have excessive skew in the TRACE timing report. This option is enabled by a program called CSM that performs optimization. The syntax of this command is as follows: **par -exp** clockSkewMin=<strategy> A indicator of a good candidate would be any FREQUENCY preference that has substantial skew on its driving clock net. This will usually occur with nets that cannot be assigned to primary or secondary routing resources by default. Check such nets to see if they are gated clocks. CSM will have no effect on gated clocks since they create interclock domains. If the candidate skewed net named “clk_c” is a pure clock net (one level only), then add the following two preferences to PRF file for rerunning PAR: PROHIBIT PRIMARY NET "clk_c" ; PROHIBIT SECONDARY NET "clk_c" ; The **clockSkewMin=1** strategy option routes from driver pin to each clock load with pre-computed delay lower bound for balance routing. This option may help when the candidate clock net has a very small span, for example, when a bounding box (BBOX) span is within two to three PLCs, it will have a smaller skew. If it creates a better result, then use this option instead. The **clockSkewMin=2** strategy option routes a clock trunk first and then routes from the trunk to each clock load with pre-computed delay with lower bound for balanced routing. This option will usually create a better result in shorter time with less memory usage. See the example and “Clock Skew Minimization” on page 608 for further details on available application notes on this feature.
M5GRipUp=(ON | OFF)	M5GRIPUP M5G-specific rip-up option. Options are **On** (default) and **Off**. Turning this option **On** will typically improve design routability.

Table 848: PAR Explorer Command Line Options

parCB=(ON | OFF)	PARCB Clock boosting option. This option forces the router to automatically insert extra wires to a Primary or Secondary route clock path to help compensate for hold time violations. Compatible families: ECP5, LatticeECP/EC, LatticeECP2/M, LatticeECP3, LatticeXP, LatticeXP2, MachXO, MACHXO2, MachXO3D, and MachXO3L families. **Note**: PARCB has shown the most benefit on design benchmarks targeted to LatticeECP3 device families. Options are **ON** and **OFF**, with **OFF** being the default condition. The syntax of this command is as follows: **par -exp** parCB=ON my.ncd Clock boosting using hardware delay taps are available for LatticeSC/M.
parPathBased=(ON | OFF)	PARPATHBASED Path-based placement option. Path-based timing driven placement will yield better performance and more predictable results in many cases. Options are **Off** (default) and **On**. The syntax of this command is as follows: **par -exp** parPathBased=ON my.ncd
parClkNetWeight=<value>	PARCLKNETWEIGHT Performance-driven clock selection option. Options are **100**, **150**, and **200** and so on. You can set this parameter to select the weight factor between fanouts and performance constraints. When using 150, the weight for critical net will be fanout * 1.5, so the critical net will be more likely selected as primary clock. if using 200, fanout * 2.0. If set value < 100, it is equivalent to 100. The syntax of this command is as follows: **par -exp** parClkNetWeight=150 my.ncd
parCDP=[0|1|Auto]	Enable the congestion-driven placement (CDP) algorithm. CDP is compatible with all Lattice FPGA device families; however, most benefit has been demonstrated with benchmarks targeted to ECP5, LatticeECP2/M, LatticeECP3, and LatticeXP2 device families. Usage: **par -exp** parCDP=[0|1|Auto] where: **0** (default) - disables congestion-driven placement. **1** - enables congestion-driven placement. **Auto** – allows par to enable CDP automatically. See parUseNBR and parCDR options for more congestion-driven options.

Table 848: PAR Explorer Command Line Options

parCDR=[0|1|Auto]	Enable the congestion-driven router (CDR) algorithm. Congestion-driven options like parCDR and parCDP can improve performance given a design with multiple congestion "hotspots." The **Layer > Congestion** option of the Design Planner Floorplan View can help visualize routing congestion. Large congested areas may prevent the options from finding a successful solution. CDR is compatible with all Lattice FPGA device families however most benefit has been demonstrated with benchmarks targeted to ECP5, LatticeECP2/M,LatticeECP3, and LatticeXP2 device families. Usage: **par -exp** parCDR=[0|1|Auto] where: **0** (default)– disables congestion-driven router. **1** – enables congestion-driven router. **Auto** – allows par to enable CDR automatically. See parUseNBR and parCDP options for more congestion-driven options.

Table 848: PAR Explorer Command Line Options

parHold=(0 | 1 | 2)	PARHOLD Additional hold time correction option. By default, hold time correction will be performed automatically if setup time error is 0. This additional option will overwrite the default setting. If parHold=0, hold time correction will be skipped. If parHold=1, hold time correction will be run even if setup error exists. If parHold=2, hold time correction will run with extra effort. This option forces the router to automatically insert extra wires to compensate for the hold time violation. When turned on, the router will automatically try to resolve any hold time violations on all registers with preferences placed on them including input I/O to registers, register to register, and register to output I/O. This will also cause negative impact on your setup time. If the setup time is more design critical, you should turn this switch off. For backwards compatibility for earlier releases of legacy Lattice software, you can use the MACHXO_HOLD value. The syntax of this command is as follows: **par -exp** parHold=1 my.ncd Other available options in auto hold time correction include: parHold=1 (turns on auto hold time correction) parHold=0 (turns off auto hold time correction) parHold=2 (run hold time correction with extra effort) parHoldSpeedGrade= M (minimum) **Note**: When hold time correction is called, the default performance grade used in hold time correction is always -M or the minimum performance grade allowable. Examples: par -w mapped.ncd output.ncd design.prf -exp parHold=1 par -p -w placed.ncd output.ncd design.prf -exp parHold=1 par -p -w placed.ncd output.ncd design.prf -exp parHold=1 par -p -w placed.ncd output.ncd design.prf -exp parHold=1:parHoldIter=5:parHoldLimit=500:parHoldSpeedGrade=6 This correction option can be used in two different manners, inside the standard PAR flow or as a standalone program. Inside the standard PAR flow, auto hold time correction is implemented as an independent router task, so it can be used together with other router tasks such as a cleanup task.

Table 848: PAR Explorer Command Line Options

parHold=(0 | 1 | 2) (*cont.*)	PARHOLD (*cont.)* Using Auto Hold Time Correction as a Standalone Program The correction option can also be called as a standalone program. If you have a previously routed NCD and you want to check if there are any hold time violations, it is useful to use the standalone auto hold time correction program. The input to the standalone program is a completely routed NCD file. The standalone program will check whether the input NCD has hold time violations in a user-specified performance grade, and will correct the violations if there are any. Using this approach, the performance grade used by the standalone program does not have to match the performance grade used in PAR. Usage Examples: 1. Run a standard PAR flow with “parHold=0” to get a completely routed NCD file, as shown below: par -w -i 6 mapped.ncd routed.ncd design.prf **-exp parHold=0** par -p –sp 5 -w -i 6 placed.ncd routed.ncd design.prf **-exp parHold=0** 2. Run the standalone auto hold time correction program with a completely routed NCD as the input as shown below: par **-kp** –w routed.ncd output.ncd design.prf -exp **parHold=1**: **parHoldOnly=1** par **-kp** –w routed.ncd output.ncd design.prf -exp **parHold=1**: **parHoldOnly=1** par **-kp** –w routed.ncd output.ncd design.prf -exp **parHold=1**: **parHoldOnly=1**:parHoldIter=5:parHoldLimit=500: parHoldSpeedGrade=6 The options in bold font in the examples above are required to run the standalone program. If no performance grade is specified, the standalone program will default to the -M or minimum performance grade. The **-kp** option is used explicitly for re-entrant routing, instructing PAR to skip placement and leave existing routing in place. There are situations where it is desirable to run the standalone auto hold time correction flow. For example, this flow is advantageous if you have a previously routed NCD and you would like to check if it has contains any hold time violations. The standalone program flow will check if the input routed NCD has hold time violations in the selected performance grade and will correct those violations.
parHoldIter=<value>	PARHOLDITER Specifies the number of automatic hold time correction iterations. If not specified with the -exp parHold PAR option, the default value is 4. For example: par -kp –sp M –w routed.ncd output.ncd design.prf -exp **parHold=1**:parHoldOnly=1:**parHoldIter=5:**parHoldLimit=500

Table 848: PAR Explorer Command Line Options

parHoldLimit=<value>	PARHOLDLIMIT This option allows you to set a limit on the number of hold time violations to be processed by the auto hold time correction option parHold. If there are more hold time violations in a design than the set limit, the auto hold time correction will disable itself and cease attempting to correct any violations and a warning message will appear. At this juncture, you should examine your design to see if you can avoid these violations. If there are too many hold time violations in a design, it may take longer runtime to correct these violations. This option provides a way to limit the number of potential violations to be processed. The default value is 250. The syntax of this command is as follows: par -exp **parHold=1**:**parHoldlimit=125** my.ncd
parHoldOnly=<1l0>	PARHOLDONLY Required option to run standalone PAR auto hold time correction flow with -exp parHold PAR option. See usage for parHold option. By default, parHold value is “0” or is turned off. When turned on, “1”, the option indicates that this PAR run is for auto hold time correction only. For example: par **-kp** –w routed.ncd output.ncd design.prf -exp **parHold=1**: **parHoldOnly=1**
parHoldSpeedGrade= <value>	PARHOLDSPEEDGRADE This option sets the performance grade to be used in auto hold time correction with the -exp parHold option. This performance grade can be different from the performance grade used in PAR. Default value is parHoldSpeedGrade =M. An example of how this may look on the command line is as follows: par -kp –sp M –w routed.ncd output.ncd design.prf -exp **parHold=1**:parHoldOnly=1:parHoldIter=6:parHoldLimit=300:parHoldSpeedGrade=5
parUseNBR=[0|1]	PARUSENBR NBR Router or Negotiation-based routing option. Supports all FPGA device families except LatticeXP and MachXO. When turned on, an alternate routing engine from the traditional Rip-up-based routing selection (RBR) is used. This involves an iterative routing algorithm that routes connections to achieve minimum delay cost. It does so by computing the demand on each routing resource and applying cost values per node. It will complete when an optimal solution is arrived at or the number of iterations is reached.

Table 848: PAR Explorer Command Line Options

timing_effort=<value>	TIMING_EFFORT This option makes the maximum effort to achieve a placement and routing solution. It is only intended to be used when you have run older legacy Lattice software on a design (ispLEVER 5.1 or earlier), then run the newer version on it, and the maximum frequency (f_{MAX}) drops as a result. The syntax of this command is as follows: par -exp timing_effort=5 my.ncd The level of effort can only be set to 5.
parASE=[0|1]	PARASE This option is used for multi-seed runs of Place & Route. It reduces overall run time by terminating placement seeds that are not producing better results. The Run Time Reduction option uses checkpoints for comparing the result of the current placement seed with the results already obtained. During the optimization phase, if clock boosting and/or automatic hold time correction have been enabled, the PAR engine will also check whether one or both options are needed and optimize the routing accordingly. A placement seed that is not producing better results will automatically be terminated.

Examples Following are a few examples of PAR command lines and a description of what each does.

Example 1 The following command places and routes the design in the file input.ncd and writes the placed and routed design to output.ncd.

par input.ncd output.ncd

Example 2 The following command skips the placement phase and preserves all routing information without locking it (re-entrant routing). After that, the command instructs PAR to run up to 999 passes of the router or stops upon completion and conformance to timing preferences found in the pref.prf file. Finally, it runs three delay-based cleanup router passes. If the design is already completely routed, the effect of this command is to just run three delay-based cleanup passes.

par -kp -i 999 -c 0 -d 3 input.ncd output.ncd pref.prf

Example 3 The following command runs 20 place and route iterations at effort Level 3. The iterations begin at cost table entry 5. Only the best 3 output design files are saved. The output design files (in .ncd format) are placed into a directory called results.dir.

par -n 20 -l 3 -t 5 -s 3 input.ncd results.dir pref.prf

Example 4 The following command copies the input design to the output design using the **-pr** option. The placement and routing phases are both skipped completely. You generate a delay file using the **-y** option, which creates a delay file that allows the user to check the delay times in the design without having PAR change any of the design's placement or routing.

par -pr -y input.ncd output.ncd

Example 5 The following example consists of two command lines. Suppose that you have determined the best level for the design to be level 3. If you wanted PAR to save the best three results running at level 3 with 20 place-and-route iterations, you would enter this command:

par -l 3 -n 20 -w -s 3 input.ncd output.dir input.prf

Now, if you wanted to run two passes of cost-based and delay-based cleanup on the three designs saved (without running placement), you would enter this command for each design:

par -kp -i 0 -c 2 -d 2 input.ncd output.ncd input.prf

Example 6 The following command below runs optimized placement and routing. The constructive placement results from a previous run are kept and refined with placement optimization. The router starts from scratch.

par -k input.ncd output.ncd input.prf pref.prf

Example 7 The command below allows re-entrant routing. Use this command when your design is only partially routed and you want to complete it. Placement and placement optimization are skipped. In this case up to 30 router passes are run (you could run up to 999).

par -kp -i 30 input.ncd output.ncd

Example 8 (Lattice FPGAs only) This is an example of **par** using the **-io** switch to generate .ncd files that contain only I/O for viewing in the PAD Specification file for adjustment of LOCATE preferences for optimal I/O placement. You can display I/O placement assignments in Diamond's Spreadsheet view and choosing **View > Display IO Placement**.

par -io -w lev1bist.ncd lev1bist_io.ncd

Example 9 The command below uses the clock skew minimization PAR Explorer (**-exp**) option (equivalent to the **-cs** option) to reduce clock skew on a clock net which had been identified as having excessive skew and fit the rest of the candidate criteria. See the option description for -exp clockSkewMin for details on usage.

par -sp 5 -i 6 -exp clockSkewMin=2 -w EC20.ncd EC20_s2.ncd par.prf

or,

par -sp 5 -i 6 -cs 2 -w EC20.ncd EC20_s2.ncd par.prf

Note that the following unique preferences must be given to select exactly which net to which you will apply clock skew minimization.

```
PROHIBIT PRIMARY NET <net_name> ;
PROHIBIT SECONDARY NET <net_name> ;
```

The above two preferences must be specified simultaneously for a particular net to be considered for clock skew minimization. And this net should have load number not exceeding 300. However, this value can be adjusted by using the -exp CLOCK_BALANCE_MAXLOADS=<value> option, if appropriate. For example:

```
# specify clock net "clk_c" to be selected for CSM
PROHIBIT PRIMARY NET "clk_c";
PROHIBIT SECONDARY NET "clk_c" ;
```

Note

If no **-exp clockSkewMin** or **-cs** option is given in the command line, the net “clk_c” specified above will be routed using regular routing resources by regular maze router as current flow works.

Using the PAR Multi-Tasking (-m) Option This section provides information about environment setup, node list file creation, and step-by-step instructions for running the PAR Multi-tasking (**-m**) option from the command line. The PAR **-m** option allows you to use multiple machines (nodes) that are networked together for a multi-run PAR job, significantly reducing the total amount of time for completion. Before the multi-tasking option was developed, PAR could only run multiple jobs in a linear or serial fashion. The total time required to complete PAR was equal to the amount of time it took for each of the PAR jobs to run.

For example, the PAR command:

par -l 5 -n 10 -i 10 -c 1 mydesign.ncd output.dir

tells PAR to run 10 place and route passes (**-n 10**) at effort level 5 (**-l 5**), a maximum of 10 router passes (**-i 10**), and one cost-based cleanup pass. It runs each of the 10 jobs consecutively, generating an output .ncd file for each job, i.e., output.dir/ 5_1.ncd, output.dir/5_2.ncd, etc. If each job takes approximately one hour, then the run takes approximately 10 hours.

Suppose, however, that you have five nodes available. The PAR Multi-tasking option allows you to use all five nodes at the same time, dramatically reducing the time required for all ten jobs.

To run the PAR multi-tasking option from the command line:

1. First generate a file containing a list of the node names, one per line as in the following example:

   ```
   # This file contains a profile node listing for a PAR multi
   # tasking job.
   [machine1]
   SYSTEM = linux
   CORENUM = 2
   [machine2]
   SYSTEM = linux
   CORENUM = 2
   Env = /home/user/setup_multipar.lin
   ```

```
Workdir = /home/user/myworkdir
```

You must use the format above for the node list file and fill in all required parameters. Parameters are case insensitive.The node or machine names are given in square brackets on a single line.

The **System** parameter can take linux or pc values depending upon your platform. However, the PC value cannot be used with Linux because it is not possible to create a multiple computer farm with PCs. **Corenum** refers to the number of CPU cores available. Setting it to zero will disable the node from being used. Setting it to a greater number than the actual number of CPUs will cause PAR to run jobs on the same CPU lengthening the runtime.

The **Env** parameter refers to a remote environment setup file to be executed before PAR is started on the remote machine. This is optional. If the remote machine is already configured with the proper environment, this line can be omitted. To test to see if the remote environment is responsive to PAR commands, run the following:

ssh <remote_machine> **par** <par_option>

See the System Requirements section for details on this parameter.

Workdir is the absolute path to the physical working directory location on the remote machine where PAR should be run. This item is also optional. If an account automatically changes to the proper directory after login, this line can be omitted. To test the remote directory, run the following,

ssh <remote_machine> **ls** <ncd_file>

If the design can be found then the current directory is already available.

2. Now run the job from the command line as follows:

```
par -m nodefile_name -l 5 -n 10 -i 10 -c l mydesign.ncd
output.dir
```

This runs the following jobs on the nodes specified.

```
NODE1: par -l 5 -i 10 -cl mydesign.ncd output.dir/5_1.ncd
NODE2: par -l 5 -i 10 -cl mydesign.ncd output.dir/5_2.ncd
NODE3: par -l 5 -i 10 -cl mydesign.ncd output.dir/5_3.ncd
NODE4: par -l 5 -i 10 -cl mydesign.ncd output.dir/5_4.ncd
NODE5: par -l 5 -i 10 -cl mydesign.ncd output.dir/5_5.ncd
```

As the jobs finish, the remaining jobs start on the nodes until all 10 jobs are complete. Since each job takes approximately one hour, all 10 jobs will complete in approximately two hours.

You cannot use the **-a** option (automatic level skipping) with the **-m** nodefile option (the Implementation Engine).

Note

If you attempt to use the multi-tasking option and you have specified only one placement iteration, PAR will disregard the **-m** option from the command and run the job in normal PAR mode. In this case you will see the following message:

```
WARNING - par: Multi task par not needed for this job. -m
switch will be ignored.
```

System Requirements **ssh** must be located through the PATH variable. On Linux, the utility program's secure shell (**ssh**) and secure shell daemon (**sshd**) are used to spawn and listen for the job requests.

The executables required on the machines defined in the node list file are as follows:

- /bin/sh
- par (must be located through the PATH variable)

Required environment variable on local and remote machines are as follows:

- FOUNDRY (points at FOUNDRY directory structure must be a path accessible to both the machine from which the Implementation Engine is run and the node)
- LM_LICENSE_FILE (points to the security license server nodes)
- LD_LIBRARY_PATH (supports par path for shared libraries must be a path accessible to both the machine from which the Implementation Engine is run and the node)

To determine if everything is set up correctly, you can run the **ssh** command to the nodes to be used.

Type the following:

```
ssh <machine_name> /bin/sh -c par
```

If you get the usage message back on your screen, everything is set correctly. Note that depending upon your setup, this check my not work even though your status is fine.

If you have to set up your remote environment with the proper environment variables, you must create a remote shell environment setup file. An example of an ASCII file used to setup the remote shell environment would be as follows for ksh users:

```
export FOUNDRY=/home/rel/rtf7_1b.28/
export PATH=$FOUNDRY/bin/lin:$PATH
export LD_LIBRARY_PATH=$FOUNDRY/bin/lin:$LD_LIBRARY_PATH
```

For csh users, you would use the setenv command.

Screen Output When PAR is running multiple jobs and is not in multi-tasking mode, output from PAR is displayed on the screen as the jobs run. When PAR is running multiple jobs in multi-tasking mode, you only see information regarding the current status of the feature.

For example, when the job above is executed, the following screen output would be generated:

```
Starting job 5_1 on node NODE1
Starting job 5_2 on node NODE2
Starting job 5_3 on node NODE3
Starting job 5_4 on node NODE4
Starting job 5_5 on node NODE5
```

When one of the jobs finishes, this message will appear:

```
Finished job 5_3 on node NODE3
```

These messages continue until there are no jobs left to run.

Running MPARTRCE from the Command Line

MPARTRCE is a command line utility that manages the place-and-route and timing wizard programs, PAR and TRCE to derive the best possible PAR run based on performance criteria and generating an optimal placed-and-routed NCD file. For details on PAR and TRACE options see the related online help topics for running each program from the command line.

For more details on the MPARTRCE methodology, performance score formula, applying weighted preferences, and other more advanced subject areas, see "Using MPARTRCE to Optimize PAR Iterations" on page 611 and "Specifying Preferences for MPARTRCE" on page 613.

Subjects included in this topic:

How MPARTRCE Works To perform its task, MPARTRCE first reads in constraints and any associated weights and penalties from the PRF file. Then, it runs PAR, TRCE, and an algorithm for selection multiple times. Using the TRACE report (.twr), it uses values to determine frequency and performance scores and creates a report in .CSV format.

In most cases, MPARTRCE picks the best implementation that meets the user preferences using the default files and settings. By default, MPARTRCE uses the same preference file that PAR uses. It extracts the timing preferences of interest (FREQUENCY, PERIOD, CLOCK_TO_OUT and INPUT_SETUP) from the preference file for use in performance score computation. The weights and penalties are read from an initialization file, if one exists or from the hard- coded factory defaults.

If MPARTRCE is interrupted after any iteration N, the results and reports correspond to the best implementation thus far. The outputs would be equivalent to what would have obtained if MPARTRCE had run with N iterations.

Running MPARTRCE MPARTRCE uses your input mapped Native Circuit Description (<design>_map.ncd) file and associated preference (.prf) file from PAR or TRCE to generate multiple new NCD file seeds to select from that best fit your performance criteria. These NCD files are automatically output to a results directory called <design>.dir that is placed in your project directory. A log file and report file is automatically generated to help you in your selection process.

- To run MPARTRCE, type **mpartrce** on the command line with, at minimum, the name of your design. A sample of a typical MPARTRCE command might be as follows:

  mpartrce mydesign

There are several commands options that do not need to be specified due to the default behavior of MPARTRCE, so please refer to the rest of the subjects in this topic for more details. See examples.

Command Line Syntax **mpartrce** [**-p** <file>] [**-f** <command_file>] [**-tf** <file>] [**-log** <file>] [**-rem**] [**-o** <reportfile>] **-pr** <preffile.prf> [**-tpr** <preffile.prf>] <design[**.ncd**]> <designout[**.ncd**]>

MPARTRCE Options The table below contains descriptions of all valid options for MPARTRCE.

Table 849: MPARTRCE Command Line Options

Option	Description
-p <file**>**	PAR command file. This is the same as the .p2t file used by PAR program. If this option is not specified, by default the <design>.p2t is used.
-f <command_file>	Execute command line arguments in the specified command file. See "The –f Option" on page 2551, "Command File Example" on page 2550, and "Using the Command File" on page 2551.

Table 849: MPARTRCE Command Line Options

Option	Description
-tf <file>	TRCE command file. This file is passed to the **trce** command with a **f** option. Refer to "Running TRACE from the Command Line" on page 2494 for details on the **f** file format.
-log <file>	Specifies a Log file name. The log collects the timing results from the .twr file for all the iterations. This option is mandatory unless you run the abbreviated command for this tool, that is, you only enter the **mpartrce** command with no other arguments. When you specify just the **mpartrce** command without arguments, a log file named <design>.log is created.
-rem	Removes the previously generated design.dir output directory before it processes new output. This directory contains multiple NCD files from PAR based on performance criteria and is generated automatically.
-o <reportfile>	Specifies a report file in CSV format. This file contains the summary report of constraints used for result selection, PSi, PA and timing score for each iteration. This option is mandatory unless you run the abbreviated command for this tool, that is, you only enter the **mpartrce** command with no other arguments. When you specify just the **mpartrce** command without arguments, a log file named <design>.csv is created.
-pr <preffile.prf>	PAR preference file. This is the same as <design>.prf file. If this option is not specified, by default <design>.prf is used.
-tpr <preffile.prf>	TRACE preference file, that is, the preference file used for the **trce** program and result selection. The preference file with the **-tpr** option can be the same as the PAR preference file or a separate **trce**-only preference file (usually, created from PAR preference file). If this option is not specified, by default <design>.prf is used for the TRACE preference file.
<design[**.ncd**]>	Design file on which to run PAR. This file is the same as <design>_map.ncd.
<designout[**.ncd**]>	Output Native Circuit Description (.ncd) file for multiple PAR seeds. The target design file is written out to an auto-generated directory within your project directory after PAR is finished. If this option is not specified, by default a the output directory is called <design>.dir. This directory contains your output NCD and TRACE report files for multiple iterations. The output directory also contains your log and your MPARTRCE summary report file in .CSV file format.
-h	Displays help on available options and syntax.

Examples The following include a few examples of MPARTRCE command lines and a description of what each does.

Example 1 The **-rem** option is used here to remove a prior output directory that was generated for MPARTRCE. The output directory will be called counter_map.dir as it takes the name of the design file by default. The **-p** option specifies the use of a PAR command file. Log and report files will be regenerated with the use of the **-log** and **-o** options, respectively with the name specified.

mpartrce -rem -p counter.p2t -pr counter.prf -log counter.log -o counter.csv counter_map.ncd counter.ncd

Example 2 The following command line example shows how to specify TRACE preference file usage with the **-tpr** option.

mpartrce -p counter.p2t -pr counter.prf -tpr counter_trc.prf -log counter.log -o counter.csv counter_map.ncd counter.ncd

Example 3 The following abbreviated command line example illustrates how to use the minimal command line argument to run **mpartrce**. To do so, you would just enter the executable with the design name argument specified. The name of your design in this case is “counter” and the placed-and-routed NCD file name would be counter.ncd.

This command will use all established input project file names (e.g., counter.prf) and output counter.log and counter.csv log and report files.

mpartrce counter

MPARTRCE Reports Below is an example of a report .CSV file that MPARTRCE generates that you can analyze.

Table 850: MPARTRCE .CSV Report File

---- MParTrce Report File ----											
	preference							constraint	weight	penalty	
constraint 1	CLOCK_TO_OUT ALLPORTS 7.000000 ns "clk"			CLKPORT				7.000 ns	1	10	
constraint 2	FREQUENCY NET "mclk" 200.000000 MHz							200.000 MHz	20	400	
constraint 3	FREQUENCY PORT "clk" 200.000000 MHz							200.000 MHz	20	400	
constraint 4	INPUT_SETUP ALLPORTS 3.000000 ns "clk"			CLKPORT				3.000 ns	1	10	
index	iteration	Actual 1(ns)	PS 1	Actual 2(MHz)	PS 2	Actual 3(MHz)	PS 3	Actual 4(ns)	PS 4	Perf. Score	timing score

Table 850: MPARTRCE .CSV Report File

1	5	5.0	2.0	202.5	1.2	238.0	16.0	2.9	0.1	19.3	0
2	10	5.2	1.8	200.7	0.4	238.0	16.0	2.4	0.6	18.7	0
3	8	5.0	2.0	200.0	0.0	238.0	16.0	2.8	0.2	18.2	1
4	3	4.9	2.1	200.0	0.0	238.0	16.0	3.0	0.0	18.1	0
5	4	5.4	1.6	200.6	0.3	238.0	16.0	2.8	0.2	18.0	0
6	6	5.6	1.4	200.1	0.1	238.0	16.0	2.9	0.1	17.5	0
7	7	5.3	1.7	199.6	-4.0	238.0	16.0	3.0	0.0	13.7	10
8	1	6.0	1.0	189.6	-109.6	238.0	16.0	2.7	0.3	-92.4	332
9	9	5.5	1.5	189.3	-113.6	238.0	16.0	2.7	0.3	-95.9	1136
10	2	4.7	2.3	187.2	-136.8	238.0	16.0	2.3	0.7	-117.9	976

5 is the best.

- "Multiple PAR Iterations" on page 610

Running TRACE from the Command Line

The **MAP TRACE** and **Place & Route TRACE** processes in the Diamond environment can also be run through the command line using the **trce** program. TRACE (Timing Reporter and Circuit Evaluator) or the **trce** program can be run on designs using the placed and routed Native Circuit Description (.ncd) and associated timing preferences specified in the design's preference (.prf) file. Using these input files, **trce** provides static timing analysis and outputs a timing report file (.tw1/.twr).

TRACE checks the delays in the Native Circuit Description (.ncd) file against your timing preferences. If delays are exceeded, TRACE issues the appropriate timing error. See "Mapping" on page 588 and associated topics for more information.

Subjects included in this topic:

Running TRCE TRCE uses your input mapped or placed-and-routed Native Circuit Description (.ncd) file and associated preference (.prf) file to create a TRACE Timing report.

- To run TRCE, type **trce** on the command line with, at minimum, the names of your input .ncd and .prf files to output a timing report (.twr) file. A sample of a typical TRCE command would be as follows:

  trce design.ncd design.prf

Note

The above command automatically generates the report file named design.twr which is based on the name of the .ncd file.

There are several command line options that give you control over the way TRCE generates timing reports for analysis. Please refer to the rest of the subjects in this topic for more details. See examples.

Command Line Syntax **trce** [**-allprefpath**] [**-fullname**] [**-clockdomain**] [**-gt** [<percentage>]] [**-e** [<n>] **-v** [<limit>]] [**-p**] [**-sp** <peformance>] [**-sphld** <peformance>] [**-min**] [**-max**] [**-c**] [**- u** <limit>] [**-mapchkpnt** <number>] [**-hld**] [**-setuphold** [v:0,2]] [**-sethld**] [**-primetime**] [**-html**] [**-o** <report[**.twr**]>] <file_name[**.ncd**]> [<file_name[**.prf**] >] [**-f** <command_file>]

TRCE Options

The table below contains descriptions of all valid options for TRCE.

Table 851: TRCE (TRACE) Command Line Options

Option	Description
-allprefpath	Specifies that a path for each timing preference be reported even if it belongs to two or more timing preferences.
-c	Prints connections not covered by the preference file. The **-c** option should be used with the verbose timing report option.
-u	Prints paths not covered by the preference file. The **-u** option cannot be used with the **-allprefpath** command line option.
-clockdomain	Performs clock domain analysis, reporting clock ports and clock nets relationships.
-e <n>	The **-e** generates an error report file in the current working directory. If this or the **-v** option is unspecified, TRACE sends a summary report to standard output. The <n> value specifies the allowable number of paths with timing errors to be reported.
-f <command_file>	Execute command line arguments in the specified command_file. See "The –f Option" on page 2551, "Command File Example" on page 2550, and "Using the Command File" on page 2551.

Table 851: TRCE (TRACE) Command Line Options

Option	Description
<file_name[.**ncd**]>	Specifies the Native Circuit Description file.
<file_name[.**prf**]>	The .prf file containing timing constraints for the design file. If a preference file is not specified, TRACE looks for one with the same root name as the .ncd file.
-fullname	Prevents TRACE from truncating COMP names in the output report. By default, truncated names appear in report file preceded by an asterisk.
-gt <percentage>	The -gt option enables auto-generation of timing preferences if there are no timing preferences found in scan chain paths. Percentage value factors are 0-100 which represent the routing percentage relative to total delay, or the routing delay plus logic delay. The generated timing preferences will be based on this delay estimation percentage.
-hld <file_name[.**ncd**]> <**-v**> <file_name[.**prf**]>	The **-hld** option performs hold time checks on FREQUENCY/PERIOD, CLOCK_TO_OUT, INPUT_SETUP and OFFSET IN/OUT preferences and outputs a verbose timing report in your working directory. When using the **-hld** option to do a hold time check, the default peformance grade of **-M** (minimum delay) is ascribed when no **-sp** option (valid peformance grade value) is specified to override this value. For setup time checks (TRACE timing analysis which does not include the **-hld** option), the default peformance grade will be derived automatically from the .ncd file based upon device selection.
-html	Outputs an HTML-like format report.
-mapchkpnt <number>	Controls the algorithm used to estimate timing for routing after MAP and prior to placement. This estimation is used in the MAP Trace report (.tw1) file and the MAP Timing Checkpoint. ▶ If <number> is between 1 and 100, use the Estimated Logic Delay algorithm. The value of <number> represents the how much of the total path delay will be from the path's logic delay. For example, **100** creates zero routing delay for a path since the logic delay represents 100 percent of the total path delay. A number of **50** causes the route delay to be equal to the logic delay, and thus the total path delay is twice the logic delay. ▶ If <number> = **0**, then the routing delay is estimated using the Timing Design Suite which is based on routing delay seen on the set of critical paths across a suite of benchmark designs. ▶ If no –mapchkpnt switch is used, then the default behavior is **–mapchkpnt 100** which results in zero routing delay.

Table 851: TRCE (TRACE) Command Line Options

Option	Description
-max	Uses maximum delay numbers only.
-min	Uses minimum delay numbers only.
-nc	Do not set constant signals as covered. When -nc is used, they will appear in the uncovered connection list.
-o <file_name[.**twr**]>	The name of the output file to contain the timing report. If no output name is specified, the report name defaults to the same root name as the .ncd file.
-**p**	Reports the number of asynchronous loops in verbose mode.
-primetime	This will create a primetime format in the report file. This only effects reporting style of path summary and the Constraint Details sections. The Constraint Details information is just organized and presented in a slightly different manner.
-sethld	Allows you to perform a standard setup analysis and a hold time analysis at the same time and generates one report output file containing both setup and hold report. To change default peformance grade for hold time using this option, use the **-sphld** option.
-setuphold	Allows you to perform standard setup analysis and a hold time analysis on I/Os in the same report file. In the summary section, you will see both setup and hold time timing for each of your INPUT_SETUP and CLOCK_TO_OUT preferences.
-sp <peformance>	Overrides the default peformance grade. When not using the **-hld** option to perform hold time checks (i.e., setup time), the default peformance grade will be derived automatically from the .ncd file based upon device selection.
-sphld <peformance>	Overrides the default peformance grade for hold analysis when using the **-sethld** option which performs both setup and hold analysis and generates one report file. Setup analysis appears first, followed by hold analysis.
-v <limit>	The **-v** option generates a verbose (full) timing report file in the current working directory. If this or the **-e** option is unspecified, TRACE sends a summary report to standard output. The <limit> value sets the allowable number of items reported for each timing preference. Valid entries are an integer value that is 0 or greater. If you enter a 0, there will be no limit in the amount of worst case paths reported (0 = no limit).

Examples Following are a few examples of TRACE command lines and a description of what each does.

Example 1 The following command verifies the timing characteristics of the design named design1.ncd, generating a summary timing report. Timing preferences contained in the file group1.prf are the timing constraints for the design. This generates the report file design1.twr.

trce design1.ncd group1.prf

Example 2 The following command produces a file listing all delay characteristics for the design named design1.ncd. Timing preferences contained in the file group1.prf are the timing constraints for the design. The file output.twr is the name of the verbose report file.

trce -v design1.ncd group1.prf -o output.twr

Example 3 The following command analyzes the file design1.ncd and reports on the three worst errors for each preference in timing.prf. The report is called design1.twr.

trce -e 3 design1.ncd timing.prf

Example 4 The following command analyzes the file design1.ncd and produces a verbose report to check on hold times on any FREQUENCY, CLOCK_TO_OUT, INPUT_SETUP and OFFSET preferences in the timing.prf file. With the output report file name unspecified here, a file using the root name of the .ncd file (i.e., design1.twr) will be output by default.

trce -v -hld design1.ncd timing.prf

Example 5 The following command analyzes the file design1.ncd and produces a summary timing report to check on both setup and hold times on any INPUT_SETUP and CLOCK_TO_OUT timing preferences in the timing.prf file. With the output report file name unspecified here, a file using the root name of the .ncd file (i.e., design1.twr) will be output by default.

trce -setuphold design1.ncd timing.prf

Example 6 The following command analyzes the file design.ncd and produces a summary timing report to check on both setup and hold times on any FREQUENCY, INPUT_SETUP, CLOCK_TO_OUT, OFFSET timing preferences in the design.prf file. With the output report file name unspecified here, a file using the root name of the .ncd file (i.e., design.twr) will be output by default. The -sphld option override is used to set the peformance grade on just the hold analysis to minimum.

trce -sp 5 -sethld -sphld M design.ncd design.prf

▶ "Command Line Program Overview" on page 2432

Running I/O Timing from the Command Line

The **I/O Timing Report** process in the Diamond environment can also be run through the command line using the **iotiming** program. For each input data port, this process will generate the setup and hold time requirements and min/max clock-to-out delay for each output port. The computation will be performed over all peformance grades and at the voltage and temperature specified in the preference file. This program also automatically determines the clocks and their associated data ports.

Subjects included in this topic:

Running IOTIMING IOTIMING uses your input placed-and-routed physical design (.ncd) file and optional associated preference (.prf) file to generate an I/O Timing Report (.ior) file.

- To run IOTIMING, type **iotiming** on the command line with, at minimum, the names of your input .ncd file. You should specify a preference file since factors such as TEMPERATURE, VOLTAGE, and DDR elements affect the I/O timing. Otherwise you may see differences between the generated I/O Timing Report (.ior) and TRACE Timing Report (.twr) files. A sample of a typical IOTIMING command would be as follows:

  iotiming input.ncd

There are several commands options that do not need to be specified due to the default behavior of IOTIMING, so please refer to the rest of the subjects in this topic for more details. See examples.

Command Line Syntax **iotiming** [**-s**] [**-v**] [**-sp** <peformance_grade>] <design.ncd> [<preference.prf>] **-o** <output_file>

IOTIMING Options The table below contains descriptions of all valid options for IOTIMING.

Table 852: IOTIMING Command Line Options

Option	Description
<design.ncd>	The input Native Circuit Description (.ncd) file that is used to generate output timing information in the I/O Timing Report .ior file. This design must be placed and routed.
-s	Specifies peformance grade in the NCD file.
-sp <peformance_grade>	Specifies the selected peformance grade.

Table 852: IOTIMING Command Line Options

Option	Description
-o <output_file>	Specifies the name of the output I/O Timing Report (.ior) file that will be generated in the current working directory unless otherwise specified. The default file name of the output if not specified is design.ior. The resulting output file contains sections for Input Setup/Hold Time and also for Clock-to-Out for every available peformance grade for the current device.
<preference.prf>	The input preference (.prf) file that contains any changes in temperature and voltage through the use of the VOLTAGE and TEMPERATURE preferences.
-v	Verbose report option that will produce an I/O Timing Report (.ior) which summarized worst case scenario data on all available peformance grades. If you do not specify this option, the program report defaults to a summary report of the worst case peformance grade for the selected device in addition to any available faster peformance grades that are available for the device. For example, if your device is offered in peformance grades -3, -4, and -5 and your selected device is a -4, then by default your report will include analyses on -4, -5, and M (minimum peformance grade).

Examples Following are a few examples of IOTIMING command lines and a description of what each does.

Example 1 This command takes the input.ncd and input.prf files and generates an io_report.ior report file in the reports directory above the current directory. Here the designer has placed new VOLTAGE and/or TEMPERATE preferences on the design, so specifying the .prf file is necessary. The resulting report will be a summary of the worst case peformance grade.

iotiming input.ncd input.prf -o ../reports/io_report

Example 2 This shortcut command performs the same function on the input.ncd, but it does not use an input preference file and will output an I/O timing report by the default name of input.ior in the current working directory.

iotiming input.ncd

Example 3 This command uses the input.ncd and input.prf files to output a verbose I/O timing report named io_report.ior in the current working directory. A verbose report (**-v**) option generates a report containing data on all available peformance grades.

iotiming -v input.ncd input.prf -o io_report

- "Command Line Program Overview" on page 2432

Running Backannotation from the Command Line

The **Generate Timing Simulation Files** process in the Diamond environment can also be run through the command line using the **ldbanno** program. The **ldbanno** program back-annotates physical information (e.g., net delays) to the logical design and then writes out the back-annotated design in the desired netlist format. Input to **ldbanno** is a Native Circuit Description file (.ncd) a mapped and partially or fully placed and/or routed design.

Subjects included in this topic:

Running LDBANNO LDBANNO uses your input mapped and at least partially placed-and-routed Native Circuit Description (.ncd) file to produce a back-annotated netlist (.v, .vhd) and standard delay (.sdf) file. This tool supports all FPGA design architecture flows.

- To run LDBANNO, type **ldbanno** on the command line with, at minimum, the type of your output netlist (i.e., Verilog or VHDL) with the **-n** option and the name of your input .ncd file. A sample of a typical LDBANNO command would be as follows:

  ldbanno -n vhdl backanno.ncd

Note

The above command back annotates backanno.ncd and generates a VHDL file backanno.v and an SDF file backanno.sdf. If the target files already exist, they will not be overwritten in this case. You would need to specify the **-w** option to overwrite them.

There are several command line options that give you control over the way LDBANNO generates back-annotated netlists for simulation. Please refer to the rest of the subjects in this topic for more details. See examples.

Command Line Syntax (VHDL) **ldbanno** [**-w**] [**-pre** <prfx>] [**-sp** <grade>] [**-neg**] [**-pos**] [**-sup**] [**-min**] [**-f** <command_file>] **-h** [<hdltype>] [**-t**] [**-x**] [**-slice**] [**-tpath**] [**-dis** [<del>]] [**-m** [<limit>]] [**-h** vhdl] [**-u**] [**-nopur**] [**-n** <type>] [**-l** <libtype>] [**-noslice**] [**-p** <prffile>] [**-o** <vhdl[**.vhd**]>] [**-d** <delays[**.sdf**]>] [<ncdfile[.**ncd**]>] {<preference[**.prf**]>}

Command Line Syntax (Verilog) **ldbanno** [**-w**] [**-pre** <prfx>] [**-sp** <grade>] [**-neg**] [**-pos**] [**-sup**] [**-min**] [**-f** <command_file>] **-h** [<hdltype>] [**-x**] [**-slice**] [**-t**] [**-dis** [<del>]] [**-m** [<limit>]] [**-u**] [**-i**] [**-nopur**] [**-n** <type>] [**-l** <libtype>] [**-s** <separator>] [**-noslice**] [**-p** <prffile>] [**-o** <verilog<.v>>] [**-d** <delays[**.sdf**]>] [<ncdfile[**.ncd**]>] {<preference[**.prf**]>}

LDBANNO Options The table below contains descriptions of all valid options for LDBANNO.

Table 853: LDBANNO Options

Option	Description
-d <delays[**.sdf**]>	Output delay file, defaults to <ldbfile>.sdf.
[**-dis** [<delay>]] [**-sig** <sig_file>]	The **-dis** option distributes routing delays by splitting the signal and inserting buffers. The <delay> value represents the maximum delay number in picoseconds between each buffer (1000 ps by default) The **-sig** option designates the use of a <sigfile> which is an ASCII file that contains all the top level signals to be split. One signal name can used per line. If **-dis** is given but **-sig** is absent, all top level signals will be distributed. These options will enable simulation of high frequency signals (e.g., clock signals), where the interconnection delay may be higher than the clock cycle. In such a case, that signal will be blocked in some simulators if the delay is not distributed.
-f <command_file>	Execute command line arguments in the specified command_file. See “The –f Option” on page 2551, “Command File Example” on page 2550, and “Using the Command File” on page 2551.
-h [<hdltype>]	The -h help option on the command line can be specified for the values **vhdl** or **verlilog** as some options are limited by the hardware description language being used.
-i	Inserts a buffer at each block input that has interconnection delay on it. **Note**: This option is valid only when the netlist type is Verilog. It is similar to the “tipd” statement in a VITAL compliant model in VHDL, which can help you to debug the design by isolating the interconnection delay and pin-to-pin delay on each input.
-l <libtype>	The orca library is the default for both VHDL and Verilog.
-m <limit>	Shortens the block names to a given character limit in terms of some numerical integer value.
-min	Replaces all timing information for backannotation with the minimum timing for all paths. This option is used for simulation of hold time requirements. Separate simulations are required for hold time verification (**-min** switch) and delay time verification (normal output).

Table 853: LDBANNO Options

Option	Description
-n <type>	Specifies the netlist type for ldbanno to write out : ▶ Verilog generic verilog format with SDF delay file ▶ VHDL generic VHDL format with SDF delay file So, accepted values are **vhdl** and **verilog**. Note that these values are not case sensitive.
-neg	For better compatibility with simulators, all negative setup/hold delay numbers in the SDF file are set to 0 by default. This may cause some discrepancies between backannotation and the TRACE result. Use the new -neg option to get the negative numbers in the SDF file and backannotation will match the TRACE report. Ensure that the simulator is able to handle negative numbers in the SDF file.
-nopur	Option prevents the writing of a PUR instance in the Verilog/VHDL backannotated netlst. You must instantiate it in the test bench.
-noslice	(optional) Verbose netlist option. If this option is excluded, a parameterized netlist format will be generated that is more compact in size and memory efficient within the simulator.
-o <netlist>	(optional) The name of the output file. The extension used for each output depends on the type of netlist being written (specified with the **-n** switch).
-p <prffile>	(optional) Preference file (only output load preferences are used).
-pos	(LatticeSC/M) Writes out zero value for negative setup/hold time.
-pre <prefix>	(optional) Prefix to add to module names to make them unique for multi-chip simulation.
-s <separator>	(<type>=Verilog) Hierarchy separator character.
-slice	(optional) Non-Verbose netlist option. If this option is included, a parameterized netlist format will be generated that is more compact in size and memory efficient within the simulator.
-sp <peformance grade>	Re-target backannotation to a different peformance grade than the one used to create the .ncd file. You are limited to those peformance grades available for the port used in the .ncd file.
-sup	Suppresses custom design MACO block in SDF output.

Table 853: LDBANNO Options

Option	Description
-t <type>	(<type>=VHDL) Target this VHDL file to Exemplar Time Explorer. (<type>=Verilog>) Write a PrimeTime compatible Verilog file.
-tpath	Transport mode of path delay in VHDL.
-u	Adds paths for top-level dangling nets.
-w	Overwrite the output file(s).
-x	If you use the **-x** option, LDBANNO will place "X" notifiers in the output file on flip-flops with setup and/or hold time violations. This option is supported by all new Lattice FPGA families. (<type> = VHDL or Verilog) Write a trce cross-reference file.
-z	Zero delay (do not calculate or write any delays). See Note for the **-a** option.
<preffile[.**prf**]>	(optional) The preference file in .prf format.
<ncdfile[.**ncd**]>	The input design file is a mapped and partially or fully placed and/or routed design in .ncd format.

Examples Following are a few examples of LDBANNO command lines and a description of what each does.

Example 1 The following command back annotates design.ncd and generates a Verilog file design.v and an SDF file design.sdf. If the target files exist, they will be overwritten.

ldbanno -w -n verilog design.ncd

Example 2 The following command back annotates design.ncd and generates a VHDL file backanno.vhd and an SDF file backanno.sdf. Any signal in the design that has an interconnection delay greater than 2000 ps (2 ns) will be split and a series of buffers will be inserted. The maximum interconnection delay between each buffer would be 2000 ps.

```
ldbanno -dis 2000 -n vhdl -o backanno design.ncd
```

Example 3 The following command re-targets backannotation to peformance grade -2, and puts a buffer at each block input to isolate the interconnection delay (ends at that input) and the pin to pin delay (starts from that input).

```
ldbanno -sp 2 -i -n verilog design.ncd
```

Example 4 The following command generates Verilog netlist and SDF files without setting the negative setup/hold delays to 0:

```
ldbanno -neg -n verilog design.ncd
```

▶ "Command Line Program Overview" on page 2432

Running LTXT2PTXT from the Command Line (ECP5 and LatticeECP3 Only)

This process converts the logical attribute text file (.txt) for the LatticeECP3 PCS block to the physcial attribute text file (.ptx). The LTXT2PTXT process is run automatically when using the Diamond GUI process flow and does not require user input. But, when when using the command line process flow, this process must be run on the command line before generating a bitstream for ECP5 and LatticeECP3 designs that utilize the PCS block.

Subjects included in this topic:

Running LTXT2PTXT LTXT2PTXT converts the logical attribute text file (.txt) for the ECP5 and LatticeECP3 PCS block to the physcial attribute text file (.ptx).

▶ To run LTXT2PTXT, type **ltxt2ptxt** on the command line.

Command Line Syntax ltxt2ptxt [-path search_path] ncd_file

ltxt2ptxt [-path dir1 -path dir2 ..] ncd_file

LTXT2PTXT Options The table below contains descriptions of all valid options for LTXT2PTXT.

Table 854: LTXT2PTXT Command Line Options

Option	Description
- path	Path where the logical text file resides.

Example Following is an example of running LTXT2PTXT from the command line.

```
ltxt2ptxt -path "c:/lscc/examples" design.ncd
```

See Also ▶"Command Line Data Flow" on page 2435

▶ "Command Line Program Overview" on page 2432

Running Bit Generation from the Command Line

The **Bitstream** process in the Diamond environment can also be run through the command line using the bit generation (**bitgen**) program. This topic provides syntax and option descriptions for usage of the **bitgen** program from the command line. The **bitgen** program takes a fully routed Native Circuit Description (.ncd) file as input and produces a configuration bitstream (bit images) needed for programming the target device.

Subjects included in this topic:

Running BITGEN BITGEN uses your input, fully placed-and-routed Native Circuit Description (.ncd) file to produce bitstream (.bit, .msk, or .rbt) for device configuration.

- To run BITGEN, type **bitgen** on the command line with, at minimum, the **bitgen** command. There is no need to specify the input .ncd file if you run **bitgen** from the directory where it resides and there is no other .ncd present. An output .bit file will be generated if you do not specify a mask file with **-m** or a raw bits file with **-b**. The sample below shows an option added that shows the **-g Address:Explicit** option specified used for testing and debugging of LatticeSC/M devices:

  bitgen -g Address:Explicit

There are several command line options that give you control over the way BITGEN outputs bitstream for device configuration. Please refer to the rest of the subjects in this topic for more details. See examples.

Command Line Syntax **bitgen** [**-b**] [**-d**] [**-jedec**] [**-w**] [**-m** <format>] [**-e**] [**-s** <secfile>] [**-k** <bekfile>] [**-f** <command_file>] [**-h** [<architecture>]] [**-o** <outfile>] [**-x**] [**-path** <search_path>] [**-j**] [**-q**] [**-t**] [**-g** option:value] [**-J r** | **w** <infile1[**.ncd**] {<infile2[**.ncd**]}] <infile[**.ncd**]> [<outfile>] [<preffile[.**prf**]>]

BITGEN Options The table below contains descriptions of all valid options for BITGEN.

Note

Many BITGEN options are only available for certain architectures. Please use the **bitgen** -h <*architecture*> help command to see a list of valid bitgen options for the particular device architecture you are targeting.

Table 855: BITGEN Command Line Options

Option	Description
-b	Create a “rawbits” (.rbt) file in ASCII format instead of a binary file. Do not use **-b** with **-m** if you want both a rawbits file and a mask file (see the **-m** command below). Instead run BITGEN twice once with the **-b** option and once with the **-m** option.
-**d**	Do not run DRC.
-**e**	(LatticeECP2S, LatticeXP2) Create an encrypted bitstream file. This must be used with the **-s** and **-k** options that specify binary security and key files. These binary files are generated using the Security Setting tool, **secuload**. Here is the basic syntax for using the **-e** option, bitgen -e -s <sec_file> -k <bek_file> See related topics under the “Setting Security Options” on page 75 topic for details on using **secuload** to generate the associated binary security (.sec) and key (.bek) files. The necessary binary key and security files for encryption can also be generated in the Diamond GUI using the **Tools > Security Setting** menu option.
-**ebrinit** <format>	(LatticeECP2 Write out Embedded Block RAM (EBR) initial values. Options are **0** which prevents bitgen from writing any initial EBR values, **1** (default) which writes out initial values for those used EBRs with valid WID, and **2**, which writes out initial values for all EBRs.
-f <command_file>	Execute command line arguments in the specified command_file. See “The –f Option” on page 2551, “Command File Example” on page 2550, and “Using the Command File” on page 2551.
-g <option>:<value>	The -g option sets FPGA configuration options. Options and values are case-insensitive. *Valid -g option values are described in the following rows*.
-g Address:<value>	ADDRESS (LatticeSC/M) Bitstream addressing mode. Options are **Increment** (default) for general use and **Explicit** for testing and debugging. bitstream has two Address modes: The **Increment** mode contains data information but no address information and each frame is loaded from lowest address to highest address. The **Explicit** mode requires data information followed by address information, one address frame or more (depending upon how many locations are to be written). The default option for Address is **Increment**. There is also an option in Explicit mode to ignore the zero frames. See the ZEROFRAMES option.

Table 855: BITGEN Command Line Options

Option	Description
-g CfgMode:<value>	CFGMODE (LatticeSC/M) Options are **Enable** (default) and **Serial**. If set to Serial, the configuration mode will be slave serial during reconfiguration, regardless of the setting of the MODE pins. (LatticeECP/EC, LatticeXP) Options are **Disable** (default), **Flowthrough**, and **Bypass**. The Flowthrough and Bypass options are for device chains. Each of these options places an instruction at the end of the bitstream. During configuration, such an instruction tells the device not to wake up because there is more data coming. If set to Flowthrough, the instruction tells the device that the data should be ignored because it is for the next device in the chain. If set to Bypass, it tells the device to read the data and serially shift it out to the next device.
-g DisableUES:<value>	(LatticeXP2) Options are **False** (default) and **True**.
-g DoneActive:<value>	DONEACTIVE Select the event that activates the DONE signal. Settings are **C1**, **C2**, **C3**, **C4** (default) (first CCLK rising edge after the length count is met, second CCLK rising edge after the length count is met, etc.).
-g DonePhase:<value>	DONEPHASE (ECP5, LatticeECP/EC, LatticeECP2/M/S, LatticeXP, LatticeXP2, LatticeECP3) This option determines the period of the wake-up sequence in which the Done pin is released or actively driven. Optional values are **T3** (default), **T2**, **T1**, and **T0**. T0 is the first sequence in the wakeup sequence, followed by T1, T2, and T3.
-g Es:<value>	ES (ECP5, LatticeECP/EC, LatticeECP2/M/S, LatticeXP, LatticeXP2, LatticeSC/M, LatticeECP3) Engineering Sample (ES) part option. Specify this option if the part you are generating bitstream for is an ES version of the chip opposed to the final production version. Optional values are **No** (default) and **Yes**.
-g ExternalClk:<value>	EXTERNALCLK Optional values are **No** (default) and **Yes**.
-g GoEphase:<value>	GOEPHASE (LatticeECP/EC, LatticeECP2/M/S, LatticeXP, LatticeXP2) (LatticeSC/M Only) This option determines the period of the wake-up sequence in which the Global Output Enable becomes active. Optional values are **T3**, **T2**, and **T1** (default).

Table 855: BITGEN Command Line Options

Option	Description
-g GrantTimeout:<value>	GRANTTIMEOUT (LatticeSC/M) Controls an internal system bus grant counter which counts the number of HCLK (sysbus clk) cycles goes by before the grant signal is taken away from the master.This prevents the system bus from locking up if anything goes wrong. Possible values are **0, 1, 2...15**. The default value is 5. See WAITSTAITTIMEOUT.
-g GsrPhase:<value>	GSRPHASE (ECP5, LatticeECP/EC, LatticeECP2/M/S, LatticeXP, LatticeXP2, LatticeECP3) This option determines the period of the wake-up sequence in which the Global Set/Reset becomes active. Optional values are **T2** (default), **T3**, and **T1**.
-g GwdPhase:<value>	GWDPHASE (ECP5, LatticeECP/EC, LatticeECP2/M/S, LatticeXP, LatticeXP2, LatticeECP3) This option determines the period of the wake-up sequence in which the Global Write Disable becomes active. Optional values are **T2** (default), **T3**, and **T1**.
-g GsrInactive:<value>	GSRINACTIVE Select the event that releases the internal set/reset to the latches and flip-flops. Optional values are **C1**, **C2** (default), **C3**, **C4**, and **Donein**.
-g Jtag:<value>	JTAG Enables or disables JTAG (boundary scan) after configuration. Optional values are **Enable** and **Disable** (default).
-g LengthBits:<value>	LENGTHBITS (LatticeSC/M) Specifies the number of bits in the bitstream length field. Options are **24** (default) and **32**.
-g Oscillator:<value>	OSCILLATOR Enables the on-chip oscillator after configuration. Options are **Enable**, **Disable** (default), and **EnableDiv8** (divide the speed by eight).
-g OutputsActive:<value>	OUTPUTSACTIVE Select the event that releases the I/O from 3-state condition and turns the configuration-related pins operational. Settings are **C1**, **C2**, **C3**, **C4**, and **Donein** (when the DONEIN signal goes high the default).
-g OutputsCfg:<value>	OUTPUTSCFG (LatticeSC/M) Optional values are **TriStateDuringReConfig** (default) and **DriveDuringReConfig**. If **TriStateDuringReConfig** is specified**,** the FPGA will not drive outputs during configuration/reconfiguration.

Table 855: BITGEN Command Line Options

Option	Description
-g RAMCfg:<value>	RAMCFG (LatticeSC/M) Optional values are **ClearDuringReConfig** (default). **ClearDuringReConfig** reinitializes the device when you download bitstream. **NoClearDuringReConfig** retains the current configuration and allows additional bitstream configuration. (ECP5, MachXO, LatticeECP/EC, LatticeECP2/M/S, LatticeXP, LatticeXP2, LatticeECP3) Optional values are **Reset** (default) and **NoReset**. **ClearDuringReConfig** reinitializes.
-g ReadBack:<value>	READBACK Allows you to extract the configuration data stored in an FPGA in order to verify the configuration. Settings are **Disable** (default), **Once** (allow one readback only; after that, readback cannot be invoked again), and **Command** (multiple readbacks). (LatticeXP Only) Optional values are **FLASH** (default) and **SRAM**.
-g ReadCapture:<value>	READCAPTURE Enable or disable readback of the configuration bitstream. Settings are **Disable** (default), **Read**, **UserNet**, and **Both**. (ECP5, LatticeECP/EC and LatticeXP Only) Optional values are **Disable** (default) and **Enable**. When Enable is selected, the GLB is targeted during readback.
-g RegisterCfg:<value>	REGISTERCFG Reset the PFU registers before configuration. Values are **Enable** (default) and **Disable**. (For LatticeSC Only) Optional values are **ResetDuringReConfig** (default) and **NoResetDuringReConfig**.
-g Rnet: <value>	RNET (LatticeSC/M) INIT, ON, OFF.
-g SPI_RECONFIG_START_ADDRESS:<value>	SPI_RECONFIG_START_ADDRESS (LatticeSC/M) Address of the next programming bitstream to be loaded from SPI Flash boot memory. It is 6 or 8 digit hex string prefixed with 0x. The default address value is 0x00000000.
-g StartupClk:<value>	STARTUPCLK (LatticeSC/M) Use CCLK or a User clock during startup. Options are **Cclk** (default) or **UserClk**.
-g SyncToDone:<value>	SYNCTODONE Synchronize the startup sequence to the external DONE signal. Optional values are **No** (default) and **Yes**.

Table 855: BITGEN Command Line Options

Option	Description
-g Sysbusconfig:<value> **-g SysbusCFG**:<value>	SYSBUSCFG (Lattice SC/M) Optional values are **ResetDuringReConfig** (default), **NoResetDuringReConfig**. The system bus is either reset or not reset at reconfiguration.
-g SysbusClkconfig:<value>	SYSBUSCLKCFG (Lattice SC/M) Optional values are **ResetDuringReConfig** (default), **NoResetDuringReConfig**. The system bus clock is either reset or not reset at reconfiguration.
-g WaitStateTimeout:<value>	WAITSTATETIMEOUT (LatticeSC/M) Controls an internal system bus timeout counter. This counter counts the number of HCLK (sysbus clk) cycles goes by while the system bus is in wait states. Possible values are **0, 1, 2...15**. 0 - Indefinitely (never times out) 1 - 2^2 HCLK cycles 2 - 2^4 HCLK cycles 3 - 2^6 HCLK cycles 4 - 2^8 HCLK cycles 5 - (default) 2^10 HCLK cycles 6 - 2^12 HCLK cycles 7 - 2^14 HCLK cycles 8 - 2^16 HCLK cycles 9 - 2^18 HCLK cycles 10- 2^20 HCLK cycles 11 - 2^22 HCLK cycles 12 - 2^24 HCLK cycles 13 - 2^26 HCLK cycles 14 - 2^28 HCLK cycles 15 - 2^31 HCLK cycles

Table 855: BITGEN Command Line Options

Option	Description
-g Xres:<value>	XRES (LatticeSC/M) Controls the calibration circuit connected to XRES pin. Options are **INIT** (default), **ON**, and **OFF**. The external resistor combined with an internal calibration control circuit is used to calibrate output drive strength and impedance. The calibration compensates for the effects of variations in process, voltage and temperature (PVT). It is connected through a 1K+/-1% resistor to ground. The **INIT** options allows the calibration circuit to monitor PVT on power-up and during configuration. The circuit latches in the control value and not allow changes after that. If voltage and temperature does not vary much during operation versus configuration time, INIT is the best choice. The **ON** option allows the calibration circuit to run all the time. If IOPVTCTRL is instantiated in the design, the XRES is controlled by the UPDATE signal. INIT and OFF options are disabled. The **OFF** option turns off the calibration circuit. The result is minimum drive on output buffer, maximum impedance and maximum termination resistor. OFF is not recommended in most FPGA implementations.
-g ZeroFrames:<value>	ZEROFRAMES (LatticeSC/M) Option to specify that data frames with all zeros be written into the bitstream. Options are **No** and **Yes** (default). This option is used with Increment Address mode. When **Yes** is specified with Increment Address mode, every data frame is written out with no address frames. When **No** is specified with Increment Address mode, all sequential non-zero data frames are written without data frames. When a (zero) data frame is skipped, the address frame for the next (non-zero) data frame is written.
-h <architecture> or **-help** <architecture>	Display available BITGEN command options for the specified architecture. The **bitgen -h** command with no architecture specified will display a list of valid architectures.
<infile[.**ncd**]>	A .mif file will be generated with a file name identical to your module name. Note that if block RAMs are already initialized by INITVAL properties in the .ncd file, addresses that are explicitly addressed in the .mif file will be overridden by the INITVAL properties.
-**j**	Do not create a bitstream file.
-**jedec**	(LatticeXP2) Creates a JEDEC format file.

Table 855: BITGEN Command Line Options

Option	Description
-J r | **w** <infile1[**.ncd**]> {<infile2[**.ncd**]}	JTAG setup. Allows the user to set JTAG port read and write on the FPGA chip by providing them with the setup bitstreams. Users will use tools other than ispVM to download these bitstreams. Example syntax: [**-J w** <infile1.ncd> {<infile2.ncd>}] [**-J r**] [**-a**] [**-o** <outfile>] where: **-J r** generates a JTAG read setup bitstream. The default output is jtagread.jbt. **-J w** generates JTAG write setup bitstream. **-a** outputs an ASCII file. **-o** <outfile> specifies the output file name. The example syntax for JTAG setup will generate JTAG write setup bitstream that specifies infile1.ncd as the target design to be downloaded, so the correct initialization bits will be added to the bitstream. If more than one design is on the command line, the bitstreams for daisy-chained devices will be generated using JTAG port. The default output is infile1.jbt.
-**k** <bek_file>	(LatticeECP2S, LatticeXP2) Only when using the **-e** encryption option, use the **-k** option to specify a binary key file. This .bek file is generated by the Security Setting tool, **secuload**. You must also specify the **-s** <sec_file> option in this command to include the related security file. For example, bitgen -e -s <sec_file> -k <bek_file> See related topics under the "Setting Security Options" on page 75 for details on using **secuload** to generate the binary key and security files. The necessary binary key and security files for encryption can also be generated in the Diamond GUI using the **Tools > Security Setting** menu option.

Table 855: BITGEN Command Line Options

Option	Description
-m <format>	Create mask files and readback files. A mask file is an ASCII file with only data frames in it. When you specify the **-m** option, **bitgen** generates a mask file for the input design. All **bitgen** options can be used with mask file option with the exception that any compressed options are ignored by mask file generation. (For LatticeSC/M, MachXO) Format value equals **0**, **1**, **2**, or **3**. The **0** value outputs files in ASCII. The value **1** outputs files in binary. The value **2** creates mask out SMI MEM cells in some special tiles and outputs files in ASCII. The value **3** creates mask out SMI MEM cells in some special tiles and outputs files in binary. There are three different mask file outputs. They are all similar in format with slight differences in content. The mask file has the following format: 01[data frame][alignment bits][checksum]11111111 (For ECP5, LatticeECP/EC, LatticeXP, LatticeXP2, LatticeECP3) Format value equals **0** or **1**. The **0** value outputs files in ASCII. The **1** value outputs files in binary. **Generic format** – In the date frames, the Vs will be positioned at the location of every configuration RAM location that is used for the device family. The Xs are positioned at the location of ever configuration RAM location that is unused for the device family. The alignment bits are 0's and the checksum is affected by relative location of the mask bits in a byte of the frame. If a mask bit is at bit 2 of byte 3 for the frame, bit 2 at the checksum is masked as “X” as well. **Design specific format** – The design specific mask file is an ASCII file containing 1s and 0s, and Xs. This file has the same structure as the Generic mask file except instead of a V in all used configuration RAM locations the actual programming data is in the appropriate locations in the data frame. The Xs are at the locations of the unused configuration RAM as in the Generic file. **Design specific format with masks for user RAM** – This format is also an ASCII file that follows the format of the design specific file with the addition of Xs in the locations of any PFUs configured as user ram in the design. This is any RAM blocks that the user has put in his design.
-o <outfile>	Specifies the output file name.

Table 855: BITGEN Command Line Options

Option	Description
<outfile>	The output file. If you do not specify an output file, BITGEN creates one in the input file's directory. If you specify -**m** on the command line, the extension is .msk. If you specify -**b**, the extension is .rbt. Otherwise the extension is .bit. A report (.bgn) file containing all of BITGEN's output is automatically created under the same directory as the output file.
-path <search_path>	(LatticeSC/M) Use to specify a search path to the directory in which PCS configuration files are located. To specify multiple **-path** options, precede each with **-path**; or combine multiple search_path specifiers after one **-path**. The syntax for combining multiple search_path specifiers for a given macro search path is as follows where dir is the directory search path: **-path** dir1;dir2;dir3 (for Windows) **-path** dir1:dir2:dir3 (for UNIX) For example, you may have to specify a path for some modules you generate in IPexpress (e.g., PCS and some Sysbus for LatticeSC), because **bitgen** needs their configuration option information to output your bitstream. Since IPexpress allows you to specify a directory other than your project directory to keep output files in, **bitgen** requires this option to find this information. See the IPexpress Help for details.
-q	Creates .bit output without header comments (for special use only).
-s <sec_file>	(LatticeECP2S, LatticeXP2) Only when using the **-e** encryption option, use the **-s** option to specify a binary security file. This .sec file is generated by the Security Setting tool, **secuload**. You must also specify the **-k** <bek_file> option in this command to include the related key file. For example, bitgen -e -s <sec_file> -k <bek_file> See related topics under the "Setting Security Options" on page 75 for details on using **secuload** to generate the binary security and key files. The necessary binary security and key files for encryption can also be generated in the Diamond GUI using the **Tools > Security Setting** menu option.
-t	(ECP5, LatticeECP/EC, LatticeXP, LatticeECP2/M, LatticeXP2, LatticeECP3) Tie down. This option ties down unused routing MUXes to a ground state, avoiding unnecessary toggling and reducing power consumption.
-w	Overwrite an existing .bit, .msk, or .rbt output file.
-x	Byte mirror. Swaps 0s with 7s, etc.

Examples Following are a few examples of BITGEN command lines and a description of what each does.

Example 1 The following command tells **bitgen** to overwrite any existing bitstream files with the **-w** option, prevents a physical design rule check (DRC) from running with **-d**, specifies a raw bits (.rbt) file output with **-b**, and specifies a **-g** option for PERSIST to be turned on. Notice how these three options can be combined with the **-wdb** syntax.

bitgen -wdb -g PERSIST:Yes

Example 2 The following command specifies a raw bits (.rbt) file output with **-b**, specifies several **-g** options for disabling features, and specifies a certain .ncd file located in the present working directory because there are several .ncd files present. The name of the output .rbt file is also specified in this case.

bitgen -b -g JTAG:Disable ReadBack:Disable ReadCapture:Disable routed.ncd output_bit.rbt

Example 3 The following command shows bitgen calling a command file named bit1d. This file can contain any number of bitgen commands. See The -f Option.

bitgen -f bit1d

Running Programmer from the Command Line

You can run Programmer from the command line. The **PGRCMD** command uses a keyword preceded by a hyphen for each command line option.

Subjects included in this topic:

Running PGRCMD PGRCMD allows you to download data files to an FPGA device.

- To run PGRCMD, type **pgrcmd** on the command line with, at minimum, the **pgrcmd** command.

There are several command line options that give you control over the way PGRCMD programs devices. Please refer to the rest of the subjects in this topic for more details.

Command Line Syntax The following describes the PGRCMD command line syntax:

pgrcmd [-**help**] [**-infile** <input_file_path>] [**-logfile** <log_file_path>] [**-processtype** <turbo|sequential> [**-cabletype** <cable>]

-cabletype

lattice [**-portaddress** < 0x0378 | 0x0278 | 0x03bc | 0x<*custom address*> >]

usb [**-portaddress** < EZUSB-0 | EZUSB-1 | ... | EZUSB-15 >]

usb2 [**-portaddress** < FTUSB-0 | FTUSB-1 | ... | FTUSB-15 >]

TCK [**0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10**]

PGRCMD Options The following are PGRCMD options.

Help (Optional)

Option	Description
-help or **-h**	Displays the Programmer command line options.

Input File (required)

Option	Description
-infile *filename*.xcf	Specifies the chain configuration file (.xcf). If the file path includes spaces, enclose the path in quotes.

Log File (optional)

Option	Description
-logfile *logfilename*.log	Specifies the location of the Programmer log file.

Process Type (optional)

Option	Description
-processtype sequential	Processes using Sequential mode (default).
-processtype turbo	Processes using Turbo mode.

This option is only valid when you process directly to the cable. It is not valid with the -outfiletype option.

Cable Type (optional)

Option	Description
-cabletype lattice	Lattice HW-DLN-3C parallel port programming cable (default).
-cabletype usb	Lattice HW-USBN-2A USB port programming cable.
-cabletype usb2	Lattice FHW-USBN-2B (FTDI) USB programming cable and any FTDI based demo boards.

Parallel Port Address (optional)

Option	Description
-portaddress 0x0378	LPT1 parallel port (default)
-portaddress 0x0278	LPT2 parallel port
-portaddress 0x03BC	LPT3 parallel port
-portaddress 0x<*custom address*>	Custom parallel port address

This option is only valid with parallel port cables.

USB Port Address (optional)

Option	Description
-portaddress EZUSB-0 ... EZUSB-15	HW-USBN-2A USB cable number 0 through 15
-portaddress FTUSB-0 ... FTUSB-15	FTDI based demo board or FTDI USB2 cable number 0 through 15

Default is EZUSB-0 and FTUSB-0. Only valid with the USB port cables.

FTDI Based Demo Board or Cable Frequency Control (optional)

Option	Description
-TCK 0, 1, 2, 3, 4, ,5 ,6 7, 8, 9, 10	0 = 30 Mhz 1 = 15 Mhz (default) 2 = 10 Mhz 3 = 7.5 Mhz 4 = 6 Mhz 5 = 5 Mhz 6 = 4 Mhz 7 = 3 Mhz 8 = 2 Mhz 9 = 1 Mhz 10 = 900 Khz

Only applicable for FTDI based demo boards or programming cable.

Return Codes

Code	Definition
0	Success
-1	Log file error
-2	Check configuration setup error
-3	Out of memory error
-4	NT driver error
-5	Cable not detected error
-6	Power detection error
-7	Device not valid error
-8	File not found error

Code	Definition
-9	File not valid error
-10	Output file error
-11	Verification error
-12	Unsupported operation error
-13	File name error
-14	File read error
-17	Build SVF file error
-18	Build VME file error
-19	Command line syntax error

Examples The following is a PGRCMD example.

```
pgrcmd -infile c:\test.xcf
```

- "Command Line Program Overview" on page 2432

Running the Deployment Tool from the Command Line

You can run the Deployment Tool from the command line. The **DDTCMD** command uses a keyword preceded by a hyphen for each command line option.

Note

If you use the Deployment Tool GUI, the correct command line for the operation your are performing will be displayed in the GUI in the "Step 4 of 4 - Generate Deployment" dialog box. The command line is also recorded in the Deployment Project File (*.ddt). You can view the Deployment Project File with a text editor and view or copy the command line.

Subjects included in this topic:

Running DDTCMD DDTCMD allows you to convert data files to other formats for one device at a time and devices in a chain. DDTCMD can also use the data files it produces to generate other data file formats.

- To run DDTCMD, type **ddtcmd** on the command line with, at minimum, the **ddtcmd** command.

There are several command line options that give you control over the way **DDTCMD** converts data files. Please refer to the rest of the subjects in this topic for more details.

Command Line Syntax The following describes the DDTCMD command line syntax:

<*install_path*>**ddtcmd**

[**-convertbidi**]

DDTCMD Options The following are DDTCMD options.

Option	Description
-h	Displays the Deployment Tool command line usage in the terminal or DOS window.
-oft <File Type>	Indicates which file type(s) will be generated.

Option	Description
-bit	Generate binary bitstream file. **-dev** <Device Name>: Indicates the name of the device. Optional. The device name must be the full device name with the performance grade replaced with two X's, and minus the industry rating or the code name. Example: LFE3-17EA-XXFN484 (with performance grade replaced with two X's). The device name will default to the device name in the data file. If a device name cannot be found in the file, it will return an error unless the name has been given with the -dev option. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default file name is the same name as the input file. binary bitstream files should end with the *.bit extension. **-compress** <on | off>: Specifies compression (optional). Default is off. **-verifyid**: On: Include the Verify ID frame. Off: Replaces Verify ID frame with NOOP (optional). Default is off. **-frequency**: Specifies the frequency of the master bitstream. Possible frequencies valid for LatticeEC/P, LatticeECP2/M, LatticeECP3, and LatticeXP/2 devices only are: 2.5, 4.3, 5.4, 6.9, 8.1, 9.2, 10, 13, 15, 20, 26, 30, 34, 41, 45, 51, 55, 60, and 130 MHz. Possible frequencies valid for for MachXO2, MachXO3D, and MachXO3L devices only are: 2.1, 2.5, 3.2, 4.3, 5.5, 7, 8.3, 9.2, 10, 13, 15, 20, 27, 30, 33, 38, 44, 53, 66, 89, and 133 MHz. Possible frequencies valid for for ECP5 devices only are: 2.4, 3.2, 4.1, 4.8, 6.5, 8.2, 9.7, 12.9, 15.5, 16.3, 19.4, 20.7, 25.8, 31, 34.4, 38.8, 44.3, 51.7, 62, 77.5, 103.3, and 155 MHz. **-crc** <frame | global>: The "frame" option includes the CRC checking for each data frame. The "global option disables the frames CRC but still calculates the global CRC at the end of the configuration data. Default uses the settings of the input file. Valid for ECP5. LatticeECP2/M, LatticeECP2S/SM, LatticeECP3, MachXO3D, MachXO3L, MachXO2, and LatticeXP/2 devices only. **-secure** <on | off>: Specifies program security (optional). On: Programs the Security Fuse (blocks read back). Off: Does not program the Security Fuse (allows read back).Default uses the settings of the input file. **-overwriteues on**: Overwrites (or replaces) the USERCODE value contained in the input file with the hex value passed in. **Note**: The encryption software patch must be installed before using the following **-encryption -key** and **-config_mode** commands. **-encryption -key hex** <Valid Key Value>: Encrypts the input file using the -key 128-bit encryption key. **-config_mode** <slave_scm | slave_pcm | jtag | spi | spim | master_pcm | slave_spi>]: Selects the appropriate configuration mode for the bitstream encryption. Valid for LatticeECP2S/MS and LatticeECP3 devices only.

Option	Description
-rbt	Generate ASCII Bitstream file. **-dev** <Device Name>: Indicates the name of the device. Optional. The device name must be the full device name with the performance grade replaced with two X's, and minus the industry rating or the code name. Example: LFE3-17EA-XXFN484 (with performance grade replaced with two X's). The device name will default to the device name in the data file. If a device name cannot be found in the file, it will return an error unless the name has been given with the -dev option. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default file name is the same name as the input file. ASCII bit files should end with the *.rbt extension. **-compress** <on | off>: Specifies compression (optional). Default is off. **-verifyid**: On: Include the Verify ID frame. Off: Replaces Verify ID frame with NOOP (optional). Default is off. **-frequency**: Specifies the frequency of the master bitstream. Possible frequencies valid for LatticeEC/P, LatticeECP2/M, LatticeECP3, and LatticeXP/2 devices only are: 2.5, 4.3, 5.4, 6.9, 8.1, 9.2, 10, 13, 15, 20, 26, 30, 34, 41, 45, 51, 55, 60, and 130 MHz. Possible frequencies valid for for MachXO2, MachXO3D, and MachXO3L devices only are: 2.1, 2.5, 3.2, 4.3, 5.5, 7, 8.3, 9.2, 10, 13, 15, 20, 27, 30, 33, 38, 44, 53, 66, 89, and 133 MHz. Possible frequencies valid for for ECP5 devices only are: 2.4, 3.2, 4.1, 4.8, 6.5, 8.2, 9.7, 12.9, 15.5, 16.3, 19.4, 20.7, 25.8, 31, 34.4, 38.8, 44.3, 51.7, 62, 77.5, 103.3, and 155 MHz. **-crc** <frame | global>: The "frame" option includes the CRC checking for each data frame. The "global option disables the frames CRC but still calculates the global CRC at the end of the configuration data. Default uses the settings of the input file. Valid for LatticeECP2/M, LatticeECP2S/SM, LatticeECP3, ECP5, MachXO2, MachXO3D, MachXO3L, and LatticeXP/2 devices only. **-secure** <on | off>: Specifies program security (optional). On: Programs the Security Fuse (blocks read back). Off: Does not program the Security Fuse (allows read back).Default uses the settings of the input file. **-overwriteues on**: Overwrites (or replaces) the USERCODE value contained in the input file with the hex value passed in. **Note**: The encryption software patch must be installed before using the following **-encryption -key** and **-config_mode** commands. **-encryption -key hex** <Valid Key Value>: Encrypts the input file using the -key 128-bit encryption key. **-config_mode** <slave_scm | slave_pcm | jtag | spi | spim | master_pcm | slave_spi>]: Selects the appropriate configuration mode for the bitstream encryption. Valid for LatticeECP2S/MS and LatticeECP3 devices only.

Option	Description
-int	Generate Intel 32-bit hex file. **-dev** <Device Name>: Indicates the name of the device. Optional. The device name must be the full device name with the performance grade replaced with two X's, and minus the industry rating or the code name. Example: LFE3-17EA-XXFN484 (with performance grade replaced with two X's). The device name will default to the device name in the data file. If a device name cannot be found in the file, it will return an error unless the name has been given with the -dev option. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default file name is the same name as the input file. Intel files should end with the *.mcs extension. **-compress** <on | off>: Specifies compression (optional). Default is off. **-verifyid**: On: Include the Verify ID frame. Off: Replaces Verify ID frame with NOOP (optional). Default is off. **-frequency**: Specifies the frequency of the master bitstream. Possible frequencies valid for LatticeEC/P, LatticeECP2/M, LatticeECP3, and LatticeXP/2 devices only are: 2.5, 4.3, 5.4, 6.9, 8.1, 9.2, 10, 13, 15, 20, 26, 30, 34, 41, 45, 51, 55, 60, and 130 MHz. Possible frequencies valid for for MachXO2, MachXO3D, and MachXO3L devices only are: 2.1, 2.5, 3.2, 4.3, 5.5, 7, 8.3, 9.2, 10, 13, 15, 20, 27, 30, 33, 38, 44, 53, 66, 89, and 133 MHz. Possible frequencies valid for for ECP5 devices only are: 2.4, 3.2, 4.1, 4.8, 6.5, 8.2, 9.7, 12.9, 15.5, 16.3, 19.4, 20.7, 25.8, 31, 34.4, 38.8, 44.3, 51.7, 62, 77.5, 103.3, and 155 MHz. **-crc** <frame | global>: The "frame" option includes the CRC checking for each data frame. The "global option disables the frames CRC but still calculates the global CRC at the end of the configuration data. Default uses the settings of the input file. Valid for ECP5, LatticeECP2/M, LatticeECP2S/SM, LatticeECP3, MachXO3D, MachXO3L, MachXO2, and LatticeXP/2 devices only. **-mirror**: Flips each byte. Default: bytes are not flipped. Optional. **-header**: Retains the input file header in the output file. Default: Replaces header with all ones (0xFF). Optional. **-secure** <on | off>: Specifies program security (optional). On: Programs the Security Fuse (blocks read back). Off: Does not program the Security Fuse (allows read back).Default uses the settings of the input file. **-overwriteues on**: Overwrites (or replaces) the USERCODE value contained in the input file with the hex value passed in. **Note**: The encryption software patch must be installed before using the following **-encryption -key** and **-config_mode** commands. **-encryption -key hex** <Valid Key Value>: Encrypts the input file using the -key 128-bit encryption key.

Option	Description
-int (cont.)	**-config_mode** <slave_scm | slave_pcm | jtag | spi | spim | master_pcm | slave_spi>]: Selects the appropriate configuration mode for the bitstream encryption. Valid for LatticeECP2S/MS and LatticeECP3 devices only. **-address** <hex address> Specifies the starting address of the memory device to store the input file. **-fast**: Using this option, the FPGA will issue the Fast Read command (0x0B) to the SPI Flash, instead of the Slow Read command (0x03). Valid for ECP5.
-mot	Generate Motorola 32-bit hex file. **-dev** <Device Name>: Indicates the name of the device. Optional. The device name must be the full device name with the performance grade replaced with two X's, and minus the industry rating or the code name. Example: LFE3-17EA-XXFN484 (with performance grade replaced with two X's). The device name will default to the device name in the data file. If a device name cannot be found in the file, it will return an error unless the name has been given with the -dev option. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default file name is the same name as the input file. Motorola files should end with the *.exo extension. **-compress** <on | off>: Specifies compression (optional). Default is off. **-verifyid**: On: Include the Verify ID frame. Off: Replaces Verify ID frame with NOOP (optional). Default is off. **-frequency**: Specifies the frequency of the master bitstream. Possible frequencies valid for LatticeEC/P, LatticeECP2/M, LatticeECP3, and LatticeXP/2 devices only are: 2.5, 4.3, 5.4, 6.9, 8.1, 9.2, 10, 13, 15, 20, 26, 30, 34, 41, 45, 51, 55, 60, and 130 MHz. Possible frequencies valid for for MachXO2, MachXO3D, and MachXO3L devices only are: 2.1, 2.5, 3.2, 4.3, 5.5, 7, 8.3, 9.2, 10, 13, 15, 20, 27, 30, 33, 38, 44, 53, 66, 89, and 133 MHz. Possible frequencies valid for for ECP5 devices only are: 2.4, 3.2, 4.1, 4.8, 6.5, 8.2, 9.7, 12.9, 15.5, 16.3, 19.4, 20.7, 25.8, 31, 34.4, 38.8, 44.3, 51.7, 62, 77.5, 103.3, and 155 MHz. **-crc** <frame | global>: The "frame" option includes the CRC checking for each data frame. The "global option disables the frames CRC but still calculates the global CRC at the end of the configuration data. Default uses the settings of the input file. Valid for ECP5, LatticeECP2/M, LatticeECP2S/SM, LatticeECP3, MachXO3D, MachXO3L, MachXO2, and LatticeXP/2 devices only. **-mirror**: Flips each byte. Default: bytes are not flipped. Optional. **-header**: Retains the input file header in the output file. Default: Replaces header with all ones (0xFF). Optional. **-secure** <on | off>: Specifies program security (optional). On: Programs the Security Fuse (blocks read back). Off: Does not program the Security Fuse (allows read back).Default uses the settings of the input file.

Option	Description
-mot (cont.)	**-overwriteues on**: Overwrites (or replaces) the USERCODE value contained in the input file with the hex value passed in. **Note**: The encryption software patch must be installed before using the following **-encryption -key** and **-config_mode** commands. **-encryption -key hex** <Valid Key Value>: Encrypts the input file using the -key 128-bit encryption key. **-config_mode** <slave_scm | slave_pcm | jtag | spi | spim | master_pcm | slave_spi>]: Selects the appropriate configuration mode for the bitstream encryption. Valid for LatticeECP2S/MS and LatticeECP3 devices only. **-address** <hex address> Specifies the starting address of the memory device to store the input file. **-fast**: Using this option, the FPGA will issue the Fast Read command (0x0B) to the SPI Flash, instead of the Slow Read command (0x03). Valid for ECP5.
-xtek	Generate Tektronix Extended hex file **-dev** <Device Name>: Indicates the name of the device. Optional. The device name must be the full device name with the performance grade replaced with two X's, and minus the industry rating or the code name. Example: `LFE3-17EA-XXFN484` (with performance grade replaced with two X's). The device name will default to the device name in the data file. If a device name cannot be found in the file, it will return an error unless the name has been given with the -dev option. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Extended Tektronix files should end with the *.xtek extension. **-compress** <on | off>: Specifies compression (optional). Default is off. **-verifyid**: On: Include the Verify ID frame. Off: Replaces Verify ID frame with NOOP (optional). Default is off. **-frequency**: Specifies the frequency of the master bitstream. Possible frequencies valid for LatticeEC/P, LatticeECP2/M, LatticeECP3, and LatticeXP/2 devices only are: 2.5, 4.3, 5.4, 6.9, 8.1, 9.2, 10, 13, 15, 20, 26, 30, 34, 41, 45, 51, 55, 60, and 130 MHz. Possible frequencies valid for for MachXO2, MachXO3D, and MachXO3L devices only are: 2.1, 2.5, 3.2, 4.3, 5.5, 7, 8.3, 9.2, 10, 13, 15, 20, 27, 30, 33, 38, 44, 53, 66, 89, and 133 MHz. Possible frequencies valid for for ECP5 devices only are: 2.4, 3.2, 4.1, 4.8, 6.5, 8.2, 9.7, 12.9, 15.5, 16.3, 19.4, 20.7, 25.8, 31, 34.4, 38.8, 44.3, 51.7, 62, 77.5, 103.3, and 155 MHz. **-crc** <frame | global>: The "frame" option includes the CRC checking for each data frame. The "global option disables the frames CRC but still calculates the global CRC at the end of the configuration data. Default uses the settings of the input file. Valid for ECP5, LatticeECP2/M, LatticeECP2S/SM, LatticeECP3, MachXO3D, MachXO3L, MachXO2, and LatticeXP/2 devices only.

Option	Description
-xtek (cont.)	**-mirror**: Flips each byte. Default: bytes are not flipped. Optional. **-header**: Retains the input file header in the output file. Default: Replaces header with all ones (0xFF). Optional. **-secure** <on | off>: Specifies program security (optional). On: Programs the Security Fuse (blocks read back). Off: Does not program the Security Fuse (allows read back).Default uses the settings of the input file. **overwriteues on**: Overwrites (or replaces) the USERCODE value contained in the input file with the hex value passed in. **Note**: The encryption software patch must be installed before using the following **-encryption -key** and **-config_mode** commands. **-encryption -key hex** <Valid Key Value>: Encrypts the input file using the -key 128-bit encryption key. **-config_mode** <slave_scm | slave_pcm | jtag | spi | spim | master_pcm | slave_spi>]: Selects the appropriate configuration mode for the bitstream encryption. Valid for LatticeECP2S/MS and LatticeECP3 devices only. **-address** <hex address> Specifies the starting address of the memory device to store the input file. **-fast**: Using this option, the FPGA will issue the Fast Read command (0x0B) to the SPI Flash, instead of the Slow Read command (0x03). Valid for ECP5.
-svf	Generate SVF file for a single device. **-dev** <Device Name>: Indicates the name of the device. Optional. The device name must be the full device name with the performance grade replaced with two X's, and minus the industry rating or the code name. Example: `LCMXO2-256ZE-XXMG64` (with performance grade replaced with two X's). The device name will default to the device name in the data file. If a device name cannot be found in the file, it will return an error unless the name has been given with the -dev option. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default file name is the same name as the input file. SVF files should end with the *.svf extension. -**op** Indicates the operation. The operation list varies depending on the device family. Use the Deployment Tool GUI to create the command line. **-nocomments**: Omit Header and Comments from SVF file. Optional. Default includes Header and Comments. **-revd**: Generate Rev D standard SVF file. Optional. Default generates Lattice Extended SVF file (not supported by all third party tools). **-runtest**: Uses RUNTEST format from SVF revision C. Optional. Default is revision D SVF file. **-skipverify:** Generates an SVF without the verify portion. Optional. **-reset**: Writes RESET in the SVF file. Optional. **-maxdata** [<8 | 16 | 32 | 64 | 128 | 256>]: Specifies the maximum data size per row (in Kbits). Optional.

Option	Description
-svfchain	Generate SVF file for chain of devices. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default file name is the same name as the input file. SVF files should end with the *.svf extension. **-nocomments**: Omit Header and Comments from SVF file. Optional. Default includes Header and Comments. **-revd**: Generate Rev D standard SVF file. Optional. Default generates Lattice Extended SVF file (not supported by all third party tools). **-runtest**: Uses RUNTEST format from SVF revision C. Optional. Default is revision D SVF file. **-skipverify:** Generates an SVF without the verify portion. Optional. **-reset**: Writes RESET in the SVF file. Optional. **-maxdata** [<8 | 16 | 32 | 64 | 128 | 256>]: Specifies the maximum data size per row (in Kbits). Optional.
-stp	Generate Standard Test and Programming Language (STAPLE) file. **-dev** <Device Name>: Indicates the name of the device. Optional. The device name must be the full device name with the performance grade replaced with two X's, and minus the industry rating or the code name. Example: `LCMXO2-256ZE-XXMG64` (with performance grade replaced with two X's). The device name will default to the device name in the data file. If a device name cannot be found in the file, it will return an error unless the name has been given with the -dev option. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default uses the input file name with *.stp extension. -**op** Indicates the operation. The operation list varies depending on the device family. Use the Deployment Tool GUI to create the command line. **-nocompress:** < ON | OFF >: Generates a compressed or uncompressed STAPL file. Default is ON. **-print** < ON | OFF >: Generates a STAPL file with all the comment statements. Default is OFF. **-skipverify**: < ON | OFF >: Generates a STAPL file without the Verify portion. Optional.

Option	Description
-stpchain	Generate Standard Test and Programming Language (STAPL) file for a chain of devices. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default uses the input file name with *.stp extension. **-nocompress:** < ON | OFF >: Generates a compressed or uncompressed STAPL file. Default is ON. **-print** < ON | OFF >: Generates a STAPL file with all the comment statements. Default is OFF. **-skipverify**: < ON | OFF >: Generates a STAPL file without the Verify portion. Optional.
-ate	Generate ATE file. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default uses the input file name with *.tst, *.gr, *.pcf, or *.asc extension, descending type. **-type**: <tst | gr | hp3070 | hp3065 | t1800 | t200> **-ispdcd**: Generates vectors in ispDCD Format. **-skipverify**: For Erase, Program, and Verify Operations, Skip Verify. **-headerfile** <file path>: Specifies a customer header file. **-splitfile** [-init] [-vectors <# vectors/file>] [-splitatlow]: Split each file at active Low. Default: Split each file at active high.
-fullvme	Generate JTAG Full VME Embedded file. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default uses the input file name with *.vme extension. **-maxdata** <8 | 16 | 32 | 64 | 128 | 256>: Maximum Memory Allocation Size Per Row of Data (Kbytes). Optional. **-hex**: Generate a Hex (.c) file along with the VME file. Optional. **-nocompress**: Do not compress data. Optional. **-compact**: Compact VME file. Optional. **-fixedpulse**: Generate a fixed pulse width VME file. Optional. **-verifyues**: Test the USERCODE. Program the device if USERCODE fails verify. Optional. **-noheader**: Omit header from VME file. Optional. **-comment**: Include comments in VME file. Optional.

Option	Description
-slimvme	Generate JTAG Slim VME Embedded file. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-ofa** "<Algorithm File Path>": Programming Algorithm file. Optional. Default use input with *.algo.vme. **-ofd** "<Data File Path>": Programming Data file. Optional. Default uses input with *.data.vme. **-nocompress**: Do not compress data. Optional. **-hex**: Generate a Hex (.c) file along with the Slim VME file. Optional.
-sspi	Generate Slave SPI embedded file. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-ofa** "<Algorithm File Path>": Programming Algorithm file. Optional. Default use input with *.algo.vme. **-ofd** "<Data File Path>": Programming Data file. Optional. Default uses input with *.data.vme. **-nocompress**: Do not compress data. Optional. **-hex**: Generate a Hex (.c) file along with the Slave SPI Embedded file. Optional. -**op** Indicates the operation. This is required when the input file is JEDEC. When the input file is an XCF, the XCF contains the operation.
-i2c	Generate I2C embedded file. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-ofa** "<Algorithm File Path>": Programming Algorithm file. Optional. Default use input with *.algo.vme. **-ofd** "<Data File Path>": Programming Data file. Optional. Default uses input with *.data.vme. **-nocompress**: Do not compress data. Optional. **-hex**: Generate a Hex (.c) file along with the VME file. Optional. -**op** Indicates the operation. This is required when the input file is JEDEC. When the input file is an XCF, the XCF contains the operation. **-address** <80 | (User Specified)> Specifies the slave I2C address. **-comment:** Include comments in I2C embedded file. Optional. **-fixedpulse**: Generate a fixed pulse width I2C embedded file. Optional.

Option	Description
-cpu	Generates sysCONFIG CPU Embedded file. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default uses the input file name with the extension of the selected **-type**. **-type** <cpu | c | hex | txt>: Indicates whether file is in binary embedded (cpu), C-code (c), Intel Hex (hex), or Text debug only (txt) format. **-verify:** Generates a sysCONFIG Embedded file that includes a verify operation. **-comment**: Include comments in sysCONFIG Embedded file. Optional. **-nocompress**: Do not compress data. Optional. **-mirror**: Flips each byte. Default: bytes are not flipped. Optional.
-boot	Generate Dual Boot Hex file. **-dev** <Device Name>: Indicates the name of the device. Optional. The device name must be the full device name with the performance grade replaced with two X's, and minus the industry rating or the code name. Example: `LFE3-17EA-XXFN484` (with performance grade replaced with two X's). The device name will default to the device name in the data file. If a device name cannot be found in the file, it will return an error unless the name has been given with the -dev option. **-golden** "<Golden File Path>" **-primary** "<Primary File Path>": Merges the Golden, Primary, and a JUMP command into one Hex file. The address location of the Golden, Primary, and JUMP command depends on the files sizes and the target device. The Deployment Toll will record the address location of each in the Status window and log file. **-format** < intel | motorola | xtek >: Specifies the output format as Intel, Motorola, or Tektronix Extended Hex. The default format is Intel Hex. Optional. Default uses the input file name with *.mcs, *exo, or *.xtek extension, depending on format type selected. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default uses the input file name with *.mcs, *exo, or *.xtek extension, depending on format type selected. **-flashsize:** Specifies size in Mb. Possible PROM sizes are 1, 2, 4, 8, 16, 32, 64, 128, 256, and 513 (512Mb). Default: 1.

Option	Description
-boot (cont.)	**-protect:** Optional. Inserts the Golden File at the beginning of the upper half of the SPI flash. This allows the upper half of the SPI flash to be write-protected, which protects the Golden File from accidental erase or reprogram. **-mirror**: Flips each byte. Default: bytes are not flipped. Optional. **-header**: Retains the input file header in the output file. Default: Replaces header with all ones (0xFF). Optional. **-optimize**: Uses the files size of the input files to determine SPI flash sector addresses for each input file. Use this option to minimize wasted memory space. The default is to use worst case file size fo the target device, which is an uncompressed file with all EBR and PCS, depending on the family. Using the worst case will ensure that all files will always be located at the same address even if any of the files/designs are updated at a later date. **-asc** <1 | 2 | 3 | 4 | 5 | 6 | 7 | 8> Indicates the number of ASC devices connected to the MachXO2 or Platform Manager 2 device. The maximum number that can be used with the MachXO2 device is 8. The maximum number that can be used with the Platform Manager 2 device is 7. The input JEDEC file and the ASC Hex files will be merged into one Hex file that can be programmed into an external SPI Flash device for Dual Boot support. Optional. **-ascfile** "<Data File Path>": Specifies the ASC Hex file path and name. If the file path includes spaces, enclose the path in quotes. There must be one "-ascfile" and path for each ASC specified by the "-asc" Optional. <**-fast** | **-dualio** | **-quad 1**>: With the -fast option, the FPGA will issue the Fast Read command (0x0B) to the SPI Flash. The -dualio option must be used if a Dual I/O SPI Flash is used. The -quad 1 option must be used if a Quad I/O SPI Flash is used. Only one of these options (-fast, -dualio, -quad 1) can be used. Without any of these options, the FPGA uses the Slow Read command (0x03). Valid for ECP5. **-encryption -key hex** <Valid Key Value>: Encrypts the input file using the -key 128-bit encryption key.
-jed	Generates JEDEC file. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-dev** <Device Name>: Indicates the name of the device. Optional. The device name must be the full device name with the performance grade replaced with two X's, and minus the industry rating or the code name. Example: `LCMXO2-256ZE-XXMG64` (with performance grade replaced with two X's). The device name will default to the device name in the data file. If a device name cannot be found in the file, it will return an error unless the name has been given with the -dev option. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default uses the input file name with *.jed extension. **-overwriteues** <**on**>: Overwrites (or replaces) the USERCODE value contained in the input file with the hex value passed in. The Checksum option overwrites the USERCODE with the JEDEC file fuse checksum value. The Disable option omits the USERCODE from the JEDEC file. **Note**: The encryption software patch must be installed before using the following **-encryption -key** commands. **-encryption -key hex** <Valid Key Value>: Encrypts the input file using the -key 128-bit encryption key.

Option	Description
-advanced	Generates Advanced SPI Flash Hex file. **-dev** <Device Name>: Indicates the name of the device. Optional. The device name must be the full device name with the performance grade replaced with two X's, and minus the industry rating or the code name. Example: LFE3-17EA-XXFN484 (with performance grade replaced with two X's). The device name will default to the device name in the data file. If a device name cannot be found in the file, it will return an error unless the name has been given with the -dev option. **-if** <Data File Path>: Indicates the input data file full path and file name. If the file path includes spaces, enclose the path in quotes. **-format** < intel | motorola | xtek >: Specifies the output format as Intel, Motorola, or Tektronix Extended Hex. The default format is Intel Hex. Optional. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default uses the input file name with *.mcs. *.exo, or *.xtek extension, depending on the format selected. **-flashsize:** Specifies size in Mb. Possible PROM sizes are 512 (512Kb), 1, 2, 4, 8, 16, 32, 64, 128 , 256, and 513 (512Mb). Default: 1. **-mirror**: Flips each byte. Default: bytes are not flipped. Optional. **-header**: Retains the input file header in the output file. Default: Replaces header with all ones (0xFF). Optional. **-userdata** <*1* | *2* | *3* | *4* | *5* | *6* | *7* | *8* | *9* | *10* | *11* | *12* | *13* | *14* | *15* | *16*> Number of data files. **-userdata**: Flips each byte of the user data files. Default: bytes are not flipped. Optional. **-userfile** "<Data File Path>" Indicates the input user data file path and file name. Must be specified for each user data file (**-userdata**). **-address** <hex address value>: SPI flash address location for the user data file. Must be specified for each user data file (**-userdata**). **-optimize**: Uses the files size of the input files to determine SPI flash sector addresses for each input file. Use this option to minimize wasted memory space. The default is to use worst case file size fo the target device, which is an uncompressed file with all EBR and PCS, depending on the family. Using the worst case will ensure that all files will always be located at the same address even if any of the files/designs are updated at a later date. **-ice**: iCE40 warm boot cold boot. **-warm** <1 | 2 | 3 | 4>: Optional. Default is cold boot. The **-warm** selects warm boot. The number selects the first boot configuration file. **-patterns** <2,3,4>: Specifies the number of iCE40 configuration files. **-bootfile** "<Data File Path>": Indicates the input configuration file path and name. Must be specified for each configuration file (**-patterns**). **-address** <hex address value>: SPI flash address location for the configuration file. Must be specified for each configuration file (**-patterns**). <**-fast** | **-dualio** | **-quad 1**>: With the -fast option, the FPGA will issue the Fast Read command (0x0B) to the SPI Flash. The -dualio option must be used if a Dual I/O SPI Flash is used. The -quad option must be used if a Quad I/O SPI Flash is used. Only one of these options (-fast, -dualio, -quad 1) can be used. Without any of these options, the FPGA uses the Slow Read command (0x03). Valid for ECP5.

Option	Description
-advanced (cont.)	**-multi** <1 | 2 | 3 | 4> Optional. The -multi option selects Multiple Boot. The number selects the number of alternate files. Must be used in conjunction with Dual Boot, since dual boot is a subset of Multiple Boot feature. The Golden file must also be selected. The data file passed in using the -if option is considered the Primary file. **-golden** "<Data File Path>" Indicates the Golden file path and file name. **-altfile** “<Data File Path>” Indicates the alternate file path and name. Must specify the alternate file for each number following the -multi option. **-address** <hex address value> SPI Flash address location for the alternate file. Must be specified for each alternate file (-altfile). **-next** <primary | alt1 | alt2 | alt3 |alt4> Indicates which will be the next pattern to boot from when the PROGRAMN pin is toggle, or the Refresh command is issued. Must be specified for each alternate file (-altfile).
-merge	**-ifdev1** “<Data File Path>” Indicates the input dta file full path and file name for the first device in the chain. If the file path includes spaces. **-ifdev2** “<Data File Path>” “Second device in the chain.” **-format** < intel | motorola | xtek >: Specifies the output format as Intel, Motorola, or Tektronix Extended Hex. The default format is Intel Hex. Optional. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default uses the input file name with *.mcs. *.exo, or *.xtek extension, depending on the format selected. **-mergeformat** <intelligent | combine> Intelligent merge will set the appropriate bits in the bitstream to support sysCONFIG Daily Chaining. Combine will merge the two files without changing any bits in the bitstreams. **-frequency**: Specifies the frequency of the master bitstream. Possible frequencies valid for LatticeEC/P, LatticeECP2/M, LatticeECP3, and LatticeXP/2 devices only are: 2.5, 4.3, 5.4, 6.9, 8.1, 9.2, 10, 13, 15, 20, 26, 30, 34, 41, 45, 51, 55, 60, and 130 MHz. Possible frequencies valid for for MachXO2 and MachXO3L devices only are: 2.1, 2.5, 3.2, 4.3, 5.5, 7, 8.3, 9.2, 10, 13, 15, 20, 27, 30, 33, 38, 44, 53, 66, 89, and 133 MHz. Possible frequencies valid for for ECP5 devices only are: 2.4, 3.2, 4.1, 4.8, 6.5, 8.2, 9.7, 12.9, 15.5, 16.3, 19.4, 20.7, 25.8, 31, 34.4, 38.8, 44.3, 51.7, 62, 77.5, 103.3, and 155 MHz. **-scoutput** <dout | qout>: For LatticeSC/M devices, indicates if the output pin is Dout or Qout. **-mirror**: Flips each byte. Default: bytes are not flipped. Optional. **-header**: Retains the input file header in the output file. Default: Replaces header with all ones (0xFF). Optional.

Option	Description
-bsm	Generates Application Specific BSDL file. **-ifd** "<Data File Path>": Indicates the input data file full path and file name.If the file name includes spaces ... **-ifb** "<BSDL File Path>": Indicates the input BSDL file full path and file name. If the file path includes spaces ... **-dev** <Device Name>: Indicates the name of the device. Optional. The device name must be the full device name with the performance grade replaced with two X's, and minus the industry rating or the code name. Example: `LCMXO2-256ZE-XXMG64` (with performance grade replaced with two X's). The device name will default to the device name in the data file. If a device name cannot be found in the file, it will return an error unless the name has been given with the -dev option. **-of** "<Data File Path>": Indicates the output file path. If the file path includes spaces, enclose the path in quotes. Optional. Default uses the input file name with *.??? extension. **-convertbidi**: Converts bidirectional I/Os to input or output only, based on the user's design. Default is to keep al bidirectional I/Os as bidirectional. Optional.
-jed2hex	Generates an ASCII Raw Hex file.
-jed2bin	Generates a Binary Raw Hex file.

Examples The following are DDTCMD examples.

Tester Examples:

SVF - Single Device:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -svfsingle -if
"C:/example/lfxp2_05ef256.jed" -dev LFXP2-5E -op "FLASH
Erase,Program,Verify" -of  "C:/ example/
lfxp2_05ef256.svf"
```

SVF - JTAG Chain:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -svfchain -if
"C:/example/demo.xcf" -of  "C:/ example/demo.svf"
```

STAPL - Single Device:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -stpsingle -if
"C:/example/ isppac_powr1220at8.jed" -dev ispPAC-
POWR1220AT8 -op "Erase,Program,Verify" -of  "C:/ example/
isppac_powr1220at8.svf"
```

STAPL - JTAG Chain:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -stpchain -if
"C:/example/demo.xcf" -of  "C:/example/demo.svf"
```

ATE - Generic Vector Format:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -ate -if " C:/
example/demo.xcf " -type tst -of " C:/example/demo.tst"
```

ATE - GenRad:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -ate -if " C:/
example/demo.xcf " -type gr -of " C:/example/demo.gr"
```

ATE - HP3070:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -ate -if " C:/
example/demo.xcf " -type hp3070 -of " C:/example/
demo.pcf"
```

ATE - HP3065:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -ate -if " C:/
example/demo.xcf " -type hp3065 -of " C:/example/
demo.pcf"
```

ATE - Teradyne 1800:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -ate -if " C:/
example/demo.xcf " -type t1800 -of " C:/example/demo.asc"
```

ATE - Teradyne L200/300:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -ate -if " C:/
example/demo.xcf " -type t200 -of " C:/example/demo.asc"
```

Embedded System Examples:

JTAG Full VME Embedded:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -fullvme -if
"C:/example/demo.xcf" -of "C:/example/demo.vme"
```

JTAG Slim VME Embedded:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -slimvme -if
"C:/example/demo.xcf" -ofa "C:/ example/demo_algo.vme" -
ofd "C:/ example/demo_data.vme"
```

Slave SPI Embedded:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -sspi -if "C:/
example/demo.xcf" -ofa "C:/example/demo_algo.sea" -ofd
"C:/example/demo_data.sed"
```

I2C Embedded:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -i2c -if "C:/
example/demo.xcf" -ofa "C:/example/demo_algo.iea" -ofd
"C:/example/demo_data.iea"
```

sysCONFIG (CPU) Embedded - Binary:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -cpu -if "C:/
example/demo.xcf" -type cpu -of "C:/example/
demo_algo.cpu"
```

sysCONFIG (CPU) Embedded - C-Code:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -cpu -if "C:/
example/demo.xcf" -type c -of "C:/example/demo_algo.c"
```

sysCONFIG (CPU) Embedded - Intel Hex:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -cpu -if "C:/
example/demo.xcf" -type hex -of "C:/example/
demo_algo.hex"
```

sysCONFIG (CPU) Embedded - Text (Debug Only):

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -cpu -if "C:/
example/demo.xcf" -type txt -of "C:/example/
demo_algo.txt"
```

External Memory Examples:

Hex Conversion - Intel Hex:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -int -dev LFE2-
6E -if "C:/example/lfec2_06ef256.bit" -of "C:/example/
lfec2_06ef256.mcs"
```

Hex Conversion - Motorola Hex:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -mot -dev LFE2-
6E -if "C:/example/lfec2_06ef256.bit" -of "C:/example/
lfec2_06ef256.exo"
```

Hex Conversion - Extended Tektronix Hex:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -xtek -dev LFE2-
6E -if "C:/example/lfec2_06ef256.bit" -of "C:/example/
lfec2_06ef256.xtek"
```

Dual Boot - Intel Hex:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -boot -dev LFE3-
95E -golden "C:/example/lfec3_095_golden.bit" -primary
"C:/example/lfec3_095.bit" -format int -flashsize 64 -of
"C:/example/lfec3_095_dual_boot.mcs"
```

Dual Boot - Motorola Hex:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -boot -dev LFE3-
95E -golden "C:/example/lfec3_095_golden.bit" -primary
"C:/example/lfec3_095.bit" -format mot -flashsize 64 -of
"C:/example/lfec3_095_dual_boot.exo"
```

Dual Boot - Extended Tektronix Hex:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -boot -dev LFE3-
95E -golden "C:/example/lfec3_095_golden.bit" -primary
"C:/example/lfec3_095.bit" -format xtek -flashsize 64 -of
"C:/example/lfec3_095_dual_boot.xtek"
```

File Conversion Examples:

Bitstream - Binary Bitstream:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -bit -dev LFXP2-
5E -if "C:/example/lfxp2_05ef256.jed" -of "C:/example/
lfxp2_05ef256.bit"
```

Bitstream - ASCII Bitstream:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd" -oft -rbt -dev LFE2-
6E -if "C:/example/lfec2_06ef256.bit" -of "C:/example/
lfec2_06ef256.rbt"
```

JEDEC - Hex and JEDEC - Binary:

```
"C:/lscc/diamond/3.5/bin/nt/ddtcmd -oft <jed2hex|jed2bin>
[-dev <Device Name>] -if "<Data File Path>" [-of "<Data
File Path>"]
```

Return Codes

Code	Definition

Running I/O SSO Analysis from the Command Line

The **I/O SSO Analysis Report** process in the Diamond environment can also be run through the command line using the SSO Analysis (**ssoana**) program. SSO analysis describes the noise on signal and supply lines caused by a large number of output drivers that are switching at the same time. The SSO analysis report helps ensure that your I/O plan meets the power integrity requirements of the PCB design.

Subjects included in this topic:

- Running SSOANA
- Command Line Syntax
- SSOANA Options
- Examples

Running SSOANA The SSOANA program generates an SSO (Simultaneous Switching Output) analysis report (.sso) based on the SSO preferences you specified in your LPF file.

- To run SSOANA, type **ssoana** on the command line with all necessary options:

  ssoana -d LFECP6E -p TQFP144 -o mydesign.sso mydesign.ncd mydesign.lpf

There are several command line options that give you control over the way SSOANNA outputs analysis files. Please refer to the rest of the subjects in this topic for more details. See examples.

Command Line Syntax **ssoana** -d <device> -p <package> -o <report_file> <design_file> <preference_file> [-ps <pref_source>]

SSOANA Options

The table below contains descriptions of all valid options for SSOANA.

Table 856: SSOANA Command Line Options

Option	Description
-d <device>	Specifies the device name.
-p <package>	Specifies the package name.
-o <report_file>	Specifies the output I/O SSO Analysis report file name.
<design_file>	Specifies the input physical design file (NCD).
<preference_file>	Specifies the input logical preference (LPF) file name.
-ps <pref_source>	Specifies the preference source. Options are **lpf** or **null**. If no -ps option is specified, the preference will be lpf and ncd and ncd will cover lpf. If lpf is specified, the preference source will be uniquely the lpf file.

Examples Following are a few examples of SSOANA command lines and a description of what each does.

Example 1 The following command generates an output (-o option) I/O SSO analysis report file (ddrg_lvr71.sso) for a LatticeECP2-12E device in a 256-ball, fine pitch Ball Grid Array package from input project NCD and LPF files:

ssoana -d LFE2-12E -p FPBGA256 ddrg_lvr71.ncd -o ddrg_lvr71.sso ddrg_lvr71.lpf

Example 2 The following command line specifies an additional “-ps lpf” option, so that SSOANA only reads preferences, such as I/O assignments, from LPF file. You can use this option to calculate the SSO of different I/O planning without replacement:

ssoana -d LFE2-12E -p FPBGA256 ddrg_lvr71.ncd -o ddrg_lvr71.sso ddrg_lv71.lpf -ps lpf

Running Various Utilities from the Command Line

The command line utilities described in this section are not commonly used by command line users, but you often see them in the auto-make log when you run design processes in the Diamond environment. Click each link below for its function, syntax, and options.

- synpwrap
- htmlrpt

Note

For information on commonly-used FPGA command line tools, see "Command Line Reference Guide" on page 2432.

synpwrap The **synpwrap** command line utility (wrapper) is used to manage Synplicity Synplify and Synplify Pro synthesis programs from the Diamond environment processes: **Synplify Synthesize Verilog File** or **Synplify Synthesize VHDL File**.

The **synpwrap** utility can also be run from the command line to support a batch interface. For details on Synplify see the ispLEVER online help. The **synpwrap** program drives **synplify** or **synplify_pro** programs with a Tcl script file containing the synthesis options and file list.

Note

This section supersedes the "Process Optimization and Automation" section of the *Synplicity Synplify and Synplify Pro for Lattice User Guide*.

This section illustrates the use of the **synpwrap** program to run Synplify or Synplify Pro (Synplify/Pro) for Lattice synthesis scripts from the command line. For more information on synthesis automation of Synplify or Synplify Pro, see the "User Batch Mode" section of the *Synplicity Synplify and Synplify Pro for Lattice User Guide*. If you use the Lattice OEM Synplify/Pro, the Lattice OEM license requires that the command line executables: **synplify** and **synplify_pro** be run by the Lattice "wrapper" program, **synpwrap**.

Command Line Syntax **synpwrap** [**-log** <*log_file*>] [**-nolog**] [**-int** <*command_file*>] [**-gui**] [**-int** <*project_file*> | **-prj** <*project_file*>] [**-dyn**] [**-notoem**] [**-oem**] [**-notpro**] [**-pro**] [**-rem**] [**-scriptonly** <*script_file*>] **-e** <*command_file*> **-target** <*device_family*> **-part** <*device_name*> [**-options** <*arguments*>]

Table 857: SYNPWRAP Command Line Options

Option	Description
-log <*log_file*>	Specifies the log file name.
-nolog	Does not print out the log file after the process is finished.
-options <*arguments*>	Passes all arguments to Synplify/Pro. Ignores all other options except -notoem/-oem and -notpro/-pro. The -options switch must follow all other synpwrap options.
-prj <*project_file*>	Runs Synplify or Synplify Pro using an external prj Tcl file instead of the Diamond command file.
-rem	Does not automatically include Lattice library files.

Table 857: SYNPWRAP Command Line Options

Option	Description
-e <*command_file*>	Runs the batch interface based on a Diamond generated command file. The synpwrap utility reads <*project*>.cmd with its command line to obtain user options and creates a Tcl script file.
-gui	Invokes the Synplify or Synplify Pro graphic user interface.
-int <*command_file*>	Enables the interactive mode. Runs Synplify/Pro UI with project per command file.
-dyn	Brings the Synplify installation settings in the Diamond environment.
-notoem	Does not use the Lattice OEM version of Synplify or Synplify Pro.
-oem	Uses the Lattice OEM version of Synplify or Synplify Pro.
-notpro	Does not use the Synplify Pro version.
-pro	Uses the Synplify Pro version.
-target <*device_family*>	Specifies the device family name.
-part <*device_name*>	Specifies the device. For details on legal <*device_name*> values.
-scriptonly <*script_file*>	Generates the Tcl file for Synplify or Synplify Pro. Does not run synthesis.

Example Below shows a synpwrap command line example.

```
synpwrap -rem -e prep1 -target LATTICE-EC -part LFEC20E
```

htmlrpt This command line tool is a report converter that converts the text format report files into HTML report files.

Command Line Syntax **htmlrpt** [-**dly** <*dlyfile*>] [-**mrp** <*mrpfile*>] [-**pad** <*padfile*>] [-**par** <*parfile*>] [-**mtwr** <*mtwrfile*>] [-**ptwr** <*ptwrfile*>] [-**bgn** <*bgnfile*>] [-**jdr** <*bgnfile*>][-**prm** <*prmfile*>] [-**info** <*infofile*>] [-**db** <*databasefile*>] [-**syn** <*synfile*>] [-**lse** <*synfile*>] [-**sso** <*ssofile*>]<*design*>

Table 858: HTMLRPT Command Line Options

Option	Description
-**dly** <*dlyfile*>	Specifies the delay file.
-**mrp** <*mrpfile*>	Specifies the map report file.
-**pad** <*padfile*>	Specifies the pad specification file.
-**par** <*parfile*>	Specifies the par report file.
-**mtwr** <*mtwrfile*>	Specifies the map trace report file.

Table 858: HTMLRPT Command Line Options

Option	Description
-**ptwr** <*ptwrfile*>	Specifies the par trace report file.
-**bgn** <*bgnfile*>	Specifies the bitgen report file.
-jdr <*bgnfile*>	Specifies the bitgen report file for XP/XP2.
-**prm** <*prmfile*>	Specifies the promgen report file.
-**info** <*infofile*>	Specifies the promgen report file.
-db <*databasefile*>	Specifies the database report file.
-syn <*synfile*>	Specifies the synthesis and NGDBUILD report file.
-lse<*synfile*>	Specifies the Lattice synthesis report file.
-sso <*ssofile*>	Specifies the I/O SSO Analysis report file.

See Also ▶"Command Line Data Flow" on page 2435

▶ "Command Line Program Overview" on page 2432

Using Command Files

This section describes how to use command files.

Creating Command Files The command file is an ASCII file containing command arguments, comments, and input/output file names. You can use any text editing tool to create or edit a command file, for example, **vi**, **emacs**, **Notepad**, or **Wordpad**.

Here are some guidelines when you should observe when creating command files:

- Arguments (executables and options) are separated by space and can be spread across one or more lines within the file.
- Place new lines or tabs anywhere white space would otherwise be allowed on the UNIX or DOS command line.
- Place all arguments on the same line, or one argument per line, or any combination of the two.
- There is no line length limitation within the file.
- All carriage returns and other non-printable characters are treated as space and ignored.
- Comments should be preceded with a # (pound sign) and go to the end of the line.

Command File Example This is an example of a command file:

```
#command line options for par for design mine.ncd
-a -n 10
-w
```

```
-l 5
-s 2 #will save the two best results
/home/users/jimbob/designs/mine.ncd
#output design name
/home/users/jimbob/designs/output.dir
#use timing preference file
/home/users/jimbob/designs/mine.prf
```

Using the Command File The –f Option Use the **–f** option to execute a command file from any command line tool. The **–f** option allows you to specify the name of a command file that stores and then executes commonly used or extensive command arguments for a given FPGA command line executable tool. You can then execute these arguments at any time by entering the UNIX or DOS command line followed by the name of the file containing the arguments. This can be useful if you frequently execute the same arguments each time you perform the command, or if the command line becomes too long. This is the recommended way to get around the DOS command line length limitation of 127 characters. (Equivalent to specifying a shell Options file.)

The **–f** indicates fast startup, which is performed by not reading or executing the commands in your .cshrc | .kshrc | .shrc (C-shell, Korn-shell, Bourne-shell) file. This file typically contains your path information, your environment variable settings, and your aliases. By default, the system executes the commands in this file every time you start a shell. The **–f** option overrides this process, discarding the 'set' variables and aliases you do not need, making the process much faster. In the event you do need a few of them, you can add them to the command file script itself.

Command File Usage Examples You can use the command file in two ways:

- To supply all of the command arguments as in this example:

par -f <command_file>

where:

<command_file> is the name of the file containing the command line arguments.

- To insert certain command line arguments within the command line as in the following example:

par -i 33 -f placeoptions -s 4 -f routeoptions design_i.ncd design_o.ncd

where:

placeoptions is the name of a file containing placement command arguments.

routeoptions is the name of a file containing routing command arguments.

Using Command Line Shell Scripts

This topic discusses the use of shell scripts to automate either parts of your design flow or entire design flows. It also provides some examples of what you can do with scripts. These scripts are UNIX-based; however, it is also possible to create similar scripts called batch files for PC but syntax will vary in the DOS environment.

Creating Shell Scripts A UNIX shell script is an ASCII file containing commands targeted to a particular shell that interprets and executes the commands in the file. For example, you could target Bourne Shell (**sh**), C-Shell (**csh**), or Korn Shell (**ksh**). These files also can contain comment lines that describe part of the script which then are ignored by the shell. You can use any text editing tool to create or edit a shell script, for example, **vi** or **emacs**.

Here are some guidelines when you should observe when creating shell scripts:

- It is recommended that all shell scripts with "#!" followed by the path and name of the target shell on the first line, for example, #!/bin/ksh. This indicates the shell to be used to interpret the script.
- It is recommended to specify a search path because oftentimes a script will fail to execute for users that have a different or incomplete search path. For example:

  PATH=/home/usr/lsmith:/usr/bin:/bin; export PATH
- Arguments (executables and options) are separated by space and can be spread across one or more lines within the file.
- Place new lines or tabs anywhere white space would otherwise be allowed on the UNIX command line.
- Place all arguments on the same line, or one argument per line, or any combination of the two.
- There is no line length limitation within the file.
- All carriage returns and other non-printable characters are treated as space and ignored.
- Comments are preceded by a # (pound sign) and can start anywhere on a line and continue until the end of the line.
- It is recommended to add exit status to your script, but this is not required.

```
# Does global timing meet acceptable requirement range?
    if [ $timing -lt 5  -o  $timing -gt 10 ]; then
         echo 1>&2 Timing \"$timing\" out of range
         exit 127
    fi
    etc...
    # Completed, Exit OK
    exit 0
```

Advantages of Using Shell Scripts Using shell scripts can be advantageous in terms of saving time for tasks that are often used, in

reducing memory usage, giving you more control over how the FPGA design flow is run, and in some cases, improving performance.

Scripting with DOS Scripts for the PC are referred to as batch files in the DOS environment and the common practice is to ascribe a .bat file extension to these files. Just like UNIX shell scripts, batch files are interpreted as a sequence of commands and executed. The COMMAND.COM or CMD.EXE (depending on OS) program executes these commands on a PC. Batch file commands and operators vary from their UNIX counterparts. So, if you wish to convert a shell script to a DOS batch file or vice-versa, we suggest you find a good general reference that shows command syntax equivalents of both operating systems.

Examples The following examples are examples of UNIX shell scripts written to run parts of the design flow.

Example 1 Using the Korn shell, this script runs to separate flows using pfu.edn and pio.edn inputs through place-and-route, respectively. It then runs the clock boosting on each flow, lists applicable files for analysis, and outputs error messages that may have resulted in an errors file.

```
#$!/bin/ksh
#
# clockboosting.script
#
PATH=/home/mjones/design_run:/usr/bin:/bin; export PATH
#
# First design flow
#
edif2ngd -l LatticeEC pfu.edn pfu.ngo
ngdbuild -a LatticeEC  pfu.ngo pfu.ngd
map -a LatticeEC pfu.ngd -o pfu.ncd test.prf
par -l 1 -n 1 -i 5 -c 0 pfu.ncd -w pfu.ncd test.prf
cst pfu.ncd test.prf
#
# Second design flow
#
edif2ngd -l LatticeEC pio.edn pio.ngo
ngdbuild -a LatticeEC pio.ngo pio.ngd
map -a LatticeEC pio.ngd -o pio.ncd test.prf
par -l 1 -n 1 -i 5 -c 0 pio.ncd -w pio.ncd test.prf
cst pio.ncd test.prf
ls *.grf *.cst > files
grep -i error *.Out *.Err >errors
```

Chapter 21

Tcl Command Reference Guide

Diamond software supports Tcl (Tool Command Language) scripting and provides extended Diamond Tcl commands that enable a batch capability for running tools in Diamond's graphical interface. The command set and the Tcl Console used to run it affords you the speed, flexibility and power to extend the range of useful tasks that the Diamond tools arealready designed to perform.

In addition to describing how to run Diamond's Tcl Console, this guide provides you with a reference for Tcl command line usage and syntax for all Diamond point tools within the graphical user interface so that you can create command scripts, modify commands, or troubleshoot existing scripts.

About the Diamond Tcl Scripting Environment The Lattice Diamond development software features a powerful script language system. The user interface incorporates a complete Tcl command interpreter. The command interpreter is enhanced further with additional Diamond-specific support commands. The combination of fundamental Tcl along with the commands specialized for use with Diamond allow the entire Diamond development environment to be manipulated.

Using the command line tools permits you to do the following:

- Develop a repeatable design environment and design flow that eliminates setup errors that are common in GUI design flows
- Create test and verification scripts that allow designs to be checked for correct implementation
- Run jobs on demand automatically without user interaction

The Diamond command interpreter provides an environment for managing your designs that are more abstract and easier to work with than using the core Diamond engines. The Diamond command interpreter does not prevent use of the underlying transformation tools. You can use either the TCL commands described in this section or you can use the core engines described in the Command Line Reference Guide.

Additional References If you are unfamiliar with the Tcl language you can get help by visiting the Tcl/tk web site at http://www.tcl.tk. If you already know how to use Tcl, see the Tcl Manual supplied with this software. For information

on command line syntax for running core tools that appear as Diamond processes, such as edif2ngd, map, par, ldbanno, and trce, see the "Command Line Reference Guide" on page 2432.

- Tcl Manual

Running the Tcl Console

The Diamond TCL Console environment is made available for your use in multiple different ways. In order to take full advantage of the FPGA development process afforded by the Diamond software you must gain access to the Diamond Tcl Console user interface.

On Windows In Windows 7 you can interact with the Tcl Console by any one of the following methods:

- To launch the Diamond GUI from the Windows Start menu, choose **Start > All Programs > Lattice Diamond > Lattice Diamond**.

  After the Diamond software loads you can click on the **TCL Console** tab. With the **TCL Console** tab active, you are able to start entering standard syntax TCL commands or the Diamond specific support commands.

- To launch the **TCL Console** independently from the Diamond GUI from the Windows Start menu choose **Start > All Programs > Lattice Diamond > Accessories > TCL Console**.

  A Windows command interpreter will be lauched that automatically runs the **TCL Console**.

- To run the interpreter from the command line, type the following:

  ```
  c:/lscc/diamond/<version_number>/bin/nt/pnmainc
  ```

  The Diamond **TCL Console** is now available to run.

- To run the interpreter from a Windows 7 PowerShell from the Windows Start menu choose **Start > All Programs > Accessories > Windows PowerShell > Windows PowerShell (x86)**.

  A PowerShell interpreter window will open. At the command line prompt type the following:

  ```
  c:/lscc/diamond/<version_number>/bin/nt/pnmainc
  ```

The Diamond **TCL Console** is now available to run.

Note

The arrangement and location of each of the programs in the Windows Start menu will differ depending on the version of Windows you are running.

On Linux In Linux operating systems you can interact with the Tcl Console by one of the following methods:

- To launch the Diamond GUI from the command line, type the following:

  `/usr/local/diamond/<version_number>/bin/lin/diamond`

  The path provided assumes the default installation directory and that Diamond is installed. After the Diamond software loads you can click on the **TCL Console** tab. With the **TCL Console** tab active, you are able to start entering standard syntax TCL commands or the Diamond specific support commands.

- To launch the **TCL Console** independently from the Diamond GUI from the command line, type the following:

  `/usr/local/diamond/<version_number>/bin/lin/pnmainc`

  The path provided assumes the default installation directory and that Diamond is installed, and that you have followed the Diamond for Linux installation procedures. The Diamond **TCL Console** is now ready to accept your input.

  The advantage of running the **TCL Console** from an independent command interpreter is the ability to directly pass the script you want to run to the Tcl interpreter. Another advantage is that you have full control over the Tk graphical environment, which allows you to create you own user interfaces.

- "Diamond Tool Tcl Command Syntax" on page 2561
- "Creating and Running Custom Tcl Scripts" on page 2558
- "Accessing Command Help in the Tcl Console" on page 2557
- Tcl Manual

Launching the EPIC Tcl Console

EPIC (Editor for Programmable Integrated Circuits) is a graphical application for viewing and configuring FPGAs. EPIC is a stand-alone tool that is run independently from the Diamond software.

The EPIC Tcl commands allow you to perform basic actions. The EPIC tool commands are described in the EPIC online help topic entitled “EPIC Tcl Commands”.

You can run EPIC tool Tcl commands using the EPIC Tcl Console (fpgac.exe).

- On Windows, from the command line, type the following:

  ```
  c:/lscc/diamond/<version_number>/bin/nt/fpgac
  ```

  The Epic **TCL Console** is now available to run.

- On Linux, from the command line, type the following:

  ```
  cd /usr/local/diamond/<version_number>/bin/lin
  source setupenv
  ./fpgac
  ```

  The path provided assumes the default installation directory and that Diamond is installed, and that you have followed the Diamond for Linux installation procedures. The Epic **TCL Console** is now ready to accept your input.

See Also ▶“Engineering Change Order Tcl Commands” on page 2598

Accessing Command Help in the Tcl Console

You can access command syntax help for all of the tools in the Tcl Console.

To access command syntax help in the Tcl Console:

1. In the prompt, type **help <tool_name>** and press **Enter** as shown below:

   ```
   help prj
   ```

   A list of valid command options appears in the Tcl Console. If you just type **help** in the console, you will be given a list of tools.

2. As directed in the window, type the name of the command or function for more details on syntax and usage. For the prj tool, for example, type and enter the following:

   ```
   prj_strgy
   ```

   A list of valid arguments for that function will appear.

Note

Although you can run Diamond’s core tools such as edif2ngd, map, par, ldbanno, and trce from the Tcl Console, the syntax for accessing help is different. For proper usage and syntax for accessing help for core tools, see the “Command Line Reference Guide” on page 2432.

- “Creating and Running Custom Tcl Scripts” on page 2558

- "Running Tcl Scripts When Launching Diamond" on page 2560
- Tcl Manual

Creating and Running Custom Tcl Scripts

This topic describes how to easily create Tcl scripts using Diamond's user interface and manual methods. FPGA design using Tcl scripts provides some distinct advantages over using the graphical user interface's lists, views and menu commands. For example, Tcl scripts allow you to do the following:

- Set the tool environment to exactly the same state for every design run. This eliminates human errors caused by forgetting to manually set a critical build parameter from a drop-down menu.
- Manipulate intermediate files automatically, and consistently on every run. For example, EDIF file errors can be corrected prior to performing additional netlist transformation operations.
- Run your script automatically by using job control software. This gives you the flexibilty to run jobs at any time of day or night, taking advantage of idle cycles on your corporate computer system.

Creating Tcl Scripts There are a couple of different methods you can use to create Diamond Tcl scripts. This section will discuss each one and provide step-by-step instructions for you to get started Tcl scripting repetitious Diamond commands or entire workflows.

One method you have available is to use your favorite text editor to enter a sequence of Diamond Tcl commands. The syntax of each the Diamond Tcl commands is available in later topics in this portion of the online help. This method should only be used by very experienced Diamond Tcl command line users.

The preferred method is to let the Diamond GUI assist you in getting the correct syntax for each Tcl command. When you interact with the Diamond user interface each time you launch a *scriptable* process and the corresponding Diamond Tcl command is echoed to the Tcl Console. This makes it much simpler to get the correct command line syntax for each Diamond command. Once you have the fundamental commands executed in the correct order, you can then add additional Tcl code to perform error checking, or customization steps.

To create a Tcl command script in Diamond:

1. Start the Diamond design software and close any project that may be open.
2. In the Tcl Console execute the custom **reset** command. This clears the Tcl Console command history.
3. Use the Diamond graphical user interface to start capturing the basic command sequence. The Tcl Console echos the commands in its window. Start by opening the project for which you wish to create the TCL script.

Then click on the processes in the Process list to run them. For example, run these processes in their chronological order in the design flow:

- Synthesize Design
- Map Design
- Place & Route Design
- Export Files

4. In the Tcl Console window enter the command,

   ```
   save_script <filename.ext>
   ```

   The <filename.ext> is any file identifier that has no spaces and contains no special characters except underscores. For example, **myscript.tcl** or **design_flow_1.tcl** are acceptable save_script values, but **my$script** or **my script** are invalid. The **<filename.ext>** entry can be preceded with a absolute or relative path. Use the **"/"** (i.e. forward slash) character to delimit the path elements. If the path is not specified explicitly the script is saved in the current working directory. The current working directory can be determined by using the TCL *pwd* command.

5. You can now use your favorite text editor to make any changes to the script you feel are necessary. Start your text editor, navigate to the directory the *save_script* command saved the base script, and open the file.

   Note

   In most all cases, you will have to clean up the script you saved and remove any invalid arguments or any commands that cannot be performed in the Diamond environment due to some conflict or exception. You will likely have to revisit this step later if after running your script you experience any run errors due to syntax errors or technology exceptions.

Sample Diamond Tcl Script The following Diamond Tcl script shows a very simple script that opens a project, runs the entire design flow through the Place & Route process, then closes the project. A typical script will contain more tasks and will check for failure conditions. Use this simple example as a general guideline.

Figure 63: Simple Diamond Script

```
prj_project open "C:/lscc/diamond/examples/edif_counter/
edif.ldf"
prj_run PAR -impl edif -forceAll
prj_project close
save_script c:/lscc/diamond/examples/edif_counter/myscript2.tcl
```

Running Tcl Scripts Diamond TCL scripts are run exclusively from the Diamond TCL Console. You can use either the TCL Console integrated into the Diamond UI, or by launching the stand-alone TCL Console.

To run a Tcl script in Diamond:

1. Launch the Diamond GUI, or the stand-alone TCL Console.

Open Diamond but do not open your project. If your project is open, choose **File > Close Project**.

2. If you are using the Diamond main window, click on the **Tcl Console tab** in the Output area at the bottom to open the console.
3. Use the TCL *source* command to load and run your TCL script. The *source* command requires, as it's only argument, the filename of the script you want to load and run. Prefix the script file name with any required relative or absolute path information. To run the example script shown in the previous section use:

   ```
   source C:/lscc/diamond/<version_number>/examples/
   edif_counter/myscript2.tcl
   ```

   As long as there are no syntax errors or invalid arguments, the script will open the project, synthesize, map, and place-and-route the design. Once the design finishes it closes the project. If there are errors in the script, you will see the errors in red in the Tcl Console after you attempt to run it. Go back to your script and correct the errors that prevented the script from running.

See Also ▶"Running the Tcl Console" on page 2555

- "Diamond Tool Tcl Command Syntax" on page 2561
- "Running Tcl Scripts When Launching Diamond" on page 2560
- Tcl Manual

Running Tcl Scripts When Launching Diamond

This topic describes how launch the Diamond software and automatically run Tcl scripts scripts using a command line shell or the stand-alone Tcl console. Your Tcl script can be standard Tcl commands as well as Diamond-specific Tcl commands.

Refer to "Creating and Running Custom Tcl Scripts" on page 2558 for more information on creating custom Tcl scripts.

To launch Diamond and run a Tcl script from a command line shell or the stand-alone Tcl console:

- Enter the following command:

  On Windows:

  ```
  pnmain.exe -t<tcl_path_file>
  ```

  On Linux:

  ```
  diamond -t<tcl_path_file>
  ```

Sample Diamond Tcl Script The following Diamond Tcl script shows a very simple script, running in Windows, that opens a project and runs the design flow through the MAP process. Use this simple example as a general guideline.

Figure 64: Simple Diamond Script

```
prj_project open C:/test/iobasic_diamond/io1.ldf
prj_run Map -impl io1
```

The above example is saved in Windows as the file mytcl.tcl in the directory C:/test. By running the following command from either a DOS shell or the Tcl console in Windows, the Diamond GUI starts, the project i01.ldf opens, and the MAP process automatically runs.

```
pnmain.exe -tc:/test/mytcl.tcl
```

- Tcl Manual

Diamond Tool Tcl Command Syntax

This part of the Tcl Command Reference Guide introduces the syntax of each of the Diamond tools and provides you with examples to help you construct your own commands and scripts.

Diamond tries to make it easy to develop TCL scripts by mirroring the correct command syntax in the Tcl Console based on the actions performed by you in the GUI. This process works well for most designs, but there are times when a greater degree of control is required. More control over the build process is made available through additional command line switches. The additional switches may not be invoked by actions taken by you when using the GUI. This section provides additional information about all of the Tcl commands implemented in Diamond.

The Tcl Commands are broken into major categories. The major categories are:

- Diamond Tcl Console Commands
- Diamond Project Tcl Commands
- Simulation Libraries Compilation Tcl Command
- Reveal Inserter Tcl Commands
- Reveal Analyzer Tcl Commands
- Power Calculator Tcl Commands
- NGD Tcl Commands

Diamond Tcl Console Commands

The Diamond Tcl Console provides a small number of commands that allow you to perform some basic actions upon the Tcl Console Pane. The Diamond Tcl Console commands differ from the other Tcl commands provided in Diamond. This dtc program's general Tcl Console commands do not use the *dtc_* prefix in the command syntax as is the convention with other tools in Diamond.

Diamond Tcl Console Command Descriptions The following table provides a listing of all valid Diamond Tcl Console-related commands.

Table 859: Diamond Tcl Console Commands

Command	Arguments	Description
history	N/A	The *history* command lists the command history in the Tcl Console that you executed in the current session. Every command entered into the Tcl Console, either by the GUI, or by direct entry in the Tcl Console, is recorded so that it can be recalled at any time. The command history list is cleared when a project is *opened* or when the Tcl Console *reset* command is executed.
reset	N/A	The *reset* command clears anything present in the Tcl Console pane, and erases all entries in the command line history.
clear	N/A	The *clear* command erases anything present in the Tcl Console pane, and prints the current *prompt* character in the upper left corner of the Tcl Console pane without erasing the command history.

Table 859: Diamond Tcl Console Commands

Command	Arguments	Description
save_script	<filename.ext>	Saves the contents of the command line history memory buffer into the script file specified. The script is, by default, stored into the current working directory. File paths using forward slashes used with an identifier are valid if using an absolute file path to an existing script folder.
set_prompt	<new_character>	The default prompt character in the Tcl Console is the “greater than” symbol or angle bracket (i.e., >). You can change this prompt character to some other special character such as a dollar sign ($) or number symbol (#) if you prefer.

Diamond Tcl Console Command Examples This section illustrates and describes a few samples of Diamond Tcl Console commands.

Example 1 To save a script, you simply use the **save_script** command in the Tcl Console window with a name or file path/name argument. In the first example command line, the file path is absolute, that is, it includes the entire path. Here you are saving “myscript.tcl” to the existing current working directory. The second example creates the same “myscript.tcl” file in the current working directory.

```
save_script C:/lscc/diamond/myproject/scripts/myscript.tcl

save_script myscript.tcl
```

See “Creating and Running Custom Tcl Scripts” on page 2558 for details on how to save and run scripts in Diamond.

Example 2 The following **set_prompt** command reassigns the prompt symbol on the command line as a dollar sign ($). The default is an angle bracket or “greater than” sign (>).

```
set_prompt $
```

Example 3 The following **history** command will print all of the command history that was recorded in the current Tcl Console session.

```
history
```

Diamond Project Tcl Commands

The Diamond Project Tcl Commands allow you to control the contents and settings applied to the tools, and source associated with your design. Projects can be opened, closed, and configured to a consistent state using the commands described in this section.

Diamond Project Tcl Command Descriptions The following table provides a listing of all valid Diamond project-related Tcl command options and describes option functionality.

Table 860: Diamond Project Tcl Commands

Command	Function (Argument)	Description
prj_project	**new** -name <project name> [-impl <initial implementation name>] [-dev <device name>] [-impl_dir <initial implementation directory>] [-lpf <lpf file name>]	Creates a new project inside the current working directory. The *new* command can only be used when no other project is currently open. The -name <project name> argument specifies the name of the project. This creates a <project name>.ldf file in the current working directory. The -impl <initial implementation name> argument specifies the active implementation when the project is created. If this left unspecified a default implemenation called “Implemenation0” is created. The -dev <device name> argument specifies the FPGA family, density, footprint, performance grade, and temperature grade to generate designs for. Use the Lattice OPN (Ordering Part Number) for the <device name> argument. The -impl_dir <initial implemenation directory> argument defines the directory where temporary files are stored. If this is not specified the current working directory is used. The -lpf <lpf filename> argument specifies the name of the active logical preference file. The <lpf filename> must have a **.lpf** file extension appended to it. The name of the project is used as a default value for the LPF file if this switch is not used.
	close	Exits the current project. Any unsaved changes are discarded.
	open <projectfile.ldf>	Opens the specified project in the software environment.
	save <projectfile.ldf>	Updates the project with all changes made during the current session and the project file is saved.

Table 860: Diamond Project Tcl Commands

Command	Function (Argument)	Description
	option [<synthesis | device> [option value]]	Allows you list or modify project options. The *option* function, when used without additional arguments, returns a Tcl list of the options associated with the project. Diamond defines two option argument values: synthesis and device. The synthesis value is the current synthesis tool, which can be either precision or synplify. The device value is the OPN of the current target FPGA. This option can be used to change FPGA device families by specifying a new OPN.
prj_src	**add** [-format VHDL] [-work <VHDL library name>] [-impl <implementation name> [-opt <name=value>]... [-exclude] <source file>...	Adds a VHDL source file to the specified or active implementation. The syntax used for the Add function depends upon the source file's implementation language. [-format VHDL]: This switch forces Diamond to consider the input file to be VHDL regardless of file extension. The switch is not required if the VHDL input files extension is one of: .vhd, or .vhdl. If there is no switch, this command will select a source type based on the file extension name, for example, .v will be Verilog, .vhd will be VHDL , and .rvl will be a Reveal project file. [-work <VHDL lib name>]: Assigns the source code to the specified library name space. [-impl <implementation name>]: This switch is used to add a source file to a Diamond implementation. If this switch is not specified the source file is added to the active implementation. [-opt name=value]: The -opt argument allows you to set a custom, user-defined option. See Example 9 for guidelines and usage. <source file>...: One or more VHDL source files to add to the specified implementation. <source file>...: One or more EDIF source files to add to the specified implementation.

Table 860: Diamond Project Tcl Commands

Command	Function (Argument)	Description
prj_src	**add** [-format VERILOG] [-include <include path list>] [-impl <implementation name> [-opt <name=value>]... [-exclude] <source file>...	Adds a Verilog source file to the specified or active implementation. The syntax used for the Add function depends upon the source file's implementation language. [-format VERILOG]: This switch forces Diamond to consider the input file to be Verilog regardless of file extension. The switch is not required if the Verilog input file's extension is .v. If there is no switch, this command will select a source type based on the file extension name, for example, .v will be Verilog, .vhd will be VHDL , and .rvl will be a Reveal project file. [-include <include path list>]: Defines a list of directory search paths for added source. When defining a list of strings, use the semi-colon as a delimiter to seperate the paths. Currently this argument is just used for Verilog source and finds files that use the include keyword. [-impl <implementation name>]: This switch is used to add a source file to a Diamond implementation. If this switch is not specified the source file is added to the active implementation. [-opt name=value]: The -opt argument allows you to set a custom, user-defined option. See Example 9 for guidelines and usage. <source file>...: One or more Verilog source files to add to the specified implementation.

Table 860: Diamond Project Tcl Commands

Command	Function (Argument)	Description
prj_src	**add** [-format EDIF] [-impl <implementation name> [-opt name=value]]... [-exclude] <source file>...	Adds an EDIF netlist source file to the specified or active implementation. The syntax used for the Add function depends upon the source file's implementation language. [-format EDIF]: This switch forces Diamond to consider the input file to be EDIF regardless of file extension. The switch is not required if the EDIF input files extension is .edi, .edn, .or edf. If there is no switch, this command will select a source type based on the file extension name, for example, .v will be Verilog, .vhd will be VHDL , and .rvl will be a Reveal project file. [-include <include path list>]: Defines a list of directory search paths for added source. When defining a list of strings, use the semi-colon as a delimiter to separate the paths. Currently this argument is just used for Verilog source and finds files that use the include keyword. [-impl <implementation name>]: This switch is used to add a source file to a Diamond implementation. If this switch is not specified the source file is added to the active implementation. [-opt name=value]: The -opt argument allows you to set a custom, user-defined option. See Example 9 for guidelines and usage. <source file>...: One or more EDIF source files to add to the specified implementation.

Table 860: Diamond Project Tcl Commands

Command	Function (Argument)	Description
prj_src	**add** [-format SCHEMATIC] [-impl <implementation name> [-opt name=value]... [-exclude] <source file>...	Adds a schematic source file to the specified or active implementation. The syntax used for the Add function depends upon the source files implementation language. [-format Schematic]: This switch forces Diamond to consider the input file to be a Diamond schematic regardless of file extension. If there is no switch, this command will select a source type based on the file extension name, for example, .v will be Verilog, .vhd will be VHDL , and .rvl will be a Reveal project file. [-include <include path list>]: Defines a list of directory search paths for added source. When defining a list of strings, use the semi-colon as a delimiter to separate the paths. Currently this argument is just used for Verilog source and finds files that use the include keyword. [-impl <implementation name>]: This switch is used to add a source file to a Diamond implementation. If this switch is not specified the source file is added to the active implementation. [-opt name=value]: The -opt argument allows you to set a custom, user-defined option. See Example 9 for guidelines and usage. The -exclude argument in prj_src add command will add the source files in a disabled state. <source file>...: One or more Schematic source files to add to the specified implementation.
	enable [-impl <implement name>] <src file> ...	Enables the excluded design sources from the current project, that is, it will activate a source file for synthesis, to be used as a preference, or for Reveal debugging.
	exclude [-impl <implement name>] <src file>	Disables the included design sources from the current project, that is, it will deactivate a source file for synthesis, to be used as a preference, or for Reveal debugging.

Table 860: Diamond Project Tcl Commands

Command	Function (Argument)	Description
	remove [-impl <implementation name>] -all | -src <source filename>...	Deletes the specified source files from the specified implementation. If an implementation is not listed explicitly the source files are removed from the active implementation. The source files are not removed from the file system, they are only removed from consideration in the specified implementation.
	option -src <source name> [-impl <implement name>] -src <source name> [-impl <implement name>] -rem <option name>… -src <source name> [-impl <implement name>] [-append] <option name> [option value list]	Allows you to add, list, or remove source options with the name <source name> in the specified or active implementation of the current project. If the -rem option is used, the following option names appearing after it will be removed. If no argument is used (i.e., “prj_src option”), the default is to list all source options. If only the <option name> argument is used (i.e., “prj_project option <option name>), then the value of that option in the project will be returned. The command will set the option value to the option specified by <option name>. If the <option value> is empty then the option will be removed and ignored (e.g., prj_src option -rem).

Table 860: Diamond Project Tcl Commands

Command	Function (Argument)	Description
prj_impl	**new** <new impl name> [-dir <implement directory>] [-lpf <lpf file name>] [-strategy <default strategy name>]	Create a new implementation in the current project with '<new impl name>'. A default .lpf file with the same name as the project name will be used if user dose not set the .lpf file name. The new implementation will use the current active implementation's strategy as the default strategy if no valid strategy is set.
	delete <implement name>	Delete the specified implementation in the current project with '< impl name>'.
	option [-impl <implement name>] [-impl <implement name>] -rem <option name>… [-impl <implement name>] [-append] <option name> [option value] -run_flow [<normal|initial|incremental>]	Allows you to add, list, or remove implementation options with the name <implement name> in the specified or active implementation of the current project. If the -rem option is used, the following option names appearing after it will be removed. If no argument is used (i.e., "prj_impl option"), the default is to list all implementation options. If only the <option name> argument is used (i.e., "prj_impl option <option name>), then the value of that option in the project will be returned. The command will set the option value to the option specified by <option name>. If the <option value> is empty then the option will be removed and ignored (e.g., prj_impl option -rem). The -run_flow argument allows you to switch from the normal mode to an "initial" incremental flow mode and "incremental" which is the mode you should be in after an intial design run during the incremental design flow. With no value parameters specified, -run_flow will return the current mode setting.
	active <implement name>	Activates the implementation with the name <implement name>.
	pre_script [-impl <implement name>] <milestone name> <script_file>	List or set the implementation's user script before running. milestone. <milestone name> should be "syn", "map", "par", "export"

Table 860: Diamond Project Tcl Commands

Command	Function (Argument)	Description
	post_script [-impl <implement name>] <milestone name> <script_file>	List or set the implementation's user script after running. milestone. <milestone name> should be "syn", "map", "par", "export"
prj_run	<milestone name> [-impl <implement name>] [-task <task name>] [-forceAll|forceOne]	Runs a milestone or task. Milestones refer to processes in the design flow such as synthesis or map and a “task” is a more specific subprocess that is run within that milestone category. Not all milestones have tasks associated with them. The following is a list of all valid milestones with any associated tasks shown in parentheses behind them: Synthesis, Translate, Map (MapTrace, MapVHDLSimFile, MapVerilogSimFile), PAR (PARTrace, IOTiming, SSO), and Export (IBIS, Bitgen, Promgen, TimingSimFileVlg, TimingSimFileVHD). forceOne: reruns only the process specified in <*task name*>. forceAll: reruns all of the process up to <*task name*>.
prj_dev	**set** [-family|-device|-package|-performance|-operation|-part] **set** [-family <family name>] [-device <device name>] [-package <package name>] [-performance <performance grade>] [-operation <operation>] [-part <part name>]	Sets or lists the project’s FPGA device family. For example, you can change the device to specified part, family, device, package or performance grade. Note: The device part used in the project can also be set or listed by using the prj_project option device command.
prj_syn	**set** <synthesis tool>	Sets project default synthesis tool or lists available synthesis tool options. Diamond supports the following synthesis tool options: **synplify** (Synplify Pro), **precision** (Precision), and **lse** (Lattice Synthesis Engine). If you simply enter prj_syn in the command without any parameters, the synthesis tool used in the current project will appear. If no tool has been used, the command will not return any value. Note: The synthesis setting also can be performed by using prj_project option synthesis command.

Table 860: Diamond Project Tcl Commands

Command	Function (Argument)	Description
prj_strgy	**set** [-impl <implementation name>] <strategy name>	Associates the strategy with the specified implementation or the active implementation in the current project.
	set_value [-strategy <strategy name>] <option name1=option value1> <option name2=option value2>...	Sets one or multiple strategy options values.
	list_value [-strategy <strategy name>] <pattern>	Lists value of strategy items.
	list_option <pattern>	Lists strategy option help.
	copy -from <source strategy name> -name <new strategy name> -file <strategy file name>	Copies an existing strategy and saves it to a newly created strategy file.
	new -name <new strategy name> -file <strategy file name>	Creates a new strategy file with the default strategy setting.
	import -name <new strategy name> -file <strategy file name>	Import an existing strategy file.
	delete <strategy name>	Deletes an existing strategy.

Diamond Project Tcl Command Examples This section illustrates and describes a few samples of Diamond Project Tcl commands.

Example 1 To create a new project, your command may appear something like the following which shows the creation of a LatticeSC device.

```
prj_project new -name "m" -impl "m" -dev LFSC3GA15E-5F900C
```

Example 2 To save a project and give it a certain name (save as), use the project save command as shown below:

```
prj_project save "my_project"
```

To simply save the current project just use the save function with no values:

```
prj_project save
```

Example 3 To open an existing project, the command syntax would appear with the absolute file path on your system as shown in the following example:

```
prj_project open "C:/projects/Diamond5/adder/my_project.bdf"
```

Example 4 To add a source file, in this case a source LPF file, use the prj_src add command as shown below and specify the complete file path:

```
prj_src add "C:/my_project/Diamond5/counter/counter.lpf"
```

Example 5 The following example below shows the prj_strgy copy command that uses source strategy “Setting 1” from a certain file path and copies and renames it “my_strategy” in the current project:

```
prj_strgy copy -from "Setting 1" -name "my_strategy"
-file "E:/my_projects/Diamond_prj/ecp2_counter/setting1.sty"
```

Example 6 The following example below shows the prj_strgy list_option command that uses * to show all the option names or you can use a specific one:

```
prj_strgy list_option par*
prj_strgy list_option par_sort_mode
```

Example 7 The following examples below shows the prj_run command being used to run various applications. In this first example, the Place & Route (PAR) tool or “milestone” process implements an output NCD file named “m” and then runs the TRACE task afterward (PARTrace), forcing the flow to only regenerate itself one level:

```
prj_run PAR -impl m -task PARTrace -forceOne
```

Below, Place & Route “milestone” process is run and an NCD file named “cnt_attr” is output to the project folder.

```
prj_run PAR -impl cnt_attr
```

In this final example, synthesis is run resulting in an output netlist file named “cnt_attr” that is generated into your project folder.

```
prj_run Synthesis -impl cnt_attr
```

Example 8 To copy another project strategy that is already established in another Diamond project from your console, use the prj_strgy copy command as shown below and specify the new strategy name and the strategy file name.

```
prj_strgy copy -name new_strategy -file strategy.stg
```

Example 9 The prj_src -opt command allows you to set a custom, user-defined option. This -opt argument value, however, cannot conflict with existing options already in the system, that is, its identifier must differ from system commands such as "include" and "lib" for example. In addition, a user-defined option may not affect the internal flow but can be queried for any usage in a user's script to arrange their design and sources. All user-defined options can be written to the Diamond project LDF file.

In the example below, the -opt argument is used as a qualifier to make a distinction between to .rvl file test cases.

```
prj_src add test1.rvl -opt "debug_case=golden_case"
prj_src add test2.rvl -opt "debug_case=bad_case"
```

Example 10 To set the current synthesis tool in your current project to a valid synthesis tool value, use the following command convention. This command shows how you set “lse” or the Lattice Synthesis Engine. The other values are Synplify and Precision.

```
prj_syn set lse
```

Now type prj_syn and it will return the current value. If you perform this in the Tcl Console, the project summary's current synthesis value will change interactively. If no tool is selected, Diamond will use Synplify by default.

Example 11 After you modify your strategy settings in the Diamond interface the values are saved to the current setting via a Tcl command. For example, a command similar to the following will be called if Synplify frequency and area options are changed.

```
prj_strgy set_value -strategy strategy1 SYN_Frequency=300
SYN_Area=False
```

Simulation Libraries Compilation Tcl Command

This section provides Simulation Libraries Compilation extended Tcl command syntax and usage examples.

Simulation Libraries Compilation Tcl Command Descriptions The following table provides a listing of all valid Simulation Libraries Compilation Tcl Command arguments and describes their usage.

Table 861: Simulation Libraries Compilation Tcl Command

Command	Function (Argument)	Description
cmpl_libs	**-sim_path** <sim_path> [-sim_vendor {mentor<default>}] [-lang {verilog|vhdl|all<default>}] [-device {sc|scm|ec|xp|ecp|machxo|ecp2| ecp2m|xp2|ecp3|machxo2|machxo3 d|machxo3l|lifmd|lptm|lptm2|ecp5u|e cp5um|all<default>}] [-target_path <target_path>]	The -sim_path argument specifies the path to the simulation tool executable (binary) folder. This option is mandatory. Currently only Modelsim and Questa simulators are supported. NOTE: If you are a Windows user and prefer the \ notation in the path, you must surround it with {}. And "" or {} will be needed if the path has spaces. The -sim_vendor argument is optional, and intended for future use. It currently supports only Mentor Graphics simulators (Modelsim / Questa). The -lang argument specifies the HDL type of the compiled libraries. This argument is optional, and the default is to compile both types of libraries. The -device argument specifies the Lattice FPGA device to compile simulation libraries for. This argument is optional, and the default is to compile libraries for all the Lattice FPGA devices. The -target_path argument specifies the target path, where you want the compiled libraries and modelsim.ini file to be located. This argument is optional, and the default target path is the current folder. NOTES: (1) This argument is recommended if you did not change the current folder from the Diamond's startup (binary) folder, or if the current folder is write-protected. (2) If you are a Windows user and prefer the \ notation in the path, you must surround it with {}. And "" or {} will be needed if the path has spaces.

Simulation Libraries Compilation Tcl Command Examples This section illustrates and describes a few examples of Simulation Libraries Compilation Tcl command.

Example 1 The following command will compile all the Lattice FPGA libraries for both Verilog and VHDL simulation, and place them under the folder specified by -target_path. The path to Modelsim is specified by -sim_path.

```
cmpl_libs -sim_path C:/modeltech64_10.0c/win64 -target_path c:/
mti_libs
```

Example 2 The following command will compile the LatticeECP3 libraries for Verilog simulation only, and place them under the current folder. The path to Modelsim is specified by -sim_path.

```
cmpl_libs -sim_path {C:\modeltech_6.6d\win32} -device ecp3 -
lang verilog
```

Reveal Inserter Tcl Commands

This section provides Reveal Inserter extended Tcl command syntax, command options, and usage examples.

Reveal Inserter Tcl Command Descriptions The following table provides a listing of all valid Reveal Inserter Tcl command options and describes option functionality.

Table 862: Reveal Inserter Tcl Commands

Command	Function (Argument)	Description
rvl_core	**set** -name <core name>	Selects core. Needed for all actions except Token. No option, return core names.
	add -name <core name>	Adds a core. Returns added core name.
	delete -name <core name>	Deletes a core. Returns deleted core name.
	rename -name <core name> <new core name>	Renames core. Returns new core name.

Table 862: Reveal Inserter Tcl Commands

Command	Function (Argument)	Description
rvl_trace	**add** -signal <signal list>	Adds signals to trace. Return new signal list. No option, return current signal list.
	delete -signal <signal list>	Delete signals from trace. Return new signal list. No option, return current signal list.
	rename -name<bus name> <new bus name>	Renames existing group. Return new group name.
	set [-sampleclk <clock signal>] [-sampleenable <on | off>] [-bufferdepth <value>] [-implementation <EBR | distram>] [-timestamp <on | off>] [-timestampbits <value>] [-capturemode <single | multiple>] [-capturemin <value>] [-includetrigger <on | off>]	If you specify no set argument options, the command will return a list of trace options. ▶ The -sampleclk argument sets sample clock. ▶ The -sampleenable argument enables or disables the sample enable. ▶ The -bufferdepth argument sets trace buffer depth. ▶ The -implementation argument sets trace implementation to ERB or distributed RAM (distram). ▶ The -timestamp argument turns timestamp on or off. ▶ The -timestampbits arguments sets the timestamp bit width value. ▶ The -capturemode argument sets capture mode. ▶ The -capturemin argument sets the minimum capture value. ▶ The -includetrigger argument sets behavior to include trigger signals as traces.
	set -radix <radix> <signal list>	Sets radix on signals (not implemented yet). Return radix.
	set -group <signal list>	Creates new group with signals.
	set -ungroup <bus list>	Ungroups signals.

Table 862: Reveal Inserter Tcl Commands

Command	Function (Argument)	Description
rvl_tu	**add** -name <TU name>	Adds TU. Return new TU name.
	delete -name <TU name>	Deletes TU. Return deleted name.
	rename -name <name> <new name>	Renames TU. Return new name.
	set [-name <TU name>] [-addsig <signal list>] [-deletesig <signal list>] [-operator {eq | ne | gt | ge| lt | | le | rise | fall | serial] [-value <value> [-radix {bin | oct | dec | hex}]	If you specify no set argument options, the command will return a list of TU. ▶ The -name argument selects the TU for the options. If no TU options, return list of options and value for the selected TU. ▶ The -addsig argument adds signals to TU. ▶ The -deletesig argument deletes signals from TU. ▶ The -operator argument sets comparison operator. Operators are equal to (eq), not equal to (ne), greater than (gt), greater than or equal to (ge), less than (lt), less than or equal to (le), rising edge (rise), falling edge (fall), and serial compare (serial). ▶ The -value argument sets TU value. ▶ The -radix argument sets TU radix. Options are binary (bin), octal (oct), decimal (dec), and hexadecimal (hex).
rvl_te	**add** -name <TE name>	Adds TE. Return new TE name.
	delete -name <TE name>	Deletes TE. Return deleted name.
	rename -name <name> <new TE name>	Renames TE. Return new name.
	set [-name <TE name>] [-expression <expression list>] [-ramtype <EBR/ slices>] [-maxdepth <value>] [-maxcount <value>]	If you specify no set argument options, the command will return a list of TE. ▶ The -name argument selects the TE for the options. If no TE options, return list of options and value for the selected TE. ▶ The -expression argument sets TE expression. ▶ The -ramtype argument sets TE ram type. ▶ The -maxdepth argument sets TE max sequence depth. ▶ The -maxcount argument sets TE max counter value.

Table 862: Reveal Inserter Tcl Commands

Command	Function (Argument)	Description
rvl_trigger	**set** [-defaultradix <radix>] [-finalcounter <on/off>] [-finalcountervalue <value>] [-triggerout <on/off>] [-triggeroutname <name>] [-triggerouttype <IO/NET/Both>] [-triggeroutpolarity <AH/AL>] [-triggeroutmpw <value>]	▶ No options will return all of the trigger options. ▶ The -defaultradix argument sets the default TU radix. ▶ The -finalcounter argument turns the final trigger counter on and off. ▶ The -finalcountervalue argument sets the final trigger counter value. ▶ The -triggerout argument turns the trigger out on and off. ▶ The -triggeroutname argument sets name for trigger out. ▶ The -triggerouttype argument sets type for trigger out. ▶ The -triggeroutpolarity argument sets polarity for trigger out. ▶ The -triggeroutmpw argument sets minimum pulse width for trigger out.
rvl_project	**open** <rvl file>	Opens rvl file.
	save <rvl file>	Saves rvl file.
	new <rvl file>	Creates new rvl file.
	close	Exits program.
	run [-drc] [-debug]	▶ The -drc argument runs DRC. ▶ The -debug argument runs Insert Debug.

Reveal Inserter Tcl Command Examples This section illustrates and describes a few samples of Reveal Inserter Tcl commands.

Example 1 To create a new Reveal Inserter project with the .rvl file extension in your project directory, use the rvl_project command as shown below using the new option.

```
rvl_project new my_project
```

Example 2 The following example shows how to set up TU parameters for Reveal Inserter:

```
rvl_tu set -name TU1 -addsig count[7:0] -operator eq -value C3
-radix hex
```

Reveal Analyzer Tcl Commands

This section provides Reveal Analyzer extended Tcl command syntax, command options, and usage examples.

Reveal Analyzer Tcl Command Descriptions The following table provides a listing of all valid Reveal Analyzer Tcl command options and describes option functionality.

Table 863: Reveal Analyzer Tcl Commands

Command	Function (Argument)	Description
rva_trace	**get**	Lists all trace signals in a core.
rva_core	**set** [-name <name>] [-run <on|off>]	▶ No arguments returns a list of cores. ▶ Selects core. Needed for other actions. ▶ The -run argument urns run check box on/off for core.
rva_tu	**rename** <name> <new name>	This function renames TU.
	set [-name <name>] [-operator {== | != | > | >= | < | <= | "rising edge" | "falling edge"}] [-value <value>] [-radix {bin | oct | dec | hex | <token>}]	▶ No arguments returns a list of TU. ▶ The -name argument selects TU. If no options, returns options and values for the selected TU. ▶ The -operator argument sets the comparison operator. Operators are equal to (==), not equal to (!=), greater than (>), greater than or equal to (>=), less than (<), less than or equal to (<=), "rising edge", "falling edge", and serial compare (serial). ▶ The -value argument sets the TU value. ▶ The -radix argument sets TU radix. Options are binary (bin), octal (oct), decimal (dec), hexadecimal (hex), or the name of a token set.
rva_te	**rename** <name> <new name>	This function renames TE.
	set [-name <name>] [-expression <expression list>] [-enable <on|off>]	▶ No arguments specified will return a list of TE. ▶ The -name argument select TE. If no options are specified, it returns options and values for the selected TE. ▶ The -expression argument sets the TE expression. ▶ The -enable argument enables or disables TE.

Table 863: Reveal Analyzer Tcl Commands

Command	Function (Argument)	Description
rva_tokenmgr	**set_tokenset** <tokenset name> -name <new token set name> -bits <new token bits>	▶ Select specific token set ▶ Rename a token set ▶ Set number of bits in tokens
	add_tokenset [-tokenset <tokenset name>] [-bits <token bits>] [-token <name=value>]	▶ No arguments, add a tokenset with default name and bits ▶ Set token set name ▶ Set token set bits ▶ Add extra tokens
	del_tokenset -all	▶ Delete all token sets
	del_tokenset <token set name>	▶ Delete the specific token set
	set_token <tokenset name> <token name> -name <new token name> -value <new token value>	▶ Select specific token in specific token set ▶ Set token name ▶ Set token value
	add_token <token set name> <name=value>	▶ Add a token with new name and value in a specific token set
	del_token <token set name> <token name>	▶ Delete a specific token in a specific token set
	export <file name>	▶ Export all token sets to a specific file
	import <file name>	▶ Import and merge all token sets from a specific file
rva_trigoptn	**set** [-teall <AND|OR>] [-finalcounter <on|off>] [-finalcountervalue <value>] [-samples <value>] [-numtriggers <value>] [-position <pre|center|post|value>]	▶ No arguments specified will return list of options. ▶ The -teall argument sets AND ALL or OR ALL for all TEs. ▶ The -finalcounter argument turns final trigger counter on/off. ▶ The -finalcountervalue argument sets final trigger counter value. ▶ The -samples argument sets number of samples to capture. ▶ The -numtriggers argument sets number of triggers to capture. ▶ The -position argument sets trigger position to pre-selected or user value.

Table 863: Reveal Analyzer Tcl Commands

Command	Function (Argument)	Description
rva_project	**open** <rva file>	The open function with a rva file argument opens an rva file.
	save <rva file>	Saves rva file.
	new [-rva <rva file>] [-xcf <xcf file>] [-rvl <rvl file>] [-dev <device:id>] -port <number> -cable <type>	Create new rva file with required options. An XCF file is required for multiple devices. Cable type values are LATTICE|USB|USB2 but optional for single devices on cable.
	close	Exits program.
	export -vcd <file name> [-module <title>]	Export VCD file. Optional to include a title in the VCD file. If the -module argument is not included, the title will be “<unknown>”.
	export -txt <file name> [-siglist <signal list>]	Export TEXT file; optional to export selected signal list only, by default all signals are exported.
	set [-frequency <frequency value>] [-period <period value>] [-tckdelay <delay value>] [-cabletype <type>] [-cableport <number>]	▶ No arguments specified will return options. ▶ The -frequency argument sets the frequency value for sample clock in MHz. ▶ The - period argument sets a period value for sample clock in ns or ps. ▶ The -tckdelay argument sets a TCK clock pin pulse width delay value (MachXO2) ▶ The -cabletype argument changes the type of cable. Values are LATTICE|USB|USB2. ▶ The -cable port argument changes the port.
	run	Runs until trigger condition to capture data.
	stop	Stops without capturing data.
	manualtrig	Manual Trigger to capture data.
	run -download [-xcf <xcf file>] [-log <log file>]	Downloads program using ispVM.

Reveal Analyzer Tcl Command Examples This section illustrates and describes a few samples of Reveal Analyzer Tcl commands.

Example 1 To create a new Reveal Analyzer project with the .rvl file extension in your project directory, use the rva_project command as shown below using the new option.

```
rva_project new my_project
```

Example 2 The following command line example shows how to specify a new project that uses a parallel cable port.

```
rva_project new –rva untitled –rvl "count.rvl" –dev "LFXP2-
5E:0x01299043" –port 888 –cable LATTICE
```

Example 3 The following example shows how to set up TU parameters for Reveal Analyzer:

```
rva_tu set -name TU1 -operator eq -value 10110100 -radix bin
```

Example 4 In this example, a MachXO2 Pico demo board requires a setting on TCK Low Pulse Width Delay to equal 2.

```
rva_project set –tckdelay 2
```

Power Calculator Tcl Commands

This section provides Power Calculator extended Tcl command syntax, command options, and usage examples.

Power Calculator Tcl Command Descriptions The following table provides a listing of all valid Power Calculator Tcl command options and describes option functionality.

Table 864: Power Calculator Tcl Commands

Command	Function (Argument)	Description
pwc_command	**open** -project <project file>	Opens project file.
	open -vcd <vcd file>	Opens vcd file.
	save -project <project file>	Saves project file.
	new -project <project file>	Creates new project.
	exit	Exits program.

Table 864: Power Calculator Tcl Commands

Command	Function (Argument)	Description
pwc_device	**list**	Lists all device info.
	list -family	Lists all current device families.
	list -device	Lists all current devices.
	list -packagetype	Lists all current package types.
	list -performance	Lists all valid device performance grades.
	list -operatingconditions	Lists all operating conditions settings.
	list -partnames	Lists all device part names.
	set -family <value>	Sets device family.
	set -device <value>	Sets device.
	set -packagetype <value>	Sets package type.
	set -performance <value>	Sets performance grade.
	set -operatingconditions <value>	Sets operating condition.
	set -partnames <value>	Sets part name.
pwc_parameters	**set -**process <value>	Sets device power process type.
pwc_thermal	**list**	Lists all thermal settings.
	set -userdefined <theta-ja value>	Sets user defined theta JA.
	set -board <value>	Sets board type.
	set -heatsink <value>	Sets heatsink type.
	set -airflow <value>	Sets airflow value.
	set -ambient <value>	Sets ambient temperature value.
pwc_settings	**list**	Lists all Power Calculator settings.
	set -af <value>	Sets default activity factor.
	set -freq <value>	Sets default frequency.
	set -freqtwr <file>	Sets usage twr file.
	set -freqtwropt <min | pref | trace>	Sets twr file options.
	set -estrouting <low | medium | high>	Sets estimated routing option.

Table 864: Power Calculator Tcl Commands

Command	Function (Argument)	Description
pwc_supply	**list**	Lists all power supplies.
	set -type <value> -mult <value> -voltage <value>	Sets multiplication factor and voltage of named power supply.
	set -type <value> -mult [<value>]	Sets multiplication factor of named power supply.
	set -type <value> -voltage [<value>]	Sets multiplication factor of named power supply.
pwc_logicblocks	**list**	Lists all logic blocks.
	add [-clockname <value>] [-freq <value>] [-af <value>] [-logicluts <value>] [-distram <value>] [-rippleslices <value>] [-registers <value>]	Adds logic block row.
	remove [-clockname <value>] [-freq <value>] [-af <value>] [-logicluts <value>] [-distram <value>] [rippleslices (value)] [-registers <value>]	Removes a logic block row.
pwc_clocks	**list**	Lists all clocks.
	add [-clockname <value>] [-freq <value>]	Adds clock.
	remove [-clockname <value>] [-freq <value>]	Removes clock.

Table 864: Power Calculator Tcl Commands

Command	Function (Argument)	Description
pwc_inout	**list** -io	List all I/Os.
	add -io [-clockname <value>] [-type <value>] [-ioregistermode <value>] [-freq <value>] [-af <value>] [-ip <value>] [-op <value>] [-cload <value>] [-bank <value>] [-pg <value>]	Adds I/O. The -pg argument is for MachXO2 only.
	remove -io [-clockname <value>] [-type <value>] [-ioregistermode <value>] [-freq <value>] [-af <value>] [-ip <value>] [-op <value>] [-cload <value>] [-bank <value>] [-pg <value>]	Removes I/O. The -pg argument is for MachXO2 only.
	list -bidir	Lists all bi-directional I/Os.
	add -bidir [-clockinputname <value>] [-type <value>] [-ioregistermode <value>] [-inputfreq <value>] [-inputaf <value>] [-bidi <value>] [-clockoutputname <value>] [-outputfreq <value>] [-outputaf <value>] [-dutycycle <value>] [-cload <value>] [-bank <value>] [-pg <value>]	Adds bi-directional I/O. The -pg argument is for MachXO2 only.
	remove -bidir [-clockinputname <value>] [-type <value>] [-ioregistermode <value>] [-inputfreq <value>] [-inputaf <value>] [-bidi <value>] [-clockoutputname <value>] [-outputfreq <value>] [-outputaf <value>] [-dutycycle <value>] [-cload <value>] [-bank <value>] [-pg <value>]	Removes bi-directional I/O. The -pg argument is for MachXO2 only.
	list -bank	Lists all bank voltages.
	set -bank <bank id> -inrdshutoff | lvdsoshutoff [<value>]	(MachXO2 only) Sets InRD Shut-off and/or LVDSO Shut-off for bank. XO2 only. The bank ID is a string and refers to the bank number. The value set for Allow InRD Shut-off or Allow LVDSO Shut-off can be “yes” or “no”.
	list -term	Lists all termination resistances and voltages.

Table 864: Power Calculator Tcl Commands

Command	Function (Argument)	Description
pwc_blockram	**list** -spram	Lists all single port block RAMs.
	add -spram [-clockname <value>] [-ebrblocks <value>] [-freq <value>] [-af <value>]	Adds single port block RAMs.
	remove -spram [-clockname <value>] [-ebrblocks <value>] [-freq <value>] [-af <value>]	Removes single port block RAMs.
	list -dpram	Lists all dual port block RAMs.
	add -dpram [-rdclockname <name>] [-rdclkfreq <value>] [-rdaf <value>] [-ebrblocks <value>] [-wrclockname <name>] [-wrclkfreq <value>] [-wraf (<value>]	Adds dual port block RAMs.
	remove -dpram [-rdclockname <name>] [-rdclkfreq <value>] [-rdaf <value>] [-ebrblocks <value>] [-wrclockname <name>] [-wrclkfreq <value>] [-wraf (<value>]	Removes all dual port block RAMs.
	list -dpramtrue	Lists all dual port true block RAMs.
	add -dpramtrue [-clockaname <name>] [-clkafreq <value>] [-clkaaf <value>] [-ebrblocks <value>] [-clockbname <value>] [-clkbfreq <value>] [-clkbaf <value>]	Adds dual port true block RAMs.
	remove -dpramtrue [-clockaname <name>] [-clkafreq <value>] [-clkaaf <value>] [-ebrblocks <value>] [-clockbname <value>] [-clkbfreq <value>] [-clkbaf <value>]	Removes dual port true block RAMs.
	list -fifodc	Lists all FIFO DC block RAMs.
	add -fifodc [-rdclockname <name>] [-outputregistersrd <value>] [-rdclkfreq <value>] [-rdaf <value>] [-ebrblocks <value>] [-wrclockname <name>] [-outputregisterswr <value>] [-wrclkfreq <value> [-wraf <value>]	Adds FIFO DC block RAMs.
	remove -fifodc [-rdclockname <name>] [-outputregistersrd <value>] [-rdclkfreq <value>] [-rdaf <value>] [-ebrblocks <value>] [-wrclockname <name>] [-outputregisterswr <value>] [-wrclkfreq <value> [-wraf <value>]	Removes FIFO DC block RAMs.

Table 864: Power Calculator Tcl Commands

Command	Function (Argument)	Description
pwc_dspblock	**list**	Lists all DSP blocks.
	add [-clockname <name>] [-freq <value>] [-af <value>] [-type <value>] [-dsp <vaue>]	Adds DSP blocks.
	remove [-clockname <name>] [-freq <value>] [-af <value>] [-type <value>] [-dsp <value>]	Removes DSP blocks.
pwc_plldll	**list** -pll	Lists all PLLs.
	add -pll [-outputclockname <name>] [-inputfreq <value>] [-n <value>] [-v <value>] [-m <value>] [-pll <value>]	Adds PLL.
	remove -pll [-outputclockname <name>] [-inputfreq <value>] [-n <value>] [-v <value>] [-m <value>] [-pll <value>]	Removes PLL.
	list -dll	Lists all DLLs.
	add -dll [-clockname <value>] [-freq (<value>] [-dll <value>]	Adds DLLs.
	remove -dll [-clockname <value>] [-freq (<value>] [-dll <value>]	Removes DLLs.
	list -dqsdll	Lists all DQSDLLs.
	add -dqsdll [-clockname <value>] [-freq (<value>] [-dqsdll <value>]	Adds DQSDLLs.
	remove -dqsdll [-clockname <value>] [-freq (<value>] [-dqsdll <value>]	Removes DQSDLLs.
	list -dqs	(MachXO only) Lists all DQS.
	add -dqs [-clockname <value>] [-freq (<value>] [-dqs <value>]	(MachXO only) Adds DQS.
	remove -dqs [-clockname <value>] [-freq (<value>] [-dqs <value>]	(MachXO only) Removes DQS.
	list -dlldel	(MachXO only) Lists all DQS.
	add -dlldel [-clockname <value>] [-freq (<value>] [-dlldel <value>]	(MachXO only) Adds DQS.
	remove -dlldel [-clockname <value>] [-freq (<value>] [-dlldel <value>]	(MachXO only) Removes DLLDEL.

Table 864: Power Calculator Tcl Commands

Command	Function (Argument)	Description
pwc_maco	**list**	Lists all MACOs.
	add [-clockname <name>] [-freq <value>] [-af <value>] [-type <value>] [-maco <value>]	Adds MACOs.
	remove [-clockname <name>] [-freq <value>] [-af <value>] [-type <value>] [-maco <value>]	Removes MACOs.
pwc_serdes	**list**	Lists all MACOs.
	add [-clockname <name>] [-freq <value>] [-channels <value>] [-gearingratio <value>] [-txpreemphasis <value>]	Adds SERDES for LatticeSC/SCM devices.
	add [-clockname <name>] [-freq <value>] [-channels <value>] [-mode <value>]	Adds SERDES for LatticeECP3/ ECP2M/ECP2MS devices.
	remove [-clockname <name>] [-freq <value>] [-channels <value>] [-gearingratio <value>] [-txpreemphasis <value>]	Removes SERDES for LatticeSC/SCM devices.
	remove [-clockname <name>] [-freq <value>] [-channels <value>] [-mode <value>]	Removes SERDES for LatticeECP3/ ECP2M/ECP2MS devices.
pwc_writereport	txt -file <file name>	Generates text report and writes to file.
	html -file <file name>	Generates HTML report and writes to file.
pwc_efb	**list** [-i2c1 | -i2c2 | -spi | -ufm | -tc | -wishbone]	(MachXO2 only) Outputs a value list of all rows in the given EFB table. Tables include I2C1, I2C2, SPI, UMF, TC, and WISHBONE, respectively. If you do not provide an EFB value, a list of all the rows for each type will be output.
	add [-i2c1 <key value>] | [-i2c2 <key value>] | [-spi <key value>] | [[-ufm <key value>] | [-tc <key value>] | [-wishbone <key value>]	(MachXO2 only) Adds rows to a given EFB table. Key values are rows of the I2C1, I2C2, SPI, UMF, TC, and WISHBONE tables, respectively. Outputs a value list of added rows in the given table.
	remove [-i2c1 <key value>] | [-i2c2 <key value>] | [-spi <key value>] | [[-ufm <key value>] | [-tc <key value>] | [-wishbone <key value>]	(MachXO2 only) Removes rows from a given EFB table. Key values are rows of the I2C1, I2C2, SPI, UMF, TC, and WISHBONE tables, respectively. Outputs a value list of the number of removed rows in the given table.

Table 864: Power Calculator Tcl Commands

Command	Function (Argument)	Description
pwc_misc	**list** [-mclk | -por | -bandgap]	(MachXO2 only) Outputs a value list of all rows in the given EFB table. Tables include MCLK, POR, and BANDGAP, respectively. If you do not provide an EFB value, a list of all the rows for each type will be output.
	set -mclk [-allowstandby <value>] [-mclkfreq <mclk freq>] [-sedfreq <sedfreq>] | -por -allowstandby [<value>] | -bandgap -allowstandby [<value>]	(MachXO2 only) The -mclk command sets standby, MCLK frequency and SED frequency of MCLK. The -allowstandby argument takes No or Yes values. Frequency values are an integer value. This command outputs a list of values in an MCLK table. The -por and -bandgap commands set standby for POR and BANDGAP in similar fashion, respectively.
pwc_power	**set** -standby [<-bandgap | -por | -osc | -pll <pll id> > Disable|Enable] dynamic [-bank <bank id> [-inrd|-lvdso|-pg Disable|Enable]]	(MachXO2 only) Sets standby and/or bank dynamic option. The PLL ID can be 0 or 1. The bank ID is the name of the bank. A value list of standby options and/or dynamic bank options are output. In addition, the Disable or Enable standby option is output.

Power Calculator Tcl Command Examples This section illustrates and describes a few samples of Power Calculator Tcl commands.

Example 1 To set the usage of the .twr file to “ON” in Power Calculator as shown in the following command below:

```
pwc_settings -freqtwr on
```

Example 2 The follow command below creates a PWC project (.pcf) file namced “abc.pcf” from an input NCD file named “abc.ncd”:

```
pwc_command new -project abc.pcf -ncd abc.ncd
```

Example 3 To add a row in the logic table with 4 logic LUTs and 5 registers (other column value is default), use a command as follows:

```
pwc_logicblocks add –logicluts 4 –registers
```

This example adds a row in the logic table with default values:

```
pwc_logicblocks add5
```

Note

You can see that the keywords “logicluts” and “registers” are just the same as the column name in the table. The keyword, however, is in lower case and is an alphanumeric character, and by rule does not include blank spaces and characters in paretheses. This rule is also applied in other component tables.

Example 4 To see the current device family use the first command shown below. To change the current device family setting to MachXO, for example, use the pwc_device set" command with the -family option:

```
pwc_device set –family
pwc_device set –family MachXO
```

Example 5 To set the default frequency to, for example, 100 Mhz:

```
pwc_settings set –freq 100
```

Example 6 To add one I2C1 in an EFB panel for a MachXO2 device, use a similar command convention to the one shown below:

```
pwc_efb add –i2c1 –i2c1 1
```

Note

The first i2c1 is the table name and the second is column name.

Example 7 The command below saves the current project to a new name:

```
pwc_command save –project newname.pcf
```

Example 8 To create an HTML report, you would run a command like the one shown below:

```
pwc_writereport  html –file c:/abc.html
```

NGD Tcl Commands

This section provides NGD extended Tcl command syntax, command options, and usage examples.

NGD Tcl Command Descriptions The following table provides a listing of all valid NGD Tcl command options and describes option functionality.

Table 865: NGD Tcl Commands

Command	Function (Argument)	Description
ngd_port	**get** [-in] [-out] [-bidi] [-tristate]	Returns list of port tcl objects in a comma-separated string in following format: port_name1,port_name2,port_name3 An empty string is returned if there is no port. If no option is specified then all ports will be returned. If more than one option is specified then a combination of results from each option is returned.
ngd_inst	**get** [-asic] [-cell] [-comp]	Returns a list of instance tcl objects in a comma-separated string in following format: hier_inst_name1,hier_inst_name2,hier_inst_name3 An empty string is returned if there is no instance. If no option is specified then all instances will be returned. If more than one option is specified then the combination of results from each option is returned.
ngd_net	**get** [-clock] [-vcc] [-gnd]	Returns a list of net/signal tcl objects in a comma-separated string in following format: hier_net_name1,hier_net_name2,hier_net_name3 An empty string is returned if there is no net. If no option is specified then all nets will be returned. If more than one option is specified then the union of results from each option is returned.
	get -inst hierInstName [-pin index | -fanin | -fanout]	Returns a list of net/signal tcl objects in a comma-separated string in following format: hier_net_name1,hier_net_name2,hier_net_name3 An empty string is returned if there is no net.

Table 865: NGD Tcl Commands

Command	Function (Argument)	Description
ngd_attr	**get** -inst hierInstName [attributeName] Acceptable attributeName values are as follows: -pincount -fanincount -fanoutcount -type: possible returned values are "asic", "cell", or "comp"	Returns a list of attributes for specified hierarchical instances.
	get -net netName [attributeName] Acceptable attributeName values are as follows: -fanincount: -fanoutcount: -fun: clock, data value: possible returned values are “gnd”, “vcc”, or “signal”	Returns a list of attributes for specified nets.
	get -port portName [attributeName] Acceptable attributeName values are as follows: -differential: possible returned values are “pos”, “neg”, or “none” - direction: possible returned values are “in”, “out”, or “bidi”	Returns a list of attributes for specified ports.

NGD Tcl Command Examples This section illustrates and describes a few samples of NGD Tcl commands.

Example 1 To return a list of port Tcl objects in your console, use the ngd_port command as shown below and specify the port type. This example uses the bidirectional port (-bidi) port type parameter.

```
ngd_port get -bidi
```

NCD View Tcl Commands

This section provides NCD view extended Tcl command syntax, command options, and usage examples.

NCD View Tcl Command Descriptions The following table provides a listing of all valid NCD view Tcl command options and describes option functionality.

Table 866: NCD View Tcl Commands

Command	Function (Argument)	Description
ncd_port	**get** [-in] [-out] [-bidi]	Returns list of port tcl objects in a comma-separated string in following format: port_name1,port_name2,port_name3 An empty string is returned if there is no port. If no option is specified then all ports will be returned. If more than one option is specified then a combination of results from each option is returned.
	export [{-csv | -lpf} filename [filePath]]	Exports pin configuration to user-specified file in either CSV or LPF format. CSV formation is generated by exporting Device Pin Layout and LPF format is generated through NCD back-annotation. If a filePath is not specified then ./ or current directory is the default.
ncd_inst	**get** [-slice] [-dcs] [-ebr] [-dsp] [-pio]	Returns list of hierarchical instance tcl objects in a comma-separated string in following format: hier_inst_name1,hier_inst_name2,hier_inst_name3 An empty string is returned if there is no port. If no option is specified then all ports will be returned. If more than one option is specified then a combination of results from each option is returned.
ncd_net	**get** -inst hierInstName [-pin | -fanin | -fanout]	For the “pin” option, enter values from 0 to max number of nets of that instance. Returns a list of net/signal tcl objects in a comma-separated string in the following format: hier_net_name1,hier_net_name2,hier_net_name3 An empty string is returned if there is no net.

Table 866: NCD View Tcl Commands

Command	Function (Argument)	Description
ncd_attr	**get** -inst hierInstName [attributeName] Acceptable attributeName values are as follows: pincount: fanincount: fanoutcount: type: slice, dcs, ebr, dsp, pio placed: yes or no	Returns a list of attributes for specified hierarchical instances.
	get -net netName [attributeName] Acceptable attributeName values are as follows: fanincount: fanoutcount: routed: yes, no or partial	Returns a list of attributes for specified nets.
	get -port portName [attributeName] Acceptable attributeName values are as follows: direction: in, out, bidi configuration: List of supported configurations. PCICLAMP, IO_TYPE, PULLMODE, SLEWRATE, and OPENDRAIN are device dependent. Please refer to Spreadsheet View topic in help for more information.	Returns a list of attributes for specified ports.

NCD View Tcl Command Examples This section illustrates and describes a few samples of NCD Tcl commands.

Example 1 To return a list of port Tcl objects in your console, use the ncd_port command as shown below and specify the port type. This example uses the bidirectional port (-bidi) port type parameter.

```
ncd_port get -bidi
```

Example 2 To return a list of net Tcl objects in your console, use the ncd_net command as shown below.

```
ncd_net get -inst hierInstName1
```

Programmer Tcl Commands

This section provides the Programmer extended Tcl command syntax, command options, and usage examples.

Programmer Tcl Command Descriptions The following table provides a listing of all valid Programmer Tcl command options and describes option functionality.

Table 867: Programmer Tcl Commands

Command	Function (Argument)	Description
pgr_project	**open** <project_file>	The open command will open the specified project file in-memory.
	save [<file_path>]	Writes the current project to the specified path. If there is no file path specified then it will overwrite the original file.
	close	Closes the current project. If a Programmer GUI is open with the associated project, then the corresponding Programmer GUI will be closed as well.
	check	Runs the check command on the current project.
	help	Displays help for the pgr_project command.

Table 867: Programmer Tcl Commands

Command	Function (Argument)	Description
pgr_program	<no_argument>	When pgr_program is run without arguments it will display the current status of the available settings. Note that specifying a key without a value will display the current value. The following keys can be used to modify those settings. Generally, the pgr_program command and its sub-commands allow you to run the equivalent process commands from the TCL Console window in the Diamond interface. These commands can override connection options that are set in user defaults.
	cable <lattice | vantis | usb>	Sets the cable type.
	portaddress <0x0378 | 0x0278 | 0x03bc | 0x0378 | 0x0278 | 0x03bc | 0x<custom address> | Ezusb-0 | Ezusb-1 | Ezusb-2 | Ezusb-3 | Ezusb-4 | Ezusb-5 | Ezusb-6 | Ezusb-7 | Ezusb-8 | Ezusb-9 | Ezusb-10 | Ezusb-11 | Ezusb-12 | Ezusb-13 | Ezusb-14 | Ezusb-15>	Sets the port address for the corresponding cable type.
	run [-progmode <turbo | sequential>] [cable <lattice | vantis | usb>] [portaddress <0x0378 | 0x0278 | 0x03bc | 0x0378 | 0x0278 | 0x03bc | 0x<custom address> | Ezusb-0 | Ezusb-1 | Ezusb-2 | Ezusb-3 | Ezusb-4 | Ezusb-5 | Ezusb-6 | Ezusb-7 | Ezusb-8 | Ezusb-9 | Ezusb-10 | Ezusb-11 | Ezusb-12 | Ezusb-13 | Ezusb-14 | Ezusb-15>]	Executes current project and project settings on the hardware. Note that there may be warnings that are displayed in the TCL Console window. These warnings will be ignored and processing will continue.
	help	Displays help for pgr_program command.
pgr_genfile	<no_argument>	The pgr_genfile command allows you to generate data files based on the currently loaded Programmer project and specify some commonly used options.
	process <svf | vme12 | slim>	Sets file type for file generation.
	slimalgorithm <file path>	Sets algorithm file for Slim VME file.
	outfile <file path>	Sets output file for pgr_genfile run.
	run	Generates file based on current settings and current project.
	help	Displays help for pgr_genfile command.

Programmer Tcl Command Examples This section illustrates and describes a few samples of Programmer Tcl commands.

Example 1 The first command below opens up a Programmer XCF project file that exists in an absolute path on the system. There can be many programming files associated with one project. In the GUI interface, the boldfaced file in Diamond is the active project file. For command line, you need to know what the active file is? <need to know this>

```
pgr_project /home/mdm/config_file/myfile.xcf
```

The second command in this example runs the Check action, and then executes all of the operations that have been set up for each device. If Check returns unsuccessful, then the operations will not be executed unless your configuration settings allow for downloading on errors. In the GUI settings you can enable the “Continue Download on Error” option in Programming Settings. <is there an option for this via command line to download on error?>

```
pgr_project check
```

Example 2 The following command runs programming in turbo mode using a USB cable at port address “Ezusb-7”.

```
pgr_program run progmode turbo cable usb portaddress Ezusb-7
```

Example 3 The following command sets the file generation type for JTAG SVF file and generates an output file to “mygenfile.xxx” in a relative path.

```
pgr_genfile run process svf outfile ../genfiles/mygenfile.xxx
```

Engineering Change Order Tcl Commands

This section provides Engineering Change Order (ECO) extended Tcl command syntax, command options, and usage examples available in Diamond Software Tcl (pnmainc.exe).

ECO Tcl Command Descriptions The following table provides a listing of all valid ECO Tcl command options and describes option functionality.

Table 868: ECO Tcl Commands

Command	Function (Argument)	Description
eco_design	**open** -ncd <ncd file> | [-prf <prf file>] [-macro]	Opens an existing design or macro.
	save [-ncd <ncd file> -prf <prf file>] | [-nmc <nmc file>]	Saves the design or macro that is currently open or saves it in a different location or with a different .ncd file name.
	close	Closes the design or macro that is currently open.

Table 868: ECO Tcl Commands (Continued)

Command	Function (Argument)	Description
eco_config	**sysio** -comp <comp name> [-bank_vccio <bank_vccio>] [-clamp <clamp>] [-diffcurrent <diffcurrent>] [-diffdrive <diffdrive>] [-diffresistor <diffresistor>] [-drive <drive>] [-eq_call <eq_call>] [-hysteresis <hysteresis>] [-impedance <impedance>] [-inf <inf>] [-io_type <io_type>] [-multdrive <multdrive>] [-opendrain <opendrain>] [-pciclamp <pciclamp>] [-pullmode <pullmode>] [-pwrsave <pwrsave>] [-refcircuit <refcircuit>] [-slewrate <slewrate>] [-terminategnd <terminategnd>] [-terminatevccio <terminatevccio>] [-terminatevtt <terminatevtt>] [-termination <termination>] [-vcmt <vcmt>] [-vref <vref>]	Edit sysIO preferences after the design has been placed and routed
	pll -comp <comp name> -type <type> [-phaseadj <phaseadj>] [-delay_val <delay>] [-fdel <fdel>] [-clkos_fdel <clkos_fdel>]	Edit sysIO preferences after the design has been placed and routed
	memufm -comp <comp name> -init_all_0 <no|yes> [-format <hex|bin>] [-mem <mem file>]	Update initial values for User Flash Memory
	memebr -instance <instance name> -init_all <0|1|no> -mem <file name> -format <hex|bin|add> -init_data <dynamic|static> -module <module name> -mode <mode value> -depth <depth value> -widtha <widthA value> -widthb <widthB value> [-area <area value>] [-ecc <ecc value>] [-bytesize <bytesize value>]	Update initial values for EBRs. Note: <mode value> is case-insensitive. It only accepts "ROM", "RAM_DQ", "RAMDPS", "RAM_DP", & "RAM_DP_TRUE".
	memdram -instance <instance name> -mem <file name> -format <hex|bin|add> -module <module name> -depth <depth value> -widtha <widthA value>	Update initial values for DRAMs
	prim -comp <comp name> -prim <mode value pair> [-prop <prop value pair>]... [-pin <pin value pair>]...	Update component's primitive settings
eco_add	**sigprobe** -site <site name> -net <net name>	Add signal probes
eco_delete	**sigprobe** -site <site name> -net <net name>	Remove signal probes

ECO Tcl Command Examples This section illustrates and describes a few samples of ECO Tcl commands.

Example 1 The following demonstrates the `sysio` command:

```
eco_config sysio -comp {c[0]} -bank_vccio 3.3 –pullmode UP
```

Example 2 The following demonstrates the `pll` command:

```
eco_config pll -comp {PLLInst_0} -type EHXPLLF -phaseadj 22.5 -
delay_val 2
```

Example 3 The following demonstrates the `memufm` command:

```
eco_config memufm -comp EFBInst_0 -init_all_0 no -format bin -
mem {d:/demo/mem.mem}
```

Example 4 The following demonstrates the `memufm` command:

```
eco_config memufm -comp {EFBInst_0} -init_all_0  yes
```

Example 5 The following demonstrates the `memebr` command:

```
eco_config memebr -instance .ip_rom -init_all no -mem {D:/UT/
Diamond/eco/Memory Initialization/ip_rom/test.mem} -format bin
-init_data dynamic -module ip_rom -mode ROM -depth 256 -widtha
8 -widthb 8
```

Example 6 The following demonstrates the `memdram` command:

```
eco_config memdram -instance u1 -format bin -mem {D:/UT/
Diamond/eco/Memory Initialization/mem_init/mem_init/mem.mem} –
module dram -depth 32 -widtha 16
```

Example 7 The following demonstrates the `memprim` command:

```
eco_config prim -comp master_dcua0_block -prim {DCUA} -prop
{D_CDR_LOL_SET=0b01} -prop {D_PLL_LOL_SET=0b01}
```

Example 8 The following demonstrates the `eco_add` command:

```
eco_add sigprobe -site A2 -net {clk_c}
```

Example 9 The following demonstrates the `eco_delete` command:

```
eco_delete sigprobe -site A2 -net {clk_c}
```

Example 10 The following demonstrates updating memory file in batch using ECO Tcl `eco_design` commands:

1. Save the following commands into a Tcl script file named “meminit.tcl”.

   ```
   eco_design open -ncd {C:/case/trilby_test_impl1.ncd} -prf
   {C:/case/trilby_test_impl1.lpf}
   eco_config memebr -instance {I492/rom4kx8_inst} -init_all no
   -mem {C:/case/trilby_8051.mem} -format add -init_data static
   -module {rom4kx8} -mode {RAM_DP_TRUE} -depth {4096} -widtha
   {8} -widthb {8}
   eco_design save -ncd {C:/case/trilby_test_impl1.ncd}
   eco_design close
   ```

2. From the command line, change the current path to the project path, and run the batch file.
   - On Windows, from the command line type:

     ```
     c:\lscc\diamond\<version_number>\bin\nt\fpgac meminit.tcl
     ```

   - On Linux, from the command line type:

     ```
     cd /usr/local/diamond/<version_number>/bin/lin
     source setupenv
     cd <project path>
     /usr/local/diamond/<version_number>/bin/lin/fpgac
     meminit.tcl
     ```

See Also "Launching the EPIC Tcl Console" on page 2556

Incremental Design Flow Tcl Commands

This section provides Incremental Design Flow Tcl command syntax, command options, and usage.

Incremental Design Flow Tcl Command Descriptions The following table provides a listing of all valid Incremental Design Flow command options and describes option functionality.

Table 869: Incremental Design Flow Tcl Commands

Command	Function (Argument)	Description
prj_incr	**set** [-enable | -disable] [-impl]	Get or set the incremental design flow mode. If you enter prj_incr without options, this will check the current implementation mode (normal or incremental). If you include the options (-enable or -disable) this will enable the incremental flow for the active implementation or for the specified implementation.
	restore [-impl] [-previous | -golden]	Set the previous or golden backup as the reference for the next incremental run.
	backup_golden [-impl]	Set the current successful results as the golden reference backup.
icf_data	**reload**	Loads or reloads the settings of the partitions from the data on disk. The changes in memory will be discarded.
	save	Saves the partition setting changes to the data on disk.

Table 869: Incremental Design Flow Tcl Commands

Command	Function (Argument)	Description
icf_part	**set_level** -part <partition name> [-value <SYNTHESIS | MAPPED | PLACED | ROUTED>]	Sets the preservation level for a partition.
	set_effort -part <part name> [-value <GUIDED | UNGUIDED>]	Sets the reimplementation effort for a partition.
	set_bbox -part <partition name> [-width <value>] [-height <value>]	Sets the bounding box for a partition.
	set_anchor -part <partition name> [-anchor <RxCy>]	Sets the anchor for a partition.
	set_color -part <partition name> [-color <RxxxGxxxBxxx>]	Sets the display color of the partition in the graphical user interface, The “xxx” represents a three-digit number ranging from 000 to 255 for the red, green, and blue value.

Note

The **idf_database** and **idf_partition** commands used in previous versions of Lattice Diamond have been removed, Starting with Lattice Diamond v2.1, these commands are replaced with the **ifc_data** and **ifc_part** commands described above.

Incremental Design Flow Tcl Command Examples The following are a few examples of tcl command lines and a description of what each does for Incremental Design.

Example 1 The following example shows the Tcl command usage for loading the partition information.

```
icf_data reload
```

Example 2 The following example shows the Tcl command usage for saving the partition information.

```
icf_data save
```

Example 3 The following example illustrates the Tcl command usage for setting the preservation level for a partition.

```
icf_part set_level -part CGROUP_GRAY0 -value MAPPED
```

Example 4 The following example illustrates the Tcl command usage for setting the reimplementation effort for a partition.

```
icf_part set_effort -part CGROUP_GRAY0 -value GUIDED
```

Example 5 The following example illustrates the Tcl command usage for setting the bounding box for a partition.

```
icf_part set_bbox -part CGROUP_GRAY0 -width 4 -height 4
```

Example 6 The following example illustrates the Tcl command usage for setting the anchor for a partition.

```
icf_part set_anchor -part CGROUP_GRAY0 -anchor R10C10
```

Example 7 The following example illustrates the Tcl command usage for setting the color for a partition.

```
icf_part set_color -part CGROUP_GRAY0 -color R0G50B255
```

Chapter 22

Glossary

A

.a An .a file is a platform library archive file in LatticeMico™ System that is automatically generated during a platform library build. It is referenced by the application build and derived from the platform library object files.

ABR ABR is an abbreviation for available bit rate, an ATM service type in which the network makes a “best effort” to meet the transmitter’s bandwidth requirements.

AC AC is an abbreviation for alternating current, which is electric current that rises to a maximum in one direction, falls back to zero, rises to a maximum in the opposite direction, and then repeats.

accumulator An accumulator is a register for adding, subtracting, or both.

active Active describes the window or design file that is currently being worked on. An active window has minimize and maximize buttons and a control menu box displayed on the title bar.

Active-HDL LE Active-HDL® LE is the Lattice edition of the Aldec Active-HDL program for performing functional and timing simulation. It is included with the Diamond software.

active high Active high (or High) is a signal whose active state is logic 1.

active low Active low (or Low) is a signal whose active state is logic 0.

activity factor An activity factor is a user-supplied variable in Power Calculator that estimates the percentage of the design that is changing state.

ADC ADC is an abbreviation for an analog-to-digital converter, which is a device that converts continuously varying analog signals to binary code that can be processed by a microprocessor or microcontroller. An ADC can be a single chip or a circuit in a chip.

adder An adder is a combinatorial circuit that computes the sum of two or more numbers.

AES Advanced Encryption Standard is a specification for the encryption of electronic data established by the U.S. National Institute of Standards and Technology (NIST) in 2001.

air flow Air flow is the movement of air around the device in a package to cool it. It is measured in linear feet per minute (LFM).

algorithm An algorithm is a specified sequence of actions performed to accomplish a task or solve a problem. It especially refers to a recursive computational procedure for solving a problem in a finite number of steps.

ALU ALU is an abbreviation for arithmetic logic unit. See “arithmetic logic unit” on page 2606.

ambient temperature The ambient temperature is the expected operating temperature, in degrees Celsius, of the medium surrounding a device in a package.

analog Analog describes a signal that is continuously variable. The characteristics of an analog signal, such as amplitude or frequency, vary continuously and infinitely. In contrast, the characteristics of a digital signal are divided into a finite number of discrete steps.

ANSI ANSI is an abbreviation for the American National Standards Institute, an industry-sponsored group that sets cooperative standards for companies to follow.

antenna effect The antenna effect is the buildup of charge on a conductor like polysilicon or metal that is not grounded, or electrically connected to silicon, during the polysilicon etch process or the ion implantation process. The voltage may build up on the interconnect to the point where it discharges and inflicts permanent physical damage. For example, damage to the gate oxides.

API API is an abbreviation for application programming interface, which is a language used by a computer application to interact with the operating system.

application build An application build is the output of the managed build process in LatticeMico System, for example, the application executable, application build makefiles, application object files, and required platform library files.

application build makefiles Application build makefiles are makefiles that enable the building of the application in LatticeMico System.

application executable The application executable is a file that results from linking the application and the platform library object file in LatticeMico System. This file is an .elf file that can be downloaded or executed using the GNU GDB debugger.

application object files Application object files are user source object files in LatticeMico System that have been compiled and assembled from the source C files.

architecture Architecture is the common logic structure of a family of programmable integrated circuits. The same architecture can be realized in different manufacturing processes.

arithmetic logic unit An arithmetic logic unit (ALU) is a logic function that performs arithmetic computations, such as addition, multiplication, and comparison operations. The ALU is one component of the central processing unit (CPU).

.asc An .asc file is an ASCII schematic file.

ASC Analog Sense and Control device used with MachXO2 and Platform Manager 2 designs.

ASIC ASIC is an acronym for application-specific integrated circuit, which is a full-custom circuit manufactured for a specific application in which every mask is defined by the customer. It can also be a semi-custom circuit (gate array) where only a few masks are defined. In large volume, ASICs are cheaper than programmable logic devices, but lead times and initial costs are large.

ASSP ASSP is an abbreviation for application-specific standard part, which is an integrated circuit created by using ASIC technology but sold as a standard device on the open market.

.asy An .asy file is an ASCII symbol file.

asynchronous Asynchronous describes an entity that is not synchronized to a shared signal like a clock.

asynchronous logic Asynchronous logic is logic that changes independently of clock changes. It is a signal whose intended function is performed immediately at the point that the signal is asserted without regard to a clock.

asynchronous transfer mode Asynchronous transfer mode (ATM) is a technique in which channel demand determines packet allocation. ATM offers fast packet technology, real time, and demand-led switching for efficient use of network resources. It is also the generic term adopted by ANSI and the ITU-TS to classify cell relay technology within the realm of broadband WANs, specifically B-ISDN.

ATE ATE is an abbreviation for automated test equipment, which refers to testers.

ATM ATM is an abbreviation for asynchronous transfer mode. See “asynchronous transfer mode” on page 2606.

attribute An attribute is an HDL constraint that is attached as text to a design object and interpreted by the Diamond software. An attribute provides information about the object. For example, it might specify where a component in the logical design must be placed in the physical device, or it might specify a frequency constraint for a net that timing-driven place and route will attempt to meet.

attribute window An attribute window is a predefined schematic area on or near a symbol or pin in which attribute values are displayed.

B

back annotation Back annotation is the process of adding post-route timing delays to the post-layout netlist in preparation for post-layout timing simulation. Before implementation, logic path delays are only estimated. The actual wiring delays (that is, the parasitic resistance and capacitance) cannot be known until after placement and routing has been performed. Back annotation substitutes the actual delays for the estimated delays in the netlist.

backplane A backplane is a circuit board containing circuitry and sockets into which additional electronic devices on other circuits boards or cards can be plugged.

bank A bank is an arrangement of identical hardware components that are electrically connected, such as I/O pads.

behavioral design Behavioral design is a technology-independent, text-based design that incorporates high-level functionality and a high-level information flow.

behavioral design method A behavioral design method is a method of defining a circuit in terms of a textual language rather than a schematic of interconnected symbols.

behavioral simulation Behavioral simulation is the same as functional simulation. See “functional simulation” on page 2623.

BER BER is an abbreviation for bit error ratio (or rate), which is the number of erroneous bits divided by the total number of bits transmitted, received, or processed over a stipulated period. BER monitoring is one of the PCS block functions.

.bgn A .bgn file is an FPGA report file showing any DRC errors or warnings associated with generating the bitstream. Running the Bitstream File process in Lattice Diamond’s Process view generates this file. See also “bitgen” on page 2608.

BIDI BIDI is an abbreviation for a bidirectional signal.

bidirectional A bidirectional is a signal or port that can act as either an input or an output.

binary Binary refers to the base 2 numbering system.

binary encoding Binary encoding is a type of state machine encoding that uses the minimum number of registers to encode the machine. Each register is used to its maximum capability.

.bit A .bit file is a binary configuration bitstream data file that is used to program an FPGA device. This file is similar to the raw bit file. See also ".rbt" on page 2651.

bitgen Bitgen is a command-line program that converts a fully routed physical design into configuration bitstream data. It is equivalent to the Bitstream File process in Lattice Diamond's Process view. The program takes a fully routed physical design, in the form of a circuit description (.ncd) file as input and produces a configuration bitstream (bit images).

bitstream A bitstream is a sequence of binary data that contains the configuration information from the physical design defining the internal logic and interconnections of the FPGA, as well as device-specific information from other files associated with the target device. When downloaded to a device, a bitstream configures the logic and programs the device so that the states of that device can be read back.

block A block is a symbol that represents lower-level circuitry; for example, a group of one or more logic functions or a schematic or symbol sheet. A block does not show any details of the circuitry, except for I/O pins. Blocks are most often used to simplify a complex schematic or to allow a large schematic to fit on a single sheet. Blocks usually represent repeated sections of circuitry but can replace any part of a schematic. As a representation of a schematic or symbol sheet, there are four types of blocks: 1) A composite block indicates that the design is hierarchical. 2) A module block is a symbol with no underlying schematic. 3) A pin block represents a schematic pin. 4) An annotate block is a symbol without electrical connectivity that is used only for documentation and graphics.

block check A block check is a physical DRC check in the EPIC software that examines one or more placed or unplaced components and reports any problems with logic, physical pin connections, or programming. It can be performed on selected components or on all components in the design. When you check all components in the design, the block check performs extra tests on the design as a whole (for example, tristate buffers sharing long lines and oscillator circuitry configured correctly) in addition to checking the individual components. You can run the block check separately or with the net check.

block modular design Block modular design is a design strategy that allows multiple designers to work on parts, or "block modules," of a single design independently. It also enables a single designer to make incremental changes with minimal impact to other portions of the design.

block symbol A block symbol is a schematic symbol that represents a schematic or HDL module at the next-lower level of hierarchy.

boundary scan Boundary scan is a method of testing electronic assemblies at the board level by inserting registers and control logic to serially scan in test patterns and scan output data registers. The primary objectives are the testing of chip I/O signals and the interconnections between ICs. It is the method for observing and controlling all new chip I/O signals through a standard interface called a test access port (TAP). The boundary scan architecture includes four dedicated I/O pins for control and is described in IEEE spec 1149.1.

breakpoints Breakpoints are a combination of signal states that are used to indicate when simulation should stop. They enable you to stop a program at certain points to examine the current state and the test environment to determine whether the program functions as expected.

BS See “boundary scan” on page 2608.

BSCAN See “boundary scan” on page 2608.

BSDL BSDL is an abbreviation for Boundary Scan Description Language, which is an IEEE language used to describe the structures for boundary scan testing.

buffer A buffer is an isolation circuit used to insulate sensitive analog or digital circuits from higher power levels or higher current levels in other portions of the chip.

burst mode Burst mode is a type of high-speed data transmission in which multiple transfers of data take place between a master and a slave within the same bus transaction.

bus A bus is a named collection of two or more wires or other buses that carry closely associated signals in an electronic design. Attaching a bus tap to a single wire “promotes” the wire to a bus. In a schematic, a bus looks like a single wire but is displayed in a different color. (The color does not appear until you name the bus.) The individual signals within a bus can be tapped off at any point along the bus, as often as needed. (Schematic Editor does not check to see if you are overloading the bus.)

bus pin A bus pin is a pin used to connect a bus to a symbol.

bus tap A bus tap is the point at which a signal enters or exits a bus.

C

C/C++ SPE C/C++ SPE is an abbreviation for the C/C++ Software Project Environment. See “SPE” on page 2657.

CAM CAM is an abbreviation for content addressable memory. Also known as “associative storage,” it is a memory chip in which each bit position can be compared. In regular dynamic RAM (DRAM) and static RAM (SRAM) chips, the contents are addressed by bit location and then transferred to the arithmetic logic unit (ALU) in the CPU for comparison. In CAM chips, the content is compared in each bit cell, allowing for very fast table lookups.

capacitance Capacitance is the ability of a conductor to store electric charge or a certain number of electrons. It is expressed in farads.

capacitive reactance Capacitive reactance is the opposition to current flow provided by a capacitor. It is measured in ohms and varies inversely with frequency.

carry logic Carry logic is logic that is designed to speed up and reduce the area of counters, adders, incrementors, decrementors, comparators, and subtractors. It is a special interconnect that speeds up the carry path of adders and counters.

CDR CDR is an abbreviation for clock data recovery. See “clock data recovery” on page 2611.

CDT CDT is an abbreviation for C/C++ development tools, which are components, or plug-ins, of the Eclipse development environment on which LatticeMico™ System is based.

cell library A cell library is the collective name given to a set of logic functions as defined by the manufacturer.

cell symbol A cell symbol is a schematic symbol that represents the primitive cells, such as transistors, resistors, and diodes, used to design integrated circuits.

CFI CFI is an abbreviation for Common Flash Interface (CFI) parallel flash memory, which is an open standard jointly developed by a number of chip vendors for a type of EEPROM that stores information without requiring a power source.

chain file A chain file is an .xcf file. See “.xcf” on page 2668.

chip check A chip check is a physical design-rule check that examines a special class of checks for nets, components, or both at the chip level, such as placement rules with respect to one side of the device.

CIB CIB is an abbreviation for a common interface block, which is a switch matrix that can be programmed to connect virtually any routing resource to any input or output of the logic element.

CIP CIP is an abbreviation for configurable interconnect point, which refers to the switching circuitry that connects routing segments on a net. It provides one or more of three basic functions: signal switching, amplification, or isolation. A net running from a PFU or PIC output (source) to a PLC or PIC input (destination) consists of one or more routing segments connected by CIPs. In EPIC, the graphic representations of CIPs are also called nodes.

cleanup routing Cleanup routing is the second stage of routing (also called delay reduction routing). During cleanup routing, the router takes the result of iterative routing, the first stage, and reroutes some connections to minimize the signal delays within the device.

CLKFB divider CLKFB is an abbreviation for feedback clock divider, which is a PLL block that multiplies the output of a PLL. The CLKFB divider is used to divide the feedback signal. Effectively, this multiplies the output clock, because the divided feedback must speed up to match the input frequency into the PLL block. The PLL block increases the output frequency until the divided feedback frequency equals the input frequency. Like the input divider, the feedback loop divider can be set to an integer value of 1 to 16. The input

and output of the feedback divider must be within the input and output frequency ranges specified in the device data sheet.

CLKI divider CLKI is an abbreviation for input clock divider, which a PLL block that divides the output of a PLL. The CLKI divider is used to control the input clock frequency into the PLL block. It can be set to an integer value of 1 to 16. The divider setting directly corresponds to the divisor of the output clock. The input and output of the input divider must be within the input and output frequency ranges specified in the device data sheet.

CLKOK divider CLKOK is an abbreviation for clock divider, which is a PLL block that obtains the divided value of the primary clock. The CLKOK divider feeds the global clock net. It divides the CLKOP signal of the PLL by the value of the divider. It can be set to values of 2, 4, 6, ...126,128.

CLKOP divider CLKOP is an abbreviation for primary clock output divider, which is a PLL block that sets the VCO operating frequency. The CLKOP divider serves dual purposes of squaring the duty cycle of the VCO output and scaling up the VCO frequency into the 420-MHz to 840-MHz range to minimize jitter.

clock A clock is a signal or square waveform used to synchronize the timing of the circuits in a digital integrated circuit. It switches between a high and a low state, usually with a 50-percent duty cycle.

clock boosting Clock boosting is the timing optimization of designs through clock skew scheduling to improve the performance in a synchronous system. Clock boosting is achieved by scheduling clock delay signals at each register to relax critical paths.

clock data recovery Clock data recovery is the process of eliminating channel-to-channel, clock-to-channel skew. It is implemented in the HSI embedded module. The clock signal is encoded in the data stream. This encoding scheme eliminates the need for a separate clock channel and assures that the clock and data are in phase, enabling higher bandwidth at lower cost.

clock enable A clock enable is a binary signal that allows or prevents synchronous logic from changing with a clock signal. When enabled, this control signal permits a device to be clocked and to become active. There are four different states. The two active high states are CE 0 disabled and CE 1 enabled. The two active low states are CE 0 enabled and CE 1 disabled.

clock frequency Clock frequency is the number of complete clock cycles that occur per unit of time. For example, a 50-MHz clock signal cycles 50 million times per second.

clock gating Clock gating is the process of using combinational logic elements, such as an AND gate, to disable the clock signal in unused circuits. Clock gating prevents power dissipation due to unnecessary charging and discharging of the unused circuits.

clock input path A clock input path is a path that starts either at an input of the chip or at the output of a flip-flop, latch, or RAM and ends at any clock pin

on a flip-flip or latch enable. The clock input path time is the maximum time required for the signal to arrive at the flip-flop clock input. Clock input paths help to determine system-level design timing.

clock latency Clock latency is the number of clock cycles that it takes data to propagate from input to output.

clock pulse A click pulse is a signal that synchronizes the operation of an electronic system. Clock pulses are continuous, precisely spaced changes in voltage.

clock skew Clock skew is the time differential between two or more destination pins in a path.

clock tree A clock tree is a network of clock signals distributed throughout a design. An optimal clock tree replaces high-fanout nets with a balanced tree of buffers to minimize clock skew.

clock-tree synthesis Clock-tree synthesis is the process of generating an optimal clock-tree network by inserting a tree of buffers to replace a high-fanout net, balancing the clock arrival times at the leaf nodes to minimize clock skew.

code-relocator code Code-relocator code is code in LatticeMico™ System that copies the software application code to a destination memory and jumps to the application start address to run the application.

combinational function A combinational function is a logic circuit whose output values depends on the current combination of values on its inputs at any given moment. See also “sequential function” on page 2655.

comparator A comparator is a logic function used to compare sets of binary values to see if they contain the same data.

compiling Compiling is the process of changing the design entry format into Boolean equations, which serve as input to simulation and device implementation programs. In general, compiling a design involves running every process after design entry. These processes include compiling and optimizing steps that can be performed on a single source or on the entire design. The Lattice Diamond software accept several design entry formats. With the exception of EDIF, all designs must be either synthesized or compiled before being placed and routed.

component A component is an instantiation or symbol reference from a library of logic elements that can be placed on a schematic. Components are constructed using primitive logic gates or primitives. For EPIC users, a component more specifically refers to a logical configuration that will, at some point, go into a site. Examples of components are logic blocks, I/O blocks, tristate buffers, GSRs, PCMs, and oscillators.

component description file See “.xml” on page 2668.

component information structure declaration The component information structure declaration is specified as part of the component

description (.xml) file in LatticeMico System and is copied into the platform description (.msb) file by the Mico System Builder (MSB). Each component in the platform is represented in the .msb file. The component's information in the .msb file includes the details about the component's source files that will need to be included in the build process. The information is then extracted from the .msb file by the build process and put into the DDStructs.h file. Each unique component must have its own unique component information structure defined within its component description file.

component instance declaration The component instance declaration declares presence of an instantiated structure for those component instances that have a corresponding information structure in LatticeMico System. It originates in the component description (.xml) file.

configuration Configuration is the process of loading design-specific bitstreams into one or more programmable devices to define the functional operation of the logical blocks, their interconnections, and the chip I/O.

congestion Congestion is the ratio of the number of wires that are actually routed across the edge of a cell to the capacity of the edge to accept them

constrained path A constrained path is a path that has a timing preference or requirement ascribed to it.

constraint file A constraint file is a file that specifies design constraint (location and path delay) information in textual form. In Lattice Diamond, a constraint file can be a logical preference file or a synthesis constraint file. See also ".lpf" on page 2635and "synthesis constraint file" on page 2660.

constraints Constraints are directives that are applied by the placement and routing programs to meet user objectives. Constraints can be declared as FPGA attributes in the HDL, schematic, or EDIF source files; or they can be declared as preferences in the logical preference file (.lpf). For designs that use the Lattice Synthesis Engine (LSE), constraints can also include Synopsys® Design constraints (SDC) that are directly interpreted by the synthesis engine.

constructive placement Constructive placement is the first stage of placement. In this stage, PAR places components into sites on the basis of such factors as the constraints specified in the input file, the length of connections, the available routing resources, the cost tables that assign random weighted values to each of the relevant factors. See also "optimizing placement" on page 2642.

core A core is a relatively large block that implements a general-purpose logic function and is used as a building block in chip design. Examples of cores are microprocessor and DSP cores. Cores are also called IP (intellectual property).

counter A counter is 1) a logic function composed of flip-flops that stores count values. The number of value states through which a counter sequences before returning to its original value is called the modulus. For example, a modulus that counts from 0 to 15 (decimal equivalent to binary) is called a modulo-16, or mod-16, counter. 2) A mechanism connected to the pattern

comparator in the Reveal core that specifies the number of times that the sampled trigger bus data must match the selected pattern in order for an event to occur.

coupling capacitance Coupling capacitance is the parasitic capacitance between two signals. It is used for allowing only certain AC signals to pass to other circuits.

CPLD CPLD is an abbreviation for complex programmable logic device, which is an erasable programmable logic device that can be programmed with a schematic or a behavioral design. CPLDs constitute a type of complex PLD based on EPROM or EEPROM technology. They are characterized by an architecture offering high speed, predictable timing, and simple software. The basic CPLD cell is called a macrocell, which is the CPLD implementation of a GLB. It is composed of AND gate arrays and is surrounded by the interconnect area.

critical path The critical path is the path through a circuit that determines the maximum speed at which the circuit can operate. The critical path is a signal in a section of combinatorial logic that limits the speed of the logic. Storage elements begin and end a critical path, which may include I/O pads.

cross-probing Cross-probing is 1) the inter-process communication between the synthesis or simulation results and the source code from which it originated 2) selecting an element in one view in Lattice Diamond and displaying the corresponding logical or physical element in a different view.

crosstalk Crosstalk is a charge injected on a net by capacitive or inductive coupling when coupled signals switch voltage.

CSR CSR is an abbreviation for a control and status register, which is a register in most CPUs that stores additional information about the results of machine instructions, for example, comparisons. It usually consists of several independent flags, such as carry, overflow, and zero. The CSR is mainly used to determine the outcome of conditional branch instructions or other forms of conditional execution.

.csv A .csv file is a file in the comma-separated values delimited data format, in which fields are separated by the comma character and records are separated by newlines. Fields that contain a comma, a newline, or double quotation marks or that start or end with white spaces to be preserved are enclosed in double quotation marks.

cycle stealing Cycle stealing is the timing optimization of designs through clock skew scheduling to improve the performance in a synchronous system. It is achieved by scheduling clock delay signals at each register to relax critical paths.

D

DAC DAC is an abbreviation for a digital-to-analog converter, which is a device that converts digital (usually binary) code to analog signals. A DAC can be a single chip or a circuit in a chip.

daisy chain A daisy chain refers to multiple FPGAs connected in a series that can be configured at the same time. A daisy chain uses a lead FPGA and one or more FPGAs configured in slave serial mode. The lead FPGA can be configured in any mode except slave parallel mode.

database See “internal database” on page 2628.

data capture mode Data capture mode is a setting in Reveal Inserter that specifies how the trace buffer in Reveal Logic Analyzer captures the trace data. It can capture data around a single trigger event or multiple trigger events.

dataset A dataset is a collection of the settings, such as trace signals, trigger signals, sample clock, and trigger output signal, for each of the logic analysis cores in Reveal Inserter and Reveal Logic Analyzer. Each dataset can include up to 16 logic analysis cores, one of which is reserved for internal use.

DC DC is an abbreviation for direct current, which is electric current that flows in one direction.

DDR DDR is an abbreviation for a double data rate, a memory interface in an SDRAM that captures data on both the rising and falling edges of the clock, doubling the performance of a single data rate interface.

debug insertion Debug insertion is the process of placing logic analysis cores into a design to debug it. Debug insertion gives you access to internal nodes inside the device so that you can observe their behavior. The Reveal Inserter application in Lattice Diamond is used to configure these cores and Reveal Logic Analyzer to debug the design.

.ddt A .ddt file is a file created by the Deployment Tool when saving a deployment.

debugging Debugging is the process of reading back or probing the states of a configured device to ensure that the device is behaving as expected while in circuit. Debugging in software is the process of locating and reducing the errors in the source code (the program logic). Debugging in hardware is the process of finding and reducing errors in the circuit design (logical circuits) or in the physical interconnections of the circuits.

decimal Decimal refers to the base 10 numbering system.

decoder A decoder is a symbol that translates n input lines of binary information into 2n output lines. It is the opposite of an encoder.

decoupled capacitance Decoupled capacitance is capacitance used to eliminate high-frequency noise from the DC voltage supply to prevent unwanted signals from passing between circuits.

delay Delay is the time associated with a logic function or timing preference placed on a component, net, or path. For example, delay calculations can measure the time that it takes a signal from a driver pin to reach a load pin. Typically, delays are given in nanoseconds. See also “pin-to-pin delay” on page 2645 and “point-to-point delay” on page 2646 delay.

delay reduction routing Delay reduction routing is the same as cleanup routing. See “cleanup routing” on page 2610.

demo board, demonstration board A demo, or demonstration, board is the same as an evaluation board. See “evaluation board” on page 2620.

density Density is the number of gates on a device.

Deployment Tool Deployment Tool is a stand-alone tool available from the Diamond Accessories. The Deployment Tool graphical user interface (GUI) is separate from the Diamond design environment. A four-step wizard allows you to select deployment type, input file type, and output file type.

derating Derating is the practice of reducing the rating of a device, such as its current rating, to provide an additional margin of safety or reliability when the device operates under unusual or extreme conditions.

design implementation Design implementation is the process of running a series of specific programs that result in the creation of a completed design based on user design specifications. The implementation process begins with checking design syntax. Language is then translated and optimized. The design logic is then mapped, placed, and routed.

design translation Design translation is the process of converting an input netlist into primitive terms that the software can understand and manipulate. The Translate Design process in Lattice Diamond converts the input EDIF file to a Native Generic Database format and builds the database, producing an .ngd file.

design methodologies Design methodologies are techniques used to enter a design, either through behavioral design or schematic entry.

design specification Design specification is the top level of a design used to define its function. The specification function is created in terms of behavioral or structural primitives. The two methods of entering a design are graphical descriptions (schematics) and textual descriptions (HDL).

detailed routing Detailed routing is the process of routing regions by assign each net specific tracks within the region.

deterministic jitter Deterministic jitter is jitter reproducible within a given system under controlled conditions. It is also known as bounded jitter. See also “jitter” on page 2630.

device A device is 1) an integrated circuit or other solid-state circuit formed in semiconducting materials during manufacturing 2) A particular architecture, such as a LatticeECP device.

device driver files Device driver files are the source .c and .h C/C++ files in LatticeMico System that contain driver code that is compiled into object files during the software build.

device family A device family is a group of Lattice Semiconductor devices based on the same architecture. Examples of device families are LatticeEC, LatticeXP, and MachXO.

device model A device model is a VHDL description of the internal and external views of a digital device, including the structure and the communication interface of the device with its environment.

Device View Device View is an integrated tool in Diamond that provides a categorized list of device resources based on the target device. It enables you to cross-probe selected components to Floorplan View and prohibit sites that you want excluded from placement and routing. See also "Floorplan View" on page 2622.

device utilization Device utilization is the relative density at which the device is packed or utilized. More specifically, device utilization refers to the percentage of available PFU sites that have been utilized on a device. The term device density, on the other hand, typically refers to the percentage of available logic gates that are being utilized on a device.

dielectric Dielectric is the insulating material between two metal plates, especially the two metal plates of a capacitor.

digest (message digest) a message digest is a cryptographic hash function containing a string of digits created by a one-way hashing formula.

digital signal processing Digital signal processing is the analyzing or changing of digital signals that have been converted from analog signals, such as sound or video.

DIP DIP is an abbreviation for dual in-line package, a through-hole-style plastic chip package.

DLL DLL is an abbreviation for a delay-locked loop, which is a digital circuit used to perform clock management functions on and off the chip.

.dly The .dly file is the delay report file, which is an FPGA place-and-route output file containing delay information for each net in the design. This file is generated when you use the -y option of the par program, which performs the placement and routing.

downloading Downloading is the process of configuring or programming a device by sending bitstream data to the device through a download cable. Configuration data from bitstream or PROM files is transmitted to the download cable through the host computer's serial communications port.

DPD DPD is an abbreviation for dedicated power down, a mode on zero-power devices. DPD is also refers to the dedicated power-down enable pin.

DPP DPP is an abbreviation for dedicated power pin, the control pin on dedicated zero-power devices. The term DPP also refers to dedicated power-down devices.

DQS DQS is a bidirectional data strobe signal used by the DDR interface in an SDRAM for high-speed operation.

DQSDLL DQSDLL is a signal that generates a 90-degree phase shift required for the DQS signal in the DDR interface of an SDRAM.

DRC DRC is an abbreviation for design rule check, which is a series of tests used to discover logical and physical errors in the design.

driver pin A driver pin is a component pin capable of transmitting a signal to one or more of its designated load pins. Output pins and tristate pins are considered drivers.

DSP DSP is an abbreviation for digital signal processing. See “digital signal processing” on page 2617.

duty cycle The duty cycle is the ratio of the time that a component, device, or system is operated to the time that it is at rest. The duty cycle can be expressed as a ratio or as a percentage.

E

E2 E2 is another term for electrically erasable, which refers to the technology of non-volatile memory using isolated capacitors that can store charge.

E^2CMOS E^2CMOS is an abbreviation for electronically erasable complementary metal oxide semiconductor, which is a proprietary Lattice Semiconductor process considered the preferred process technology for PLDs because of its inherent performance, reprogrammability, and testability benefits.

EBR EBR is an abbreviation for embedded block RAM.

Eclipse Eclipse is an open-source platform that provides application frameworks for software application development. The LatticeMico System interface is based on the Eclipse environment. See also “LatticeMico System” on page 2632.

ECO ECO is an abbreviation for engineering change order, which is the process of rebuilding a design after limited engineering changes have been made to it.

ECDSA Elliptical Curve Digital Signature Algorithm (ECDSA) is the elliptical curve analogue of the DSA.

.edf An .edf file is a file containing an EDIF netlist. It is the default netlist file that is generated by the Precision synthesis tool.

edge clock An edge clock is a clock that resides at the perimeter of an FPGA. Edge clocks are used for very localized clocking of I/O elements. Because edge clocks incur significant skew (like secondary clocks), they are not suited for clocking large buses. Edge clock routing resources reside on separate mask layers of the FPGA in order not to interfere with other signals or clocking resources in the design.

edge-sensitive signal An edge-sensitive signal is an input that only affects a function when it transitions from one logic value to another. See also "level-sensitive signal" on page 2633.

.edi An .edi file is an internal netlist file generated by Diamond. The file extension must be changed to .edf or .edn in order to import it into a project.

EDIF EDIF is an acronym for Electronic Design Interchange Format, which is a format used to exchange design data between different ECAD systems. It is designed to be written and read by computer programs that are constituent parts of EDA systems or tools. Its syntax, which is similar to LISP, has been designed for easy machine parsing. It is an essential part of the Electronic Industries Alliance's (EIA) service to the electronics industry. Since its inception over thirteen years ago, EDIF has become a vital part of the Electronic Design Automation (EDA) industry. The Diamond software supports EDIF Version 2 0 0.

edif2ngd Edif2ngd is a command-line program that, together with ngdbuild, converts netlists into a generic database that uses native primitive terms that the Diamond software can implement. It is equivalent to the Translate Design process.

.edn An .edn file is a file containing an EDIF netlist. It is the default netlist file that is generated by the Synplify synthesis tool.

EEPROM EEPROM is an acronym for electrically erasable programmable read-only memory, which is a programmable memory chip that holds its content without power and can be re-programmed in place without exposure to ultraviolet light.

EFB EFB is an abbreviation for embedded function block, an IP module with hardened functions such as SPI, I2C, and Timer/Counter. The EFB block is connected to the device from a Wishbone bus. See also "Wishbone Bus" on page 2667.

Effective Theta JA Effective Theta JA is a measurement of the sum of all the package and board thermal resistances outside of a JEDEC-defined environment. It indicates how well the heat dissipates from the die to the ambient (air) for a particular thermal network.

effort level Effort level refers to how hard the implementation process tries to place a design. The effort level settings are: 1) High, which provides the highest quality placement but requires the longest execution time. Use high effort on designs that do not route or do not meet your performance requirements. 2) Normal, which is the default effort level. It provides the best trade-off between execution time and high-quality placement for most designs. 3) Low, which provides a lower-quality placement but requires the shortest execution time.

electromigration Electromigration is the erosion of a metal conductor by the flow of electrons in an integrated circuit because of Joule heating and high current density.

Electronic Design Interchange Format See "EDIF" on page 2619.

.elf An .elf file is a file in executable linked format that contains the software application code written in C/C++ SPE.

embedded block RAM An embedded block RAM is a RAM cell in an FPGA that can be configured for RAM, ROM, FIFO, CAMs, and so forth.

EPIC EPIC is an acronym for Editor for Programmable ICs, which is a Lattice Diamond stand-alone application for displaying and configuring FPGAs. It can be used for placing and routing critical components before running the automatic place-and-route tools on an entire design. It can also be used for manually finishing the placement and routing if the routing program was unable to route the design to completion. EPIC enables both automatic and manual component placement and routing. It also interacts with the preference (.prf) file to read, write, and undo certain preferences.

.epl An .epl file is an EPIC Device Editor log file that tracks all commands performed on the design file in an active file session. The commands are written into a temporary command log file called <*design_name*>.epl in the same directory where the design is stored.

EPROM EPROM is an acronym for electrically programmable read-only memory, which is a programmable memory chip that holds its content without power and must be placed under ultraviolet light for erasure before reprogramming.

.err The .err file is an error output file.

evaluation board An evaluation board is a platform on which to evaluate, test, and debug user designs.

event An event in Reveal Inserter and Reveal Logic Analyzer is a trigger bus pattern that occurs a programmable number of times.

event counter An event counter in Reveal Inserter and Reveal Logic Analyzer is the maximum size of the count of all the trigger expression outputs combined.

.exo The .exo file is a PROM-formatted configuration file in Motorola EXORmacs format.

EXORmacs EXORmacs is a PROM file format from Motorola.

external clock An external clock is the system clock that is used on the target board during synchronous mode debugging. To use an external clock, connect the system clock to the CLKI pin and connect the download cable CLKO pin to the system clock loads.

external net An external net is a net outside of a macro instance connected to one of the macro's external pins. Part of an external net may lie within the macro, if the macro library file contained a net that was connected to an external pin.

External Netlist Format External Netlist Format is a netlist format created by Xilinx. See also ".xnf" on page 2668.

external pin An external pin is a macro pin used to connect the components in an instantiated macro to other components in a design (outside of the macro).

F

fab Fab is an abbreviation of fabrication, which is the process of wafer fabrication or the fabrication facility itself.

fall time Fall time is the time it takes the falling edge of a pulse to go from 90 percent of peak voltage to 10 percent of peak voltage.

falling edge A falling edge is a signal transition from a logic 1 to a logic 0. It is also called a negative edge.

fanin Fanin is the maximum number of digital inputs that a single logic gate can accept.

fanout Fanout is the maximum number of digital logic gates that can be driven by the output of a single logic gate.

.fdc An .fdc file is a constraint file used with the Synplify Pro synthesis tool. The file uses the same constraint format as the Synopsys Design Constraint (SDC) language and replaces the .sdc files used in earlier versions of Synplify Pro. FDC is an abbreviation for FPGA Design Constraint. See also "SDC" on page 2654 and "synthesis constraint file" on page 2660.

FDM FDM is an abbreviation for frequency division multiplexing, which is a technology that transmits multiple signals simultaneously over a single transmission path, such as a cable or wireless system. Each signal path travels within its own unique frequency range (carrier), which is modulated by the data (text, voice, video, and so forth).

.fdo The .fdo file is a batch file output by ModelSim/Questa.

FEC FEC is an abbreviation for forward error correction, a system of error control for data transmission in which the receiving device has the capability of detecting and correcting any character or code block that contains fewer than a predetermined number of symbols in error. FEC is performed by using a predetermined algorithm to add bits to each transmitted character or code block.

feedthrough A feedthrough is a signal net within a cell that can be connected to the top-level routing at multiple locations simultaneously. It is commonly used in cells intended to be assembled by abutment to form a continuous net passing through the cells. The feedthrough may or may not connect to the circuitry in the cell.

FFT FFT is an abbreviation for fast fourier transform, which is an algorithm for converting data from the time domain to the frequency domain. It is often used in signal processing.

FIFO FIFO is an acronym for first in, first out, a method of data storage in which data is retrieved in the same order as in was put in.

FIR filter A FIR (finite impulse response) filter is a filter whose output is a weighed sum of the current and past inputs. It is one of two types of filters used in digital signal processing. The IIR (infinite impulse response) filter is the other. FIR filters are used more frequently than IIR filters because they are stable; require no feedback; can be designed to be linear phase filters, which delay the input signal but do not distort its phase; and are simple to implement. However, FIR filters are less efficient than IIR filters.

flash memory Flash memory is a type of programmable chip that retains data even when the power is turned off.

flat design A flat design is a design composed of multiple sheets at the top-level schematic.

flattening Flattening is the process of resolving all the hierarchy references in a design. If a design contains several instantiations of a logic module, the flattened version of that design duplicates the logic for each instantiation. A flattened design still contains hierarchical names for instances and nets.

flip chip A flip chip is a surface mount chip technology in which the chip is packaged in place on the board and then underfilled with an epoxy. A common technique for attachment is to place solder balls on the chip, “flip” the chip over onto the board, and melt the solder.

flip-flop A flip-flop is a simple two-state logic buffer activated by a clock and fed by a single input working in combination with the clock. The states are high and low. When the clock goes high, the flip-flop works as a buffer as it outputs the value of the D input at the time the clock rises. The value is kept until the next clock cycle (rising clock edge). The output is not affected when the clock goes low (falling clock edge).

Floorplan View Floorplan View is a view in the Diamond that provides a convenient large-component layout of your design. It shows placement and routing and provides toolbar and menu commands for displaying UGROUPS

and REGIONs, utilized and reserved resources, and connections. Floorplan View allows you to create REGIONs and bounding boxes for UGROUPs, and reserve resources on the layout.

floorplanning Floorplanning is the process of choosing the best grouping and connectivity of logic in a design. It is also the process of manually placing blocks of logic in an FPGA device, where the goal is to increase density, routability, or performance.

flow Flow is an ordered sequence of processes that are executed to produce an implementation of a design.

f_{MAX} f_{MAX} is 1) the maximum number of times per second that a chip can generate logic functions. 2) the symbol for the maximum operating clock frequency, expressed in hertz. The maximum frequency is a function of the longest combinatorial delay between registered elements. See also “clock frequency” on page 2611.

FPGA FPGA is an abbreviation for field-programmable gate array, a type of gate array that is programmed by the user rather than by a semiconductor manufacturer. Most FPGAs are based on SRAM technology, although there are some flash and antifuse versions. FPGAs are similar in function to CPLDs but have different architectural structures.

.fp1 A .fp1 file is an ORCAstra configuration file. This file stores an FPGA configuration as defined in a main Visual Window. See also “ORCAstra” on page 2642 and “Visual Window” on page 2667.

.fpm A .fpm file is an ORCAstra macro file. Macros can be used to automate some operations in ORCAstra. See also “ORCAstra” on page 2642.

frame See “trace frame” on page 2663.

fringing capacitance Fringing capacitance is the same as peripheral capacitance. See “peripheral capacitance” on page 2644.

functional simulation Functional simulation is the process of identifying logic errors in a design before the design is implemented in a device. Because timing information for the design is not available, the simulator tests the logic in the design using unit delays. Functional simulation is usually performed on designs that are entered using a hardware definition language (HDL). It is usually performed at the pre-synthesis stage of the design process. Functional simulation verifies that the HDL code describes the desired design behavior.

fuse A fuse, or fusible link, is a metal wire or strip that melts when a current reaches a specified temperature, opening the circuit in which it is embedded to protect the circuit from an overcurrent condition.

fuse map A fuse nap is a design file in which the fuse data is already prearranged in exactly the same format as the physical layout of the fuse array of the device.

G

gate A gate is 1) an integrated circuit composed of several transistors and capable of representing any primitive logic state, such as AND, OR, XOR, or NOT inversion conditions. Gates are also called digital, switching, or logic circuits. 2) the terminal in a field effect transistor (FET) that applies voltage to cause the transistor to switch.

gate array A gate array is a chip that contains logic elements that have not been interconnected. When the metal layers that provide the connections are adhered to the chip, the masking stage is completed and the chip is finished. This final stage is less costly than designing a chip from scratch. The gate array is composed of basic cells containing a number of transistors and resistors, depending on the vendor. You use a cell library (gates, registers, and so forth.) and a macro library (more complex functions) to design the chip, and the vendor's software generates the masks that connect the transistors.

gated clock See "clock gating" on page 2611.

GDB GDB is an abbreviation for GNU GDB Debugger, which is a source-level debugger based on the GNU compiler. It is part of the C/C++ SPE debugger. It is connected to the various launch configurations connected to ISS or ispVM.

generic database file A generic database file is an .ngd file. See ".ngd" on page 2640.

global routing Global routing is the process of establishing a routing plan for each net. Sections of each net are assigned to specific routing regions according to a particular objective function, for example, total wire length.

glue logic Glue logic refers to simple logic gates used to wire more complex functions together.

GNU Compiler Collection (GCC) The GNU Compiler Collection (GCC) is a set of programming language compilers. It is free software produced by the GNU Project.

graphic symbol A graphic symbol is a schematic symbol that adds information that is not part of the circuitry, such as tables and notes.

ground bounce Ground bounce is an increase in voltage that occurs on the ground network of an integrated circuit because of the current flowing through the resistance of the ground network itself. It is caused by a large number of outputs switching simultaneously.

GROUP A GROUP is a set of FPGA design elements specified with the DEFINE GROUP preference. The GROUP definition enables you to place timing constraints on grouped elements using preferences such as MAXDELAY and MULTICYCLE.

GSR GSR is an abbreviation for a global set/reset signal. In LatticeECP/EC, LatticeXP, and LatticeSC devices, a low signal on the global set reset (GSR) input pin of the GSR component initializes all flip-flops and latches.

guided mapping Guided mapping is an incremental flow that enables you to use a previously generated mapped or routed .ncd file to guide the remapping of the design in a subsequent run after minor changes have been made. Guided mapping preserves the original mapped design while processing just the changes. See also ".ncd" on page 2640.

guided place & route Guided place & route is an incremental flow that enables you to use a previously placed and routed .ncd file to guide subsequent placement and routing of the design after minor changes have been made. Guided place & route preserves the original placed and routed design while processing just the changes. See also ".ncd" on page 2640.

H

HAL HAL is an acronym for hardware abstraction layer, which is the programmer's model of the hardware platform. It enables you to change the platform with minimal impact to your C code.

hard macro A hard macro is a macro that has already gone through internal placement and routing and is simply pasted down on the die. Traditional design reuse is based on hard macros. Such macros change their performance very little when they are moved from one design to another, so the industry has assumed that they require little timing analysis and validation. But hard macros are completely inflexible--their internal logic cannot be altered, even to the extent of changing the size of a buffer or the sense of a logic signal. For this reason and others, most IP providers have focused on soft macros. See also "soft macro" on page 2656.

hardware debugger module The hardware debugger module is a component of C/C++ SPE that is used to find problems in the software application.

hardware platform A hardware platform is the embedded microprocessor in an SoC (system on a chip) design and the attached components, buses, component properties, and their connectivity.

HDL HDL is an abbreviation for hardware description language, which is a textual coding language that describes circuits in a technology-independent manner using a high level of abstraction. The two most widely accepted HDLs are VHDL and Verilog.

heat sink A heat sink is any material or object that dissipates unwanted heat from a device by absorbing it and conducting it away to a surface from which it dissipates into its surroundings.

hexadecimal Hexadecimal refers to the base 16 numbering system.

HGROUP HGROUP is a hierarchical group, an HDL attribute that is used for grouping components that are to be instantiated multiple times. During synthesis, the HGROUP is expanded into individual instances. Each instance is then displayed as a unique UGROUP in the Group sheet of Spreadsheet View. The design mapper translates the HGROUP instances into PGROUPS and includes a hierarchy identifier for each, which enforces strict hierarchical control.

hierarchical design Hierarchical design is a design with more than one level. A large, complex design is typically broken into components, or modules. Circuitry for a specific function or interface can be abstracted as a separate module. The design represented by the module is said to be one level below the design in which the module appears. Or, the design is one level above the module.

hold time The hold time is the period after the clocking edge during which the data input to a latch or flip-flop must be held constant in order to guarantee that the latched data is correct.

HSI HSI is an abbreviation for high-speed interface circuits, which are included in some Lattice Semiconductor devices.

HTML HTML is an abbreviation for Hypertext Markup Language, which is a markup language used to create documents for the Worldwide Web.

hysteresis Hysteresis is the delay between the cause and the observed effect. In Schmitt trigger circuits, it is the difference between the upper and lower trigger points.

I

I2C I2C is an abbreviation for inter-integrated circuit, a multi-master serial single-ended computer bus that attaches low-speed peripherals to a motherboard, embedded system, cellphone, or other electronic device.

I/O blocks I/O blocks are the input/output logic of a device containing a pin.

I/O marker An I/O marker is an indicator that identifies a net name as a device input, output, or bidirectional signal. It establishes net polarity (direction of signal flow) and indicates that the net is externally accessible.

I/O pads I/O pads are the input/output pads that interface between the design logic and the pins of the device.

IBIS model An IBIS, or I/O Buffer Information Specification (IBIS), model is a standard simulation format for modeling the behavior of a digital integrated circuit's input/output (I/O) pins and buffers.

IBUF IBUF is an abbreviation for input buffer, which is an input I/O buffer from a pin to the global routing pool.

IEEE IEEE is an abbreviation for Institute of Electrical and Electronic Engineers, an engineering society.

IEEE 1164 Standard The IEEE 1164 Standard is the standard for Verilog HDL supported by Open Verilog International.

impedance Impedance is the sum of all resistance and reactance of a circuit to the flow of alternating current. It is the opposition that a component in a circuit offers to the flow of alternating current at a given frequency. If the frequency changes, the impedance changes, too. It is similar to resistance but applies to AC circuits.

implementation Implementation is 1) The synthesis and translation, mapping, placement, and routing phases of the design process. See “design implementation” on page 2616. 2) A version of a design project in Lattice Diamond. Each implementation defines the design structural elements and is associated with a specific strategy. See also “strategy” on page 2659.

implementation engine The implementation engine is a PAR multi-run job option that enables you to use multiple machines (nodes) that are networked together, significantly reducing the total amount of time to completion.

indelay Indelay is extra routing delay inserted in MachXO devices on the path from the input pad if you set a hold-time constraint.

inductance Inductance is 1) A property of an electric circuit by which a changing magnetic field creates an electromotive force, or voltage, in that circuit or a nearby circuit. 2) A property of an electric circuit that opposes any change in current.

inductive reactance Inductive reactance is the opposition to the flow of AC current produced by an inductor. It is measured in ohms and varies in direct proportion to the frequency.

.ini (epic) An .ini file (EPIC) is an EPIC Device Editor initialization file. During installation, an EPIC initialization file named epic.ini is placed in the software that is specific to each supported architecture in $FOUNDRY/data, where $FOUNDRY is the path pointed to/defined by the $FOUNDRY environment variable.

.ini (epicuser) The .ini file (EPICUSER) is a file that enables you to customize an epic.ini file. You create the epicuser.ini file in your home directory. This file can be used to modify or add to the epic.ini file so that it performs any commands that you want when the EPIC window opens.

input pad registers and latches Input pad registers and latches are D-type registers or latches located in the I/O pad sections of the device.

inrush current Inrush current is the peak instantaneous current drawn by a power supply when it is first turned on.

insert debug See “debug insertion” on page 2615.

instance An instance is an occurrence or implementation of a specific gate or hierarchical element in a design or netlist (for example, a component, net, site, or macro). The term “symbol” often describes instances in a schematic drawing. Instances are interconnected by pins and nets. Pins are ports through which connections are made from an instance to a net. A design that is flattened to its lowest-level constituents is described with primitive instances.

instantiation Instantiation is the process of placing a symbol that represents a primitive or a macro in a design or netlist. It is also used as a synonym for “instance.”

interconnect Interconnect refers to the physical wires and vias that electrically connect gates and other components in an integrated circuit.

internal database An internal database is the database generated in Diamond after you have created a project and imported the design files. The input for this database is an EDIF file, which can be generated from a standalone synthesis tool and imported into Diamond or created automatically from a Verilog or VHDL design using the integrated synthesis flow within the Diamond software. When you run the Translate Design process, Diamond converts the EDIF file to a Lattice Semiconductor internal database. If the design uses parameterized modules and IP cores (Lattice Semiconductor LPMs and LatticeCOREs), or user firm macros, the cores are expanded in this process.

internal net An internal net is a net within the macro library file that does not have a connection to any of the macro’s external pins.

IOB IOB is an abbreviation for an input/output block.

.ior An .ior file is an I/O Timing Analysis Report that provides worst case I/O summaries for a placed and routed design. For each input data port in the design, it provides the setup and hold time requirements; for each output port, it provides the min/max clock-to-out delay. The .ior file is generated when you run the I/O Timing Analysis process in the Lattice Diamond Process view.

iotiming Iotiming is a command-line program that generates the I/O Timing report (.ior) for a placed and routed design. It is equivalent to the I/O Timing Analysis process in the Lattice Diamond Process view.

IP core An IP, or intellectual property, core is a block of logic that can be used in making ASICs and FPGAs. Examples of IP cores are UARTs, CPUs, ethernet controllers, and PCI interfaces.

IPexpress IPexpress is an application that enables you to generate parameterized modules and IP cores from templates supplied by Lattice Semiconductor and third-party vendors.

.ipx An .ipx file is a manifest file. This file is loaded into IPexpress so that modifications can be made to the module.

IR drop IR drop is a reduction in voltage that occurs on the VDD network of an integrated circuit because of the current flowing through the resistance of the VDD network itself.

IRQ IRQ is an abbreviation for interrupt request, which is the means by which a hardware component requests computing time from the CPU. There are 16 IRQ assignments (0-15), each representing a different physical (or virtual) piece of hardware. For example, IRQ0 is reserved for the system timer, while IRQ1 is reserved for the keyboard. The lower the number, the more critical the function.

ISC ISC is an abbreviation for In System Configuration, a data file standard based on the IEEE 1532 standard for programming one or more compliant devices concurrently while they are mounted on a board or embedded in a system.

ISO ISO is an abbreviation for the International Standards Organization, which is an international collaboration of many different organizations that set industry standards for manufacturing companies. In the U.S., the American National Standards Institute is an industry-sponsored group that belongs to ISO. See also “ANSI” on page 2605.

ISO9000 ISO9000 is a standard of quality for manufacturing companies. See also “ISO” on page 2629.

ISP ISP is an abbreviation for in-system programmable, a four- or five-wire serial programming scheme with internally generated programming voltages. There are two types in Lattice Semiconductor devices: Lattice ISP, and IEEE 1149.1 TAP/BSCAN programming.

ispClock ispClock is a family of Lattice Semiconductor analog devices that can be programmed in-system to generate multiple clock frequencies, compensate each output for differences in clock trace lengths, match trace impedances and drive clock nets with different signaling requirements. Programmable features of ispClock devices can be configured using the Lattice PAC-Designer® software. See also “PAC-Designer” on page 2642.

ispPAC ispPAC (Programmable Analog Circuits) is a group of Lattice Semiconductor programmable analog devices that offers WYSIWYG analog design results. Programmable features can be configured using the Lattice PAC-Designer software. ispPAC devices include Power Manager, Platform Manager, and ispClock. See also “PAC-Designer” on page 2642.

ispSTREAM ispSTREAM is a utility that converts JEDEC files to a bit-packed format, which consumes one-eighth the storage space of the original file. See also “JEDEC” on page 2630.

ispVM System ispVM System is Lattice Semiconductor’s second-generation device download technology, which is used to program, or configure, JTAG programmable devices. It is based on the concept of a portable virtual machine which provides multi-vendor programming support, improved performance, and increased functionality.

ISR ISR is an abbreviation for interrupt service routine, which is a set of instructions in an operating system that executes in response to an interrupt.

ISS ISS is an abbreviation for instruction set simulator, which is a simulation model that imitates the behavior of a microprocessor. Often included in a debugger such as GDB, an ISS enables you to develop and debug a software program while the target hardware is still under development

iterated instance An iterated instance is a single symbol instance that represents multiple instances in a parallel connection.

iterative routing Iterative routing is the first stage of routing, where the router performs an iterative procedure to converge on a solution that routes the design to completion or minimizes the number of unrouted nets.

J

JEDEC JEDEC is an acronym for Joint Electron Design Engineering Committee, which is a group that sets standards for programmable devices. PLD companies refer to programming files as JEDEC files.

jitter Jitter refers to small rapid variations in a waveform resulting from fluctuations in the voltage supply. It can introduce errors and loss of synchronization. More jitter is encountered with longer cables, cables with higher attenuation, and signals at higher data rates. Jitter is also called phase jitter, timing distortion, or intersymbol interference.

Joule heating Joule heating is the excessive heating of a segment of wire because of high currents. It is a cause of electromigration.

.job A .job file is a Model 300 project file.

.js A .js file is a JScript file.

JScript JScript is the Microsoft version of the ECMAScript language. JScript can be used with ORCAstra to automate tests and to define functions in Visual Windows. See also “ORCA” on page 2642 and “Visual Window” on page 2667.

JTAG JTAG is an acronym for Joint Test Access Group, which is a set of specifications that enables board- and chip-level functional verification of a board during production. JTAG also refers to the IEEE1149.1 standard test access port and boundary-scan architecture (TAP/BSCAN).

JTAG chain A JTAG chain is one or more devices connected in a serial chain, where the output of one device feeds the input to the next. Pins on the JTAG connector are the start and end points of the chain.

JTAG ports JTAG ports are pins on an FPGA device that can capture data and programming instructions. In Reveal, they are the pins through which Reveal Logic Analyzer extracts the contents of the trace memory to display in

its graphical user interface. Through the download cable, you can also use the JTAG ports to update the patterns and counters that define a trigger.

junction temperature The junction temperature is the temperature of the die in the device package, in degrees Celsius.

L

latch A latch is a two-state buffer fed by two inputs, D and L. When the L input is low, it acts as a transparent input; in this case, the latch acts as a buffer and outputs the value input by D. When the L input is high, it ignores the D input value.

latch-up Latch-up is a condition in which a circuit draws uncontrolled amounts of current across a pn junction, forcing certain voltages up to a certain level and resulting in a degradation of system performance.

latched input A latched input is an input that captures asynchronous inputs.

lateral capacitance Lateral capacitance is the capacitance between conductors on the same layer.

LATTICE LATTICE refers to a type of download cable.

Lattice parallel port The Lattice parallel port is a port for a Lattice download cable.

Lattice Synthesis Engine Lattice Synthesis Engine (LSE) is the synthesis tool that is integrated with the Lattice Diamond software for supported device families, including MachXO, MachXO2, and Platform Manager. See ".ldc" on page 2633.

LatticeCORE IP module A LatticeCORE IP module is a Lattice Semiconductor large modular design block that implements popular industry-standard functions. It can be reused and easily placed within a programmable logic design. Lattice Semiconductor LatticeCORE IP modules are optimized for use with the Lattice Semiconductor device families.

LatticeEC LatticeEC (EConomy) is a family of Lattice FPGA devices characterized by low cost, LUT-based logic, distributed and embedded memory, PLLs and support for mainstream I/Os, and dedicated DDR memory interface logic without dedicated function blocks.

LatticeECP LatticeECP (EConomyPlus) is a family of Lattice Semiconductor FPGA devices that combines the optimized LatticeEC fabric with dedicated high-performance DSP blocks on-chip tailored for the implementation of common DSP functions. It also features LUT-based logic, distributed and embedded memory, PLLs, support for mainstream I/Os, and dedicated DDR memory interface logic.

LatticeECP2 See "LatticeECP2/M" on page 2632.

LatticeECP2/M LatticeECP2/M (EConomyPlus second generation) is a family of Lattice Semiconductor FPGA devices based on 90-nanometer technology and characterized by advanced DSP blocks, high-speed SERDES with PCS (LatticeECP2M family only), high-speed source synchronous interfaces, LUT-based logic, distributed and embedded memory, phase-locked loops (PLLs), delay-locked loops (DLLs), pre-engineered source synchronous I/O support, enhanced sysDSP blocks, and advanced configuration support, including dual boot capabilities.

LatticeECP2MS LatticeECP2MS devices are the same as LatticeECP2M devices but they also include security encryption of the bitstream. See “LatticeECP2/M” on page 2632.

LatticeECP2S LatticeECP2S devices are the same as LatticeECP2 devices but they also include security encryption of the bitstream. See “LatticeECP2/M” on page 2632.

LatticeECP3 LatticeECP3 is a family of Lattice Semiconductor FPGA devices that offers multi-protocol 3.2G SERDES with XAUI jitter compliance, DDR3 memory interfaces, DSP capabilities, high density on-chip memory and up to 149K LUTS, with low power consumption.

LatticeMico System LatticeMico System is a set of tools that are used to implement a soft microcontroller and attached peripheral components in a Lattice FPGA device. It is based on the Eclipse C/C++ Development Tools (CDT) environment, an industry open-source development and application framework for building software. The two integrated tools in LatticeMico System are used in combination with the Lattice Diamond software to coordinate the building of an embedded processor system on an FPGA device and write the software to drive it. See also “MSB” on page 2639 and “SPE” on page 2657.

LatticeSC LatticeSC is a family of Lattice Semiconductor FPGA devices characterized by a high-performance FPGA fabric, high-speed SERDES with embedded advance PCS (physical coding sub-layer), high-performance I/Os, up to 7.8 megabits of sysMEM embedded block RAM, and dedicated logic to support system level standards, such as RAPIDIO, SPI4.2, SFI-4, UTOPIA, XGMII, and CSIX. The devices in this family feature clock multiply, divide, and phase-shift PLLs, numerous DLLs, and dynamic glitch-free clock MUXs.

LatticeSCM LatticeSCM is a family of Lattice Semiconductor FPGA devices characterized by the same features as LatticeSC devices but that also include MACO (masked array for cost optimization): up to 12 embedded structured ASIC blocks per device with a variety of pre-engineered IP blocks.

LatticeXP LatticeXP (eXpanded Programmability) is a family of Lattice Semiconductor FPGA devices that combines the optimized FPGA architecture used in the LatticeEC (EConomy) family with the ispXP technology in a single low-cost chip. It is implemented on a low-cost, 130-nm flash process to provide instant-on, high-security, non-volatile, and reconfigurable features.

LatticeXP2 LatticeXP2 (eXpanded Programmability second generation) is a family of Lattice Semiconductor FPGA devices that combine a look-up table

(LUT)-based FPGA fabric with flash non-volatile cells in an architecture referred to as flexiFLASH. FlexiFLASH features instant-on, small footprint, on-chip storage with FlashBAK-embedded block memories and Serial TAG memory and design security. LatticeXP2 parts also support live updates with TransFR, 128-bit AES encryption, and dual-boot technologies. They include LUT-based logic, distributed and embedded memory, phase locked loops (PLLs), pre-engineered source synchronous I/O, and enhanced sysDSP blocks.

LBE LBE is an abbreviation for logic block editor, which is a module in EPIC that enables you to edit the logic of a selected component to one of its present configuration modes.

.lci The .lci file is the constraint file, a flat ASCII file that is used to specify optimization options and hardware-specific parameters and is read by the Diamond software.

ldbanno Ldbanno is a command-line program that distributes the physical design information back to the logical design to generate a timing simulation file. The ldbanno program back annotates physical information (for example, net delays) to the logical design and then writes out the back-annotated design in the desired netlist format. The ldbanno program is equivalent to the Design > Back Annotate Assignments command in Lattice Diamond.

.ldc An .ldc file is a constraint file used with the Lattice Synthesis Engine for integrated synthesis. The .ldc file uses the same constraint format as the Synopsys Design Constraint (SDC) language. An .ldc file can be edited in the LDC Editor as well as a text editor. See also “SDC” on page 2654 and “synthesis constraint file” on page 2660.

LDC Editor The LDC Editor is a Lattice Diamond application for editing Lattice Design Constraint (.ldc) files.

.ldf An .ldf file is a Lattice Diamond project file.

level-sensitive signal A level-sensitive signal is an input that only affects a function when it is at 1 or 0, and not when it transitions from one logic value to another. See also “edge-sensitive signal” on page 2619.

LFSR LFSR is an abbreviation for linear feedback shift register, which is a shift register with feedback from two or more points in the register chain. The points are called taps. LSFRs are particularly useful in encryption and decryption applications.

.lib The .lib file, is a collection of library elements compatible with most Lattice FPGA device families. Libraries of symbols can be managed using the Symbol Library Manager in Lattice Diamond.

library A library is a set of macros, such as adders, buffers, and flip-flops, used to create schematic designs.

Linux Linux is the UNIX operating system adapted to personal computers. See “UNIX” on page 2665.

load A load is the resistance, capacitance, or both associated with the inputs of one or more devices driven by an output.

lock constraint A lock constraint locks a component. A pin lock constraint specifies that the current routing cannot be changed or unrouted.

LogiBuilder LogiBuilder is a utility within the Lattice PAC-Designer software that allows you to define a power supply sequence controller and monitor or other control circuits using Power Manager or Platform Manager devices. See also “Power Manager” on page 2647 and “Platform Manager” on page 2646.

logic Logic is one of the three major classes of ICs in most digital electronic systems: microprocessors, memory, and logic. Logic is used for data manipulation and control functions that require higher speed than a microprocessor can provide.

logic analysis Logic analysis is the process of capturing digital data from a device so that you can observe the behavior of the signals and locate any failures in the device. It includes the ability to trigger on a complicated sequence of digital events, copy a large amount of digital data from the device under test through the device’s JTAG ports, and display the data in a graphical user interface.

logic analysis core A logic analysis core is a precharacterized piece of logic (intellectual property) specifically designed for logic analysis. See also “Reveal core” on page 2652.

Logic Block View Logic Block View is a view within the Lattice Diamond software that enables you to examine the logic details of one or selected components that have been placed and routed. Logic Block View can be accessed from Floorplan View, Physical View, and NCD View.

logic cell A logic cell is a predefined group of unconnected components that are replicated across the surface of a gate array. It is also called a basic cell. Sometimes PFUs are referred to as the logic cell because they are the major physical portion of the cell.

logic circuit A logic circuit is a set of components that performs a processing or controlling function.

logic element A logic element is a building block defining the logic in a design. These elements are typically primitives—that is, flip-flops, AND gates, OR gates, NOR gates, and so forth—or macros, which are higher-level combinations of primitives.

logic function A logic function is any Boolean logic expression or set of expressions implemented by using a single logic gate or a complex component containing many logic gates used on an integrated circuit.

logic gate A logic gate is the physical implementation of a logic function.

logic optimization Logic optimization is the process of decreasing the area or increasing the speed of a design.

logic synthesis Logic synthesis is the process of starting from a high level of logic abstraction (typically Verilog or VHDL) and automatically creating a lower level of logic abstraction using a library containing primitives.

logical diagram A logical diagram is a schematic that shows component connections with nets and other components in a functional or logical manner.

lookup table (LUT) A lookup table (LUT) is an architectural element within a LatticeECP/EC PFU for implementing combinational logic or memory.

.lpc The .lpc file is the Lattice Semiconductor parameter configuration file, which contains the configuration parameters that you selected in IPexpress.

.lpf The logical preference file (.lpf) is a post-synthesis source file for storing design constraints known as preferences. This file is automatically generated when you create a new project in Lattice Diamond, and it is used as input for developing and implementing the design. The .lpf file can be edited in one of Diamond's preference-editing views such as Spreadsheet View or in a text editor. See also "Spreadsheet View" on page 2657.

LSE See "Lattice Synthesis Engine" on page 2631.

LSR LSR is an abbreviation for a local set/reset signal. In LatticeECP/EC, LatticeXP, and LatticeSC devices, a low signal on the local set reset (LSR) input pin of the LSR component initializes all flip-flops and latches.

lumped capacitance Lumped capacitance is the total capacitance of a net or segment of a net.

LUT LUT is an acronym for lookup table. See "lookup table (LUT)" on page 2635.

LVDS LVDS is an acronym for low-voltage differential signaling, a high-speed, low-power data transmission standard. LVDS is standardized in the ANSI/TIA/EIA-644-1995 electrical characteristics standard. LVDS is a generic interface standard for high-speed data transmission.

LVPECL LVPECL is an acronym for low-voltage positive emitter-coupled logic. An LVPECL is a digital circuit composed of bipolar transistors in which the emitter ends are wired together. It uses a low-voltage power supply rather than the more common negative power supply.

M

MAC MAC is an acronym for multiply accumulates, which is the FIR operation of multiplying a coefficient by the corresponding delayed data sample and accumulating the result.

MachXO MachXO is a family of Lattice Semiconductor programmable logic devices that combines 256 to 2280 optimized look-up table (LUT) components with Lattice Semiconductor's ispXP technology. It provides high

pin-to-pin performance and instant-on associated with CPLDs and the flexibility of FPGAs. This family provides 73 to 271 I/Os with extensive package options in a low-cost device.

MachXO2 MachXO2 is a family of Lattice Semiconductor programmable logic devices that combines an optimized look-up table (LUT) architecture with 65-nm embedded Flash process technology. MachXO2 devices include hardened versions of commonly used functions such as User Flash Memory (UFM), I2C, SPI and timer/counter. Architectural features are included that help manage static and dynamic power consumption: programmable low swing differential I/Os and the capability of turning off I/O banks, on-chip PLLs, and oscillators dynamically.

MACO MACO is a technology that enables ASIC gates to be put into an FPGA device using a few layers of metal.

MACO block A MACO block is the portion of the MACO hard IP that is assigned to a MACO site. If the MACO IP consumes only one MACO site, the MACO block and MACO hard IP are the same.

MACO default timing model The MACO default timing model is the timing data for the MACO block boundary timing. It includes setup and clock_to_out based on conservative clock injection delay.

MACO hard HDL MACO hard HDL is the HDL that forms a MACO block.

MACO hard IP MACO hard IP is the portion of a MACO IP that is implemented using MACO technology.

MACO logical port A MACO logical port is the port MACO block. It is mapped to a MACO physical port (MACO site pin).

MACO physical port A MACO physical port is the pin on the MACO site.

MACO routing MACO routing is the dedicated routing to and from the MACO site. It is a fast but highly restrictive resource. There are three types: MACO_PIO_routing, MACO_EBR_routing, and MACO_FPGA_routing.

MACO site A MACO site is a physical site on the device where MACO hard IP gates can be placed.

MACO soft HDL MACO soft HDL is the portion of a MACO IP that is implemented using standard FPGA resources, such as PIOs, EBRs, SLICEs, or PLLs/DLLs. It refers to the minimum FPGA design required to interface to the MACO hard IP.

macro A macro is 1) a component composed of nets and primitives, flip-flops, or latches that implements high-level functions, such as adders, subtractors, and dividers. Soft macros and relationally placed macros (RPMs) are types of macros. 2) A control language built into ORCAstra that can be used to automate some operations. See also “ORCAstra” on page 2642.

macro instance A macro instance is a copy of a macro library file inserted in a design file. When you add a macro instance to a design you instantiate

the macro. A design may contain multiple instances of the same library file, and each will receive a unique name. Since the library file is copied into the design file when you instantiate a macro, if you then change the library file the changes will not be reflected in the macro instantiated in the design file. In the EPIC User's Guide, the word macro may be used instead of macro instance. A macro library file will always be referred to as a "macro library file." A macro can only be added if the design file and the macro library file you are adding are of the same device family.

macro library file A macro library file is a file containing the definition of a macro. Macro library files, which have an .nmc extension, are created and edited in EPIC, operating in macro mode. See also "physical macro" on page 2644.

macro mode Macro mode is the set of EPIC options available while you work on a physical macro. To be in macro mode, you must have a physical macro file (.nmc) loaded by either opening or creating one.

makefiles Makefiles are files in LatticeMico System that contain scripts that define what files the make utility must use to compile and link during the build process. There are many makefiles employed in the LatticeMico System build process. The makefile file is the application build makefile, calling all of the other makefiles that allow the generation and build of the platform library and for eventually generating the final executable image.

Manhattan routing Manhattan routing is rectilinear routing, that is, routing in which all the routing tracks are perpendicular to one other.

manual placement Manual placement is the process of placing components and macros in the EPIC Editing area by using the place command. When you use manual placement, you select both a source component or macro and the destination site in which to place the component or macro.

manual routing Manual routing is the process of routing the connections between components in the EPIC Editing area by using the route command. When you use the route command, you specify the path the signal routing will take by selecting the net pins or pinwires to be connected and the routing resources to be used (for example, long lines, local lines). After executing the command, the system routes the path you have specified.

map Map is a command-line program that maps a design to an FPGA. It is equivalent to the Map Design process in Lattice Diamond. The input to the map program is one or more EDIF netlists. The output is a physical design (.ncd file), which is a physical description of the components in the target architecture.

map register retiming Map register retiming is a technique for improving timing by moving registers across logic to shift the path delay from one side of a register to the other side.

mapping Mapping is the process of converting a design represented as a logical network of device-independent components, such as gates and flip-

flops, into a network of device-specific components, such as programmable functional units

master port A master port is a port that can initiate read and write transactions.

master symbol A master symbol is a schematic symbol used for title blocks, logos, revision blocks, and other standardized graphic symbols.

MATLAB/Simulink MATLAB/Simulink is a third-party tool from The Mathworks® that provides an interactive graphical environment and a customizable set of block libraries that enable you to accurately design, simulate, implement, and test control, signal processing, communications, and other time-varying systems.

maximum event counter The maximum event counter in Reveal Inserter and Reveal Logic Analyzer determines the maximum size of the count in the trigger expression. The count is how many times a sequence must occur before a THEN statement.

maximum sequence depth The maximum sequence depth is the maximum number of sequences that can be used in a trigger expression in Reveal Inserter and Reveal Logic Analyzer. Sequences are sequential states connected by THEN operators.

.mcs The .mcs file is a PROM-formatted configuration file in Intel MCS-86 format. It is generated when you run the PROM File process in Lattice Diamond or the promgen command-line program.

MCS-86 MCS-86 is a PROM file format from Intel.

.mem The .mem file is the memory initialization file in ASCII format that contains memory contents for a module. It is the input for FPGA module generation. It consists of lines of addresses with corresponding data, all in hexadecimal format. If a memory file is not used, all the RAM contents are initialized to 0. This file is invisible when you generate FPGA modules with IPexpress.

.men (epic) The .men (epic) file is a customizable EPIC menu bar and pull-down menu definitions file in $FOUNDRY/data, where $FOUNDRY is the path pointed to or defined by the $FOUNDRY environment variable.

Mico System Builder See “MSB” on page 2639.

.mif A .mif file is a memory image file output for FPGA module generation. It is used to initialize memory in SmartModels. This file is invisible when you generate modules with the IPexpress.

mixed mode Mixed mode describes operation in the digital and analog domains, such as mixed-mode simulation.

mixed-mode design Mixed-mode design is a design that consists of both schematic and non-schematic blocks.

mixed-signal Mixed-signal describes electronic circuits that include both analog and digital sections.

ModelSim ModelSim is a simulation tool from Mentor Graphics that supports Verilog and VHDL simulation and verification.

module A module is an expanded symbol generated from parameters representing the desired size and operating modes of the symbol.

MPARTRCE MPARTRCE is a multiple place and route (multi-PAR) program that uses a performance score for selecting the best place & route iteration. It is available from the command line.

.mrp The . mrp file is an FPGA report file that contains mapping information. The .mrp file lists any DRC errors found in the design and provides details about how the design was mapped (for example, the schematic constraints specified, the logic that was removed or added, and how signals and symbols in the logical design were mapped into signals and components in the physical design). The .mrp file is generated when you run the Map Design process in Lattice Diamond. See also “map” on page 2637.

.msb An .msb file is an XML-format file output by Mico System Builder (MSB).

MSB MSB is an abbreviation for Mico System Builder, which is an integrated development environment based on Eclipse for choosing components, such as a memory controller and serial interface, to attach to the Lattice Semiconductor 32-bit embedded microprocessor. It also enables you to specify the connectivity between these elements. MSB then enables you to generate a top-level design that includes the microprocessor and the chosen components. It uses the same graphical user interface as C/C++ SPE. See also “SPE” on page 2657.

multiplexer A multiplexer, or mux, is a device that combines several electrical signals into a single signal.

multiplexing/demultiplexing Multiplexing is the process by which two or more signals are transmitted over a single communications channel. Demultiplexing is the separation of two or more channels previously multiplexed.

mux Mux is an abbreviation of “multiplexer.” See “multiplexer” on page 2639.

N

.nam The .nam file is a binary waveform name file.

native circuit description file See “.ncd” on page 2640.

native generic database file See “.ngd” on page 2640.

.ncd An .ncd, or native circuit description, file is a binary-format FPGA post-map physical design database file that is generated by the Map Design process in Lattice Diamond. The .ncd file includes mapping information and, potentially, placement and routing information.

NCD View NCD View is a design view in Lattice Diamond that becomes available after a successful run of Place & Route. NCD View provides a categorized index of synthesized design resources and consumption based on the target device and the in-memory native circuit description (NCD) database.

net A net is 1) A logical connection between two or more symbol instance pins. After routing, the abstract concept of a net is transformed to a physical connection called a wire. 2) An electrical connection between components or nets. It can also be a connection from a single component. It is the same as a wire or a signal.

net check A net check is a physical DRC check in the EPIC software that examines one or more routed or unrouted nets and reports any problems with pin counts, tristate buffer inconsistencies, floating segments, antennae, and partial routes. It can be performed on selected objects or on all of the signals in the design. You can run the net check separately or together with the block check.

net name A net name is the name that identifies a net.

net pin A net pin is a pin that exists on a given net. When a component has been placed but has not yet been routed, the connection between that component's net pins (those pins on the net) and net pins from other components is logical, not physical. The pins are associated with each other, even though there is no electrical connection between them. In the EPIC tool's Editing area, these logical connections making up a net show up as ratsnest lines: direct point-to-point connections between net pins. When the net is routed, electrical connections are made between the net's net pins. In the Editing area, these routed connections appear as lines following the routing resources available on the device (long lines, pinwires, switch boxes, and so forth). See "pin" on page 2644 and "net" on page 2640.

netlist A netlist is an ASCII file describing the logical components in a design and how they are connected. It is basically a list of connectors, a list of instances, and, for each instance, a list of the signals connected to the instance terminals. In addition, the netlist contains attribute information.

Netlist View Netlist View is a design view available in Lattice Diamond that displays the design elements of a post-synthesis native generic database (NGD) netlist. It interacts with Package View for dragging and dropping selected signals to the desired locations on the pin layout to establish LOCATE preferences. See also "Package View" on page 2642.

network A network is a collection of logic elements and the wires (nets or connections) that define how they interconnect.

.ngd An .ngd, or native generic database, file is a binary-format FPGA pre-map logical design database file generated by the Translate Design process

in Lattice Diamond. The .ngd file represents the logical design information in the ASCII EDIF netlist.

ngdbuild Ngdbuild is a command-line program that, together with edif2ngd, converts netlists into a generic database that uses native primitive terms that the Lattice Diamond software can implement. It is equivalent to the Translate Design process.

.ngo An .ngo file is a native generic object file, a binary-format FPGA pre-map logical design database generated by the EDIF-to-NGD translation phase of the Translate Design process in Lattice Diamond. It contains all of the data in the input .ngd file, as well as information on the physical design produced by the mapping. The .ngo file typically represents one or more hierarchical branches of a larger logical design.

.nmc An .nmc file is an EPIC physical macro file. In addition to components and nets, the file can contain placement information, routing information, or both. See also “physical macro” on page 2644.

noise Noise is the appearance of unexpected voltage values on a net resulting from transitioning nets or circuitry and coupling through interconnect or substrate parasitics. Noise is usually high-frequency AC.

non-Manhattan routing Non-Manhattan routing is routing that is partially rectilinear but includes tracks that are not vertical or horizontal.

O

.o A .o file is a platform library object file in LatticeMico System that is the compiled output of the library source files. It is also the input for creating the platform library archive files.

octal Octal refers to the base 8 numbering system.

OEM OEM is an abbreviation for original equipment manufacturer, a company that purchases components made by other companies and assembles them into products resold under its own brand name.

one-hot encoding One-hot encoding is a type of state machine design that attempts to increase performance by simplifying decode logic. In one-hot encoding, an individual state register is dedicated to only one state. Only one flip-flop can be active, or hot, at a time. The bit position represents the value. For example, in state machine language, each state is assigned its own storage register (flip-flop), and only one state can be active at a time.

optimization Optimization is 1) The process of decreasing the area or increasing the speed of a design. 2) Part of the design implementation process in Lattice Diamond. The design is re-synthesized with the constraints that you specify.

optimizing placement Optimizing placement is the second stage of the placement process. In this stage, the results of the constructive placement are refined. The first stage of placement is called constructive placement.

ORCA ORCA is an acronym for optimized reconfigurable cell array, a type of FPGA from Lattice Semiconductor.

ORCAstra ORCAstra is a Lattice application that enables you to reconfigure and monitor FPGAs in development boards in real time. ORCAstra gives read and write access to registers that control FPGA configuration, PLLs and DLLs, and registers in logic. With this access you can experiment with different configurations and see the results immediately, without going through any of the design implementation processes.

P

PAC-Designer PAC-Designer is a set of Lattice design entry, simulation, and programming tools that support the Lattice ispPAC families of analog devices, including Power Manager, Platform Manager, and ispClock. See also “Power Manager” on page 2647, “Platform Manager” on page 2646, and “ispClock” on page 2629.

package A package is the ceramic or plastic housing in which an integrated circuit is sealed. Fine gold or aluminum wires connect the chip pads to the larger package pins.

Package View Package View is a view in Lattice Diamond that shows the pin layout of the device and displays the assignments of signals to device pins. Package View interacts with Netlist View for assigning pins, enabling you to drag selected signals to the desired locations on the pin layout to establish LOCATE preferences. See also “Netlist View” on page 2640.

.pad A .pad file is an FPGA report file containing a listing of all programmable interface cells (PIC) used in the design, their associated primary pins, and any assigned preferences. The .pad file is generated when you run the Place & Route process in Lattice Diamond.

pad A pad is a metallized area on an integrated circuit that connects the I/O circuits in the chip to the package or substrate with wires or solder balls. All signals on a chip must enter and leave by way of a pad. Pads are connected to package pins in order for signals to enter or leave an integrated circuit package.

.par A .par file is an FPGA report file generated by the Place & Route process in Lattice Diamond. It summarizes the information from all placement and routing iterations. It also shows the steps taken as the program converges on a placement and routing solution.

par Par is a command-line program that performs FPGA placement and routing. It is equivalent to the Place & Route Design process in the Lattice Diamond software. See also .

parameterized module A parameterized module is a core in which you can set the values of one or more inputs without having to regenerate the module. For example, you can specify the input bit width or whether to create RPMs.

parasitic capacitance Parasitic capacitance is any capacitance causing unwanted effects between conductors or in devices.

partitioning Partitioning is 1) The process of splitting a single design among multiple devices. 2) The maximum level of integration (density concern).

path A path is a connected series of nets and logic elements. A path has a start point and an end point that are different, depending on the type of path. The time taken for a signal to propagate through a path is referred to as the path delay.

path delay Path delay is the time it takes for a signal to propagate through a path.

pattern A pattern is a configuration of data values that defines what an event will be or how the event is recognized by the trigger logic of the Reveal core.

pattern comparator A pattern comparator is the part of the Reveal core that compares the input pattern to the sampled trigger bus data to see if they match. It is connected to a signal that goes from 0 to 1 to indicate that the comparator has made a match.

PCB PCB is an abbreviation for printed circuit board. See “printed circuit board” on page 2648.

.pcf A .pcf file is a Power Calculator project file.

PCM PCM is an abbreviation for programmable clock manager. It is a special function block that is used to modify or condition clock signals for optimum system performance. Some of the functions that can be performed with the PCM are clock-skew reduction, duty-cycle adjustment, clock multiplication, clock-delay reduction, and clock-phase adjustment. If you use PLC logic resources in conjunction with the PCM, many other functions, such as frequency synthesis, are possible.

PCS PCS is an abbreviation for physical coding sublayer, a device layer that is frequently used in defining physical layers for high-speed functions such as the 10 Gb Ethernet and for SERDES applications. The PCS supports advanced system level standards, including RapidIO, Sonet, Gigabit Ethernet, 10 Gb Ethernet, Fibre Channel, and PCI Express.

PCS SERDES PCS SERDES is an abbreviation for physical coding sublayer serializer/deserializer. It is the same as a SERDES. See “SERDES” on page 2655.

period A period is the number of steps in a clock pattern multiplied by the step size.

peripheral capacitance Peripheral capacitance, also called fringing capacitance, is the extra capacitance between the edges of the top plate of a parallel plate capacitor and its bottom plate.

perspective A perspective is a combination of windows, menus, and toolbars in the LatticeMico System graphical user interface that enables you to perform a particular task. For example, the Debug perspective has views that enable you to debug the programs that you created in C++ SPE.

PES PES is an abbreviation for programmer's electronic signature. See "programmer's electronic signature" on page 2649.

PFF PFF is an abbreviation for programmable function unit fast, which is a programmable function unit without RAM.

PFU PFU is an abbreviation for programmable function unit. See "programmable function unit (PFU)" on page 2649.

phase-locked loop A phase-locked loop (PLL) is an electronic circuit with a voltage- or current-driven oscillator that is constantly adjusted to match in phase and therefore lock on the frequency of an input signal. In addition to stabilizing a particular communications channel (keeping it set to a particular frequency), a PLL can be used to generate a signal, modulate or demodulate a signal, reconstitute a signal with less noise, or multiply or divide a frequency. PLLs are more commonly used for digital data transmission but can also be designed for analog information.

physical design file The physical design file is the same as an .ncd file. See ".ncd" on page 2640.

physical macro A physical macro is a logical function that has been created from components of a specific device family. Physical macros are stored in files with the .nmc extension. In addition to components and nets, the file can contain placement information, routing information, or both. A macro can be unplaced, partially placed, or fully placed, and it can also be unrouted, partially routed, or fully routed.

Physical View Physical View is a device layout view in Diamond that provides a more detailed small-component floorplan of your design and enables you to view components such as switch boxes and pin wires.

PIC PIC is an abbreviation for programmable interface cell. See "programmable interface cell (PIC)" on page 2649.

.pin A .pin file is a netlist file containing a generic netlist by pin.

pin A pin can be either a symbol pin or a package pin. A symbol pin, also referred to as an instance pin, is the connection point of an instance to a net. A package pin is a physical connector on an integrated circuit package that carries signals into and out of an integrated circuit.

pin layout file A pin layout file is a customizable report of pin information for a targeted Lattice device. The report is exported from Diamond's Spreadsheet View in delimiter-separated text format. The pin layout file can be as simple as

a list of available pins, pad names, functions, and banks; or it can include details such as differential polarity, type, user assignments, default attributes, and custom column information. You select the types of information you want included in the file, specify the order of presentation, and select the delimiter to be used as the value separator. The pin layout file can be viewed and edited in an external spreadsheet application; it can then be imported back in to Spreadsheet View.

pin migration Pin migration is the process of moving a design's pin assignments from the current device to a device that is compatible, usually a device a of the same package and family. The process involves finding out which pins in your current device will be unavailable or have different functions when you switch devices. Lattice Diamond makes this information available through the "Incompatible Pins" dialog box in Spreadsheet View and Package View.

pinout file A pinout file is a comprehensive report of all device pins in a Lattice targeted device, including available and unbonded pins. It is exported from Diamond's Spreadsheet View as a comma-separated value file (.csv) and can be examined in an external spreadsheet application.

pin-to-pin delay Pin-to-pin delay is delay that is contained within a logic function (intrinsic); that is, it is measured from the transition at the logic gate's input to its corresponding transition at that gate's output. Pin-to-pin delay often is mistakenly used interchangably with point-to-point delay.

PIO PIO is an abbreviation for programmable I/O cell. See "programmable I/O cell" on page 2649.

pipelining Pipelining is the insertion of additional pipeline registers to achieve better clock frequency. Clock latency is introduced in pipelining.

pitch Pitch is the center-to-center distance between two parallel wires on a layer at the closest spacing allowed by the design rules.

Place & Route Place & Route (PAR) is the post-map process in Lattice Diamond that assigns device-specific components to specific locations on the device floorplan and then establishes physical connections to join the components in an electrical network.

placer A placer is a software program that maps logic from a design into specific locations in the target FPGA chip.

placing Placing is the process of assigning the device-specific components produced by the mapping process to specific locations on the device.

platform See "hardware platform" on page 2625.

platform description file See ".msb" on page 2639.

platform library A platform library is a set of files in LatticeMico™ System that contain subroutine code referencing the necessary application files for linking during the build process.

platform library archive (.a) file See ".a" on page 2604.

platform library build The platform library build is an integral part of the managed build process in LatticeMico™ System. Another is the application build. The platform library files contain code that is necessary to the linking during the build process. The platform library build also outputs a platform library archive (<*platform*>.a) file that is referenced by the application build. It allows you to override any default software implementation.

platform library object file See ".o" on page 2641.

Platform Manager Platform Manager is a family of Lattice Semiconductor devices that features programmable analog, with CPLD and FPGA blocks all on one chip to integrate power and digital board management functions. Power management functions include MOSFET OR'ing, hot-swap control, power feed, supply sequencing, monitoring, trimming and margining functions. Digital board management functions include reset distribution, power-on configuration, I2C/SPI interface, fault logging, and glue logic. The Lattice PAC-Designer software is provided as the primary design entry tool for Platform Manager devices. See also "PAC-Designer" on page 2642.

platform settings file The platform settings file is the user.pref file that is generated during the build process in LatticeMico System. It contains information on the platform used by the current project.

PLC PLC is an abbreviation for programmable logic cell. See "programmable logic cell" on page 2649.

PLD PLD is an abbreviation for programmable logic device. See "programmable logic device" on page 2649.

PLL PLL is an abbreviation for phased-locked loop. See "phase-locked loop" on page 2644.

PMI PMI is an abbreviation for parameterized module interface, which is a method of generating the core description of a module or IP once in the HDL code, then changing parameter values in the HDL code when values need to be changed. It is an alternative to regenerating the module or IP whenever values need to be changed.

point-to-point delay Point-to-point delay is delay that occurs between driver gate and load gate (extrinsic); that is, it is measured from the output of the driver gate to the input of the load gate.

polarity Polarity is the orientation of a signal, either positive or negative.

POR POR is an abbreviation for power-on reset. See "power-on reset" on page 2647

POS POS is an abbreviation for product-of-sums. See "product-of-sums" on page 2649.

post-synthesis simulation Post-synthesis simulation is a type of simulation that is usually performed after the HDL code has been expanded

into gates. Post-synthesis simulation is similar to behavioral simulation, since it checks design behavior. The difference is that in post-synthesis simulation the synthesis tool's results are checked. If the post-synthesis and behavioral simulations match, the HDL synthesis tool has interpreted the HDL code correctly.

Power Calculator Power Calculator is a Lattice Diamond application that estimates the power dissipation for a given design. Power Calculator uses parameters such as voltage, temperature, process variations, air flow, heat sink, resource utilization, activity, and frequency, to calculate the device power consumption. It reports both static and dynamic power consumption.

Power Controller Power Controller is a low-power device architectural feature that ensures smooth transitions into and out of standby mode.

Power Guard Power Guard is a low-power device architectural feature that controls dynamic power consumption by blocking signals at the input buffers. Power Guard's biggest impact is in standby mode when it can be used to switch off clock inputs that are distributed using general routing resources.

Power Manager Power Manager is a Lattice Semiconductor family of devices that integrates common board power management functions into a single chip for a wide variety of microprocessors and DSPs. Power Manager devices can be programmed in-system through the JTAG interface. The power management algorithm can be designed using the PAC-Designer software. See also "PAC-Designer" on page 2642.

power-on reset Power-on reset is a device function that guarantees the state of all registers when the device's power is initially turned on. Power-on reset also refers to the circuitry that implements the reset.

PPR PPR is an abbreviation for programmable pullup resistors. See "programmable pullup resistor" on page 2649.

pre-placed component A pre-placed component is a component that is placed in a macro library file.

pre-routed net A pre-routed net is a net that is completely routed in a macro library file. When you instantiate a pre-routed macro into a design, the design may require a substantially longer time to place and route, depending on the route complexity.

Precision RTL Synthesis Precision® RTL Synthesis is a synthesis tool from Mentor Graphics that can be integrated into the ispLEVER suite. It supports logic synthesis for device designs in VHDL or Verilog.

preferences Preferences are constraints that guide the design toward performance goals. They include groups, locations, I/O types, and timing specifications. Preferences are interpreted by the design mapping and place-and-route phases of the flow to assign design logic to physical resources. They can be created and edited using Lattice Diamond's preference-editing views, or they can be created and edited manually in the logical preference file (.lpf) using a text editor.

.prf The .prf file is the physical preference file, an ASCII output of the Map Design process. Preferences saved in the logical preference file (.lpf) are written to the native circuit description (.ncd) and to the .prf file during the map process. The map process rewrites the physical preference file each time it is executed. The .prf file is used as an input file to placement and routing and TRACE.

PRF PRF is an abbreviation for programmable resistor fuses, which are the cells that select the programmable pullup resistors. The resistors are sometimes referred to as PRFs.

primitive A primitive is a basic gate or logic element, such as an AND, OR, XOR, NAND, or NOR gate; inverter; flip-flop; or latch that is a building block of complex logic functions, such as comparators, multiplexers, TBUFs, and decoders. 2) A logic element that directly corresponds, or maps, to one of these basic elements.

printed circuit board A printed circuit board (PCB) is a flat, insulated board of typically 2 to 10 layers to which chips and other electronic components are attached and connected by copper wiring. The main PCB in a system is called a “system board” or “motherboard,” and the smaller boards that plug into the slots in the main board are called “boards” or “cards.”

.prm A .prm file is an FPGA report file that shows address mapping information for generated PROM files. The .prm file is generated when you run the PROM File process in Lattice Diamond.

probing Probing is the process of examining the states of a device.

process A process is the running of concurrent logic blocks. The difference between hardware and software programming is that hardware programming is for concurrent processes and software programming is for linear processes.

process corners Process corners are the conditions under which an integrated circuit is manufactured, such as the temperature and voltage. Process corners are specified for fast, typical, and slow conditions to reflect the amount of current handled by the circuit, whether maximum, average, or minimum, respectively.

product term A product term is a wired NOR of E2 cells that functions as a large AND gate in a sum-of-products realization.

product term disable A product term disable is bits that render a product term permanently low voltage. It is simply a row of cells that are always selected in normal operation. These are different from miser bits that actually disable sense amplifiers to lower power consumption. See also “product term” on page 2648.

product term ground Product term ground (PTG) is the common ground terminal for a row of E2 cells. For most cells, it is not really at ground but is fed into the sense amplifier. On some cell configurations, PTG is also used for programming and verifying. Other cell types have a separate signal called progPTG for programming.

product-of-sums Product-of-sums (POS) is a method of logic representation where the outputs are the product of multiple summing terms. More simply, it is OR-AND logic. By inverting the inputs and outputs, it can be used to represent AND-OR logic for the purposes of reducing logic.

progPTG ProgPTG is the programming product term ground, which is the tunneling source for programming E2 cells.

programmable function unit (PFU) A programmable function unit (PFU) is a block within the LatticeECP/EC device that implements combinational logic, memory, and registers. The core of the architecture consists of PFU blocks that can be programmed to perform logic, arithmetic, distributed RAM, and distributed ROM functions.

programmable I/O cell A programmable I/O cell (PIO) is an architectural element within an FPGA that handles actual input and output functions.

programmable interface cell (PIC) A programmable interface cell (PIC) is a cell within the Lattice Semiconductor FPGA device architecture that contains a group of two PIOs. The edges of the architecture consist of PIC blocks that contain two PIOs connected to sysIO buffers. PICs provide high-speed I/O registers and buffering to support a variety of signal interface standards.

programmable logic cell A programmable logic cell (PLC) is a cell containing four slices to which logic components can be assigned. PLCs are distributed uniformly across an FPGA.

programmable logic device A programmable logic device (PLD) is a prefabricated programmable device containing different types of logic circuits that can be connected in accordance with your specifications. CPLDs and FPGAs are classes of PLDs.

programmable pullup resistor A programmable pullup resistor (PPR) is an internal pullup resistor on device input and output pins that can be turned on or off by programming E2 cells known as programmable resistor fuses, or PRFs. The two terms are frequently used interchangeably.

programmable read-only memory Programmable read-only memory (PROM) is a permanent memory device that is programmed by the customer rather than by the device manufacturer. It differs from a ROM, which is programmed at the time of manufacture. PROMs have been mostly superseded by EEPROMs, which can be reprogrammed.

Programmer Programmer is a tool that supports serial, concurrent (turbo), and microprocessor programming of Lattice devices in PC and Linux environments. Device chains can be scanned automatically using the Programmer graphical user interface. Programmer is integrated into the Diamond software environment, and is also available in a standalone version.

programmer's electronic signature A programmer's electronic signature (PES) is an internal storage area that provides programming parameters to the programming software. On HD devices, this is only necessary for pLSI (non-ISP) devices.

project A project is a collection of all files that are necessary to create and implement a design and download it to the selected device. Each project in Lattice Diamond has a directory, device family, device, and a set of implementations (versions) and strategies. The strategy associated with a given implementation contains options that enable the Lattice Diamond software to display and run the processes appropriate for the targeted device and design flow. In LatticeMico System, a project is the software application code written in C/C++ SPE.

project settings file A project settings file is an .xml file in LatticeMico called settings.xml, which contains information about the parent project and its settings, as well as information on the platform referenced by the parent project.

PROM PROM is an acronym for programmable read-only memory. See “programmable read-only memory” on page 2649.

PROM file A PROM file is a file consisting of one or more bitstream files formed into one or more data streams. The file is formatted in one of three industry-standard formats: Intel MCS86 HEX, Tektronics TEKHEX, or Motorola EXORmacs. The PROM file includes headers that specify the length of the bitstreams, as well as all the framing and control information necessary to configure the FPGAs. It can be used to program one or more devices.

promgen Promgen is a command-line program that converts one or more bitstreams into a PROM-formatted file for PROM configuration. It is the equivalent of the PROM File process in Lattice Diamond. The process takes one or more bitstreams files (.bit or .rbt) and creates a PROM image of the bitstream for PROM configuration. When bitstream files are converted to PROM-formatted files (.mcs, .exo, or .tek), the process will also yield a .prm file or PROM image file that includes a memory map to program the PROM.

propagation delay Propagation delay (symbolized by tpd) is the time required for a digital signal to travel from the inputs of a logic gate to the output. If all other factors are held constant, the average propagation delay in a logic-gate IC increases as the complexity of the internal circuitry increases. Propagation delay has a direct effect on the speed at which a digital device, such as a computer, can operate.

PT PT is an abbreviation for product term. See “product term” on page 2648.

PTD PTD is an abbreviation for product term disable. See “product term disable” on page 2648.

PTG PTG is an abbreviation for product term ground. See “product term ground” on page 2648.

pull-down resistor A pull-down resistor is a device or circuit used to reduce the output impedance of a device. It is often a resistor network that holds a device or circuit output at or less than the zero input level of a subsequent digital device in a system.

pull-up resistor A pull-up resistor is a device or method used to keep the output voltage of a device at a high level. It is often a resistor network connected to a positive supply voltage.

PUR PUR is an abbreviation for power-up set/reset (PUR) signal that, for LatticeECP/EC, LatticeXP, and LatticeSC devices, resets the device on power up as a reset and is active high.

Q

Questa Questa is a simulation tool from Mentor Graphics that supports Verilog and VHDL simulation and verification.

R

radix A radix is the base value in a numbering system. For example, in the binary numbering system, the radix is 2.

RAM RAM is an acronym for random-access memory. See “random-access memory” on page 2651.

random-access memory Random-access memory (RAM) is a read/write memory that has an access time independent of the physical location of the data. RAM can be used to change the address values of the function generator that it is a part of.

ratsnest Ratsnest refers to the straight point-to-point lines (flight lines) that indicate connectivity between logic placed on the floorplan.

.rbt An .rbt file is raw bitstream file, which is an FPGA file containing ASCII ones and zeros representing the bits in the bitstream file. If you are using a microprocessor to configure a single FPGA, you can include the RBT file in the source code as a text file to represent the configuration data. The sequence of characters in the RBT file is the same as the bit sequence that will be written into the FPGA. The raw bitstream file differs from the binary bitstream file (.bit) in that it contains design information in the first six lines.

.rcv An .rcv file is an ASCII-based EPIC recovery file.

RC extraction RC extraction is the process of computing an electronic circuit’s resistance and capacitance.

read-only memory Read-only memory (ROM) is a memory chip that permanently stores instructions and data. It retains a state indefinitely, even when the power is turned off. It can be part of a function generator.

rectification Rectification is the process of converting alternating current (AC) to direct current (DC).

reference component A reference component is a component in the macro library file used as a reference when a macro instance is placed, moved, or copied. Placement and routing of all other pre-placed macro components are determined relative to this component. If at least one of the macro's components is pre-placed, the macro will have a reference component. If none of the macro components are pre-placed, the macro will not have a reference component.

region A region is a specified area of the design that is set aside for the placement of physical groups.

register A register is a set of flip-flops in a chip used to store data. It is an accumulator used for all arithmetic operations.

register-transfer level Register-transfer level (RTL) is a high-level hardware description language (HDL) for defining digital circuits in terms of the data flow between registers. It describes circuits as a collection of registers, Boolean equations, control logic, and complex event sequences. VHDL and Verilog are examples of RTL.

Reports View Reports View is a Lattice Diamond application for viewing, but not editing, the various report files generated by the Lattice Diamond software.

resistance Resistance is opposition that a material has to current flow and the resulting dissipation of energy in the form of heat. Resistance is expressed in ohms.

resistor A resistor is an electrical component that limits the flow of current through resistance or impedance. It allows a specific amount of current to flow, as determined by the voltage applied to it.

retiming Retiming is logic optimization to balance the logic (levels) among register pairs to maximize the clock rate.

Reveal core A Reveal core, also called a logic analysis or debugging core, is a precharacterized piece of logic (intellectual property) specifically designed for logic analysis.

Reveal Inserter Reveal Inserter is an application for FPGAs that enables you to select which design signals to use for debug tracing or triggering, then generates a core on the basis of these signals and their usage. After generating the required core, it generates a modified design with the necessary debug connections and links it to the signals.

Reveal Analyzer Reveal Analyzer is a Lattice Diamond application for FPGAs that enables you to capture and examine signals internal and external to the design. It enables you to set trigger configurations and extract Reveal information from a programmed device through the JTAG ports. Its graphical user interface allows you to trace signals and buses in a waveform viewer.

RF RF is an abbreviation for radio frequency, which refers to 1) That portion of the electromagnetic spectrum used for communications 2) The circuitry used to work with high-frequency signals.

rise time Rise time is the time it takes for the leading edge of a pulse to rise from 10 percent of its peak voltage to 90 percent of its peak voltage.

rising edge A rising edge is a signal transition from a logic 0 to a logic 1. It is also called a positive edge.

ROM ROM is an acronym for read-only memory. See “read-only memory” on page 2651.

route-through A route-through is a net that passes through a logic block.

router A router is a software program that connects all appropriate pins to create the design’s nets.

routing Routing is the process of assigning logical nets to physical wire segments that interconnect logic cells in the device.

RTL RTL is an abbreviation for register-transfer level. See “register-transfer level” on page 2652.

Run Manager Run Manager is a Lattice Diamond application that enables you to run multiple implementations (versions) of your design project and compare the results. You can use Run Manager to run multiple synthesis and place and route passes, monitor the progress, view reports, and identify the best implementation.

running Running is the process of executing a software program.

.rva The .rva file is output by Reveal Analyzer. It contains the project name, the core configuration trace and trigger signals, the trigger and event settings, and the Reveal chain acquisition data. This file is also an input file when you re-open a project that you previously saved.

.rvl An .rvl file is a Reveal Inserter project file, which contains the connections for each core and all the settings of the debugging logic.

.rvs An .rvs file is a Reveal Inserter project file, which contains the connections for each core and all the settings of the debugging logic.

Rx channel An Rx channel is the receive channel in a PCS SERDES.

S

sample A sample is a trace data value captured from the trace bus and written into the trace memory in Reveal.

saturation logic Saturation logic is logic in which the transistors are operating at or beyond their fully conducting state.

_sc A -sc file is a Schematic Editor log file.

scan chain A scan chain, or scan shift register, is a set of scannable flip-flops, or scan cells, linked in a chain for testing purposes.

scan net A scan net is a net whose pins are all scan pins.

.sch An .sch file is a Schematic Editor file.

schematic A schematic is a drawing representing a design in terms of user and library components.

Schematic Editor Schematic Editor is an application that enables you to create and edit schematic files that can represent a complete design or any component of a hierarchical design.

Schmitt trigger A Schmitt trigger is a type of comparator circuit that forces certain input signals to conform to the shape of true digital signals, or waveforms, before passing them to other parts of the logic circuit: signals with slow rise times, slow fall times, or both; noisy signals; or analog signals. The trigger for this circuit to change states is the input voltage level. The Schmitt trigger uses two voltage thresholds, a high threshold during low-to-high transitions, and a low threshold during high-to-low transitions. It changes its output state only when the input voltage level rises above the higher threshold, then uses hysteresis to prevent the output from automatically switching back until the input voltage level goes below the lower voltage threshold. A Schmitt trigger stabilizes a circuit by preventing noise from triggering rapid switching back and forth between the two output states when the inputs are close to the threshold.

.scr An .scr file is an ASCII-based EPIC command script file.

script A script is a series of commands that automatically execute a complex operation, such as the steps in a design flow. See also “JScript” on page 2630 and “VBScript” on page 2666.

.sdf An .sdf file is an industry-standard file format for specifying timing information. It is usually used for simulation. It is required by ModelSim / Questa for timing simulation.

SDC SDC is Synopsys’ widely used design constraints format that describes the design intent and surrounding constraints for synthesis, clocking, timing, power, test, and environmental and operating conditions. The Lattice Synthesis Engine can read and process SDC. See also “.fdc” on page 2621 and “.ldc” on page 2633.

SDF SDF is an abbreviation for standard delay format. See “.sdf” on page 2654.

SDR SDR is an abbreviation for single data rate, a memory interface in an SDRAM that captures data on one edge of the clock.

SDRAM SDRAM is an abbreviation for synchronous dynamic random-access memory, which is a type of dynamic random-access memory (DRAM) that can run at much higher clock speeds than conventional memory.

sequence depth The sequence depth is the number of sequences used in a trigger expression in Reveal Inserter and Reveal Analyzer. Sequences are sequential states connected by THEN operators.

sequential function A sequential function is a logic circuit whose output values depend on both its current input values and on a sequence of previous input values. See also “combinational function” on page 2612.

sequential logic Sequential logic is a logic network that is built around flip-flops. Examples of sequential circuits are counters and state machines. Sequential logic circuits are not necessarily synchronous just because they contain clocked elements.

SERDES SERDES is an abbreviation of serializer/deserializer, which is an integrated circuit transceiver that converts serial data to parallel data, and parallel data to serial data. SERDES devices are used in telecommunications systems to facilitate the transmission of parallel data between two points over serial streams, reducing the number of data paths and therefore the number of connecting pins or wires required.

serial boot PROM A serial boot PROM is a method of configuring a Lattice Semiconductor FPGA at startup.

serial PROM A serial PROM is a PROM that is read one bit at a time. See also “programmable read-only memory” on page 2649.

set/reset Set/reset is an operation made possible by the asynchronous set/reset property. This function is also implemented by the global reset STARTUP primitive.

setup time Setup time is the period before the clocking edge during which the data input to a latch or flip-flop must be held constant in order to guarantee that the latched data is correct.

sheet A sheet is a page of a schematic.

shift register A shift register is a register in which data is loaded in parallel and shifted out of the register again. It refers to a chain of flip-flops connected in cascade.

sidewall capacitance Sidewall capacitance is the same as lateral capacitance. See “lateral capacitance” on page 2631.

signal A signal is a wire or a net. See also “net” on page 2640.

signal integrity Signal integrity is a signal’s freedom from noise and unpredictable delay caused by increasing coupling capacitance between neighboring signals.

signature a digital signature guarantees the authenticity of an electronic document of message in digital communication and uses encryption techniques to provide proof of original and unmodified documentation.

simulation Simulation is the process of verifying the logic and timing of a design.

simultaneously switching outputs (SSOs) Simultaneously switching outputs (SSOs) are multiple output drivers that change state at the same time, which can result in power supply disturbances or noise.

site A site is an unused or vacant resource on a device where a component can possibly be placed.

skew See “clock skew” on page 2612.

skin effect The skin effect is the tendency of alternating current to flow near the surface of a conductor.

slack Slack is the difference between the expected delay and the required delay. A positive slack time in a static timing analysis report indicates that the delay is acceptable, but a negative slack time indicates that the timing of the design does not meet the timing requirements.

slave port A slave port is a port that cannot initiate transactions but can respond to transactions initiated by a master port if it determines that it is the targeted component for the initiated transaction.

slew rate The slew rate is the speed with which the output voltage level transitions from low to high or high to low. The slew rate determines how fast the transistors on the outputs change states.

slice A slice is an architectural element within an FPGA consisting of two LUT4 lookup tables that feed two registers (programmed to be in FF or latch mode) and some associated logic that allows the LUTs to be combined to perform functions such as LUT5, LUT6, LUT7, and LUT8. It also includes control logic to perform set/reset functions (programmable as synchronous/asynchronous), clock select, chip select, and wider RAM/ROM functions. The registers in the slice can be configured for positive or negative and edge or level clocks. There are four interconnected slices per PFU block. Each slice in a PFU is capable of four modes of operation: logic, ripple, RAM, and ROM. Each slice in the PFF is capable of all modes except RAM.

slope Slope is the same as the slew rate. See “slew rate” on page 2656.

SoC SoC is an abbreviation for system-on-a-chip, which is an integrated circuit that includes all the components of a computer: microprocessors, memories, logic, and I/O interfaces.

soft macro A soft macro is the logical design that determines how logical elements are interconnected functionally, but not the physical or actual wiring pattern on a chip. A soft macro can be altered with a simple text editor. Such macros are provided in synthesizable Verilog or VHDL. But it is virtually impossible for the IP provider to predict the timing of the macro, even if the customer does not modify it. The process of placement and routing is simply too unstable. See also “hard macro” on page 2625.

software application code The software application code is the code that runs on the LatticeMico32 microprocessor or LatticeMico8 microcontroller to control the components, the bus, and the memories. The application is written in a high-level language such as C++.

SOP SOP is an abbreviation for sum-of-products, a method of logic representation in which the outputs are the sum of multiple product terms. More simply, it is AND-OR logic.

Source Editor Source Editor is a Lattice Diamond application that enables you to create and edit text-based files, such as HDL files, test stimulus files, and project documentation files.

SPE SPE is an abbreviation for Software Project Environment, one of the integrated environments of LatticeMico System. The Lattice Software Project Environment enables you to develop the C or C++ application code that runs on platforms created with Mico System Builder (MSB), use the debugger to validate the code, and deploy the application code to on-chip or flash memory. SPE uses a GNU C/C++ tool chain (compiler, assembler, linker, debugger, and other utilities such as objdump) optimized for the LatticeMico process. It uses the same graphical user interface as Mico System Builder (MSB).See also “LatticeMico System” on page 2632 and “MSB” on page 2639.

speed grade The speed grade specifies the frequency of the internal clock of a design. The higher the number is, the faster the clock speed. For example, -5 is faster than -3, and 5 is faster than 3.

.spf An .spf file is a simulation project file, a script file produced by the Diamond Simulation Wizard. The .spf script file enables you to run the simulator for your project from Diamond.

SPI SPI is an acronym for serial peripheral interface, a core that allows high-speed synchronous serial data transfers between microprocessors, microcontrollers, and peripheral devices. It can operate either as a master or as a slave.

SPI serial flash SPI (serial peripheral interface) serial flash is a method of configuring a Lattice Semiconductor FPGA at startup.

SPICE SPICE is an acronym for Simulation Program with Integrated Circuit Emphasis, which is a simulation program originally developed at UC Berkeley as a transistor-level circuit simulator. It is now often used to refer to any transistor-level circuit simulator.

SPLD SPLD is an abbreviation for simple programmable logic device, which is a PLD with fewer than 1000 gates. It is also known as a low-density PLD.

Spreadsheet View Spreadsheet View is the main application in Lattice Diamond for creating and editing design constraints known as preferences. Spreadsheet View includes separate sheets for Port Assignments, Pin Assignments, Clock Resource, Route Priority, Cell Mapping, Global Preferences, Timing Preferences, Group, and Misc Preferences. Preferences are written to the logical preference file (.lpf), and can also be edited in a text editor. See also “.lpf” on page 2635.

Spreadsheet View – TPF Spreadsheet View – TPF is a Lattice Diamond application that enables you to modify timing preferences for the purpose of experimentation and timing analysis. It is a part of Diamond's Timing Analysis View and contains sheets for Global Preferences, Timing Preferences, and Group. When you make timing preference changes, the modifications are written to a timing preference file (.tpf). You can create multiple .tpf files and access them from the Analysis Files folder of Diamond's File List view. See also "Timing Analysis View" on page 2662

SRAM SRAM is an abbreviation for static random-access memory. See "static random-access memory" on page 2659.

SRL SRL is an abbreviation for shift register latch, a serial shift register used to access the programming circuitry in Lattice Semiconductor devices.

SSO See "simultaneously switching outputs (SSOs)" on page 2656.

STA See "static timing analysis" on page 2659

standard cell A standard cell is a completed design for a logic function on an integrated circuit. The function can be as simple as a clock circuit or as complex as a microcoprocessor. Since standard cells are made using blank wafers rather than partially fabricated wafers, they are more efficient than gate arrays but more costly.

standard delay format See ".sdf" on page 2654.

standard encoding Standard encoding is a type of state machine encoding that forms clusters of states and uses binary encoding for each cluster. One-hot encoding is a special case of standard encoding in which each cluster contains exactly one state. Binary encoding is a special case in which all states belong to a single cluster.

STAPL STAPL is an abbreviation for Standard Test and Program Language. A STAPL file is an output data file generated from a JEDEC input file by the Lattice Deployment tool. See also "Deployment Tool" on page 2616.

state A state is the set of values stored in the memory elements of a device that represent the state of that device at a particular point. To each state there corresponds a specific set of logical values.

state diagram A state diagram is a pictorial representation of the outputs and required inputs for each state transition, as well as the sequencing between states. Each circle in a state diagram contains the name of a state. Arrows to and from the circles show the transitions between states and the input conditions that cause state transitions. These conditions are written next to each arrow.

state machine A state machine is a set of combinatorial and sequential logic elements arranged to operate in a predefined sequence in response to specified inputs. The hardware implementation of a state machine design is a set of storage registers (flip-flops) and combinatorial logic, or gates. The storage registers store the current state, and the logic network performs the operations to determine the next state.

static random-access memory Static random-access memory is a device that holds a value as long as power is continually supplied. It loses its contents when the power is turned off. It is sometimes called volatile memory.

static timing analysis Static timing analysis (STA) is the process of verifying circuit timing by totaling the propagation delays along paths between clocked or combinational elements in a circuit. The analysis can determine and report timing data such as the critical path, setup- and hold-time requirements, and the maximum frequency. The primary advantage of timing analysis is that it can be run at any time and requires no input test vectors, which can be very time-consuming and tedious to create. Although timing analysis does not give you a complete timing picture, it is an excellent way to quickly verify the speed of critical paths and identify performance bottlenecks. See also "timing simulation" on page 2662.

static timing analyzer A static timing analyzer is a tool that analyzes the timing of the design on the basis of its paths. See also "TRACE" on page 2663 and "Timing Analysis View" on page 2662.

Steiner tree A Steiner tree is the shortest route for connecting a set of pins.

strategy In Lattice Diamond, a strategy is a collection of settings for controlling the different stages of the design implementation process, including logic synthesis, mapping, and place and route. Each implementation (version) of a design project in Lattice Diamond is associated with a specific strategy. A default strategy, Strategy1, is automatically assigned to a new project. A strategy can also be a predefined strategy or a customized strategy, and any number of them can be applied to a project to find the best solution to meet design objectives. See also "implementation" on page 2627.

.sty An .sty file is a Lattice Diamond strategy file.

.svf An .svf file is a file in serial vector format, which is a software language that is tailored to drive test access port controllers. An .svf file is an ASCII file that stores programming data for programming one or more fixed algorithm devices in automatic test equipment-type programming environments.

SVF SVF is an abbreviation for serial vector format, which is a software language that is tailored to drive test access port controllers. See also "TAP" on page 2661.

SWL SWL is an abbreviation for soft-wired lookup table, which is a fast, programmable connection between the LUTs in an PFU that allows for very wide combinational functions. See also "lookup table (LUT)" on page 2635.

_sy A -sy file is a Symbol Editor log file.

.sym An .sym file is a Symbol Editor file.

symbol A symbol is a graphical representation of one level of hierarchy.

symbol attributes Symbol attributes are characteristics or properties associated with a symbol.

Symbol Editor Symbol Editor is an application that comes with a standard symbol library. Use Symbol Editor to create symbols or primitive elements that represent an independent schematic module. You can also use Symbol Editor to create decorative symbols, such as title blocks.

symbol origin The symbol origin is the point on a symbol that attaches to the cursor when the symbol is placed in Schematic Editor.

symbolic state machine A symbolic state machine is a state machine that makes no reference to the actual values stored in the state register for the different states in the state table. The software determines what these values should be. All that is defined in a symbolic state machine is the relationship among the states in terms of how input signals affect transitions between them, the values of the outputs during each state, and in some cases, the initial state.

synchronous Synchronous describes an entity that is synchronized to a shared signal like a clock.

synchronous clock A synchronous clock is a synchronous control in which flip-flops are set or reset on the rising edge of the clock.

Synplify Pro for Lattice Synplify Pro® for Lattice is a synthesis tool from Synopsys that is integrated into the suite of the Diamond software tools. It supports logic synthesis for device designs in VHDL or Verilog. It can be invoked from the main window or run as a stand-alone process. Synplify starts with high-level designs written in Verilog or VHDL hardware description languages (HDLs) and converts the HDL into small, high-performance design netlists that are optimized for Lattice Semiconductor devices.

synthesis Synthesis is the process of translating a high-level RTL design description (which might consist of state machines, truth tables, Boolean equations, or all three) into a process-specific gate-level implementation.

synthesis constraint file A synthesis constraint file is a source file that describes the design intent and surrounding constraints for synthesis, clocking, timing, power, test, and environmental and operating conditions. See also “SDC” on page 2654, “.fdc” on page 2621, and “.ldc” on page 2633.

synthesis package A synthesis package is a fixed library of cells, with each cell containing the implementation details in terms of primitive logic.

sysCLOCK sysCLOCK is a Lattice PLL and DLL technology for managing clock distribution and skew to improve overall system performance. See also “PLL” on page 2646 and “DLL” on page 2617.

sysCONFIG sysCONFIG is a Lattice Semiconductor interface that provides multiple configuration modes, as well as the dedicated ispJTAG port and boundary scan, so that configuration memory can be loaded automatically at power-up, or any time that you want to update the device.

sysDSP sysDSP is a Lattice DSP block used to develop digital signal processing functions.

sysI/O sysI/O is a Lattice I/O buffer that supports a variety of single-ended and differential signaling standards, as well as the DQS strobe signal that is required for interfacing with the DDR memory.

sysMEM sysMEM is a Lattice embedded block RAM that can operate as single-port or dual-port RAM.

T

TAP TAP is an acronym for test access port, which is a four-wire serial interface port used in boundary scan. See also "boundary scan" on page 2608.

TAP controller A TAP controller is a state machine with 16 possible states that controls operations associated with boundary scan cells. The basic operation is controlled through four pins: Test Clock (TCK), Test Mode Select (TMS), Test Data In (TDI), and Test Data Out (TDO). The TCK and TMS pins direct signals between TAP controller states. The TDI and TDO pins receive the data input and output signals for the scan chain. Optionally, a fifth pin, TRST, can be implemented as an asynchronous reset signal to the TAP controller.

TBUF A TBUF is an abbreviation for a tristate buffer, or 3-state buffer. It is a special logic gate that can output three different states: 0, 1, or Z. It is based on a standard buffer, with a control input called an enable added to the logic configuration.

TCK TCK is an abbreviation for the Test Clock pin, one of the pins that controls operations associated with boundary scan cells.

Tcl Tcl is an abbreviation for Tool Control Language, an interpreted string-command language that can be used for a wide range of functions, including manipulating text, creating variables, building loops, developing functions, and making operating system function calls.

TDI TDI is an abbreviation for the Test Data In pin, one of the pins that controls operations associated with boundary scan cells.

TDM TDM is an abbreviation for time division multiplexing, which is a technology that transmits multiple signals simultaneously over a single transmission path. Each lower-speed signal is merged into one high-speed transmission.

.tdo The .tdo file is a batch file output by ModelSim/Questa.

TDO TDO is an abbreviation for the Test Data Out pin, one of the pins that controls operations associated with boundary scan cells.

TekHex TekHex is a PROM file format from Tektronix.

Template Editor Template Editor is a feature of the Lattice Diamond Source Editor application. The Template Editor provides a library of system templates that you can insert into a source file. It also enables you to add your own customized templates to a User Templates folder.

test bench A test bench is a VHDL test stimulus file that specifies the input waveforms for simulation. You can manually create a VHDL test bench file (*.vhd), use a VHDL test bench template file (*.vht), or export a VHDL test bench file with the Waveform Editor. See also “Waveform Editor” on page 2667.

test vector A test vector is a set of input stimulus values and corresponding expected outputs that can be used with both functional and timing simulators.

thermal impedance model A thermal impedance model is a feature of Power Calculator that helps calculate the thermal impedance for a given device when it is mounted on the board. A thermal impedance model covers scenarios related to board sizes, air flows, and heat sinks.

Theta JA Theta JA is a measurement of the thermal impedance between the silicon die and the ambient air within a JEDEC-defined environment. See also “Effective Theta JA” on page 2619.

threshold A threshold is the crossover point when something occurs or is observed or indicated. The CMOS threshold and TTL threshold are examples.

tick A tick is one clock cycle.

Timing Analysis View Timing Analysis View is a Lattice Diamond graphical user interface for the static timing analysis program, TRACE. Timing Analysis View’s main window allows you to view the path delay tables and TRACE report of your timing preferences after placement and routing. Additionally, Timing Analysis View includes a TPF version of Spreadsheet View, which allows you to experiment with different sets of timing preferences through the use of timing preference files (.tpf). See also “Spreadsheet View – TPF” on page 2658.

timing closure Timing closure is the iterative process of identifying timing problems in a design, correcting them, and rechecking the design until the timing is optimal.

timing preference A timing preference is an attribute assigned to a path that specifies a timing requirement.

timing simulation Timing simulation is a method of verifying that the timing of a digital design meets your requirements. It gives you detailed information about gate delays and worst-case circuit conditions. Because total delay of a complete circuit depends on the number of gates the signal sees and on the way the gates have been placed in the device, timing simulation can only be run after the design has been implemented. See also “static timing analysis” on page 2659.

TMS TMS is an abbreviation for the Test Clock pin, one of the pins that controls operations associated with boundary scan cells.

.tokens Tokens are labels that you can assign to trigger unit values in Reveal Inserter and display on the waveforms in the Waveform View tab of Reveal Analyzer. These labels identify all bus values the same way for clarity, without regard to the radix notation in which the values appear.

token set A token set is multiple tokens that apply to a specific bus in Reveal Analyzer. You can define multiple token sets in Reveal Inserter so that you can use different radixes for different buses in Reveal Analyzer.

top-down design Top-down design is a hierarchical design methodology that starts a design with the highest level of abstraction and gradually designs underlying blocks until the complete design is implemented in the target technology. Top-down design is often technology-independent at the highest levels of design abstraction. This methodology enables you to focus on the functions (and their interaction) rather than on the device that implements them. At the same time, you are free to view or modify an individual module.

top-level file The top-level file is the main file of a Lattice Diamond design. It contains design control information and either design equations or references to include files containing design equations.

.tpf A .tpf file is a timing preference file that is used with Lattice Diamond's Timing Analysis View for the purpose of timing analysis and experimentation. See also "Timing Analysis View" on page 2662.

.tpl A .tpl file is a Text Editor template file.

TRACE TRACE is an acronym for timing reporter and circuit evaluator, an FPGA application that provides static timing analysis based on timing preferences. TRACE performs two major functions: 1) Timing verification, which is the process of verifying that the design meets your timing preferences 2) Reporting, which is the process of enumerating input preference violations and placing them into an accessible file. TRACE can be run on completely placed and routed designs or on designs that are placed and/or routed to any degree of completion. The report issued by TRACE depends on the completeness of the placement and routing of the input design. See also ".twr" on page 2665.

trace control block The trace control block is the part of a Reveal core that controls the writing of the data values into the trace memory around the trigger events.

trace frame A trace frame is the same as a sample in Reveal. See "sample" on page 2653.

trace memory The trace memory is where the data samples captured at the rising edge of the sample clock are stored in the Reveal core.

transceiver A transceiver is an electronic device or circuit that both transmits and receives analog or digital signals.

transistor A transistor is a semiconductor device that allows or prevents current flow between two terminals, as determined by the voltage or current delivered to a third terminal. It can be used as an amplifier or an electronic

switch. The two major types of transistor are the field-effect transistor (FET) and the bipolar junction transistor (BJT).

transition time The transition time is the same as the slew rate. See “slew rate” on page 2656.

translation See “design translation” on page 2616.

trce Trce is a command-line program that generates reports that can be used for static timing analysis. It is equivalent to the Map Trace and Place & Route Trace processes in Lattice Diamond.

trigger A trigger is a specific state or range of states that causes a trace to be stored for review and debugging in Reveal Analyzer.

trigger expression A trigger expression is a combinatorial or sequential equation of trigger units or both used in Reveal Inserter and Reveal Analyzer.

trigger out A trigger out is a trigger output signal in Reveal Inserter and Reveal Analyzer. It can be a signal in a core that can be connected to the trigger input signal of another core or an I/O signal that can trigger outside the chip or both.

trigger unit A trigger unit is the mechanism for defining the trigger signals and conditions that initiate the collection of data on the trace signals for each logic analysis core in Reveal Inserter and Reveal Analyzer. A trigger unit consists of the signals in the trigger bus, a comparator, a value representing the desired pattern of highs and lows on each trigger bus, and a radix for this value.

tristate A tristate is a buffer that places an output signal in a high-impedance state to prevent it from contending with another output signal.

tristate buffer A tristate buffer is the same as TBUF. See “TBUF” on page 2661.

TRST TRST is an abbreviation for the test reset pin, which is an optional pin that can be implemented as an asynchronous reset signal to the TAP controller in boundary scan.

truth table A truth table is a table that defines the behavior for a block of digital logic. Each line of a truth table lists the input signal values and the resulting output value.

TSALLN TSALLN is a global tristate all signal. In LatticeECP/EC, LatticeXP, and LatticeSC devices, it puts all PIC cells on the device in a tristate condition when it is low. When it is enabled in MachXO devices, it can disable all I/Os.

.tw1 A .tw1 file is an FPGA TRACE file that reports timing results for a mapped design. It shows to what extent the timing constraints for a design have been met. Running the Map Design process in Lattice Diamond generates this file. See also “TRACE” on page 2663.

.twr A .twr file is an FPGA TRACE file that reports the timing results for a placed and routed design. The .twr file enables you to determine to what extent the timing constraints for a design have been met. Running the Place & Route Trace process in Lattice Diamond generates this file. See also "TRACE" on page 2663.

Tx channel A Tx channel is the transmit channel in a PCS SERDES.

U

UART A UART is an acronym for universal asynchronous receiver/transmitter, which is a computer component that handles asynchronous serial communication. Every computer contains a UART to manage the serial ports. Some internal modems have their own UART.

.udo The .udo file is a batch file output by ModelSim/Questa.

UES UES is an abbreviation for user's electronic signature, an internal storage area for the end user to store dates, lots, revisions, and so forth. It does not affect the logical operation of the device.

UGROUP A UGROUP (universal group) is logical constraint that specifies a group of logical components that are to be packed close together. A UGROUP instructs the mapper not to pack unrelated logic into the same block. The mapping process translates the UGROUP to a placement group (PGROUP) in the physical preference file (.prf). A UGROUP can include PFU, PFF, EBR, and DSP blocks.

unconstrained path An unconstrained path is a path that does not have a timing preference or requirement ascribed to it.

unit delay simulation Unit delay simulation is a simplified form of timing simulation in which every digital gate is assumed to introduce one unit of delay to a signal.

UNIX UNIX is an acronym for Universal Interactive Executive, which is a multi-user, multi-task operating system for workstations.

USB USB is an abbreviation for universal serial bus, a type of download cable.

USF USF is an abbreviation for user security fuse, an E2 cell that can be programmed to protect the internal arrays from being read out of the device. It protects custom patterns.

V

.v A .v file is Verilog test fixture file used by ModelSim/Questa for timing simulation. A .v file is also a Verilog file output by Mico System Builder (MSB) in LatticeMico System.

Vantis Vantis is a type of download cable.

.vbs A .vbs file is a VBScript file.

VBScript VBScript is a subset of Visual Basic. VBScript can be used with ORCAstra to automate tests and to define functions in Visual Windows. See also “ORCAstra” on page 2642 and “Visual Window” on page 2667.

.vcd A .vcd file is a value change dump file whose format is specified in the IEEE 1364 standard. It is an ASCII file containing header information, variable definitions, and variable value changes. You can export .vcd file information from the Reveal Logic Analyzer software. The .vcd file preserves waveform information that can be displayed in third-party tools such as ModelSim / Questa.

vector A vector is 1) The logical state of a set of nodes within a circuit as a function of time. 2) A group of signals that has been renamed for convenience during simulation. It is similar to a bus. “Bus” refers to a group of signals on the schematic, and “vector” refers to a group of signals during simulation.

verification See “timing simulation” on page 2662 and “static timing analysis” on page 2659.

Verilog Verilog is a hardware description language (HDL) used to design and document electronic systems. Verilog HDL allows you to design at various levels of abstraction. All Lattice Semiconductor devices support Verilog HDL design.

.vhd A .vhd file is a VHDL test bench file required by ModelSim / Questa for timing simulation.

VHDL VHDL is an abbreviation for VHSIC Hardware Description Language, which is an industry-standard hardware description language for describing the structure and function of integrated circuits. All Lattice Semiconductor devices support VHDL design.

VHDL library A VHDL library is a library of design sources required by VHDL. VHDL also allows named libraries that can contain one or more files. VHDL design units can access other design units in the same and different libraries by declaring the name of the library and design unit to make visible.

.vho A .vho file is a VHDL netlist file required by ModelSim / Questa for timing simulation.

.vht A .vht file is a VHDL test bench template file. You must edit and rename this file with the .vhd extension before you can use it for simulation. See also “.vhd” on page 2666.

via A via is a connection point between two adjacent metal routing layers defined by a pad in each layer.

.vis A .vis file defines a Visual Window for ORCAstra.

Visual Window A Visual Window is a window in ORCAstra that provides a variety of control and display functions for testing designs in FPGAs. ORCAstra comes with several Visual Windows (main and secondary Visual Windows). You can also create your own, custom Visual Windows. See also "ORCAstra" on page 2642.

.vo A .vo file is a Verilog netlist file required by ModelSim / Questa for timing simulation.

W

watchpoint A watchpoint is a type of breakpoint that stops the execution of a software program whenever the value of a specific expression changes, without indicating where this may occur. A watchpoint halts program execution, even if the new value being written is the same as the old value of the field.

.wav A .wave file is a file containing Waveform Viewer waveforms and trigger information.

waveform A waveform is a graphical representation of a set of simulation transitions that depicts the digital or electrical values of a node on the schematic.

Waveform Editor Waveform Editor is a Lattice Diamond application that enables you to graphically create a test stimulus file by clicking and dragging with the mouse. You see exactly what each waveform will look like, as well as its timing relationship to all the other waveforms.

.wdl A .wdl file is a Waveform Editor display file.

.wet A .wet file is a Waveform Editor database file.

.wir The .wir file is a WIR netlist format file created by Viewlogic.

wire A wire is the physical implementation of a net or a signal. See also "net" on page 2640.

wired logic Wired logic is a wire connection between two gate outputs, providing a specific logic function.

Wishbone Bus A WISHBONE Bus is a free, open-source hardware computer bus that enables parts of an integrated circuit to communicate with each other. It is especially useful in digital systems that require usage of IP cores. The Wishbone Bus encourages IP reuse by defining a common interface among IP cores.

workspace A workspace is a basic Eclipse-based software feature that contains all of your LatticeMico System projects, files, and folders and stores everything in a “workspace” folder. Basically a workspace represents everything you do in the LatticeMico System software, what is available, how you view it, and what options are available to you through the different perspectives based upon your settings.

_wt A -wt file is a Waveform Editing Viewer log file.

_wv A -wv file is a Waveform Viewer log file.

X

.xcf An .xcf file is a configuration file used by the Diamond Programmer and by ispVM System for programming devices in a JTAG daisy chain. The XCF file contains information about each device, the data files targeted, and the operations to be performed.

.xml An .xml file is a file written in Extensible Markup Language. In LatticeMico System, it contains code declarations called component instance definitions that define the structure of each component. This file resides in the <*install_dir*> components folder. When a build is generated, this information is copied into the platform description (.msb) file by the Mico System Builder (MSB).

XML XML is an abbreviation for Extensible Markup Language, which is a general-purpose markup language used to create special-purpose markup languages for use on the Worldwide Web.

.xnf .xnf is a file in the external netlist format created by Xilinx.

XOR XOR is an exclusive OR gate. On high-density devices, it is a logical XOR gate in the architecture.

Y

yield Yield is the percentage of defect-free (usable) die on a silicon wafer.
